Article	2016	Katzi, DA	Dramatic Increase in Pre-Exposure Prophylaxis Use among Men who have Sex with Men in King County, Washington (vol 30, pg 515, 2016)	AIDS	-	-	-	0269-9370	doi: 10.1097/QAD.0000000000000937	https://pubmed.ncbi.nlm.nih.gov/26562845/	Objective: HIV preexposure prophylaxis (PrEP) is efficacious, but uptake has been slow. In Washington State, most insurance plans, including Medicaid, pay for PrEP, and the state supports a PrEP drug assistance program. We assessed trends in PrEP awareness and use among MSM in Washington. Design and setting: Serial cross-sectional survey conducted annually at the Seattle Pride Parade between 2009 and 2015. Methods: In a convenience sample of MSM who reside in Washington State and deny ever testing HIV positive (n = 2168), we evaluated the association between calendar year and self-report of PrEP uptake and awareness using descriptive statistics and multivariable relative risk and logistic regression. Regression models included HIV risk and demographic covariates. Results: In 2015, 23% [95% confidence interval (CI): 16%, 31%] of high-risk MSM reported currently taking PrEP. The percentage of high-risk MSM who reported ever taking PrEP increased from 5% in 2012 to 31% in 2015. PrEP use among lower-risk MSM was low and stable, between 1 and 3% in 2012-2015. In multivariable analyses, PrEP use was associated with later calendar years (2015 vs. 2012: adjusted relative risk = 2.29, 95% CI: 1.16, 4.52) and elevated HIV risk (adjusted relative risk = 2.92, 95% CI: 2.00, 4.25). The percentage of high and lower-risk MSM who had heard of PrEP increased from 13 to 86% and from 29 to 58%, respectively. Conclusion: PrEP awareness is high and the use has rapidly increased over the last year among MSM in Seattle, Washington, USA. These findings demonstrate that high levels of PrEP use can be achieved among MSM at high-risk for HIV infection. Article	2016	Kelvin, Elizabeth A.; Cheruvillil, Sonia; Christian, Stephanie; Mantell, Joanne E.; Milford, Cecilia; Rambally-Greener, Letitia; Mosery, Nzwakie; Greener, Ross; Smit, Jennifer A.	Choice in HIV testing: the acceptability and anticipated use of a self-administered at-home oral HIV test among South Africans.	African Journal of AIDS Research	-	-	-	1727-9445 1608-5906	10.2989/16085906.2016.1189442	https://pubmed.ncbi.nlm.nih.gov/27399040/	Combination HIV prevention is being widely promoted by funders. This strategy aims to offer HIV prevention choices that can be selected and combined to decrease HIV risk in ways that fit with each individual's situation. Treatment as prevention and pre-exposure prophylaxis are two new evidence-based strategies to decrease HIV incidence, both of which require high HIV testing rates to be effective, and the Joint United Nations Programme on HIV/AIDS (UNAIDS) has set a goal of 90% of HIV-positive individuals knowing their status by 2030. However, HIV testing rates in many countries remain suboptimal. Just as no single HIV prevention method is ideal for all people in all situations, no single HIV testing modality is likely to be acceptable to everyone. By offering HIV testing choices, we may be able to increase testing rates. However, many low-resourced countries have been slow to take up new HIV testing options such as the self-administered at-home oral HIV test that is currently available in the United States. In this paper, we present findings from 20 in-depth interviews, conducted in 2010, documenting opinions about self-administered at-home oral HIV testing, a testing modality still largely unavailable in Africa. Participants were clients of three primary healthcare clinics in South Africa. Self-testing was seen as enabling confidentiality/privacy, saving time, and facilitating testing together with partners. However, concerns were raised about psychological distress when testing at home without a counsellor. Some suggested this concern could be minimised by having experienced clinic-based HIV testing and counselling before getting self-testing kits for home use. Thus, self-administered HIV testing could be an option added to the current testing modalities to address some important barriers to testing. Article	2016	Kendrick, Katherine; Brown, Veronica; Lords, Caleb; Matthias, James; Henning, Ian; Blackmore, Carina; Likos, Anna	Full House: A Retrospective Analysis of High Sexually Transmitted Infection Prevalence among Adult Film Actors at a Singular Residence.	Sexually Transmitted Diseases	-	-	-	1537-4521	10.1097/OLQ.0000000000000483	https://dx.doi.org/10.1097/OLQ.0000000000000483	BACKGROUND: During a routine human immunodeficiency virus (HIV) investigation, Florida Department of Health staff identified a house (house A) in which over 150 individuals had resided at least briefly. Further investigation revealed that house A is used by the producer of a small adult film production company to board his actors. This report describes sexually transmitted infection (STI) prevalence among male actors in gay adult films residing in a common Florida residence. METHODS: LexisNexis Accurint was used to identify house A residents since October 2002 when the producer arrived. Information on STIs and interview data were obtained from Florida's STI surveillance system. An infection was considered to be associated with residence in house A if the date of diagnosis occurred 6 months before an individual's residence start date through 6 months after his residence end date. RESULTS: Excluding the producer, 150 men resided in house A starting from September 2003 to July 2015. Forty-six individuals had a reported case of HIV, syphilis, gonorrhea, and/or chlamydia with 92 infections total. Forty-two (46%) infections among 24 men were considered associated with residence in house A. CONCLUSIONS: LexisNexis Accurint was a useful tool for identifying house A residents, a highly mobile and highly sexually active population. There is a high prevalence of STIs among residents, but it is unclear where transmission is occurring. Settings like house A are good candidates for HIV pre-exposure prophylaxis and active STI screenings and may be an opportunity for public health officials to intervene in high-risk groups to reduce STI rates in the community. Article	2016	Kesler M.A.; Kaul R.; Myers T.; Liu J.; Loutfy M.; Remis R.S.; Gesink D.	Perceived HIV risk, actual sexual HIV risk and willingness to take pre-exposure prophylaxis among men who have sex with men in Toronto, Canada	AIDS Care	-	-	-	9540121	10.1080/09540121.2016.1178703	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84965074955&doi=10.1080%2f09540121.2016.1178703&partnerID=40&md5=ce56fac45120ecd94d8b0a94e2472166	Pre-exposure prophylaxis (PrEP) reduces HIV acquisition. Our goal was to determine the willingness of men who have sex with men (MSM) to take PrEP given perceived and actual HIV risk. HIV-negative MSM were recruited from September 2010 to June 2012 and asked about PrEP willingness and perceived HIV risk. Actual sexual HIV risk was measured by three condom-use components generated through principal components analysis. General HIV risk was measured using the HIV Incidence Risk Index for MSM (HIRI-MSM). Model 1 measured PrEP willingness given perceived and actual HIV risk. Model 2 included actual HIV sexual risk, perceived HIV risk and general HIV risk. Model 3 removed actual sexual HIV risk. We recruited 150 HIV-negative MSM. About 55% were willing to take PrEP. Reasons for PrEP unwillingness were: low perceived risk (64%), side-effect concerns (44%), daily pill burden (16%) and efficacy concerns (4%). Model 1: MSM with high compared to low actual sexual HIV risk were more willing to use PrEP (OR 27.11, 95% CI 1.33–554.43) after adjusting for perceived risk, which was not significantly associated with PrEP willingness (OR 4.79, 95% CI 0.72–31.96). Model 2: MSM with high compared to low actual sexual HIV risk were more willing to use PrEP (OR 29.85, 95% CI 1.39–640.53) after adjusting for perceived and general HIV risk, neither of which was significantly associated with PrEP willingness (OR 5.07, 95% CI 0.73–35.09) and (OR 1.58, 95% CI 0.37–6.79), respectively. Model 3: After removing actual sexual HIV risk, MSM with high compared to low perceived risk were more willing to use PrEP (OR 6.85, 95% CI 1.23–38.05), and the HIRI-MSM general risk index was not associated with PrEP willingness (OR 1.87, 95% CI 0.54–6.54). Therefore, actual sexual HIV risk was the best predictor of PrEP willingness and general HIV risk did not inform PrEP willingness. © 2016 Informa UK Limited, trading as Taylor & Francis Group.	actual HIV risk; men who have sex with men; Perceived HIV risk; pre-exposure prophylaxis; principal components analysis	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Quantitative
Article	2016	Khanna, Aditya S; Michaels, Stuart; Skaathun, Britt; Morgan, Ethan; Green, Keith; Young, Lindsay; Schneider, John A	Preexposure Prophylaxis Awareness and Use in a Population-Based Sample of Young Black Men Who Have Sex With Men. Article	2016	Klein, Charles; Lomonaco, Carmela	Real Talk: Developing a Computer-Delivered Sexual Health Program for Black Men Who Have Sex With Men.	AIDS Education and Prevention	-	-	-	1943-2755 0899-9546	10.1521/aeap.2016.28.6.455	https://pubmed.ncbi.nlm.nih.gov/27925486/	HIV disproportionately affects Black men who have sex with men (MSM), yet there are few evidence-based programs that respond to the diverse realities of Black MSM communities. This article examines the development of Real Talk, a new harm reduction-based, sexual health intervention for Black MSM. We first analyze the key themes from our formative research: (1) stigma, discrimination, and intersectionalities in the lives of Black MSM, (2) the importance of safe spaces and community provided by health promotion programs, and (3) moving beyond condoms in sexual health messaging. We then describe our agile design product development process and present an overview of the intervention's components and how they respond to the issues identified in the formative research. In conclusion, we discuss dissemination opportunities and challenges in an age of decreased prevention funding, pre-exposure prophylaxis (PrEP), and the increased use of e-health promotion modalities. Article	2016	Knight, Rod; Small, Will; Carson, Anna; Shoveller, Jean	Complex and Conflicting Social Norms: Implications for Implementation of Future HIV Pre-Exposure Prophylaxis (PrEP) Interventions in Vancouver, Canada	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0146513	https://pubmed.ncbi.nlm.nih.gov/26756474/	Background HIV Pre-Exposure Prophylaxis (PrEP) has been found to be efficacious in preventing HIV acquisition among seronegative individuals in a variety of risk groups, including men who have sex with men and people who inject drugs. To date, however, it remains unclear how socio-cultural norms (e.g., attitudes towards HIV; social understandings regarding HIV risk practices) may influence the scalability of future PrEP interventions. The objective of this study is to assess how socio-cultural norms may influence the implementation and scalability of future HIV PrEP interventions in Vancouver, Canada. Methods We conducted 50 interviews with young men (ages 18-24) with a variety of HIV risk behavioural profiles (e.g., young men who inject drugs; MSM). Interviews focused on participants' experiences and perceptions with various HIV interventions and policies, including PrEP. Results While awareness of PrEP was generally low, perceptions about the potential personal and public health gains associated with PrEP were interconnected with experiences of complex and sometimes conflicting social norms. Some accounts characterized PrEP as a convenient form of reliable protection against HIV, likening it to the female birth control pill. Other accounts cast PrEP as a means to facilitate 'socially unacceptable' behaviour (e.g., promiscuity). Stigmatizing rhetoric was used to position PrEP as a tool that could promote some groups' proclivities to take 'risks'. Conclusion Stigma regarding 'risky' behaviour and PrEP should not be underestimated as a serious implementation challenge. Pre-implementation strategies that concomitantly aim to improve knowledge about PrEP, while addressing associated social prejudices, may be key to effective implementation and scale-up. Article	2016	Ko, Nai-Ying; Chen, Bo-Jie; Li, Chia-Wen; Ku, Wen-Wei; Hsu, Su-Ting	Willingness to Self-Pay for Pre-exposure Prophylaxis in Men Who Have Sex With Men: A National Online Survey in Taiwan.	AIDS Education and Prevention	-	-	-	1943-2755	10.1521/aeap.2016.28.2.128	https://dx.doi.org/10.1521/aeap.2016.28.2.128	High cost of pre-exposure prophylaxis (PrEP) is a major concern for acceptability. This study determined the willingness of men who have sex with men to self-pay for PrEP and factors associated with the likelihood of condom use if taking PrEP. The Taiwan 2014 MSM Online Sex Survey was conducted and data such as demographics, attitudes toward PrEP, and sexual behaviors in the previous 3 months were collected. Of the 1,151 MSM who participated, 56% were willing to take PrEP, but only 23% were willing to self-pay $340 for PrEP. Willingness to self-pay for PrEP was significantly associated with the previous receipt of nonoccupational post-exposure prophylaxis (adjusted odds ratio AOR, 3.02, 95%CI 1.49, 6.12), and positive attitudes toward PrEP (AOR, 3.02, 95%CI 2.19, 4.17). Of MSM who are willing to use PrEP, 73.6% would maintain condom use if taking PrEP. If PrEP is made available in Taiwan, more efforts should be focused on increasing awareness of MSM who are practicing risky behaviors. Article	2016	Kojima N.; Klausner J.D.	Is emtricitabine-tenofovir disoproxil fumarate preexposure prophylaxis for the prevention of human immunodeficiency virus infection safer than aspirin?	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/ofid/ofv221	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85000500182&doi=10.1093%2fofid%2fofv221&partnerID=40&md5=5b3541b6d5e42e909743e759836ae7a8	Background. The safety and effectiveness studies of emtricitabine-tenofovir disoproxil fumarate (FTC-TDF) for human immunodeficiency virus (HIV) infection pre-exposure prophylaxis (PrEP) in men and women showed that daily use reduced the risk of HIV acquisition, but there still may concerns about safety. Methods. A narrative review was done in September 2015 comparing the 5 major studies on PrEP for HIV infection-Preexposure Prophylaxis Initiative (N = 2499; 3324 person-years), Partners Preexposure Prophylaxis (N = 4747; 7830 person-years), TDF2 (N = 1219; 1563 person-years), Preexposure Prophylaxis Trial for HIV Prevention among African Women (N = 2056; 1407 personyears), and Vaginal and Oral Interventions to Control the Epidemic (N = 4969; 5509 person-years)-and the 2 major studies on aspirin safety-Physicians' Health Study (N = 22 071; over 110 000 person-years) and the Women's Health Study (N = 39 876; approximately 400 000 person-years). The numbers needed to harm (NNH) were calculated for FTC-TDF for HIV infection PrEP and aspirin. Results. The NNH for FTC-TDF in men who have sex with men and transgender women was 114 for nausea and 96 for unintentional weight loss; in heterosexual couples, the NNH was 68 for moderate decreased absolute neutrophil count. For aspirin, the NNH was 909 for major gastrointestinal bleeding, 123 for any gastrointestinal bleeding, and 15 for any bleeding problems in men. In women, the NNH for easy bruising was 10. Conclusions. We conclude that FTC-TDF for PrEP for HIV infection favorably compares with aspirin in terms of user safety. Although long-term studies are needed, providers should feel reassured about the safety of short- and medium-term PrEP for HIV infection with FTC-TDF. © The Author 2016. Article	2016	Krakower D.S.; Maloney K.M.; Grasso C.; Melbourne K.; Mayer K.H.	Primary care clinicians' experiences prescribing HIV pre-exposure prophylaxis at a specialized community health centre in Boston: Lessons from early adopters: Lessons	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.19.1.21165	https://pmc.ncbi.nlm.nih.gov/articles/PMC5061879/	Introduction: An estimated 1.2 million Americans have indications for using antiretroviral pre-exposure prophylaxis (PrEP) to prevent HIV acquisition. For many of these at-risk individuals, the best opportunity to learn about and receive PrEP will be during routine visits to their generalist primary care clinicians. However, few generalist clinicians have prescribed PrEP, primarily because of practical concerns about providing PrEP in primary care settings. The experiences of specialized primary care clinicians who have prescribed PrEP can inform the feasibility of PrEP provision by generalists. Methods: During January to February 2015, 35 primary care clinicians at a community health centre in Boston that specializes in the care of sexual and gender minorities completed anonymous surveys about their experiences and practices with PrEP provision. Responses were analyzed with descriptive statistics. Results and discussion: Thirty-two clinicians (response rate=91%) completed the surveys. Nearly all clinicians (97%) had prescribed PrEP (median 20 patients, interquartile range 11-33). Most clinicians reported testing and risk-reduction counselling practices concordant with U.S. Centers for Disease Control and Prevention guidelines for PrEP. Clinicians indicated that patients using PrEP experienced medication toxicities infrequently and generally reported high adherence. However, some clinicians' practices differed from guideline recommendations, and some clinicians observed patients with increased risk behaviours. Most clinicians (79%) rated PrEP provision as easy to accomplish, and 97% considered themselves likely to prescribe PrEP in the future. Conclusions: In a primary care clinic with specialized expertise in HIV prevention, clinicians perceived that PrEP provision to large numbers of patients was safe, feasible and potentially effective. Efforts to engage generalist primary care clinicians in PrEP provision could facilitate scale-up of this efficacious intervention. © 2016 Krakower D S et al; licensee International AIDS Society.	community health centre; early adopters; HIV; implementation; pre-exposure prophylaxis; primary care providers	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Article	2016	Krakower, Douglas S; Mayer, Kenneth H	The role of healthcare providers in the roll out of preexposure prophylaxis.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0000000000000206	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4676563	PURPOSE OF REVIEW: To review the most recent studies assessing the preparedness of healthcare practitioners to provide anti-HIV preexposure prophylaxis (PrEP) and suggest areas for future implementation research. RECENT FINDINGS: As PrEP is a biobehavioral intervention, healthcare providers are likely to play a critical role in implementing PrEP in care settings. Studies suggest that many specialized providers are aware of PrEP and support its provision as a public health intervention, though knowledge and acceptance are less among generalists. Therefore, utilization of PrEP by clinicians has been limited to a few early adopters. Concerns about the efficacy and long-term safety of PrEP, and perceived barriers to prescribing PrEP, could limit prescribing behaviors and intentions. Resistance to performing routine HIV risk assessments by clinicians is an additional barrier to implementing PrEP, although innovative tools to help clinicians routinely perform risk assessments, are being developed. SUMMARY: Interventions are needed to engage a broader array of healthcare providers in PrEP provision. Utilizing a framework based on diffusion of innovation theory, this review proposes strategies that can be implemented and evaluated to increase PrEP prescribing by healthcare providers. If resources are invested in training clinicians to provide PrEP, then these stakeholders could enhance the use of PrEP as part of a prevention package by primary providers. Editorial	2016	Krakower, Douglas S; Mayer, Kenneth H	Renal Function and Tenofovir Disoproxil Fumarate for Preexposure Prophylaxis: How Safe Is Safe Enough?	Journal of Infectious Diseases	-	-	-	1537-6613	10.1093/infdis/jiw169	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5021225	Recent studies have demonstrated that daily use of oral tenofovir disoproxil fumarate (TDF), with or without emtricitabine (FTC), for preexposure prophylaxis (PrEP) against human immunodeficiency virus (HIV) infection can decrease the incidence of HIV infection in diverse populations, including men who have sex with men (MSM), transgender women, at-risk heterosexuals, and persons who use injection drugs [1–4]. In these studies, efficacy was directly correlated with medication adherence. Based on the evidence from these studies, in 2012 the Food and Drug Administration approved once-daily, coformulated TDF and FTC (TDF-FTC) for use as PrEP, and in 2014 the Centers for Disease Control and Prevention issued guidelines recommending TDF-FTC PrEP for HIV prevention [5]. Subsequent studies of PrEP use by at-risk MSM in care settings have observed high levels of adherence and very low HIV infection incidences despite high rates of sexually transmitted infections, suggesting that PrEP can be highly effective under real-world conditions [6, 7]. Article	2016	Krishnaratne, Shari; Hensen, Bernadette; Cordes, Jillian; Enstone, Joanne; Hargreaves, James R.	Interventions to strengthen the HIV prevention cascade: a systematic review of reviews.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(16)30038-8	https://pubmed.ncbi.nlm.nih.gov/27365205/	BACKGROUND: Much progress has been made in interventions to prevent HIV infection. However, development of evidence-informed prevention programmes that translate the efficacy of these strategies into population effect remain a challenge. In this systematic review, we map current evidence for HIV prevention against a new classification system, the HIV prevention cascade. METHODS: We searched for systematic reviews on the effectiveness of HIV prevention interventions published in English from Jan 1, 1995, to July, 2015. From eligible reviews, we identified primary studies that assessed at least one of: HIV incidence, HIV prevalence, condom use, and uptake of HIV testing. We categorised interventions as those seeking to increase demand for HIV prevention, improve supply of HIV prevention methods, support adherence to prevention behaviours, or directly prevent HIV. For each specific intervention, we assigned a rating based on the number of randomised trials and the strength of evidence. FINDINGS: From 88 eligible reviews, we identified 1964 primary studies, of which 292 were eligible for inclusion. Primary studies of direct prevention mechanisms showed strong evidence for the efficacy of pre-exposure prophylaxis (PrEP) and voluntary medical male circumcision. Evidence suggests that interventions to increase supply of prevention methods such as condoms or clean needles can be effective. Evidence arising from demand-side interventions and interventions to promote use of or adherence to prevention tools was less clear, with some strategies likely to be effective and others showing no effect. The quality of the evidence varied across categories. INTERPRETATION: There is growing evidence to support a number of efficacious HIV prevention behaviours, products, and procedures. Translating this evidence into population impact will require interventions that strengthen demand for HIV prevention, supply of HIV prevention technologies, and use of and adherence to HIV prevention methods. Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	https://doi.org/10.1097/qai.0000000000000923	https://escholarship.org/uc/item/5zs686mz	Association of HIV-1-specific T-cell responses to infection risk in seronegative individuals is controversial. We quantified and phenotypically characterized gp120-specific T-cell responses in HIV-1 exposed, but uninfected subjects enrolled in the global Pre-exposure Prophylaxis Initiative (iPrEx) chemoprophylaxis trial. IFNγ ELISpot responses were detected in 24% of subjects irrespective of infection outcome. HIV-1 gp120 envelope-specific T-cell responses were more uniformly IFN-γ+TNF-α+Mip-1β+ in persistently seronegative subjects relative to subjects who later seroconverted (median frequency of 76.5% and 66.5%, respectively). IFNγ responses targeted the V2 loop for subjects who remained seronegative. HIV-1 gp120 envelope V2 loop-specific CD8 T-cell responses may help to protect against HIV-1 acquisition. Article	2016	Kuhns L.M.; Reisner S.L.; Mimiaga M.J.; Gayles T.; Shelendich M.; Garofalo R.	Correlates of PrEP Indication in a Multi-Site Cohort of Young HIV-Uninfected Transgender Women	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-015-1182-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84940676536&doi=10.1007%2fs10461-015-1182-z&partnerID=40&md5=eba45f0612defe634e68b442eb6859ee	Transgender women are at high risk of HIV infection, with younger transgender women (YTW) particularly vulnerable. Pre-Exposure Prophylaxis (PrEP) has shown efficacy in reducing HIV acquisition, but little is known about PrEP indication or initiation among YTW. Baseline data from 180 YTW age 18–29 years enrolled in Project LifeSkills, an on-going HIV prevention intervention for YTW, were analyzed to examine factors associated with PrEP indication. The sample (mean age = 23.4, SD = 3.2) was comprised largely of women of color (69 %) and of low socioeconomic status (71 % unemployed). Overall, 62 % met criteria for PrEP indication, but only 5 % reported ever taking PrEP. Factors associated with increased odds of PrEP indication were: PrEP interest (aOR 3.24; 95 % CI 1.44, 7.33), number of recent anal sex partners (aOR 1.23; 95 % CI 1.04, 1.46), and lower collective self-esteem scores (aOR 0.67; 95 % CI 0.47, 0.94). Despite high levels of PrEP indication, there remain low levels of PrEP awareness and uptake among YTW. © 2015, Springer Science+Business Media New York. Article	2016	Kung, Vanessa; Kahn, Danielle; Dougherty, Jacob; Elderbrook, Megan; Schumann, Casey; Gasiorowicz, Mari; Vergeront, James; Hess, Timothy; Westergaard, Ryan	The Potential Impact of Pre-exposure Prophylaxis (PrEP) Implementation at Centers for Disease Control and Prevention (CDC)-Funded Nonclinical Human Immunodeficiency Virus (HIV) Testing Venues	Open Forum Infectious Diseases	-	-	-	2328-8957	https://doi.org/10.1093/ofid/ofw172.365	https://academic.oup.com/ofid/article/3/suppl_1/502/2636866	Background. Targeted HIV testing programs in nonclinical settings are supported by CDC to deliver testing services to individuals who are at high-risk for HIV but are not engaged in routine medical care. These programs may similarly be effective but under-utilized venues for implementing pre-exposure prophylaxis (PrEP). To provide insight into the potential impact of scaling-up PrEP implementation at CDC-funded, nonclinical HIV testing sites, we evaluated the proportion of new HIV diagnoses in the U.S. resulting from tests conducted at these sites. Methods. We analyzed publicly-available data from the CDC Annual HIV Testing Report and HIV Surveillance Report from 2014 to determine the proportion of new HIV diagnoses in each U.S. state resulting from testing events in nonclinical settings. To assess the potential number of HIV cases that might prevented under ideal conditions when PrEP is universally delivered to high-risk clients who test negative, we then analyzed client-level data collected from the Wisconsin Division of Public Health's Confidential HIV Testing and Referral (CTR) Program. Using a unique identification code entered by clients at the time of testing, we identified cases of confirmed new HIV diagnosis that could be linked to a prior, negative HIV testing event at a CTR site. Results. Of 39,566 new diagnoses of HIV reported to CDC from 49 states during 2014, 5136 were made at CDC-funded nonclinical settings (13% overall, range 0% to 28%). In Wisconsin, 52 of 218 (24%) diagnoses occurred in such settings. Using Wisconsin HIV surveillance data, we found that among 790 new HIV diagnoses made between 2008 and 2015, 119 provided a client ID that matched an earlier negative test, representing a client who was engaged in CTR services both before and after HIV transmission occurred. Conclusion. A substantial number of HIV infections may be preventable if there was a robust mechanism for linking CTR clients to highly effective prevention services. Our findings are subject to numerous limitations, including analysis of data aggregated from published reports, which may not reflect site-specific variations in data collection or reporting. Implementation and evaluation of PrEP programs in non-clinical settings appears warranted. Article	2016	Kuo, Irene; Olsen, Halli; Patrick, Rudy; Phillips, Gregory; Magnus, Manya; Opoku, Jenevieve; Rawls, Anthony; Peterson, James; Hamilton, Flora; Kharfen, Michael; Greenberg, Alan	Willingness to use HIV pre-exposure prophylaxis among community-recruited, older people who inject drugs in Washington, DC.	Drug and Alcohol Dependence	-	-	-	1879-0046	10.1016/j.drugalcdep.2016.02.044	https://dx.doi.org/10.1016/j.drugalcdep.2016.02.044	INTRODUCTION: Use of pre-exposure prophylaxis (PrEP) among people who inject drugs (PWID) has been shown to be effective in preventing HIV transmission. We examined correlates of the willingness to use PrEP among community-recruited older PWID in Washington, DC. METHODS: PWID were recruited using respondent-driven sampling (RDS) and completed a behavioral interview for the National HIV Behavioral Surveillance system in 2012. Participants reported on willingness to use PrEP and how it might affect their drug use and sexual behaviors. We reported RDS-weighted proportions and multivariable correlates of being willing to use PrEP. RESULTS: Among 304 participants, 69% were male, and the majority was aged ≥50 and black. Only 13.4% had ever heard of using anti-HIV medication to prevent HIV; none had ever used PrEP or knew anyone who used it in the past year. Forty-seven percent were very likely and 24% were somewhat likely to take PrEP if it were available without cost; 13% agreed they would be more likely to sterilize/clean needles or use condoms if taking PrEP. Correlates of being very likely to use PrEP included being younger (<50years), sharing cookers, cotton or water in the past year, and believing they would no longer need to use clean needles. CONCLUSION: Nearly half of PWID reported being very willing to use PrEP if it were available without cost. Younger PWID and those at higher risk of sharing cookers, cotton or water were more willing to use PrEP, suggesting a focus on these groups to explore PrEP use among PWID. Article	2016	Kurkjian, KM; Winz, M; Yang, J; Corvese, K; Colón, A; Levine, SJ; Mullen, J; Ruth, D; Anson-Dwamena, R; Bayleyegn, T; Chang, DS	Assessing Emergency Preparedness and Response Capacity Using Community Assessment for Public Health Emergency Response Methodology: Portsmouth, Virginia, 2013	Disaster Medicine and Public Health Preparedness	-	-	-	1935-7893	10.1017/dmp.2015.173	https://pubmed.ncbi.nlm.nih.gov/26795137/	Objective For the past decade, emergency preparedness campaigns have encouraged households to meet preparedness metrics, such as having a household evacuation plan and emergency supplies of food, water, and medication. To estimate current household preparedness levels and to enhance disaster response planning, the Virginia Department of Health with remote technical assistance from the Centers for Disease Control and Prevention conducted a community health assessment in 2013 in Portsmouth, Virginia. Methods Using the Community Assessment for Public Health Emergency Response (CASPER) methodology with 2-stage cluster sampling, we randomly selected 210 households for in-person interviews. Households were questioned about emergency planning and supplies, information sources during emergencies, and chronic health conditions. Results Interview teams completed 180 interviews (86%). Interviews revealed that 70% of households had an emergency evacuation plan, 67% had a 3-day supply of water for each member, and 77% had a first aid kit. Most households (65%) reported that the television was the primary source of information during an emergency. Heart disease (54%) and obesity (40%) were the most frequently reported chronic conditions. Conclusions The Virginia Department of Health identified important gaps in local household preparedness. Data from the assessment have been used to inform community health partners, enhance disaster response planning, set community health priorities, and influence Portsmouth's Community Health Improvement Plan.	emergency preparedness; disaster planning; needs assessment	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2016	Kurtz S.P.; Buttram M.E.	Misunderstanding of Pre-Exposure Prophylaxis Use among Men Who Have Sex with Men: Public Health and Policy Implications	LGBT Health	-	-	-	23258292	10.1089/lgbt.2015.0069	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85001950501&doi=10.1089%2flgbt.2015.0069&partnerID=40&md5=242d6c79585ca076530144601eff3db3	Purpose: Street markets in antiretroviral medications for HIV have been documented, but sources of demand are not well understood. We report unexpected findings from qualitative research suggesting that some demand is for informal pre-exposure prophylaxis (PrEP). Methods: Focus groups with young men who have sex with men (N = 31) yielded information on their understanding and use of PrEP. Results: Of those who had heard of it, few understood PrEP to be a physician-prescribed regimen; most believed it to be a pill taken before and/or after sex and acquired on the street or through HIV-positive friends. Conclusion: Implications for PrEP rollout and public health policy are discussed. © 2016, Mary Ann Liebert, Inc. Article	2016	Kwakwa, Helena A; Bessias, Sophia; Sturgis, Donielle; Mvula, Natasha; Wahome, Rahab; Coyle, Catelyn; Flanigan, Timothy P	Attitudes Toward HIV Pre-Exposure Prophylaxis in a United States Urban Clinic Population	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1407-9	https://www.proquest.com/scholarly-journals/attitudes-toward-hiv-pre-exposure-prophylaxis/docview/1795745986/se-2?accountid=8113	A majority of US studies on attitudes toward PrEP focus on men who have sex with men with little representation of African Americans. This cross-sectional study seeks to determine openness to PrEP, and examine motivations for openness among Philadelphia residents. Patients undergoing HIV rapid testing between May 2012 and December 2014 in a public setting were administered a survey. Questions included openness to PrEP and reasons for openness to PrEP. Multivariate logistic regression models were used to investigate associations between openness and potential predictors. Analyses were conducted using R version 3.2.4 and the epitools and car packages. Of 5606 respondents, over 90 % were African American. Men were more likely to express openness (61.4 % of men, 54.8 % of women, p < 0.0001). Predictors of openness were younger age, black race, higher perceived risk for HIV by patient or as assessed by Tester, intermittent /no condom use, greater number of partners in 12 months and previous STI testing. The main reason for openness was fear of HIV, and for disinterest was lack of recognition of risk. Understanding openness to PrEP, and reasons for openness to or disinterest in PrEP are critical to determining the best approaches to facilitate engagement in PrEP care by communities and persons at elevated risk for HIV acquisition. Further study is needed on how best to manage disinterest in PrEP by those at high risk for HIV, and how openness to PrEP translates into concrete steps to take PrEP. Article	2016	Lachowsky, Nathan J; Lin, Sally Y; Hull, Mark W; Cui, Zishan; Sereda, Paul; Jollimore, Jody; Rich, Ashleigh; Montaner, Julio S G; Roth, Eric A; Hogg, Robert S; Moore, David M	Pre-exposure Prophylaxis Awareness Among Gay and Other Men who have Sex with Men in Vancouver, British Columbia, Canada.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-016-1319-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4903956	Men who have sex with men (MSM) account for approximately half of Canada's new HIV infections. Pre-exposure prophylaxis (PrEP), a recently established and effective HIV prevention tool for MSM is currently not approved nor publicly funded. We recruited MSM via respondent-driven sampling to complete a self-administered computer-based interview. Stratified by HIV status, multivariable logistic regression identified factors associated with PrEP awareness. Of 673 participants, 102/500 (20.9 %) HIV-negative and 63/173 (26.5 %) HIV-positive men were aware of PrEP, but none had used it. One third of PrEP-aware MSM spoke about it with friends or sex partners. Self-declared knowledge was limited. Factors associated with PrEP awareness varied by HIV status, but included greater HAART optimism for HIV-negative MSM. Among HIV-negative MSM, being PrEP unaware was associated with younger age, not always having condoms, and preferring receptive versus insertive anal sex. Future longitudinal research should identify early adopters of PrEP and its associated impacts. Theses and Dissertations	2016	Lade, Julie M	Anti-HIV Drug Human Biotransformation and Structure-Activity Relationship of Pregnane X Receptor Activation	-	-	Johns Hopkins University	-	NA	NA	http://jhir.library.jhu.edu/handle/1774.2/60754	With the advent of antiretroviral drug therapy in the late 1980s, human immunodeficiency virus (HIV) is no longer a death sentence, but remains to be a chronic disease. Of concern, however, an estimated 2.1 million individuals were newly infected with HIV globally as of 2015. Further, HIV remains to be a pandemic that requires attention from scientific researchers to push forward the development of novel drug therapies that mitigate viral resistance and improve overall safety profiles. Rilpivirine (RPV) a second generation non-nucleoside reverse transcriptase inhibitor (NNRTI) was FDA approved in 2011 for administration to treatment-naïve HIV-infected individuals. Prior to this work, the hepatic metabolism of RPV was unknown. By in vitro assay, we observed that cytochrome P450s CYP3A4 and CYP3A5 primarily contributed to the oxidative metabolism of RPV and that uridine diphosphate glucuronosyl transferases UGT1A1 and UGT1A4 could contribute to the conjugative metabolism of RPV and its metabolites. In these studies, it was observed RPV could modulate CYP3A4 mRNA expression through activation of the nuclear receptor and xenobiotic sensor pregnane X receptor (PXR). In line with this, efavirenz (EFV) a first generation NNRTI and the most-widely prescribed antiretroviral despite exhibiting a poor safety profile, has been previously observed to activate PXR. Using an array of structural analogs of EFV, we explored the structure-activity relationship of EFV-mediated activation of PXR. In doing so, we identified a lower size limit ranging of > 223 Da to < 289 Da for ligand-dependent activation of PXR. In addition, we observed that the addition of a hydroxyl group to the Cl-phenyl ring of EFV did not impede ligand binding but attenuated PXR activation potentially through destabilizing a key hydrophobic area within the ligand-binding pocket. Building upon this work, we identified other hepatic pathways that may be stimulated by EFV and/or impacted by PXR activation. To this end, we observed EFV, but not RPV, could disrupt hepatic cholesterol homeostasis by stimulating lipid droplet formation as evidenced in primary mouse hepatocytes. EFV was also observed to increase the expression of the nuclear receptor small heterodimer partner (SHP), which has been implicated in facilitating the developments of dyslipidemia. However, further studies need to be performed in order to determine whether an EFV-mediated increase of SHP has a causal role in lipid droplet formation. In addition to studying antiretrovirals within the context of chronic HIV maintenance therapy, we also investigated RPV and the nucleoside reverse transcriptase inhibitor tenofovir (TFV) as pharmacological agents for HIV pre-exposure prophylaxis (PrEP). Moreover, in retrospective analyses, we identified genetic variants in the genes encoding enzymes responsible for RPV and TFV metabolism and activation, respectively. These findings lay the groundwork for future pharmacogenetic studies investigating inter-individual variability and toxicity associated with HIV PrEP. Article	2016	Landovitz, Raphael J; Kofron, Ryan	The promise and pitfalls of long-acting injectable agents for HIV prevention	Curr Opin HIV AIDS	-	-	-	1746-630X	https://doi.org/10.1097/coh.0000000000000219	https://escholarship.org/uc/item/5b10p7zs	Purpose of reviewPreexposure prophylaxis for HIV prevention is highly effective when taken as prescribed. Adherence to required dosing regimens for protection may pose challenges. Long-acting agents for HIV prevention may have the potential to improve adherence via favorable pharmacokinetics supportive of infrequent dosing. This review focuses on the potential benefits and considerations for the study and use of 2 long-acting injectable agents, cabotegravir (GSK1265744LA, CAB LA) and rilpivirine (TMC278LA, RPV LA), for use as chemoprophylaxis for HIV prevention.Recent findingsOral RPV is United States Food and Drug Administration approved for HIV treatment (in combination with other antiretrovirals). Both CAB LA and RPV LA are currently in phase 2a safety/tolerability/pharmacokinetic studies in anticipation and support of future efficacy evaluation. Both agents have favorable pharmacokinetics, and use is complicated by injection site reactions.SummaryLong-acting injectable formulations, if safe and well tolerated, may improve pharmacokinetic coverage of exposures to HIV infection. Complexities around safety, tolerability, and starting/stopping protocols require careful consideration. Article	2016	Leal, Lorna; Torres, Berta; León, Agathe; Lucero, Constanza; Inciarte, Alexy; Diaz-Brito, Vicens; de Lazzari, Elisa; Gatell, José María; García, Felipe	Predictive Factors for HIV Seroconversion Among Individuals Attending a Specialized Center After an HIV Risk Exposure: A Case-Control Study.	AIDS Research and Human Retroviruses	-	-	-	1931-8405 0889-2229	10.1089/AID.2016.0062	https://pubmed.ncbi.nlm.nih.gov/27457508/	OBJECTIVE: To better target our current prevention strategies, we assessed factors associated with HIV seroconversion in individuals attending a specialized center after a risk exposure. MATERIALS AND METHODS: We studied individuals from an HIV Unit's contact risk cohort at a tertiary care hospital in Barcelona, Spain, between 2003 and 2013 and performed a retrospective matched case-control study. Cases were individuals who seroconverted to HIV after at least 3 months since first follow-up visit for a contracting risk. Controls were HIV-negative individuals from the same cohort. Demographics and behavior variables were studied and compared using a McNemar test assessing factors associated with seroconversion. Univariate analysis and binary logistic regression were performed to develop a model for predicting probability of HIV seroconversion. We also evaluated sensitivity and specificity of our model and an area under Receiver Operating Characteristic (ROC) curve was estimated. RESULTS: Sixty-nine (2.2%) individuals seroconverted after a median (interquartile range) of 24 (9-34) months since last follow-up. Seroconverters were predominantly male (96%) and men who have sex with men (MSM) (94%). No differences were observed regarding risk of exposure. Being MSM odds ratio (OR) 5.2 (1.4-20.2), p = .01, having a known HIV-positive partner OR 2.7 (1.2-6.2), p = .02, previous postexposure prophylaxis (PEP) OR 3.9 (1.0-15.6), p = .05, and having previous sexually transmitted infections (STIs) OR 4.6 (1.9-10.9), p = .001 were the factors independently associated with HIV seroconversion. The sensitivity and specificity of our model were 64.06% and 73.53%, respectively, and the area under ROC curve was 0.777. DISCUSSION: HIV seroconversions were observed frequently between individuals attending a specialized center because of a risk exposure. Being MSM, having had previous PEP, an HIV-positive sexual partner, and previous STI were predictive factors for HIV seroconversion. Closer and longer follow-up and/or pre-exposure prophylaxis should be considered to prevent HIV infections in this high-risk population. Article	2016	Lebouché B.; Engler K.; Machouf N.; Lessard D.; Thomas R.	Predictors of interest in taking pre-exposure prophylaxis among men who have sex with men who used a rapid HIV-testing site in Montreal (Actuel sur Rue)	HIV Medicine	-	-	-	14642662	10.1111/hiv.12286	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84956877154&doi=10.1111%2fhiv.12286&partnerID=40&md5=5e20449bce7a5a5fc520d9b30906c8ad	Objectives: The effective use of pre-exposure prophylaxis (PrEP) as an HIV prevention strategy depends on its uptake by individuals at high risk of infection. Few Canadian data are available on interest in PrEP among men who have sex with men (MSM). This study aimed to identify predictors of interest in PrEP among MSM clients of a rapid HIV-testing site in Montreal's gay village (Actuel sur Rue). Methods: Data were collected using a self-administered and a community agent-administered questionnaire. Among men reporting at least one male sexual partner and visiting the site between July 2012 and November 2013, we aimed to identify sociodemographic, sexual and temporal predictors of interest in taking effective PrEP with logistic regression analyses (univariate and multivariable). Results: Over half (55%; n=653) of the sample of 1179 MSM were interested in PrEP. Among the 14 variables considered in the univariate analyses, only (younger) age, (greater) number of sexual partners (in the past 3 months), being part of a serodiscordant couple (in the past 12 months), ever combining sex with drugs and temporal events were associated with interest in PrEP at P<0.20 and were included in the multivariable analyses. In the multivariable model, only being part of a serodiscordant couple adjusted odds ratio (aOR) 2.56; 95% confidence interval (CI) 1.44-4.58, having >10 partners (aOR 1.73; 95% CI 1.17-2.55) and responding after the publication of Quebec's interim PrEP guidelines (aOR 1.82; 95% CI 1.22-2.71) proved significant. Conclusions: In this assessment of predictors of PrEP interest among Canadian MSM, partnering issues and the arrival of PrEP guidelines in Quebec (10 July 2013) were most closely linked to PrEP interest. © 2016 British HIV Association. Theses and Dissertations	2016	Leech, Ashley Ann	Examining access and cost implications for HIV serodiscordant couples seeking conception services: an integrative approach	-	-	Boston University	-	NA	NA	http://hdl.handle.net/2144/19589	The FDA approved pre-exposure prophylaxis (PrEP) with Truvada® in 2012 as the first drug to reduce the risk of HIV infection among uninfected individuals (FDA 2012). There is a strong scientific base for its effectiveness among uninfected heterosexual individuals who engage in sexual intercourse with HIV-infected partners. Studies further reveal no significant differences by HIV-infection status in regard to childbearing motivations or future pregnancy motivations (Finocchario-Kessler 2012). Historically, serodiscordant couples comprised of an HIV-positive male and HIV-negative female have faced challenges to accessible, affordable options for safe conception. Assisted reproductive technologies (ART) are often prohibitively expensive and also largely inaccessible to this population. The CDC suggests PrEP as another reproductive option for these couples to reduce the risk of sexual HIV acquisition during periconception and pregnancy. Truvada® for PrEP, however, is also costly and may provide only modest additional prevention benefits to serodiscordant couples in which the HIV-infected partner is already on anti-retroviral therapy with suppressed HIV viremia. cART for the infected partner is recommended regardless of conception plans due to proven health benefits for people living with HIV (PLHIV). However, there is also a prevention benefit to the non-infected partner when the HIV-positive partner is on cART, with a relative risk reduction of 96% (Cohen et al. 2011). While Truvada® for PrEP is potentially a more accessible option for these couples compared to assisted reproductive technology services, adoption of PrEP has been slow among providers. In addition to better understanding the impact of PrEP when the male partner is consistently on cART, it is also critical to understand the barriers to prescribing Truvada® for this indication. There is also insufficient information on the ability of HIV-serodiscordant couples to access other reproductive options outside of PrEP. Whether for the purpose of risk reduction or for supported fertility, serodiscordant couples should have access to the same spectrum of reproductive services as non-HIV affected couples. The overall research question this thesis addressed was: What are the access and cost implications for HIV serodiscordant couples seeking conception services in the United States? To address these issues, I used the following methods: (1) a cross-sectional survey of infectious disease, internal medicine, and family medicine providers to determine prescribing behaviors and perceptions of PrEP utilization; results analyzed using multivariate regression modeling; (2) "secret shopper" methodology whereby a physician and "patient" carried out scripted phone calls to fertility clinics to gauge a more realistic picture of access; results analyzed using McNemar tests to assess marginal homogeneity and chi square goodness of fit; and (3) cost effectiveness analysis using a Markov state-transition model to project long-term clinical outcomes, costs, and…	Public health	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Quantitative
Article	2016	Lelutiu-Weinberger, Corina; Golub, Sarit A	Enhancing PrEP Access for Black and Latino Men Who Have Sex With Men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001140	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5110381	OBJECTIVE: Implementation of HIV pre-exposure prophylaxis (PrEP) programs for populations with highest incidence is critical to reducing new infections in the United States. Black and Latino men who have sex with men (BLMSM) are disproportionately burdened by HIV. We examined differences in perceived barriers and facilitators to PrEP access for BLMSM compared with other men who have sex with men (MSM). METHOD: MSM who met the Centers for Disease Control and Prevention criteria for PrEP (n = 491) completed measures of barriers and facilitators to PrEP at the systems, provider, and individual levels. Multivariate analyses examined differences by race/ethnicity, adjusting for other sociodemographic factors. RESULTS: Compared with other MSM, BLMSM (56% of the sample) were more likely to have public insurance and to access health care via public clinics adjusted odds ratio(aOR) 3.2, P < 0.001; aOR 2.4, P < 0.01. BLMSM were more likely to regard having to talk to their doctor about their sex life as a barrier to PrEP (aOR 3.7, P < 0.001) and were less likely to endorse agency in medical decision making (aOR 0.58, P < 0.001). BLMSM were more likely to report PrEP stigma (aOR 2.3, P < 0.001) and concerns regarding PrEP efficacy (aOR 1.6, P < 0.05). BLMSM were more likely to consider access to free sexual health care (aOR 2.1, P < 0.01) and additional supportive services, eg, counseling (aOR 3.1, P < 0.001) or text-based support (aOR 2.9, P < 0.001) to be significant facilitators of PrEP use. CONCLUSIONS: Findings suggest specific points of multilevel intervention to increase PrEP access for BLMSM and increase representation of BLMSM along the PrEP continuum of care. Article	2016	Liu A.Y.; Cohen S.E.; Vittinghoff E.; Anderson P.L.; Doblecki-Lewis S.; Bacon O.; Chege W.; Postle B.S.; Matheson T.; Rivet Amico K.; Liegler T.; Keith Rawlings M.; Trainor N.; Blue R.W.; Estrada Y.; Coleman M.E.; Cardenas G.; Feaster D.J.; Grant R.; Philip S.S.; Elion R.; Buchbinder S.; Kolber M.A.	Preexposure prophylaxis for HIV infection integrated with municipal-and community-based sexual health services	JAMA Internal Medicine	-	-	-	21686106	10.1001/jamainternmed.2015.4683	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84954562396&doi=10.1001%2fjamainternmed.2015.4683&partnerID=40&md5=06ee432447623d78c1874c04b3f6b9a0	Importance Several randomized clinical trials have demonstrated the efficacy of preexposure prophylaxis (PrEP) in preventing human immunodeficiency virus (HIV) acquisition. Little is known about adherence to the regimen, sexual practices, and overall effectiveness when PrEP is implemented in clinics that treat sexually transmitted infections (STIs) and community-based clinics serving men who have sex with men (MSM). Objective To assess PrEP adherence, sexual behaviors, and the incidence of STIs and HIV infection in a cohort of MSM and transgender women initiating PrEP in the United States. Design, Setting, and Participants Demonstration project conducted from October 1, 2012, through February 10, 2015 (last date of follow-up), among 557 MSM and transgender women in 2 STI clinics in San Francisco, California, and Miami, Florida, and a community health center inWashington, DC. Data were analyzed from December 18, 2014, through August 8, 2015. Interventions A combination of daily, oral tenofovir disoproxil fumarate and emtricitabine was provided free of charge for 48 weeks. All participants received HIV testing, brief client-centered counseling, and clinical monitoring. Main Outcomes and Measures Concentrations of tenofovir diphosphate in dried blood spot samples, self-reported numbers of anal sex partners and episodes of condomless receptive anal sex, and incidence of STI and HIV acquisition. Results Overall, 557 participants initiated PrEP, and 437 of these (78.5%) were retained through 48 weeks. Based on the findings from the 294 participants who underwent measurement of tenofovir diphosphate levels, 80.0%to 85.6%had protective levels (consistent with 4 doses/wk) at all follow-up visits. African American participants (56.8%of visits; P =.003) and those from the Miami site (65.1%of visits; P <.001) were less likely to have protective levels, whereas those with stable housing (86.8%; P =.02) and those reporting at least 2 condomless anal sex partners in the past 3 months (88.6%; P =.01) were more likely to have protective levels. The mean number of anal sex partners declined during follow-up from 10.9 to 9.3, whereas the proportion engaging in condomless receptive anal sex remained stable at 65.5%to 65.6%. Overall STI incidence was high (90 per 100 person-years) but did not increase over time. Two individuals became HIV infected during follow-up (HIV incidence, 0.43 95%CI, 0.05-1.54 infections per 100 person-years); both had tenofovir diphosphate levels consistent with fewer than 2 doses/wk at seroconversion. Conclusions and Relevance The incidence of HIV acquisition was extremely low despite a high incidence of STIs in a large US PrEP demonstration project. Adherence was higher among those participants who reported more risk behaviors. Interventions that address racial and geographic disparities and housing instabilitymay increase the impact of PrEP. © 2016 American Medical Association. All rights reserved. Article	2016	Lu Y.; Goti V.; Chaturvedula A.; Haberer J.E.; Fossler M.J.; Sale M.E.; Bangsberg D.; Baeten J.M.; Celum C.L.; Hendrix C.W.	Population pharmacokinetics of tenofovir in HIV-1-uninfected members of serodiscordant couples and effect of dose reporting methods	Antimicrobial Agents and Chemotherapy	-	-	-	664804	10.1128/AAC.00559-16	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84983315103&doi=10.1128%2fAAC.00559-16&partnerID=40&md5=714c0171d1e4d8a324e1cfdfe8b2e5d1	Antiretroviral preexposure prophylaxis (PrEP) with once-daily dosing of tenofovir and tenofovir-emtricitabine was shown to be effective for preventing HIV-1 infection in individuals who had HIV-1-seropositive partners (the Partners PrEP Study). We developed a population pharmacokinetic model for tenofovir and investigated the impacts of different dose reporting methods. Dosing information was collected as patient-reported dosing information (PRDI) from 404 subjects (corresponding to 1,280 drug concentration records) from the main trial and electronic monitoring-based adherence data collected from 211 subjects (corresponding to 327 drug concentration records) in an ancillary adherence study. Model development was conducted with NONMEM (7.2), using PRDI with a steady-state assumption or using PRDI replaced with electronic monitoring records where available. A two-compartment model with first-order absorption was the best model in both modeling approaches, with the need for an absorption lag time included when electronic monitoring-based dosing records were included in the analysis. Age, body weight, and creatinine clearance were significant covariates on clearance, but only creatinine clearance was retained in the final models per backward elimination. Sex was not a significant covariate on clearance. Tenofovir population pharmacokinetic parameter estimates and the precisions of the parameters from the two final models were comparable with the point estimates of the parameters, differing from 0% to 35%, and bootstrap confidence intervals widely overlapped. These findings indicate that PRDI was sufficient for population pharmacokinetic model development in this study, with a high level of adherence per multiple measures. Article	2016	Luecke E.H.; Cheng H.; Woeber K.; Nakyanzi T.; Mudekunye-Mahaka I.C.; Van Straten A.D.	Stated product formulation preferences for HIV pre-exposure prophylaxis among women in the VOICE-D (MTN-003D) study	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.19.1.20875	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84974534340&doi=10.7448%2fIAS.19.1.20875&partnerID=40&md5=fbf2340f9c1032192ca92a39ba617c4f	Introduction: The effectiveness of HIV pre-exposure prophylaxis (PrEP) requires consistent and correct product use, thus a deeper understanding of women's stated product formulation preferences, and the correlates of those preferences, can help guide future research. VOICE-D (MTN-003D), a qualitative ancillary study conducted after the VOICE trial, retrospectively explored participants' tablet and gel use, as well as their preferences for other potential PrEP product formulations. Methods: We conducted an analysis of quantitative and qualitative data from VOICE-D participants. During in-depth interviews, women were presented with pictures and descriptions of eight potential PrEP product formulations, including the oral tablet and vaginal gel tested in VOICE, and asked to discuss which product formulations they would prefer to use and why. Seven of the original product formulations displayed were combined into preferred product formulation categories based on exploratory factor and latent class analyses. We examined demographic and behavioural correlates of these preferred product formulation categories. In-depth interviews with participants were conducted, coded, and analyzed for themes related to product preference. Results: Of the 68 female participants who completed in-depth interviews (22 South Africa, 24 Zimbabwe, 22 Uganda), median age was 28 (range 21–41), 81% were HIV negative, and 49% were married or living with a partner. Four preferred product formulation categories were identified via exploratory factor analysis: 1) oral tablets; 2) vaginal gel; 3) injectable, implant, or vaginal ring; and 4) vaginal film or suppository. A majority of women (81%) expressed a preference for product formulations included in category 3. Characteristics significantly associated with each preferred product category differed. Attributes described by participants as being important in a preferred product formulation included duration of activity, ease of use, route of administration, clinic- versus self-administration, and degree of familiarity with product. Conclusions: While there was interest in a variety of potential PrEP product formulations, a majority of VOICE-D participants preferred long-acting methods. More research is needed to gain insight into end-users' product formulation preference to inform messaging and market segmentation for different PrEP products and resources to invest in products that target populations are most interested in using. HIV-1-neutralizing IgA detected in genital secretions of highly HIV-1-exposed seronegative women on oral preexposure prophylaxis	Journal of Virology	-	-	-	0022538X	10.1128/JVI.01482-16	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84994060602&doi=10.1128%2fJVI.01482-16&partnerID=40&md5=8481966bf777b6de50f4c4b762c70d77	Although nonhuman primate studies have shown that simian immunodeficiency virus/simian-human immunodeficiency virus (SIV/SHIV) exposure during preexposure prophylaxis (PrEP) with oral tenofovir can induce SIV immunity without productive infection, this has not been documented in humans. We evaluated cervicovaginal IgA in Partners PrEP Study participants using a subtype C primary isolate and found that women on PrEP had IgA with higher average human immunodeficiency virus type 1 (HIV-1)-neutralizing magnitude than women on placebo (33% versus 7%; P = 0.008). Using a cutoff of ≥90% HIV-1 neutralization, 19% of women on-PrEP had HIV-1-neutralizing IgA compared to 0% of women on placebo (P = 0.09). We also estimated HIV-1 exposure and found that the proportion of women with HIV-1-neutralizing IgA was associated with the level of HIV-1 exposure (P = 0.04). Taken together, our data suggest that PrEP and high levels of exposure to HIV may each enhance mucosal HIV-1-specific humoral immune responses in sexually exposed but HIV-1-uninfected individuals. © 2016, American Society for Microbiology. Theses and Dissertations	2016	Lyu, Yafei	Development of Tenofovir Prodrugs as Rectal Microbicides for HIV Prevention	-	-	University of Pittsburgh	-	NA	NA	http://d-scholarship.pitt.edu/29219/	Receptive anal intercourse is common among men who have sex with men (MSM), transgender women, and practiced by women around the world. The risk of becoming infected with HIV through receptive anal intercourse is 20 times greater than vaginal intercourse. Hence, there is an urgent need for the development of rectal specific topical pre-exposure prophylaxis (PrEP) products. In the current study, our lab developed enemas containing tenofovir (TFV) for rectal application, which may provide some advantages with respect to user acceptability and compliance. In addition to evaluation of TFV in enemas, prodrugs of TFV: tenofovir alafenamide fumarate (TAF) and hexadecyloxypropyl (HDP)-tenofovir (CMX157) were evaluated due to their increased potency and better safety profile. In this project, a high performance liquid chromatography (HPLC) method for TAF was developed and qualified. Preformulation studies for TAF including solubility, hydrolytic, thermal, photolytic, and oxidative stability and preservative compatibility were conducted. TAF was found to be susceptible to hydrolytic degradation in acidic pH (pH≤4) and degraded when exposed in an aqueous solution to temperatures greater than 25°C. TAF hypotonic and isotonic enema formulations (1.76 mg/mL) were developed and characterized with respect to pH, osmolality, and drug content. One-week stability of these enemas was assessed in 40°C/75% RH, 30°C/65% RH and 25°C/60% RH environmental chambers. TAF enemas were stable for one week. In addition to the TAF enema, formulation efforts were initiated with CMX157. A preliminary HPLC method for CMX157 was developed. Prototype CMX157 enemas were prepared and pH and osmolality testing conducted. Additional formulation optimization is required to enhance TAF stability in an enema format. Further investigation of the prototype CMX157 enema developed with respect to its physiochemical characteristics and stability is needed. Article	2016	MacFadden D.R.; Tan D.H.; Mishra S.	Optimizing HIV pre-exposure prophylaxis implementation among men who have sex with men in a large urban centre: A dynamic modelling study	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.19.1.20791	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85015941564&doi=10.7448%2fIAS.19.1.20791&partnerID=40&md5=64dcc4761bc7f575c8b1f9d701911733	Introduction: Once-daily tenofovir/emtricitabine-based pre-exposure prophylaxis (PrEP) can reduce HIV acquisition in men who have sex with men (MSM), by 44% in the iPrEx trial, and reaching up to 99% with high adherence. We examined the potential population-level impact and cost-effectiveness of different PrEP implementation strategies. Methods: We developed a dynamic, stochastic compartmental model of HIV transmission among the estimated 57,400 MSM in Toronto, Canada. Parameterization was performed using local epidemiologic data. Strategies examined included (1) uniform PrEP delivery versus targeting the highest risk decile of MSM (with varying coverage proportions); (2) increasing PrEP efficacy as a surrogate of adherence (44% to 99%); and (3) varying HIV test frequency (once monthly to once yearly). Outcomes included HIV infections averted and the incremental cost ($CAD) per incremental quality-adjusted-life-year (QALY) gained over 20 years. Results: Use of PrEP among all HIV-uninfected MSM at 25, 50, 75 and 100% coverage prevented 1970, 3427, 4317, and 4581 infections, respectively, with cost/QALY increasing from $500,000 to $800,000 CAD. Targeted PrEP for the highest risk MSM at 25, 50, 75 and 100% coverage prevented 1166, 2154, 2816, and 3012 infections, respectively, with cost/QALY ranging from $35,000 to $70,000 CAD. Maximizing PrEP efficacy, in a scenario of 25% coverage of high-risk MSM with PrEP, prevented 1540 infections with a cost/QALY of $15,000 CAD. HIV testing alone (Q3 months) averted 898 of infections with a cost savings of $4,000 CAD per QALY. Conclusions: The optimal implementation strategy for PrEP over the next 20 years at this urban centre is to target high-risk MSM and to maximize efficacy by supporting PrEP adherence. A large health benefit of PrEP implementation could come from engaging undiagnosed HIV-infected individuals into care. Copyright © 2016 MacFadden DR et al; licensee International AIDS Society. Article	2016	Machado, Alexandra; Cunha-Reis, Cassilda; Araújo, Francisca; Nunes, Rute; Seabra, Vítor; Ferreira, Domingos; das Neves, José; Sarmento, Bruno	Development and in vivo safety assessment of tenofovir-loaded nanoparticles-in-film as a novel vaginal microbicide delivery system.	Acta Biomaterialia	-	-	-	1878-7568 1742-7061	10.1016/j.actbio.2016.08.018	https://pubmed.ncbi.nlm.nih.gov/27544812/	Topical pre-exposure prophylaxis (PrEP) with antiretroviral drugs holds promise in preventing vaginal transmission of HIV. However, significant biomedical and social issues found in multiple past clinical trials still need to be addressed in order to optimize protection and users' adherence. One approach may be the development of improved microbicide products. A novel delivery platform comprising drug-loaded nanoparticles (NPs) incorporated into a thin polymeric film base (NPs-in-film) was developed in order to allow the vaginal administration of the microbicide drug candidate tenofovir. The system was optimized for relevant physicochemical features and characterized for biological properties, namely cytotoxicity and safety in a mouse model. Tenofovir-loaded poly(lactic-co-glycolic acid) (PLGA)/stearylamine (SA) composite NPs with mean diameter of 127nm were obtained with drug association efficiency above 50%, and further incorporated into an approximately 115μm thick, hydroxypropyl methylcellulose/poly(vinyl alcohol)-based film. The system was shown to possess suitable mechanical properties for vaginal administration and to quickly disintegrate in approximately 9min upon contact with a simulated vaginal fluid (SVF). The original osmolarity and pH of SVF was not affected by the film. Tenofovir was also released in a biphasic fashion (around 30% of the drug in 15min, followed by sustained release up to 24h). The incorporation of NPs further improved the adhesive potential of the film to ex vivo pig vaginal mucosa. Cytotoxicity of NPs and film was significantly increased by the incorporation of SA, but remained at levels considered tolerable for vaginal delivery of tenofovir. Moreover, histological analysis of genital tissues and cytokine/chemokine levels in vaginal lavages upon 14days of daily vaginal administration to mice confirmed that tenofovir-loaded NPs-in-film was safe and did not induce any apparent histological changes or pro-inflammatory response. Overall, obtained data support that the proposed delivery system combining the use of polymeric NPs and a film base may constitute an exciting alternative for the vaginal administration of microbicide drugs in the context of topical PrEP. STATEMENT OF SIGNIFICANCE: The development of nanotechnology-based microbicides is a recent but promising research field seeking for new strategies to circumvent HIV sexual transmission. Different reports detail on the multiple potential advantages of using drug nanocarriers for such purpose. However, one important issue being frequently neglected regards the development of vehicles for the administration of microbicide nanosystems. In this study, we propose and detail on the development of a nanoparticle-in-film system for the vaginal delivery of the microbicide drug candidate tenofovir. This is an innovative approach that, to our best knowledge, had never been tested for tenofovir. Results, including those from in vivo testing, sustain that the proposed system is safe and holds potential for further development as a vaginal microbicide product. Article	2016	Marcus J.L.; Volk J.E.; Pinder J.; Liu A.Y.; Bacon O.; Hare C.B.; Cohen S.E.	Successful Implementation of HIV Preexposure Prophylaxis: Lessons Learned From Three Clinical Settings	Current HIV/AIDS Reports	-	-	-	-	15483568	10.1007/s11904-016-0308-x	https://www.scopus.com/inward/record.url?eid=2-s2.0-84955816964&doi=10.1007%2Fs11904-016-0308-x&partnerID=40&md5=2a9b8d520da0c31f2b519875d1d19e2c7	The past 3 years have marked a transition from research establishing the safety and efficacy of HIV preexposure prophylaxis (PrEP) to questions about how to optimize its implementation. Until recently, PrEP was primarily offered as part of randomized controlled trials or open-label studies. These studies highlighted the key components of PrEP delivery, including regular testing for HIV and other sexually transmitted infections (STIs), adherence and risk-reduction support, and monitoring for renal toxicity. PrEP is now increasingly provided in routine clinical settings. This review summarizes models for PrEP implementation from screening through initiation and follow-up, focusing on the strengths and weaknesses of three delivery systems: a health maintenance organization, an STI clinic, and a primary care practice. These early implementation experiences demonstrate that PrEP can be successfully delivered across a variety of settings and highlight strategies to streamline PrEP delivery in clinical practice. © 2016, Springer Science+Business Media New York. Article	2016	Marcus, Jala L; Hurley, Leo B; Hare, C Bradley; Silverberg, Michael J; Volk, Jonathan E	Disparities in Uptake of HIV Preexposure Prophylaxis in a Large Integrated Health Care System.	American Journal of Public Health	-	-	-	-	1541-0048	10.2105/AJPH.2016.303339	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5024380/	Although uptake of HIV preexposure prophylaxis (PrEP) is increasing,1,2 lower uptake among key HIV risk groups could further increase existing disparities in the HIV epidemic.3,4 However, it is unknown whether certain demographic subgroups are underrepresented among PrEP users compared with individuals who recently acquired HIV infection. Thus, we compared demographic characteristics of PrEP users with those of recent HIV seroconverters within the Kaiser Permanente Northern California (KPNC) health care system. KPNC provides comprehensive medical services to 3.9 million members, approximately 25% of the population in this region.5 METHODS: We identified KPNC members who initiated PrEP or acquired HIV infection during the first 3 years of PrEP availability in the population. We included KPNC members who either initiated PrEP or acquired HIV infection. PrEP users were those who initiated PrEP after the US Food and Drug Administration (FDA) approval (i.e., July 2012–December 2014). Because the demographic composition of those who acquired HIV infection may have changed as high-risk individuals have initiated PrEP, we included HIV seroconverters from the three years just before FDA approval of PrEP (i.e., July 2009–June 2012). Seroconversion were defined as a first lifetime HIV diagnosis at KPNC after a negative HIV test during the three-year pre-PrEP period. Seroconverters were identified using the KPNC HIV registry, and demographic data were collected from the electronic health record. Complete data were not available on transgender identity or HIV-transmission risk factor. We identified 235 HIV seroconverters and 972 PrEP users (Table 1). Seroconverters were significantly younger than PrEP users (mean age = 34.9 vs 37.9 years; P < .001), with 37.9% of seroconverters younger than 30 years compared with 25.7% of PrEP users. Nearly all seroconverters and PrEP users were male (98.3% vs 97.9%; P = .73). There were differences between HIV seroconverters and PrEP users with respect to race/ethnicity (P < .001), compared with PrEP users, HIV seroconverters were more frequently Black (23.0% vs 6.5%) or Hispanic (39.7% vs 12.2%), and less frequently White (45.9% vs 69.6%). Article	2016	Marcus, Jala L; Hurley, Leo B; Hare, Charles Bradley; Nguyen, Dong Phuong; Phengrasamy, Tony; Silverberg, Michael J; Shirley, Juliet E; Volk, Jonathan E	Preexposure Prophylaxis for HIV Prevention in a Large Integrated Health Care System: Adherence, Renal Safety, and Discontinuation.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000001129	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5426417/	BACKGROUND: Placebo-controlled and open-label studies have demonstrated the safety and efficacy of daily oral preexposure prophylaxis (PrEP) in preventing HIV infection, but data are limited on real-world PrEP use. METHODS: We conducted a cohort study from July 2012 through June 2015 of Kaiser Permanente Northern California members initiating PrEP. We assessed pharmacy refill adherence and seroconversions, decreases in estimated glomerular filtration rate (eGFR), and sexually transmitted infection (STI)/HIV incidence. RESULTS: Overall, 972 individuals initiated PrEP, accumulating 850 person-years of PrEP use. Mean adherence was 92% overall. Black race/ethnicity adjusted risk ratio (aRR) 3.0; 95% confidence interval: 1.7 to 5.1, P < 0.001, higher copayments (aRR 2.0; 1.2 to 3.3, P = 0.005), and smoking (aRR 1.6; 1.1 to 2.3, P = 0.023) were associated with <80% adherence. PrEP was discontinued by 219 (22.5%), female sex (aRR 2.6; 1.5 to 4.4, P < 0.001) and drug/alcohol abuse (aRR 1.8; 1.1 to 2.6, P = 0.002) were associated with discontinuation. Among 909 with follow-up creatinine testing, 161 (15.5%) had an eGFR <70 mL/min/1.73 m2 and 53 (5.6%) stopped PrEP because of low eGFR. Among 972 PrEP users, 9 seroconverted (incidence 1.06 per 100 person-years), 7 of whom were prescribed PrEP <80% of days covered. Two seroconverters were not prescribed PrEP and 1 was enrolled in a PrEP demonstration project. Seroconverters were younger than PrEP users (median age = 34.9 vs 37.9 years, P = .001), with 37.9% of seroconverters younger than 30 years compared with 25.7% of PrEP users. Nearly all seroconverters and PrEP users were male (98.3% vs 97.9%, P = .73). There were differences between HIV seroconverters and PrEP users with respect to race/ethnicity (P < .001), compared with PrEP users, HIV seroconverters were more frequently Black (23.0% vs 6.5%) or Hispanic (39.7% vs 12.2%), and less frequently White (45.9% vs 69.6%).	preexposure prophylaxis (PrEP), HIV, sexually transmitted infections (STI), renal insufficiency, medication adherence	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Integration of Social, Cultural, and Biomedical Strategies into an Existing Couple-Based Behavioral HIV/STI Prevention Intervention: Voices of Latino Male Couples.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0152561	https://pubmed.ncbi.nlm.nih.gov/27028873/	INTRODUCTION: Successful HIV prevention and treatment requires evidence-based approaches that combine biomedical strategies with behavioral interventions that are sociably and culturally appropriate for the population or community being prioritized. Although there has been a push for a combination approach, how best to integrate different strategies into existing behavioral HIV prevention interventions remains unclear. Latino men who have sex with men (MSM) are disproportionately affected by HIV, particularly transgender women. Their increased vulnerability to HIV is due to multiple issues, including biological (eg, increased efficiency of HIV transmission through receptive anal sex), epidemiological (eg, increased likelihood of having HIV-infected partners), structural (eg, social stigma limiting employment options), and individual factors (eg, internalized stigma leading to depression and substance use and risk-taking behaviors). There have been limited culturally appropriate HIV prevention interventions for transgender people, with many key questions remaining. The One Love Couples Project was developed to address this gap. METHODS: We conducted a process evaluation of the One Love Couples Project to understand how to integrate transgender people's risk for HIV acquisition. The current supplement of JAIDS is designed to review what is known about HIV prevention for transgender people and highlight new insights and best practices. The study reviews recent epidemiologic data, the pharmacology of HIV prophylactic agents in individuals who may be using exogenous hormones, and several recent multi-component interventions designed to address the lived experience of transgender people. Additionally, the study reviews the work going on at the NIH to address transgender health in general and HIV prevention as specific, as well as two important papers related to clinical trial design issues and the ethical conduct of research in this frequently disenfranchised population. It is the hope of the HIV Prevention Trials Network (HPTN) that this supplement will promote new knowledge around transgender health and the requisite issues that need to be addressed in order to conduct optimal clinical trials. The ultimate hope is that the information distilled in this supplement will inform investigators, clinicians, and public health officials in order to design further research to develop optimal prevention interventions for transgender people and to implement these interventions in ways that are culturally congruent and health promoting. Article	2016	Meyer K.H.; Oldenburg C.E.; Novak D.S.; Elsesser S.A.; Krakower D.S.; Mimiaga M.J.	Early Adopters Correlates of HIV Chemoprophylaxis Use in Recent Online Samples of US Men Who Have Sex with Men	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-015-1227-1	https://www.scopus.com/inward/record.url?eid=2-s2.0-84946129644&doi=10.1007%2Fs10461-015-1227-1&partnerID=40&md5=12e3980e69bcbc40d0f13bc7e7fca094	To date, little data on pre-exposure prophylaxis (PrEP) users outside of the clinical trial setting are available. A repeated cross-sectional survey of one of the largest social and sexual networking websites for men who have sex with men (MSM) in the United States was conducted in August 2013 (Wave 1) and January 2014 (Wave 2). Multivariable logistic regression models were used to examine factors associated with having heard of and having taken post-exposure prophylaxis (PEP) and PrEP in Wave 1 (N = 4043) and Wave 2 (N = 2737) separately. In Wave 1, 147 (3.6 %) and 61 (1.5 %) reported using PrEP and PEP, respectively, compared to 119 (4.4 %) and 82 (2.2 %) in Wave 2. Higher-risk sexual behaviors were associated with having taken PEP and PrEP, and younger MSM were associated with having taken PrEP. Understanding factors that are associated with early use of PrEP may help inform wider utilization of PrEP by at-risk MSM. © 2015, Springer Science+Business Media New York. Article	2016	McCormack, Sheena Mary; Noseda, Veronica; Molina, Jean-Michel	PrEP in Europe - expectations, opportunities and barriers.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.19.7.21103	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5577371/	INTRODUCTION: In contrast to the global trend showing a decline in new HIV infections, the number reported in the World Health Organization (WHO) region of Europe is increasing. Health systems are disparate, but even countries with less access to screening and treatment observe continuing high rates of new infections in key populations, notably men who have sex with men (MSM). Pre-exposure prophylaxis (PrEP) is highly effective in reducing HIV incidence among populations at substantial risk of HIV infection. However, where PrEP should be prioritised, and for which of the troubled health systems, DISCUSSION: Health systems and governance commitment to HIV prevention and care, both financial and political, differ considerably between the countries that make up Europe. A common feature is that funds for prevention are a small fraction of funds for care. Although care is generally good, access is limited in the middle-income countries of Eastern Europe and central Asia, and only 19% of people living with HIV received antiretroviral therapy in 2014. It is challenging to motivate governments or civil society to implement PrEP in the context of this unmet treatment need, which is driven by limited national health budgets and diminishing assistance from foreign aid. The high-income countries of Western Europe have hesitated to embrace PrEP for different reasons, initially due to key gaps in the evidence. Now that PrEP has been shown to be highly effective in European MSM in two randomised controlled trials, it is clear that the major barrier is the cost of the drug which is still on patent, although inadequate health systems and diminishing investment in civil society are also key challenges to overcome. CONCLUSIONS: The momentum to implement PrEP in European countries is increasing and provides a welcome opportunity to expand and improve clinical services and civil society support focused on HIV and related infections among other sexually transmitted and blood-borne infections. Article	2016	McGillen J.B.; Anderson S.-J.; Hallett T.B.	PrEP as a feature in the optimal landscape of combination HIV prevention in sub-Saharan Africa	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.19.7.21102	https://www.scopus.com/inward/record.url?eid=2-s2.0-84953883824&doi=10.7448%2FIAS.19.7.21102&partnerID=40&md5=1a1d2f4b87cf1355042213c3187815f4	Introduction: The new WHO guidelines recommend offering pre-exposure prophylaxis (PrEP) to people who are at substantial risk of HIV infection. However, where PrEP should be prioritised, and for which population groups, remains an open question. The HIV landscape in sub-Saharan Africa features limited prevention resources, multiple options for achieving cost saving, and epidemic heterogeneity. This paper examines what role PrEP should play as optimal prevention in this complex and dynamic landscape. Methods: We use a model that was previously developed to capture subnational HIV transmission in sub-Saharan Africa. With the model, we can consider how prevention funds could be distributed across and within countries throughout sub-Saharan Africa to enable optimal HIV prevention (that is, avert the greatest number of infections for the lowest cost). Here, we focus on PrEP to elucidate where, and to whom, it would optimally be offered in prevention and distinguish whether subnational need (circumcision, treatment as prevention, and behaviour change communication). Over a range of continental expenditure levels, we use our model to explore prevention patterns that incorporate PrEP, include PrEP but exclude it, and maximise the health impact without PrEP. Results: Our results show that PrEP can substantially improve the health impact of prevention expenditure: for example, PrEP can provide the same health impact as a 50% increase in prevention funding without PrEP. Prioritisation of PrEP would expand with increasing total expenditure, such that the optimal prevention portfolios would include PrEP in more subnational regions and increasingly for men who have sex with men (MSM) and the lower incidence general population. The marginal benefit of including PrEP among the available interventions increases with overall expenditure by up to 14% (relative to excluding PrEP). The minimum baseline incidence for the optimal offer of PrEP declines for all population groups as expenditure increases. We find that using a fixed incidence benchmark to guide PrEP decisions would incur considerable losses in impact (up to 7%) compared with an approach that uses PrEP more flexibly in light of prevailing budget conditions. Conclusions: Our findings suggest that, for an optimal distribution of prevention resources, choices of whether to implement PrEP in subnational regions should depend on the scope for impact of other possible interventions, local incidence in population groups, and total resources available. If prevention funding were to become restricted in the future, it may be suboptimal to use PrEP according to a fixed incidence benchmark, and other prevention modalities may be more cost-effective. In contrast, expansions in funding could permit PrEP to be used to its full potential in epidemiologically driven prevention portfolios and thereby enable a more cost-effective HIV response across Africa. © 2016 McGillen JB et al; licensee International AIDS Society. The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(16)30113-8	https://dx.doi.org/10.1016/S2352-3018(16)30113-8	BACKGROUND: Long-acting injectable antiretroviral agents are being developed for HIV-1 prevention. The MWRI-01 study was done to characterise the safety, acceptability, and pharmacokinetic and pharmacodynamic profile of long-acting rilpivirine. METHODS: We did a phase 1 open-label study at the University of Pittsburgh. We enrolled healthy individuals (aged 18–45 years) who were seronegative for HIV-1. Participants were assigned alternately one intramuscular dose of either 1200 mg or 900 mg long-acting rilpivirine, beginning with the 1200 mg dose. We obtained plasma specimens, genital and rectal fluids, and mucosal cells (rectal, cervical, and vaginal) before dose and after exposure to long-acting rilpivirine for assessment of pharmacokinetics and ex-vivo mucosal challenge with HIV-1. The primary objective was to characterise product safety, and the analysis included all enrolled participants. This trial is registered with ClinicalTrials.gov, number NCT01509859. FINDINGS: 20 participants were enrolled and received 1200 mg (n=10) or 900 mg (n=10) long-acting rilpivirine. Rilpivirine was detected in all genital and rectal fluid samples collected from participants who received 1200 mg. The most common adverse events were mild injection-site pain and headache. All grade 3 and 4 adverse events were deemed not related to rilpivirine. Geometric mean (90% CI) concentrations in plasma of rilpivirine at day 28 post dose were 53 ng/mL (38–67) in women and 41 ng/mL (23–61) in men for the 1200 mg dose and 28 ng/mL (19–37) in women and 17 ng/mL (9·26) in men for the 600 mg dose. The tissue-to-plasma ratio for rilpivirine in rectal tissue was about two-fold higher than in vaginal and cervical tissue (1·16 (1·13 to 9·61–0·72 and 0·50–0·71, respectively). Exposure to long-acting rilpivirine suppressed viral replication significantly in rectal tissue (p<0·0001), and this suppression persisted for up to 4 months. By contrast, no viral suppression was seen in cervical or vaginal tissue. INTERPRETATION: Ongoing research will characterise longer term safety and acceptability of multiple injections and help ascertain whether long-acting rilpivirine should advance to assessment of efficacy in preventing HIV-1 infection. Article	2016	Mugo, Nelly R; Ngure, Kenneth; Kiragu, Michael; Irungu, Elizabeth; Kilonzo, Nduku	The preexposure prophylaxis revolution: from clinical trials to programmatic implementation.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0000000000000224	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4900628/	PURPOSE OF REVIEW: An investment in preexposure prophylaxis (PrEP) delivery must have public health impact in reducing HIV infections. Sustainable delivery of PrEP requires policy, integration of PrEP delivery platforms, and resource mobilization. We review the evidence for PrEP implementation and highlight research gaps and opportunities. RECENT FINDINGS: Daily oral PrEP (tenofovir/emtricitabine, TDF/FTC) is highly efficacious in preventing HIV infection among men who have sex with men, people who inject drugs, and heterosexuals in clinical trials. PrEP delivery has been delayed by concerns about adherence and delivery in 'real world' settings. Demonstration projects and clinical service delivery models are providing evidence of PrEP effectiveness with an impact much higher than that found in randomized clinical trials. Data confirm that PrEP uptake, adherence, and retention has been high, more so by persons who perceive themselves at high risk for HIV infection, and PrEP is well tolerated. PrEP delivery is more than dispensation of a pill and programs should address other risk drivers, which differ by population. In Africa, barriers to PrEP uptake and adherence include stigma among MSM and low HIV risk perception among young women. Additional data have provided insight into optimal points of service delivery, provider training requirements and quality assurance needs. Of the 2 million new HIV infections in 2014, 70% were in Africa. PrEP use is not lifelong, and was limited to periods of risk may be both effective and cost-effective for the continent. SUMMARY: HIV prevention programs should determine strategies to identify those at substantial risk for HIV infection, formulate and deliver PrEP as combination with interventions that target social drivers of HIV, and address barriers to uptake and adherence. Cost and cost-effectiveness analyses to inform resource allocation and investment decisions for PrEP programs are required. Cost-effectiveness and efficiency data are essential for policy guidance to navigate ethical questions over use of antiretroviral therapy for HIV-negative individuals when treatment coverage has not been attained in many parts of Africa. Countries need to invest in purposeful advocacy at both local and global forums. Failure to implement PrEP will be a failure to protect future generations. Article	2016	Mugwanya, Kenneth K; Hendrix, Craig W; Mugo, Nelly R; Marrazzo, Mark; Katabira, Elly T; Ngure, Kenneth; Semiyaga, Nula R; Johnson-Stewart, Grace; Muwonge, Timothy R; Muthuri, Gabriel; Bergcotzka, Andy; Celum, Connie L; Baeten, Jared M	Pre-exposure Prophylaxis Use by Breastfeeding HIV-Uninfected Women: A Prospective Short-Term Study of Antiretroviral Excretion in Breast Milk and Infant Absorption.	PLOS Medicine	-	-	-	-	1549-1676	10.1371/journal.pmed.1002132	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5038951/	BACKGROUND: As pre-exposure prophylaxis (PrEP) becomes more widely used in heterosexual populations, an important consideration is its safety in infants who are breastfed by women taking PrEP. We investigated whether tenofovir and emtricitabine are excreted into breast milk and then absorbed by the breastfeeding infant in clinically significant concentrations when used as PrEP by lactating women. METHODS AND FINDINGS: We conducted a prospective short-term, open-label study of daily oral emtricitabine-tenofovir disoproxil fumarate PrEP among 50 HIV-uninfected breastfeeding African mother-infant pairs between 1-24 wk postpartum (ClinicalTrials.gov Identifier: NCT02776748). The primary goal was to quantify the steady-state concentrations of tenofovir and emtricitabine in infant plasma ingested through breast milk. Secondary objectives were to estimate the infant absorption of tenofovir and emtricitabine from breast milk and to assess the safety of PrEP in breastfeeding infants. Infant plasma and breast milk were obtained at drug concentration steady states on days 7 and 15, and a single infant plasma sample was obtained on day 7. Peak breast milk samples were obtained 1-2 h after the maternal DOT PrEP dose, while maternal trough samples were obtained at the end of the PrEP dosing interval (i.e., 23 to 24 h) after maternal DOT PrEP dose. Tenofovir and emtricitabine concentrations were quantified using liquid chromatography-tandem mass spectrometry (LC-MS/MS) assays. Of the 50 mother-infant pairs enrolled, 48% were ≤6 months postpartum, and median maternal age was 25 y (interquartile range [IQR 22-28). During study follow-up, the median (IQR) daily reported frequency of infant breastfeeding was 15 times (12 to 18) overall, 16 (14 to 19) for the ≤6 months, and 14 (12 to 17) for the ≥6 months postpartum strata. For the 12-24-wk infant age groups, Overall, median (IQR) time-averaged peak concentration in breast milk was 0.3 ng/mL (0.2 to 0.5) for tenofovir and 212.5 ng/mL (140.0 to 405.0) for emtricitabine. Similarly, median (IQR) time-averaged trough concentrations in breast milk were 3.3 ng/mL (2.3 to 4.4) for tenofovir and 183.4 ng/mL (113.0 to 250.0) for emtricitabine. The estimated median (IQR) infant daily dose of tenofovir ingested through breastfeeding was 0.47 μg/kg/day (0.30 to 0.71) for tenofovir and 290.0 μg/kg/day (174.0 to 402.0) for emtricitabine. Tenofovir was detectable in 47/49 (96%) infant plasma samples (median IQR concentration: 11.2 ng/mL: 9.3 to 16.7). The estimated equivalent doses an infant would ingest daily from breastfeeding were 0.47 μg/kg/day (IQR 0.35 to 0.71) for tenofovir and 31.5 μg/kg/day (IQR 21.0 to 60.8) for emtricitabine, translating into a <0.01% and 0.5% relative dose when compared to the 6 mg/kg dose that is proposed for therapeutic treatment of infant HIV infection and for prevention of infant postnatal HIV infection; a dose that has not shown safety concerns. No serious adverse effects were recorded during study follow-up. The key study limitation was that only a single infant sample was collected to minimize venipuncture for the children. However, maternal daily DOT and specimen collection at drug concentration steady state provided an adequate approach to address the key research question. Importantly, there was minimal variation in breast milk concentrations of tenofovir and emtricitabine (respective median trough-to-peak concentration ratio ~1), demonstrating that infants were exposed to consistent drug dosing via breast milk. CONCLUSION: In this short-term study of daily directly observed oral PrEP in HIV-uninfected breastfeeding women, the estimated infant doses from breast milk and resultant infant plasma concentrations for tenofovir and emtricitabine were 12,500 and >200-fold lower than the respective proposed infant therapeutic doses, and tenofovir was not detected in 96% of infant plasma samples. These data suggest that PrEP can be safely used during breastfeeding with minimal infant drug exposure. TRIAL REGISTRATION: ClinicalTrials.gov, Identifier: NCT02776748. Article	2016	Mugwanya, Kenneth K; Wyatt, Christine; Celum, Connie; Donnell, Deborah; Kurie, James; Ronald, Allan; Baeten, Jared M	Reversibility of Glomerular Renal Function Decline in HIV-Uninfected Men and Women Discontinuing Emtricitabine-Tenofovir Disoproxil Fumarate Pre-Exposure Prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000000868	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4770897/	BACKGROUND: Tenofovir disoproxil fumarate (TDF) pre-exposure prophylaxis (PrEP) use is associated with a small but statistically significant decline in estimated glomerular filtration rate (eGFR). We investigated the reversibility of eGFR decline among HIV-uninfected adults discontinuing PrEP. METHODS: Data were from the Partners PrEP Study, a randomized trial of daily oral TDF and emtricitabine (FTC)/TDF vs. placebo. Participants who discontinued study drug and had 2 eGFR measurements ≥90 days apart were included. Reversibility was defined as an increase of ≥1 month 1 and 2 after discontinuation. eGFR was calculated using the Chronic Kidney Disease Epidemiology Collaboration Equation. RESULTS: A total of 1024 individuals had a poststudy drug serum creatinine measurement after the scheduled drug discontinuation (127 for TDF, 1306 for FTC-TDF, and 1345 for placebo); 65% were men, median age was 35 (range 18-64) years. Median time on study drug was 33 (interquartile range 25-36) months overall, and 36 months (interquartile range 30-36) for TDF and FTC-TDF. Mean eGFR at the last on-treatment visit was 129 mL/min/1.73 m for TDF and 130 mL/min/1.73 m for FTC-TDF versus 131 mL/min/1.73 m for placebo (2-3 mL/min/1.73 m mean decline for PrEP versus placebo, P=0.0004, 0.01), and this difference reversed by 4 weeks after drug discontinuation (mean eGFR at the first postdrug visit 130 mL/min/1.73 m in all groups). More than 96% of participants had a confirmed >75% eGFR rebound to baseline level by 8 weeks after drug discontinuation, with similar proportions across treatment groups. CONCLUSIONS: In this large, placebo-controlled study of TDF-based PrEP, the small reduction in mean eGFR associated with PrEP reversed within weeks after discontinuation. Article	2016	Mugwanya, Kenneth; Baeten, Jared; Celum, Connie; Donnell, Deborah; Nickolas, Thomas; Mugo, Nelly; Branch, Andrea; Tappero, Jordan; Kiarie, James; Ronald, Allan; Yin, Michael; Wyatt, Christina	Low Risk of Proximal Tubular Dysfunction Associated With Emtricitabine-Tenofovir Disoproxil Fumarate Preexposure Prophylaxis in Men and Women.	Journal of Infectious Diseases	-	-	-	-	1537-6613	10.1093/infdis/jiw125	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5021224	OBJECTIVE: Tenofovir disoproxil fumarate (TDF) is associated with proximal tubular dysfunction (tubulopathy) when used in the treatment of human immunodeficiency virus (HIV) infection. We evaluated whether TDF causes tubulopathy when used as HIV preexposure prophylaxis (PrEP) and whether tubulopathy predicts clinically relevant decline (≥25%) in the estimated glomerular filtration rate (eGFR). METHODS: A subgroup analysis of the Partners PrEP Study, a randomized, placebo-controlled trial of daily oral TDF, alone or with emtricitabine (FTC), in HIV-uninfected African men and women (Clinicaltrials.gov NCT00557245). Tubulopathy was assessed in concurrently obtained urine and serum samples at the 24-month or last on-treatment visit, predefined as ≥2 of the following: tubular proteinuria, euglycemic glycosuria, increased urinary phosphate, and uric acid excretion. RESULTS: Of 1549 persons studied (776 receiving FTC-TDF, 773 receiving placebo), 64% were male, and the median age was 37 years. Over a median 24 months of study-drug exposure, the frequency of tubulopathy was 1.7% for FTC-TDF versus 1.3% for placebo (odds ratio, 1.30; 95% confidence interval, .52-3.33; P = .68); Tubulopathy occurred in 2 of 52 persons (3.8%) with versus 3 of 208 (1.4%) without ≥25% eGFR decline (adjusted odds ratio, 1.39; .10-14.0; P > .99). CONCLUSIONS: Daily oral FTC-TDF PrEP was not significantly associated with tubulopathy over the course of 24 months, nor did tubulopathy predict clinically relevant eGFR decline. Article	2016	Mujugira, Andrew; Celum, Connie; Coombs, Robert W.; Campbell, James D.; Ndase, Patrick; Ronald, Allan; Were, Edwin; Bukusi, Elizabeth A.; Mugo, Nelly; Kiarie, James; Baeten, Jared M.	HIV Transmission Risk Persists During the First 6 Months of Antiretroviral Therapy.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000001019	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5106226/	OBJECTIVE: Combination antiretroviral therapy (ART) decreases the risk of sexual HIV transmission by suppressing blood and genital HIV RNA concentrations. We sought to determine HIV transmission risk prior to achieving complete viral suppression. DESIGN: Prospective cohort study. METHODS: Using data from the Partners PrEP Study, a prospective study of 4747 heterosexual HIV-serodiscordant couples in Kenya and Uganda, we examined multiple markers of HIV transmission risk during the first months after ART initiation: time to viral suppression in blood, persistence of HIV RNA in genital specimens, sexual risk behavior, pregnancy incidence, and HIV transmission using survival analysis and generalized estimating equations logistic regression. RESULTS: The cumulative probabilities of achieving blood viral suppression (<80 copies per milliliter) 3, 6, and 9 months after ART initiation were 65.3%, 84.8%, and 89.1%, respectively. Endocervical and seminal HIV RNA were detectable in 12% and 21% of samples obtained within 6 months of ART. Pregnancy incidence was 8.8 per 100 person-years during the first 6 months of ART, and sex unprotected by condoms was reported at 10.5% of visits. Among initially uninfected partners, HIV incidence before ART was 2.08 per 100 person-years (55 infections; 2644 person-years), 1.79 for 0-6 months after ART initiation (3 infections; 168 person-years), and 0.00 with >6 months of ART (0 infections; 167 person-years). CONCLUSIONS: Residual HIV transmission risk persists during the first 6 months of ART, with incomplete viral suppression in blood and genital compartments. For HIV-serodiscordant couples in which the infected partner starts ART, other prevention options are needed, such as pre-exposure prophylaxis, until viral suppression is achieved. Article	2016	Mujugira, Andrew; Celum, Connie; Tappero, Jordan W.; Ronald, Allan; Mugo, Nelly; Baeten, Jared M.	Younger Age Predicts Failure to Achieve Viral Suppression and Virologic Rebound Among HIV-1-Infected Persons in Serodiscordant Partnerships.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/AID.2015.0296	https://pubmed.ncbi.nlm.nih.gov/26670218/	BACKGROUND: Antiretroviral therapy (ART) markedly reduces the risk of HIV-1 transmission in serodiscordant partnerships. We previously found that younger age and higher CD4 counts were associated with delayed initiation of ART by HIV-1-infected partners in serodiscordant partnerships. Among those initiating ART, we sought to explore whether those same factors were associated with failure to achieve viral suppression. METHODS: In a prospective study of HIV-1-infected persons who had a known heterosexual HIV-1-uninfected partner in Kenya and Uganda Partners Pre-Exposure Prophylaxis (PrEP) Study, we used Cox proportional hazards regression to evaluate correlates of failure to achieve viral suppression (HIV-1 RNA >80 copies/ml). RESULTS: Of 1,035 HIV-1-infected participants initiating ART, 867 (84%) achieved viral suppression: 77% by 6 months and 86% by 12 months. Younger age adjusted hazard ratio (aHR) 1.05 for every 5 years younger; p = .006, lower pretreatment CD4 count (aHR 1.26; p = .009 for ≤250 compared with >250 cells/μl), and higher pretreatment HIV-1 RNA quantity (aHR 1.21 per log10; p < .001) independently predicted failure to achieve viral suppression. Following initial viral suppression, 8.8% (76/867) experienced virologic rebound (HIV-1 RNA >200 copies/ml): 6.3% and 11.5% by 6 and 12 months after initial suppression, respectively. Age was the only factor associated with increased risk of virologic rebound (aHR 1.33 for every 5 years younger; p = .005). CONCLUSIONS: For HIV-1-infected persons in serodiscordant couples, younger age was associated with delayed ART initiation, failure to achieve viral suppression, and increased risk of virologic rebound. Motivating ART initiation and early adherence is a key to achieving and sustaining viral suppression. Article	2016	Mukandavire, Zindoga; Mitchell, Kate M; Vickerman, Peter	Comparing the impact of increasing condom use or HIV pre-exposure prophylaxis (PrEP) use among female sex workers.	Epidemics	-	-	-	-	1878-0067	10.1016/j.epidem.2015.10.002	https://dx.doi.org/10.1016/j.epidem.2015.10.002	In many settings, interventions targeting female sex workers (FSWs) could significantly reduce the overall transmission of HIV. To understand the role HIV pre-exposure prophylaxis (PrEP) could play in controlling HIV transmission amongst FSWs, it is important to understand how its impact compares with scaling-up condom use-one of the proven HIV prevention strategies for FSWs. It is important to remember that condoms also have other benefits such as reducing the incidence of sexually transmitted infections and preventing pregnancy. A dynamic deterministic model of HIV transmission amongst FSWs, their clients and other male partners (termed 'pimps') was used to compare the protection provided by PrEP for HIV-negative FSWs with FSWs increasing their condom use with clients and/or pimps. For different HIV prevalence scenarios, levels of pimp interaction, and baseline condom use, we estimated the coverage of PrEP that gives the same reduction in endemic FSW HIV prevalence or HIV infections averted as different increases in condom use. To achieve the same impact on FSW HIV prevalence as increasing condom use by 1%, the coverage of PrEP has to increase by >2%. The relative impact of PrEP increases for scenarios where pimps contribute to HIV transmission, but not greatly, and decreases with higher baseline condom use. In terms of HIV infections averted over 10 years, the relative impact of PrEP compared to condoms was reduced, with a >3% increase in PrEP coverage achieving the same impact as a 1% increase in condom use. Condom promotion interventions should remain the mainstay HIV prevention strategy for FSWs, with PrEP only being implemented once condom interventions have been maximised or to fill prevention gaps where condoms cannot be used. Article	2016	Mukhopadhya, Indrani; Murray, Graeme I.; Duncan, Linda; Yuecel, Raif; Shattock, Robin; Kelly, Charles; Iannelli, Francesco; Pozzi, Gianni; El-Omar, Emad M.; Hold, Georgina L.; Hijazi, Karolin	Transporters for Antiretroviral Drugs in Colorectal CD4+ T Cells and Circulating α4β7 Integrin CD4+ T Cells: Implications for HIV Microbicides.	Molecular Pharmaceutics	-	-	-	-	1543-8392 1543-8384	10.1021/acs.molpharmaceut.6b00351	https://pubmed.ncbi.nlm.nih.gov/27467446/	CD4+ T lymphocytes in the colorectal mucosa are key in HIV-1 transmission and dissemination. As such they are also the primary target for antiretroviral (ARV)-based rectal microbicides for pre-exposure prophylaxis. Drug transporters expressed in mucosal CD4+ T cells determine ARV distribution across the cell membrane and, most likely, efficacy of microbicides. We describe transporters for antiretroviral drugs in colorectal mucosal CD4+ T lymphocytes and compare gene expression with circulating α4β7+CD4+ T cells, which traffic to the intestine and have been shown to be preferentially infected by HIV-1. Purified total CD4+ T cells were obtained from colorectal tissue and blood samples by magnetic separation. CD4+ T cells expressing α4β7 integrin were isolated by fluorescence-activated cell sorting from peripheral blood mononuclear cells of healthy volunteers. Expressions of 15 efflux and uptake drug transporter genes were quantified using Taqman qPCR assays. Expression of efflux transporters MRP3, MRP5, and BCRP and uptake transporter CNT2 were significantly higher in colorectal CD4+ T cells compared to circulating CD4+ T cells (p = 0.01-0.03). Conversely, circulating α4β7+CD4+ T cells demonstrated significantly higher expression of OATPD compared to colorectal CD4+ T cells (p = 0.001). To the best of our knowledge this is the first report of drug transporter gene expression in colorectal CD4+ and peripheral α4β7+CD4+ T cells. The qualitative and quantitative differences in drug transporter gene expression profiles between α4β7+CD4+ T cells and total mucosal CD4+ T cells may have significant implications for the efficacy of rectally delivered ARV-microbicides. Most notably, we have identified efflux drug transporters that could be targeted by selective inhibitors or beneficial drug-drug interactions to enhance intracellular accumulation of antiretroviral drugs. Article	2016	Mullins T.L.K.; Zimet G.; Lally M.; Kahn J.A.	Adolescent Human Immunodeficiency Virus Care Providers' Attitudes Toward the Use of Oral Pre-Exposure Prophylaxis in Youth	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2016.0048	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84978933141&doi=10.1089%2fapc.2016.0048&partnerID=40&md5=f2b861fd69cf580ab7adf09dd4489948	Oral pre-exposure prophylaxis (PrEP) for human immunodeficiency virus (HIV) prevention is currently indicated for use in adults in the United States and may soon be indicated for minor adolescents. However, implementation of PrEP use among minors may present unique barriers. We conducted 15 individual, semi-structured interviews among US clinicians caring for HIV-infected and at-risk youth. The theory-driven interview guide assessed demographics, perceived role of oral PrEP in HIV prevention among adolescents, perceived barriers to and facilitating factors for use of PrEP in adolescents, and clinician-reported likelihood of prescribing PrEP. Transcripts were analyzed using framework analysis. Overall, clinicians viewed PrEP as a time-limited intervention that is one part of a comprehensive approach to HIV prevention among adolescents. Perceived barriers to prescribing to minors included concerns about: confidentiality, legality of minors consenting to PrEP without parental involvement, ability of minors to understand the risks/benefits of PrEP, the possible impact of PrEP on bone accrual, off-label use of PrEP medication in minors, and the high costs associated with PrEP use. Clinician-reported facilitating factors for prescribing PrEP to youth included educating communities and other clinicians about PrEP, ensuring adequate financial resources and infrastructure for delivering PrEP, developing formal guidance on effective behavioral interventions that should be delivered with PrEP, and gaining personal experience with prescribing PrEP. Clinicians indicated greater comfort with prescribing PrEP to adults versus minors. For PrEP to become more widely available to youth at risk for HIV infection, barriers that are unique to PrEP use in minors must be addressed. © 2016, Mary Ann Liebert, Inc. Article	2016	Musinguzi, N; Muganzi, CD; Boum, Y; Ronald, A; Marzinke, MA; Hendrix, CW; Celum, C; Baeten, JM; Bangsberg, DR; Haberer, JE	Comparison of subjective and objective adherence measures for preexposure prophylaxis against HIV infection among serodiscordant couples in East Africa	AIDS	-	-	-	-	NA	10.1097/QAD.0000000000001024	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01259822/full	BACKGROUND: Preexposure prophylaxis (PrEP) efficacy is highly dependent on adherence. Yet, it is unclear which adherence measures perform best for PrEP. METHODS: We compared three types of self-reported adherence questions (rating of ability to adhere, frequency of doses taken, percentage of doses taken) and three forms of objective adherence measurement unannounced pill counts (UPC), electronic monitoring, plasma tenofovir levels using data from an ancillary adherence study within a clinical trial of PrEP among East African serodiscordant couples (Partners PrEP Study). Monthly measures were assessed for the first 6 months of follow-up. RESULTS: One thousand, one hundred and forty-seven participants contributed 6048 person-months of data to this analysis. Median adherence was high: self-reported rating (90%), self-reported frequency (93%), and self-reported percentage (97%); UPC (99%); and electronic monitoring (97%). Prevalence of steady-state daily dosing (SSDD; ≥40 ng/ml) was 74% in a random subset of tenofovir samples obtained from 365 participants. Discrimination of SSDD versus less than SSDD levels was poor for self-reported rating area under the receiver-operating curve (AROC 0.54), self-reported frequency (AROC 0.52), self-reported percentage (AROC 0.56) and UPC (AROC 0.58), but moderate for electronic monitoring (AROC 0.70). Correlation was moderate among self-reported measures, adherence (0.61-0.66), but low for these self-reported measures compared with UPC (0.32-0.36) and with electronic monitoring (0.22-0.28). CONCLUSION: Electronic monitoring was the only adherence measure with meaningful ability to discriminate between SSDD and less than SSDD plasma tenofovir levels. Correlation between subjective and objective measures was poor. Future research should explore novel approaches to adherence measurement as PrEP moves into demonstration projects and programmatic implementation. Article	2016	Nagot, Nicolas; Kankasa, Chipepo; Tumwine, James K; Meda, Nicolas; Hofmeyr, G Justus; Vallo, Roselyne; Mwiya, Mwiya; Kwagala, Mary; Traore, Hugues; Sunday, Amwe; Singata, Mandisa; Siuluta, Chafye; Some, Eric; Rutagwera, David; Neboua, Desire; Ndeezi, Grace; Jackson, Debra; Maréchal, Valérie; Neveu, Dorine; Engebretsen, Ingunn M S; Lombard, Carl; Blanche, Stéphane; Sommerfelt, Halvor; Rekacewicz, Claire; Tylleskär, Thorkild; Van de Perre, Philippe	Extended pre-exposure prophylaxis with lopinavir-ritonavir versus lamivudine to prevent HIV-1 transmission through breastfeeding up to 50 weeks in infants in Africa (ANRS 12174): a randomised controlled trial.	The Lancet	-	-	-	-	1474-547X	10.1016/S0140-6736(15)00984-8	https://dx.doi.org/10.1016/S0140-6736(15)00984-8	BACKGROUND: Strategies to prevent postnatal mother-to-child transmission of HIV-1 in Africa, including infant prophylaxis, have never been assessed past 6 months of breastfeeding, despite breastfeeding being recommended up to 12 months after birth. We aimed to compare the efficacy and safety of infant prophylaxis with the two drug regimens (lamivudine or lopinavir-ritonavir) to prevent postnatal HIV-1 transmission up to 50 weeks of breastfeeding. METHODS: We did a randomised controlled trial in four sites in Burkina Faso, South Africa, Uganda, and Zambia in children born to HIV-1-infected mothers not eligible for antiretroviral therapy (CD4 count >350 cells per μL). An independent researcher electronically generated a randomisation schedule; we then used sequentially numbered envelopes to randomly assign (1:1) HIV-1-uninfected breastfed infants aged 7 days to either lopinavir-ritonavir or lamivudine (paediatric liquid formulations, twice a day) up to 1 week after complete cessation of breastfeeding or at the final visit at week 50. We stratified the randomisation by country and used permuted blocks of four and six. We used a study label on drug bottles to mask participants, study physicians, and assessors to the treatment allocation. The primary outcome was infant HIV-1 infection between age 7 days and 50 weeks, diagnosed every 3 months with HIV-1 DNA PCR, in the modified intention-to-treat population (all who attended at least one follow-up visit). This trial is registered with ClinicalTrials.gov, number NCT00640263. FINDINGS: Between Nov 16, 2009, and May 7, 2012, we enrolled and randomised 1273 infants and analysed 1236; 615 assigned to lopinavir-ritonavir or 621 assigned to lamivudine. 17 HIV-1 infections were diagnosed in the study period (eight in the lopinavir-ritonavir group and nine in the lamivudine group), resulting in cumulative HIV-1 infection of 1.4% (95% CI 0.4-2.5) and 1.5% (0.7-2.5), respectively. Infection rates did not differ between the two drug regimens (hazard ratio HR of lopinavir-ritonavir versus lamivudine of 0.90, 95% CI 0.35-2.34; p=0.83). Clinical and biological severe adverse events did not differ between groups; 251 (51%) infants had a grade 3-4 event in the lopinavir-ritonavir group compared with 246 (50%) in the lamivudine group. INTERPRETATION: Infant HIV-1 prophylaxis with lopinavir-ritonavir was not superior to lamivudine and both drugs led to very low rates of HIV-1 postnatal transmission for up to 50 weeks of breastfeeding. Infant pre-exposure prophylaxis should be extended until the end of HIV-1 exposure and mothers should be informed about the persistent risk of transmission throughout breastfeeding. Article	2016	Namey, Emily; Agot, Kawango; Ahmed, Khatija; Odhiambo, Jacob; Skhosana, Joseph; Guest, Greg; Corneli, Amy	When and why women might suspend PrEP use according to perceived seasons of risk: implications for PrEP-specific risk-reduction counselling	Culture, Health & Sexuality	-	-	-	-	13691058	10.1080/13691058.2016.1164899	https://www.proquest.com/scholarly-journals/when-why-women-might-suspend-prep-use-according/docview/1823245695/se-2?accountid=8113	Oral pre-exposure prophylaxis (PrEP) using the antiretroviral drug emtricitabine/tenofovir disoproxil fumarate (Truvada) has been shown to dramatically reduce the risk of HIV acquisition for women at higher risk of infection if taken daily. Understanding when and why women would intentionally stop using an efficacious oral PrEP drug within the context of their 'normal' daily lives is essential for delivering effective PrEP risk-reduction counselling. As part of a larger study, we conducted 60 qualitative interviews with women at higher risk of HIV in Bondo, Kenya, and Pretoria, South Africa. Participants charted their sexual contacts over the previous six months, indicated whether they would have taken PrEP if available and discussed whether and why they would have suspended PrEP use. Nearly all participants said they would have used PrEP in the previous six months; half indicated they would have suspended PrEP use at some point. Participants' reasons for an extended break from PrEP were related to partnership dynamics (e.g., perceived low risk of a stable partner) and phases of life (e.g., trying to conceive). Life events (e.g., holidays and travel) could prompt shorter breaks in PrEP use. These circumstances may or may not correspond to actual contexts of lower risk, highlighting the importance of tailored PrEP risk-reduction counselling. Article	2016	Nanda, K; Callahan, R; Taylor, D; Wang, M; Agot, K; Jenkins, D; Van Damme, L; Dorflinger, L	Medroxyprogesterone acetate levels among Kenyan women using depot medroxyprogesterone acetate in the FEM-PrEP trial	Contraception	-	-	-	-	0010-7824	10.1016/j.contraception.2016.03.003	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01266040/full	OBJECTIVE: To describe medroxyprogesterone acetate (MPA) levels among Kenyan depot medroxyprogesterone acetate (DMPA) users in the FEM-PrEP HIV prevention trial, and to compare MPA levels between ARV for HIV prevention (treatment) and placebo groups. STUDY DESIGN: We measured MPA in previously collected plasma samples from 63 Kenyan trial participants who used DMPA for one or two complete intervals. We separately assessed MPA levels among the nine DMPA users who became pregnant at this site. RESULTS: Mean MPA levels at the end of each 12week injection interval were 0.37ng/ml (95% CI: 0.25, 1.99) and 0.28ng/ml (95% CI: 0.19, 1.22) among participants assigned TDF/FTC and 0.49 (95% CI: 0.40, 1.27) and 0.39 (95% CI: 0.31, 1.17) among those assigned placebo. The difference between groups was not statistically significant overall, or in an analysis which adjusted for the observed low adherence to TDF/FTC. Unanticipated findings of this analysis were low 12-week MPA levels among DMPA users in both study arms. Of 61 women who contributed data for the first DMPA injection interval, 26.2% had MPA levels<0.1ng/ml and 9.8% had levels below the detection level (0.02ng/ml) at 12weeks post-injection. Levels were similar at the end of the second injection interval. Five of nine women who became pregnant had levels below 0.15ng/mL at the time of their last negative pregnancy test. CONCLUSIONS: Use of TDF/FTC did not appear to affect serum MPA levels, however we found lower than expected MPA concentrations at the end of the dosing interval among DMPA users in the FEM-PrEP trial, the cause of which are unknown. IMPLICATIONS: This study presents some of the few available data on MPA levels among DMPA users in Africa. The low levels among users described here, together with a number of pregnancies among DMPA users, are potentially concerning and require further investigation.	*Kenyan; *contraceptive agent/cr Drug Concentration; *depot medroxyprogesterone acetate/cr Drug Concentration; *drug blood level; *medroxyprogesterone acetate; *medroxyprogesterone acetate/cr Drug Concentration; Adolescent; Adult; Africa; Article; Blood sampling; Clinical trial; Contraceptive Agents, Female *administration & dosage; Controlled study; Delayed-Action Preparations administration & dosage; Drug Interactions; Drug dosage form; Emtricitabine therapeutic use; Female; HIV Infections prevention & control; Human; Human immunodeficiency virus infection/pc Prevention; Human tissue; Humans; Infection prevention; Injection; Kenya; Kenyan; Major clinical study; Medroxyprogesterone Acetate *administration & dosage, *blood; Physical examination; Placebo; Plasma; Pregnancy; Pregnancy Tests; Pregnancy test; Prevention study; Pre-Exposure Prophylaxis; Study design; Tenofovir therapeutic use; Unclassified drug; Young Adult; Young adult	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Newcomb M.E.; Mongrella M.C.; Weis B.; McMillen S.J.; Mustanski B.	Partner Disclosure of PrEP Use and Undetectable Viral Load on Geosocial Networking Apps: Frequency of Disclosure and Decisions about Condomless Sex	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000000819	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84955606201&doi=10.1097%2fQAI.0000000000000819&partnerID=40&md5=579c6fe1ab02aa93f8556e22d1672283	Background: Recent advances in biomedical prevention strategies, including pre-exposure prophylaxis (PrEP) and achieving an undetectable viral load (UVL) among HIV-infected persons, show promise in curbing the rising incidence of HIV among men who have sex with men (MSM) in the United States. This mixed-methods study aimed to investigate the frequency with which MSM encounter potential sex partners on geosocial networking apps who disclose biomedical prevention use, and how MSM make decisions about condom use after these disclosures. Method: Participants were recruited through advertisements placed on a large geosocial networking app for MSM. A total of 668 and 727 participants, respectively, responded to questionnaires assessing partner disclosure of PrEP use and UVL. Each questionnaire included an open-ended item assessing reasons for condomless anal sex (CAS) with partners using biomedical prevention. Results: Across both surveys, most respondents encountered potential sex partners who disclosed PrEP use or UVL, and the majority of those who met up with these partners engaged in CAS at least once. Qualitative analyses found that most participants who reported CAS did so after making a calculated risk about HIV transmission. We also describe a novel risk reduction strategy, "biomed-matching," or having CAS only when both individuals use PrEP or have UVL. We report serostatus differences in both quantitative and qualitative findings. Conclusions: Disclosure of PrEP use and UVL is not uncommon among MSM. Many MSM make accurate appraisals of the risks of CAS with biomedical prevention, and mobile apps may aid with disclosing biomedical prevention use. © 2015 Wolters Kluwer Health, Inc. Article	2016	Ngure K.; Heffron R.; Curran K.; Vusha S.; Ngutu M.; Mugo N.; Celum C.; Baeten J.M.	I knew I would be safer. Experiences of Kenyan HIV serodiscordant couples soon after pre-exposure prophylaxis (PrEP) initiation	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2015.0259	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84957701394&doi=10.1089%2fapc.2015.0259&partnerID=40&md5=33b0029e95a441b87a6243159440fd29	Pre-exposure prophylaxis (PrEP) for HIV-uninfected persons is highly efficacious for HIV prevention. Understanding how people at risk for HIV will use PrEP is important to inform PrEP scale-up and implementation. We used qualitative methods to gather insights into couples' early experiences with PrEP use within the Partners Demonstration Project, an open-label implementation study evaluating integrated delivery of PrEP and antiretroviral therapy (ART). PrEP is offered to HIV uninfected partners until the HIV-infected partner initiates and sustains ART use (i.e., PrEP as a "bridge" to ART initiation and viral suppression). From August 2013 to March 2014 we conducted 20 in-depth dyadic interviews (n = 40) with heterosexual HIV serodiscordant couples participating at the Thika, Kenya study site, exploring how couples make decisions about using PrEP for HIV prevention. We developed and applied deductive and inductive codes to identify key themes related to experiences of PrEP initiation and use of time-limited PrEP. Couples reported that PrEP offered them an additional strategy to reduce the risk of HIV transmission, meet their fertility desires, and cope with HIV serodiscordance. Remaining HIV negative at follow-up visits reinforced couples' decisions and motivated continued adherence to PrEP. In addition, confidence in their provider's advice and client-friendly services were critical to their decisions to initiate and continue use of PrEP. Strategies for wide-scale PrEP delivery for HIV serodiscordant couples in low resource settings may include building capacity of health providers to counsel on PrEP adoption while addressing couples' concerns and barriers to adoption and continued use. © Mary Ann Liebert, Inc. 2016. Article	2016	Ngure, Kenneth; Vusha, Sophie; Mugo, Nelly; Emmanuel-Fabula, Mira; Ngutu, Mariah; Celum, Connie; Baeten, Jared M.; Heffron, Renee	"I never thought that it would happen … " Experiences of HIV seroconverters among HIV-discordant partnerships in a prospective HIV prevention study in Kenya.	AIDS Care	-	-	-	-	1360-0451 0954-0121	10.1080/09540121.2016.1191610	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5140887/	In spite of access to behavioral and biomedical HIV prevention strategies, HIV transmission occurs. For HIV-serodiscordant couples, prevention programs can be tailored to address individual and couples' needs to preserve their relationship while minimizing HIV risk. Programs for serodiscordant couples may benefit from learning from experiences of couples who transmit HIV. We conducted 20 individual in-depth interviews with 10 initially HIV-serodiscordant couples who transmitted HIV during prospective follow-up at a peri-urban research site in Thika, Kenya. Data were analyzed inductively to identify situations that led to prevention failure and coping mechanisms. Inconsistent condom use driven by low HIV risk perception and alcohol use often preceded seroconversion while persistent blame frequently hindered couples' communication soon after seroconversion. In this emerging era of antiretroviral-based HIV prevention, couples' counseling can capitalize on opportunities to foster a supportive environment to discuss initiation and adherence to time-limited pre-exposure prophylaxis and lifelong antiretroviral therapy, in addition to strategies to reduce alcohol use, diffuse blame, and use condoms. Article	2016	Nichols B.E.; Boucher C.A.B.; van der Valk M.; Rijnders B.J.A.; van de Vijver D.A.M.C.	Cost-effectiveness analysis of pre-exposure prophylaxis for HIV-1 prevention in the Netherlands: a mathematical modelling study	The Lancet Infectious Diseases	-	-	-	-	14733099	10.1016/S1473-3099(16)30311-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84996524245&doi=10.1016%2fS1473-3099%2816%2930311-5&partnerID=40&md5=c1ce92e9639cf55d7839d141e4e6a83b	Background Pre-exposure prophylaxis (PrEP) with tenofovir and emtricitabine prevents HIV infections among men who have sex with men (MSM). PrEP can be given on a daily or intermittent basis. Unfortunately, PrEP is not reimbursed in most European countries. Cost-effectiveness analyses of PrEP among MSM in Europe are absent but are key for decision makers to decide upon PrEP implementation. Methods We developed a deterministic mathematical model, calibrated to the well defined Dutch HIV epidemic among MSM, to predict the effect and cost-effectiveness of PrEP. PrEP was targeted to 10% of highly sexually active Dutch MSM over the coming 40 years. Cost-effectiveness ratios were calculated to predict the cost-effectiveness of daily and on-demand PrEP. Cost-effectiveness ratios below €20 000 were considered to be cost-effective in this analysis. Findings Within the context of a stable HIV epidemic, at 80% effectiveness and current PrEP pricing, PrEP can cost as much as €11 000 (IQR 9400–14 100) per quality-adjusted life-year (QALY) gained when used daily, or as little as €2000 (IQR 1300–3000) per QALY gained when used on demand. At 80% effectiveness, daily PrEP can be considered cost-saving if the price of PrEP is reduced by 70%, and on-demand PrEP can be considered cost-saving if the price is reduced by 30–40%. Interpretation PrEP for HIV prevention among MSM in the Netherlands is cost-effective. The use of PrEP is most cost-effective when the price of PrEP is reduced through on-demand use or through availability of generic PrEP, and can quickly be considered cost-saving. Article	2016	Oldenburg C.E.; Le B.; Huyen H.T.; Thien D.D.; Quan N.H.; Biello K.B.; Nunn A.; Chan P.A.; Mayer K.H.; Mimiaga M.J.; Colby D.	Antiretroviral pre-exposure prophylaxis preferences among men who have sex with men in Vietnam: Results from a nationwide cross-sectional survey	Sexual Health	-	-	-	-	14485028	10.1071/SH15144	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84990855895&doi=10.1071%2fSH15144&partnerID=40&md5=d217158142fc49d57de723e2dd038eb5	Background The HIV/AIDS epidemic in Vietnam is concentrated in subgroups of the population, including men who have sex with men (MSM). Pre-exposure prophylaxis (PrEP) is a viable strategy for HIV prevention, but knowledge about and preferences for PrEP delivery among Vietnamese MSM are not well understood. Methods: In 2015, an online survey was conducted with recruitment via social networking websites for MSM and peer recruitment. A description of daily oral, long-acting injectable, and rectal microbicide formulations of PrEP was provided to participants. Participants were asked about their prior awareness of and interest in PrEP, and ranked their most preferred PrEP modality. Multivariable logistic regression models were used to assess factors associated with having heard of PrEP and preference for each PrEP modality. Results: Of 548 participants who answered demographic and PrEP-related questions, 26.8% had previously heard of PrEP and most (65.7%) endorsed rectal microbicides as their most preferred PrEP delivery modality. Commonly-cited perceived barriers to uptake of PrEP included concern about side-effects, perception about being HIV positive, and family or friends finding out about their sexual behaviour. In multivariable models, older participants less often endorsed rectal microbicides (adjusted odds ratio (AOR) 0.95 per year, 95% confidence interval (CI) 0.91-0.99) and more often endorsed long-acting injectables (AOR 1.08 per year, 95% CI 1.03 to 1.14) as their preferred PrEP modality. Participants who were willing to pay more for PrEP less often endorsed rectal microbicides (AOR 0.81, 95% CI 0.72-0.92) and more often endorsed long-acting injectables (AOR 1.17, 95% CI 1.01-1.35) and daily oral pills (AOR 1.16, 95% CI 1.00-1.35) as their preferred form of PrEP. Conclusions: A variety of PrEP modalities were acceptable to MSM in Vietnam, but low knowledge of PrEP may be a barrier to implementation. © 2016 CSIRO. Article	2016	Oldenburg C.E.; Le B.; Toan T.; Thien D.D.; Huyen H.T.; Friedman M.R.; Stall R.; Colby D.	HIV Pre-exposure Prophylaxis Indication and Readiness Among HIV-Uninfected Transgender Women in Ho Chi Minh City, Vietnam	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1483-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84978699244&doi=10.1007%2fs10461-016-1483-x&partnerID=40&md5=6fb7b9b3a881b45f57ce9e3558d48ac1	Few studies have considered acceptability of HIV pre-exposure prophylaxis (PrEP) among transgender women in Southeast Asia. We assessed PrEP indications and readiness among a sample of HIV-uninfected transgender women in Ho Chi Minh City, Vietnam. Of 168 HIV-uninfected transgender women, 72.6 % met criteria for PrEP based on United States CDC guidelines. PrEP indication was inversely associated with PrEP interest (76.0 % interested among those for whom PrEP was indicated; 89.1 % among those for whom it was not; aOR 0.16, 95 % CI 0.04–0.67, P = 0.01). PrEP readiness, defined as having heard of, being interested in taking, and believing that PrEP is efficacious, was low (7.7 %). The results of this study indicate potential need for PrEP among transgender women in Ho Chi Minh City, but very low awareness of PrEP in the community. Future PrEP implementation programs should include counseling on HIV risk and eligibility for PrEP to ensure that PrEP is available to those who may benefit the most from it. © 2016, Springer Science+Business Media New York. Article	2016	Oldenburg C.E.; Mitty J.A.; Biello K.B.; Closson E.F.; Safren S.A.; Mayer K.H.; Mimiaga M.J.	Differences in Attitudes About HIV Pre-Exposure Prophylaxis Use Among Stimulant Versus Alcohol Using Men Who Have Sex with Men	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-015-1226-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84944526555&doi=10.1007%2fs10461-015-1226-4&partnerID=40&md5=5bf6c66bd10f5a211e828b654c652ab8	Alcohol and stimulant use are independently associated with increased HIV acquisition among men who have sex with men (MSM). We assessed differences in acceptability and perceived barriers to uptake of pre-exposure prophylaxis (PrEP) among stimulant and alcohol-using MSM in Boston. From September 2012–2013, a quantitative assessment was conducted with 254 MSM respondents who reported recent condomless sex in the context of concurrent stimulant (crack/cocaine and crystal methamphetamine; n = 132) or alcohol use (n = 122). Thirteen (5.1 %) reported previous PrEP use. In multivariable models, stimulant users were more likely to be concerned that substance use would affect PrEP adherence (aRR = 2.79, 95 % CI 1.63–4.77), and were less concerned about HIV stigma as a barrier to PrEP uptake (aRR = 0.52, 95 % CI 0.30–0.90) compared to alcohol users. Barriers to PrEP uptake and adherence differ by type of substance used. Different strategies may be required for PrEP implementation among MSM who use stimulants and alcohol. © 2015, Springer Science+Business Media New York. Article	2016	Ong, Jason J.; Landika, Andre; Fairley, Christopher K.; Bradshaw, Catriona; Chen, Marcus; Read, Tim R. H.; Chow, Eric P. F.	Characteristics, sexual practices and sexually transmissible infections diagnoses of men who have sex with men and use non-occupational HIV post-exposure prophylaxis in Victoria, Australia.	Sexual Health	-	-	-	-	1448-5028	10.1071/SH16092	https://pubmed.ncbi.nlm.nih.gov/27537936/	Background Non-occupational post-exposure prophylaxis (NPEP) is available to people with a potential risk for HIV exposure within the preceding 72h. We sought to determine if men who have sex with men (MSM) and receive NPEP had a significantly different risk profile (before the preceding 72h) from MSM not receiving NPEP. If this is the case, NPEP consultations may act as a cue for also discussing pre-exposure prophylaxis. METHODS: We conducted a retrospective analysis to compare the demographic characteristics, sexual practices and clinical diagnoses of MSM who were NPEP users and those who were non-NPEP users attending Melbourne Sexual Health Centre from January 2008 to December 2014. Univariate and multivariate logistic regression models were used to examine the association between NPEP use and risk practices. Generalised estimating equations were used to adjust for within-individual correlations related to multiple visits of the same individual. RESULTS: Of the 40395 MSM consultations included in the study, 1776 consultations (4%) were related to NPEP prescription. NPEP prescribing was associated with ever having injected drugs (adjusted odds ratio (AOR) 1.8, 95% confidence interval (CI): 1.4-2.3), sex with males only (AOR 1.9, 95% CI: 1.6-2.3), more than three male partners in the past 3 months (AOR 1.5, 95% CI: 1.4-1.7) and inconsistent condom use with these partners within the past 3 months (AOR 2.1, 95% CI: 1.9-2.4). Sex workers (AOR 0.6, 95% CI: 0.3-0.9), and men reporting sex overseas within the past 12 months (AOR 0.7, 95% CI: 0.6-0.8) were less likely to receive NPEP. MSM who used NPEP were more likely to test positive for any sexually transmissible infection (AOR 1.2, 95% CI: 1.0-1.4). CONCLUSIONS: MSM receiving NPEP generally had a higher risk profile than MSM not requesting NPEP, indicating that NPEP was used by MSM at higher risk for HIV. Therefore, consultations for NPEP may be an opportune time for also discussing pre-exposure prophylaxis for HIV.	*Homosexuality, Male; Adult; Humans; Male; HIV Infections/*prevention & control/transmission; Risk Assessment; Retrospective Studies; *Post-Exposure Prophylaxis; *Sexual Behavior; Sexual and Gender Minorities; Victoria	English	United States	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Quantitative
Article	2016	Palacios, R., Pérez-Hernández, I. A., Martínez, M. A., Mayorga, M. L., González-Domenech, C. M., Omar, M., Olalla, J., Romero, A., Romero, J. M., Pérez-Camacho, I., Hernández-Quero, J., & Santos, J.	Efficacy and safety of switching to abacavir/lamivudine (ABC/3TC) plus rilpivirine (RPV) in virologically suppressed HIV-infected patients on HAART.	European Journal of Clinical Microbiology & Infectious Diseases	-	-	-	-	NA	https://doi.org/10.1007/s10096-016-2602-3	https://link.springer.com/article/10.1007/s10096-016-2602-3#citeas	We analysed the efficacy and safety of switching from a regimen based on nonnucleoside reverse transcriptase inhibitors (NNRTI) or integrase inhibitors (INI) to ABC/3TC + RPV in virologically suppressed HIV-infected patients. This multicentre, retrospective study comprised asymptomatic HIV-infected patients who switched from 2 NRTI + NNRTI or 2 NRTI + INI to ABC/3TC + RPV between February 2013 and December 2013; all had undetectable HIV viral load prior to switching. Efficacy and safety, and changes in lipids and cardiovascular risk (CVR) were analysed at 48 weeks. Of 85 patients (74.1 % men, mean age 49.5 years), 83 (97.6 %) switched from a regimen based on NNRTI (EFV 74, RPV 5, ETV 2, NVP 2), and 45 (53 %) switched from TDF/FTC to ABC/3TC. The main reasons for switching were toxicity (58.8 %) and convenience (29.4 %). At 48 weeks, 78 (91.8 %) patients continued taking the same regimen; efficacy was 88 % by intention to treat, and 96 % by per protocol. Two patients were lost to follow-up and five changed the new regimen (4 due to adverse effects and 1 virologic failure). Mean CD4 cell counts increased (744 vs. 885 cells/μL; p = 0.0001), and there were mean decreases in fasting total cholesterol (-15.9 mg/dL; p < 0.0001) and LDL-cholesterol (-11.0 mg/dL; p < 0.004), with no changes in HDL-cholesterol, triglycerides, total cholesterol:HDL-cholesterol ratio, and CVR. ABC/3TC + RPV is effective and safe in virologically-suppressed patients on antiretroviral therapy (ART). Forty-eight weeks after switching the lipid profile improved with decreases in total and LDL cholesterol. Article	2016	Parikh U.M.; Mellors J.W.	Should we fear resistance from tenofovir/emtricitabine preexposure prophylaxis?	Current Opinion in HIV and AIDS	-	-	-	-	1746630X	10.1097/COH.0000000000000209	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84950248860&doi=10.1097%2fCOH.0000000000000209&partnerID=40&md5=45208312a51ffa88605a0abf82546d3d	Purpose of review To review current data on HIV-1 resistance arising from the use of fixed dose combination tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) for preexposure prophylaxis (PrEP) to prevent HIV-1 infection. Recent findings Resistance to tenofovir (TNV) or FTC is infrequently selected by TDF/FTC PrEP if started before HIV-1 infection has occurred, but is much more common when inadvertently started during undiagnosed acute infection. Mathematical modeling predicts that the number of HIV-1 infections averted by the use of PrEP far exceeds the increase in drug-resistant infections that could occur from PrEP. Studies in macaques show that TNV-resistant virus but not FTC-resistant virus can cause breakthrough infection despite TDF/FTC PrEP. FTC resistance with M184V/I occurs more frequently than TFV resistance with K65R in seroconverters from clinical trials of TDF/FTC PrEP. Summary The benefit of preventing HIV-1 infections with TDF/FTC PrEP far outweighs the risk of drug-resistant infection, provided PrEP is not started in persons with undiagnosed HIV-1 infection. We should respect but not fear HIV-1 resistance from TDF/FTC PrEP and recognize that most TNV or FTC resistance will arise from its use for antiretroviral therapy (ART). Preventing ART failure or detecting it early is most important for preventing the spread of HIV-1 resistance to TDF/FTC and preserving its effectiveness for both PrEP and ART. Article	2016	Parsons J.T.; Rendina H.J.; Whitfield T.H.F.; Grov C.	Familiarity with and Preferences for Oral and Long-Acting Injectable HIV Pre-exposure Prophylaxis (PrEP) in a National Sample of Gay and Bisexual Men in the U.S.	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1370-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961786629&doi=10.1007%2fs10461-016-1370-5&partnerID=40&md5=ad893ef55f9104ff8d539d31a2f49ff8	We sought to determine preferences for oral versus long-acting injectable (LAI) PrEP among gay and bisexual men (GBM). We surveyed a national U.S. sample of 1071 GBM about forms of PrEP. LAI PrEP was found to be acceptable among 43.2 % of men when injected monthly compared with 53.6 % of men when injected every 3 months. When asked to choose between forms of PrEP, 46.0 % preferred LAI, 14.3 % oral, 21.7 % whichever was most effective, 10.1 % had no preference, and 7.8 % would not take PrEP. There were no differences in PrEP preferences by race/ethnicity, income, region of residence, or relationship status. Those unwilling to take PrEP were significantly older than those who preferred LAI PrEP and those who would take either. Those who preferred the most effective form were younger, had less education, and reported more recent club drug use. Those who reported condomless anal sex and those who thought they were good PrEP candidates were more willing to take PrEP. Long-term health and side effects were of the greatest concern for both LAI and oral PrEP. The availability of LAI PrEP has the potential to increase uptake among GBM. The results of ongoing clinical trials of LAI PrEP will need to demonstrate similar or greater efficacy as daily Truvada for uptake to be maximized. © 2016, Springer Science+Business Media New York. Article	2016	Patel R.C.; Stanford-Moore G.; Odoyo J.; Pyra M.; Wakhungu I.; Anand K.; Bukusi E.A.; Baeten J.M.; Brown J.M.	"Since both of us are using antiretrovirals, we have been supportive to each other": Facilitators and barriers of pre-exposure prophylaxis use in heterosexual HIV serodiscordant couples in Kisumu, Kenya: Facilitators	Journal of the International AIDS Society	-	-	-	-	17582652	10.7448/IAS.19.1.21134	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85001941006&doi=10.7448%2fIAS.19.1.21134&partnerID=40&md5=7549586de1accc197c666060eb5997f5	Introduction: Since 2015, the World Health Organization recommends pre-exposure prophylaxis (PrEP) for all persons at substantial risk for HIV, including HIV-uninfected partners in serodiscordant relationships in resource-limited settings. As PrEP moves from clinical trials to real-world use, understanding facilitators of and barriers to PrEP initiation and adherence is critical to successful PrEP implementation and rollout. Methods: We conducted 44 in-depth individual or couple interviews with 63 participants (30 without HIV and 33 with HIV) enrolled in the Partners Demonstration Project in Kisumu, Kenya, between August and September 2014. The semi-structured interviews discussed the following: 1) perceived advantages and disadvantages of antiretroviral therapy (ART)/PrEP; 2) reasons for accepting or declining ART/PrEP and 3) influence of prevention of transmission to partner or infant on ART/PrEP use. Transcripts from the interviews were iteratively analyzed using inductive content analysis. Results: Our study identified three key factors that may facilitate initiation of PrEP in this population. First, participants using PrEP felt reduced stress and increased trust in their HIV serodiscordant relationships. Second, greater community-wide knowledge of PrEP was thought to likely increase PrEP acceptance. Third, greater education and counselling by providers on PrEP was also considered to likely increase the adoption of PrEP. We also identified three key barriers to initiation and adherence to PrEP. First, most participants who declined PrEP expressed doubts about the relative additional effectiveness of PrEP in combination with other prevention tools. Second, perceived stigma related to PrEP use was an important barrier to PrEP initiation. Third, many struggled with overcoming perceived side effects or logistical challenges of taking daily PrEP, particularly when they themselves were not ill. Conclusions: Leveraging the facilitators and overcoming barriers to PrEP uptake may enhance the successful rollout of PrEP among HIV serodiscordant couples in Kenya and other areas in sub-Saharan Africa, thereby reducing sexual transmission of HIV. Further research focused on how best to provide counselling on combination HIV prevention tools in the context of PrEP use is a crucial next step to delivering PrEP. © 2016 Patel R C et al; licensee International AIDS Society.	barriers; facilitators; heterosexual; HIV serodiscordant couples; Kenya; pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2016	Patel, Rena C; Odoyo, Josephine; Anand, Keerthana; Stanford-Moore, Gaelen; Wakhungu, Imeldah; Bukusi, Elizabeth A; Baeten, Jared M; Brown, Joelle M	Facilitators and Barriers of Antiretroviral Therapy Initiation among HIV Discordant Couples in Kenya: Qualitative Insights from a Pre-Exposure Prophylaxis Implementation Study	PLOS One	-	-	-	-	NA	10.1371/journal.pone.0168057	https://www.proquest.com/scholarly-journals/facilitators-barriers-antiretroviral-therapy/docview/1847443059/se-2?accountid=8113	Introduction The World Health Organization now recommends antiretroviral therapy (ART) initiation for all HIV-infected individuals regardless of CD4 cell count or disease status. Understanding the facilitators and barriers to initiation of and adherence to ART is essential to successful scale-up of "universal" ART. Methods To investigate facilitators and barriers to ART initiation, we conducted 44 in-depth individual or couple interviews with 63 participants (33 participants with HIV and 30 without HIV) already enrolled in a prospective implementation study of oral antiretroviral-based prevention in Kisumu, Kenya between August and September 2014. A semi-structured interview guide discussed questions on: 1) perceived advantages and disadvantages of ART; 2) reasons for accepting or declining ART initiation; and 3) influence of prevention of transmission to partner or infant influencing ART use. Transcripts from the interviews were iteratively analyzed using inductive content analysis. Results HIV-infected participants indicated that living a healthier life, preventing HIV transmission to others, and appearing "normal" or "healthy" again facilitated their initiation of ART. While appearing "normal" allowed these individuals to interact with their communities without stigmatization, they also perceived community opposition to their initiating ART, because appearing "normal" again prevented community members from easily identifying infected individuals in their community. Denial of diagnosis, disclosure stigma, perceived side-effects, and challenges in obtaining refills were additional barriers to ART initiation. Conclusions Community perceptions play an important role in both facilitating and inhibiting ART initiation. Perceived stigma, including perceived community opposition to widespread ART use, is an important barrier to ART initiation. Addressing such barriers, while capitalizing on facilitators, to ART initiation should be central to universal ART scale-up efforts. Article	2016	Penrose K.J.; Parikh U.M.; Hamanishi K.A.; Else L.; Back D.; Boffito M.; Jackson A.; Mellors J.W.	Selection of Rilpivirine-Resistant HIV-1 in a Seroconverter From the SSAT 040 Trial Who Received the 300-mg Dose of Long-Acting Rilpivirine (TMC278LA)	Journal of Infectious Diseases	-	-	-	-	221899	10.1093/infdis/jiv528	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84964798477&doi=10.1093%2finfdis%2fjiv528&partnerID=40&md5=b5cfded454d948d3a2a9c405006088c8	The injectable long-acting formulation of rilpivirine (TMC278LA) is a promising preexposure prophylaxis (PrEP) candidate for prevention of human immunodeficiency virus type 1 (HIV-1) infection. We evaluated HIV-1 in plasma obtained from an unexpected seroconverter in the 300-mg arm of the SSAT040 TMC278LA pharmacokinetic study for rilpivirine (RPV) resistance. Infection with wild-type HIV-1 was confirmed on day 84 after TMC278LA injection, and the K101E mutation was detected on day 115. Plasma-derived HIV-1 clones containing K101E had 4-fold increased resistance to RPV and 4-8-fold increased cross-resistance to etravirine, nevirapine, and efavirenz compared with wild-type HIV-1 plasma-derived clones from the same individual. This case is a unique instance of infection with wild-type HIV-1 and subsequent selection of resistant virus by persistent exposure to long-acting PrEP. © 2015 The Author. All rights reserved. Article	2016	Pereira L.F.; Goschin S.; Ashley K.B.	PrEP: A Review for Mental Health Professionals	Journal of Gay & Lesbian Mental Health	-	-	-	-	19359705	10.1080/19359705.2015.1106221	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84954314818&doi=10.1080%2f19359705.2015.1106221&partnerID=40&md5=2ff85aceaf932782792a43e5626f16a8	Despite the significant advances in the knowledge and treatment of the human immunodeficiency virus (HIV) infection, it remains responsible for a worldwide epidemic. Research in macaques, using antiretrovirals as systemic pre-exposure prophylaxis (PrEP) showed encouraging results in preventing HIV transmission and led to several clinical trials in humans. In this article, we review the results of eight key PrEP studies using either tenofovir disoproxil fumarate (TDF) alone or in combination with emtricitabine (FTC): iPrEX, FEM-PrEP, Partners PrEP, TDF-2, VOICE, Bangkok Tenofovir Study, IPERGAY and PROUD. The results revealed that PrEP is well tolerated and its efficacy is related to adherence of the recommended regimen. The highest overall efficacy, 86%, was found in the IPERGAY and PROUD studies. Only one study found a suggestion of risk compensation. None of the studies identified an increase in the incidence of other sexually transmitted infections. The use of PrEP in individuals not known to be HIV-infected can increase the risk of development of drug resistance. More studies are warranted to monitor the possible long term side effects of TDF, as well as strategies to increase adherence in real life settings. Mental health professionals should be aware of PrEP and of its use. © 2016, Taylor & Francis Group, LLC. Article	2016	Philbin, Morgan M; Parker, Caroline M; Parker, Richard G; Wilson, Patrick A; Garcia, Jonathan; Hirsch, Jennifer S	The Promise of Pre-Exposure Prophylaxis for Black Men Who Have Sex with Men: An Ecological Approach to Attitudes, Beliefs, and Barriers.	AIDS Patient Care and STDs	-	-	-	-	1557-7449	10.1089/apc.2016.0037	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4913505	Research has demonstrated the clinical effectiveness of pre-exposure prophylaxis (PrEP) for HIV prevention, but little is known about how factors at the individual-, interpersonal-, community-, and structural levels impact PrEP use for black men who have sex with men (BMSM). We advance existing work by examining how all levels of the ecological framework must be addressed for PrEP to be successfully implemented as an effective HIV prevention approach. We interviewed 31 BMSM three times each and 17 community stakeholders once each; interviews were taped, transcribed, and analyzed using the constant comparative method. Factors that influence how BMSM experienced PrEP emerged across all levels of the ecological framework: At the individual level, respondents were wary of giving medication to healthy people and of the potential side-effects. At the interpersonal level, BMSM believed that PrEP use would discourage condom use and that PrEP should only be one option for HIV prevention, not the main option. At the community level, men described not trusting the pharmaceutical industry and described PrEP as an option for others, not for themselves. At the structural level, BMSM talked about HIV and sexuality-related stigmas and how they must overcome those before PrEP engagement. BMSM are a key population in the US National HIV/AIDS Strategy, yet few individuals believe that PrEP would be personally helpful. Our research indicates the urgent need to raise awareness and address structural stigma and policies that could be substantial barriers to the scale-up and implementation of PrEP-related services. Article	2016	Pialoux G.; Delaugerre C.; Cotte L.; Raffi F.; Cua E.; Molina J.-M.	Pre-exposure prophylaxis: a useful tool to prevent human immunodeficiency virus infection?	Clinical Microbiology and Infection	-	-	-	-	1198743X	10.1016/j.cmi.2016.08.029	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84995666111&doi=10.1016%2fj.cmi.2016.08.029&partnerID=40&md5=64e910a26a2a0f8ec06976e0d1db60a3	The aim of preventive measures against human immunodeficiency virus (HIV) is to reduce the incidence of HIV infection in the general population and in high-risk groups, such as men having sex with men (MSM), and to reduce the risk that a given individual will contract or spread the virus. Male and female condoms, post-exposure prophylaxis and circumcision are preventive methods currently recognized or promoted worldwide. Although modest success has been reported in a phase-III vaccine trial, other methods are being evaluated, such as vaginal and rectal microbicides, and pre-exposure prophylaxis (PrEP). Herein, we discuss results from prevention trials, especially those focusing on PrEP and particularly on recent results from 'on-demand' PrEP regimens. The efficacy of PrEP (rates of 0%–86%) is strongly correlated with adherence and plasma concentrations of antiretrovirals. Adverse events are rare. Selection of emtricitabine-resistant strains is mainly reported in individuals with an undiagnosed HIV infection using PrEP. PrEP is now strongly recommended in WHO prevention programmes for individuals at substantial risk for HIV with a view to controlling this epidemic by 2030. © 2016 European Society of Clinical Microbiology and Infectious Diseases	Adherence; Human immunodeficiency virus; Pre-exposure prevention; Resistance; Tenofovir/emtricitabine	English	United Kingdom	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Review

Article	2016	Poon, Art F Y	Impacts and shortcomings of genetic clustering methods for infectious disease outbreaks.	Virus Evolution (Virus Evol)	-	-	-	2057-1577	10.1093/ve/vew031	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5210264/	For infectious diseases, a genetic cluster is a group of closely related infections that is usually interpreted as representing a recent outbreak of transmission. Genetic clustering methods are becoming increasingly popular for molecular epidemiology, especially in the context of HIV where there is now considerable interest in applying these methods to prioritize groups for public health resources such as pre-exposure prophylaxis. To date, genetic clustering has generally been performed with ad hoc algorithms, only some of which have since been encoded and distributed as free software. These algorithms have seldom been validated on simulated data where clusters are known, and their interpretation and similarities are not transparent to users outside of the field. Here, I provide a brief overview on the development and inter-relationships of genetic clustering methods, and an evaluation of six methods on data simulated under an epidemic model in a risk-structured population. The simulation analysis demonstrates that the majority of genetic clustering algorithms are conservative, in the sense that false positive clusters is sampling rates among subpopulations, nor variation in transmission rates. I discuss these results in the context of previous work and the implications for public health applications of genetic clustering.	genetic clustering; infectious diseases; molecular epidemiology; phylodynamics	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Quantitative
Article	2016	Price J T.; Wheeler S.B.; Straatz-Chibuzuk L.; Houdt S.G.; Heather Watts D.; Silvery G.K.; Spiegel H.M.L.; Stringer J.S.; Chi B.H.	Cost-effectiveness of pre-exposure HIV prophylaxis during pregnancy and breastfeeding in Sub-Saharan Africa	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001063	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84979092924&doi=10.1097%2FQAI.0000000000001063&partnerID=40&md5=9505f9585d3c318e7b2a2522c235e833	Introduction: Antiretroviral pre-exposure prophylaxis (PrEP) for the prevention of HIV acquisition is cost-effective when delivered to those at substantial risk. Despite a high incidence of HIV infection among pregnant and breastfeeding women in sub-Saharan Africa (SSA), a theoretical increased risk of preterm birth on PrEP could outweigh the HIV prevention benefit. Methods: We developed a decision analytic model to evaluate a strategy of daily oral PrEP during pregnancy and breastfeeding in SSA. We approached the analysis from a public health care system perspective across a lifetime time horizon. Model inputs were derived from existing literature and local sources. The incremental cost-effectiveness ratio (ICER) of PrEP versus no PrEP was calculated in 2015 U.S. dollars per disability-adjusted life year (DALY) averted. We conducted 1-way and probabilistic sensitivity analyses. Results: In the base case, PrEP cost $1,474 per DALY averted and $1,609 per life-year saved (LYS). Compared with no PrEP, PrEP averted 0.92 DALYs. In a base case of 10,000 women, the administration of PrEP averted 301 HIV infections but resulted in 278 more preterm births. PrEP was more costly per person ($450 versus $117), but resulted in fewer disability-adjusted life years (DALYs) (13.15 versus 3.49). The incremental cost-effectiveness ratio of $965 DALY averted was below the recommended regional threshold for cost-effectiveness of $6462 DALY. Probabilistic sensitivity analyses demonstrated robustness of the model. Conclusions: Providing PrEP to pregnant and breastfeeding women in SSA is likely cost-effective, although more data are needed about adherence and safety. For populations at high risk of HIV acquisition, PrEP may be considered as part of a broader combination HIV prevention strategy. © 2016 Wolters Kluwer Health, Inc. All rights reserved. Article	2016	Punyacharoensin N.; Edmunds W.J.; De Angelis D.; Delpech V.; Hart G.; Elford J.; Brown A.; Gill O.N.; White R.G.	Effect of pre-exposure prophylaxis and combination HIV prevention for men who have sex with men in the UK: A mathematical modelling study	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(15)00056-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84958103743&doi=10.1016%2FS2352-3018%2815%2900056-9&partnerID=40&md5=94ad14ac7ae8ce9ea9ca222a6e505e9b	Background: HIV transmission in men who have sex with men (MSM) in the UK has shown no sign of decreasing in the past decade. Additional prevention measures are needed. We aimed to estimate the effect of various potential interventions implemented individually and in combination on prevention of HIV infection. Methods: We extended a deterministic partnership-based mathematical model for HIV transmission among MSM in the UK to incorporate pre-exposure prophylaxis (PrEP), and sexual behavioural changes. We did sensitivity analyses on risk compensation. Findings: We predicted an increase in the baseline of 16 955 new infections (IQR 13 156-21 049) in MSM in the UK during 2014-20. At a coverage of ≥50%, testing twice a year outperformed all other interventions. Of all intervention combinations, only the combined effect of test and treat and annual HIV testing (63·5%, IQR 47·2-81·8, of total incidence) was greater than the sum of effects of the two interventions individually (32·0%, 22·7-40·6, and 23·9%, 16·5-33·1, respectively). Simultaneous PrEP, expansion of HIV testing, and initiation of test-and-treat programme in 25% of high-activity MSM could save 7399 (IQR 5587-9013) UK MSM from HIV infection (41·6%, IQR 32·9-57·9, of total incidence). An increase in unsafe sex or sexual partners to 50% or more could substantially reduce the effect of intervention, but is unlikely to negate the prevention benefit completely. Interpretation: PrEP could prevent a large number of new HIV infections if other key strategies including HIV testing and treatment are substantially expanded and improved. Without PrEP, HIV incidence in MSM in the UK is unlikely to decrease substantially by the end of this decade. Funding: Health Protection Agency (now Public Health England); © 2016 Elsevier Ltd. Article	2016	Quaife, Matthew; Eakle, Robyn; Cabrera, Maria; Vickerman, Peter; Tsepe, Motlalepule; Cianci, Fiona; Delany-Moretlwe, Sinead; Terris-Prestholt, Fern	Preferences for ARV-based HIV prevention methods among men and women, adolescent girls and female sex workers in Gauteng Province, South Africa: a protocol for a discrete choice experiment.	BMJ Open	-	-	-	2044-6055	10.1136/bmjopen-2015-010042	https://bmjopen.bmj.com/content/6/6/e010042	INTRODUCTION: For the past few decades, condoms have been the main method of HIV prevention. Recent advances in antiretroviral (ARV)-based prevention products have substantially changed the prevention landscape, yet little is known about how popular these products will be among potential users, or whether new methods might be used in conjunction with, or instead of, condoms. This study will investigate the preferences for ARV-based HIV prevention methods among men and women, adolescent girls and female sex workers in Gauteng Province, South Africa. The findings will be used to inform estimates of their potential impact on the HIV epidemic in South Africa. We consider preferences for: oral pre-exposure prophylaxis, a vaginal microbicidal gel, a long-acting vaginal ring, a SLCS diaphragm used in concert with gel, and a long-acting ARV-based injectable. METHODS AND ANALYSIS: This study will gather data from 4 populations: 200 women, 200 men, 200 adolescent girls (aged 16-17 years) and 200 female sex workers. The DCE attributes and design will be developed through a literature review, supplemented by a thematic analysis of qualitative focus group discussions. Extensive piloting will be carried out in each population through semistructured interviews. The final survey will be conducted using computer tablets in a household sample (for women, men and adolescents) and respondent-driven sampling (for female sex workers), and DCE data analysed using a range of multinomial logit models. ETHICS AND DISSEMINATION: This study has been approved by the University of the Witwatersrand Human Research Ethics Committee and the Research Ethics Committee at the London School of Hygiene and Tropical Medicine. Findings will be presented to international conferences and peer-reviewed journals. Meetings will be held with opinion leaders in South Africa, while results will be disseminated to participants in Hazlehurst through a public meeting or newsletter. Article	2016	Race K.	Reluctant objects: Sexual pleasure as a problem for his biomedical prevention	GLQ	-	-	-	10642684	10.1215/10642684-3135217	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84949747567&doi=10.1215%2F10642684-3135217&partnerID=40&md5=e9b4b1fc5f2f653ea48902b7ffc86	Pre-exposure prophylaxis (PrEP) has so far emerged as a reluctant object in much gay community discourse, primarily because of its association with the supposed excesses of unbridled sex. In approval in the United States sparked bitter debate and a new round of sexual health moralism issuing mainly from gay community-based commentators, with initial uptake much slower than critics. This article considers early gay community responses to PrEP and connects them to the failure of existing HIV scientific practices to produce inhabitable sexual pedagogies. The controversy surrounding PrEP speaks to how condoms have been a very low-tech, cheap command fears about sexual excess in the era of AIDS, presenting not only a latex barrier but also symbolic reassurance that gay sex might in some way be made "safe." Another mode of attending to what is risky and exciting about sexual and sexual and scientific encounters might be possible in concerning them as events. © 2015 by Duke University Press.	pre-exposure prophylaxis, biomedical prevention, event, pleasure, gay sex	English	United States	Western and Central Europe and North America	Australia	Asia and the Pacific	NA	NA	Qualitative

Gerardo	Combination Emtricitabine and Tenofovir Disoproxil Fumarate Prevents Vaginal Simian/Human Immunodeficiency Virus Infection in Macaques Harboring Chlamydia trachomatis and Trichomonas vaginalis.	The Journal of Infectious Diseases	-	-	-	1537-6613 0022-1899	10.1093/infdis/jiw002	https://pubmed.ncbi.nlm.nih.gov/26743466/	Genital inflammation associated with sexually transmitted infections increases receptivity to human immunodeficiency virus (HIV), but it is unclear whether it can reduce the efficacy of pre-exposure prophylaxis (PrEP). We investigated whether coinfection of macaques with Chlamydia trachomatis and Trichomonas vaginalis decreases the prophylactic efficacy of oral emtricitabine (FTC)/tenofovir disoproxil fumarate (TDF). Macaques were exposed to simian/human immunodeficiency virus (SHIV) vaginally each week for up to 16 weeks and received either FTC/TDF or placebo. TDF/FTC prevented coinfection, although the infection of 2 macaques signals a modest loss of PrEP activity. Article	2016	Rahman S.M.A.; Vaidya N.K.; Zou X.	Impact of cavity treatment progression on HIV epidemics: An immunity-based mathematical model	Mathematical Biosciences	-	-	-	255564	10.1016/j.mbs.2016.07.009	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84980395656&doi=10.1016%2Fj.mbs.2016.07.009&partnerID=40&md5=ff8e822bdbe85c9d3916d13b03d6e4	While studies on pre-exposure prophylaxis (PrEP) and post-exposure prophylaxis (PEP) have demonstrated substantial advantages in controlling HIV transmission, the overall benefits of the programs with early initiation of antiretroviral therapy (ART) have not been fully understood and are still in debate. Here, we develop an immunity-based CD4+ T cell compartmental model to investigate the impact of early treatment programs on HIV epidemics and the overall community-level immunity. The model is parameterized using the HIV prevalence data from South Africa and fully analyzed for stability of equilibria and infection persistence criteria. Using our model, we evaluate the effects of early treatment on the new infection transmission, decrease-decline recruitment, HIV prevalence, and the community-level immunity. Our model predicts that the programs with early treatments significantly reduce the new infection transmission and increase the community-level immunity, but the treatments alone may not be enough to eliminate HIV epidemics. These findings, including the community-level immunity, might provide helpful information for proper implementation of HIV treatment programs. © 2016 Elsevier Inc. Article	2016	Reza-Paul S.; Lazarus L.; Doshi M.; Heiker Gi Rahman S.; Ramaiah M.; Maiya R.; Venugopal M.S.; Venukumar K.T.; Sundararaman S.; Becker M.; Moses S.; Lorway R.	Prioritizing risk in preparation for a demonstration project: A mixed methods feasibility study of oral pre-exposure prophylaxis (PREP) among female sex workers in South India	PLOS One	-	-	-	19326203	10.1371/journal.pone.0166889	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84980237656&doi=10.1371%2Fjournal.pone.0166889&partnerID=40&md5=2a4d2c9385c5ba0b5f4f8b2f3d2	Background HIV prevalence among female sex workers (FSWs) in India remains well above the national average. Pre-exposure prophylaxis (PrEP), a new HIV prevention technology, may help to reduce HIV incidence, but there is a dearth of research that can inform the potential scale-up of PrEP in India. In partnership with Arkodaya Samithi, a local sex worker collective, we conducted a feasibility study to assess acceptance of a planned PrEP demonstration project, willingness to use PrEP, and recommendations for project roll-out among FSWs in southern Karnataka. Methods From January-April 2015, 4 focus group discussions, 47 in-depth interviews, and 427 interviewer-administered questionnaires were completed by female sex workers. All participants were 18 years of age or older and practiced sex work. Questionnaires assessed: socio-demographics, sex work practices, experiences with violence, utilization of existing HIV prevention services, and acceptability of existing or new prevention technologies that places control at the hands of FSWs and provides a "double safety" in combination with condom use. Participants expressed concern about potential side effects of PrEP, and provides a "double safety" in combination with condom use. Participants expressed concern about potential side effects of PrEP, risk in their occupational environments should be prioritized for enrollment into a demonstration project. Quantitative. 406 participants (95%) expressed interest in PrEP. Participants prioritized the inclusion of FSWs under the age of 25 (79%), those who do not use condoms when clients offer more money (58%), who do not consistently use condoms with regular partners (57%), who drink alcohol regularly (49%), and who do not use condoms consistently with clients (48%). Discussion This feasibility study indicated strong interest in PrEP and a desire to move forward with the demonstration project. Participants expressed their responses in terms of public health discourses surrounding risk, pointing to the importance of situating PrEP scale-up within the trusted spaces of community-based organizations as a means of supporting PrEP uptake and adherence. © 2016 Reza-Paul et al. Intimate Partner Violence and Adherence to HIV Pre-exposure Prophylaxis (PrEP) in African Women in HIV Serodiscordant Relationships: A Prospective Cohort Study	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001093	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84959904646&doi=10.1097%2FQAI.0000000000001093&partnerID=40&md5=9192e4594ea0a1f8dc31d3b4ae6e1bbb	Background: Intimate partner violence (IPV) is associated with higher HIV incidence, reduced condom use, and poor adherence to antiretroviral therapy and other medications. IPV may also affect adherence to pre-exposure prophylaxis (PrEP). Methods: We analyzed data from 1785 HIV-uninfected women enrolled in a clinical trial of PrEP among African HIV serodiscordant couples. Experience of verbal, physical, or economic IPV was assessed at monthly visits by face-to-face interviews. Low PrEP adherence was defined as clinic-based pill counts <80%. Drug concentrations in dried blood spots (DBS) and plasma tenofovir (adjusted risk ratio 1.51, 95% confidence interval: 1.06 to 2.15). Verbal, economic, and physical IPV were all associated with low adherence. However, the impact of IPV diminished and was not statistically significant 3 months after the reported exposure. In qualitative interviews, women identified several ways in which IPV affected adherence, including stress and forgetting, leaving home without pills, and partners throwing pills away. Conclusions: Women who reported recent IPV in the Partners PrEP Study were at increased risk of low PrEP adherence. Strategies to mitigate PrEP nonadherence in the context of IPV should be evaluated. © Copyright 2016 Wolters Kluwer Health, Inc. Article	2016	Ross E.L.; Cioni S.K.; Hutton D.W.	Implementation and Operational Research Epidemiology and Prevention: A Cost-Effective, Clinically Actionable Strategy for Targeting HIV Preexposure Prophylaxis to High-Risk Men Who Have Sex with Men	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000000967	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961231762&doi=10.1097%2FQAI.0000000000000967&partnerID=40&md5=4a66e4ee9ea677c924ede8cb1e4ffd6b	Background: Preexposure prophylaxis (PrEP) is effective at preventing HIV infection among men who have sex with men (MSM), but there is uncertainty about how to identify high-risk MSM who should receive PrEP. Methods: We used a mathematical model to assess the cost-effectiveness of using the HIV Incidence Risk Index for MSM (HIRI-MSM) questionnaire to target PrEP to high-risk MSM. We simulated strategies of no PrEP, PrEP available to all MSM, and eligibility thresholds set to HIRI-MSM scores between 5 and 45, in increments of 5 (where a higher score predicts greater HIV risk). Based on the iPrEx, IPERGAY, and PROUD trials, we evaluated PrEP efficacies from 44% to 86% and annual costs from $5900 to $700. We designate strategies with incremental cost-effectiveness ratio (ICER) <$100,000/quality-adjusted life-year (QALY) as "cost-effective." Results: Over 20 years, making PrEP available to all MSM is projected to prevent 33.5% of new HIV infections, with an ICER of $1,474,000/QALY. Increasing the HIRI-MSM score threshold reduces the prevented infections, but improves cost-effectiveness. A threshold score of 25 is projected to be optimal (most QALYs gained while still being cost-effective) over a wide range of realistic PrEP efficacies and costs. At low cost and high efficacy (IPERGAY), thresholds of 15 or 20 are optimal across a range of other input assumptions; at high cost and low efficacy (iPrEx), 25 or 30 are generally optimal. Conclusions: The HIRI-MSM provides a clinically actionable means of guiding PrEP use. Using a score of 25 to determine PrEP eligibility could facilitate cost-effective use of PrEP among high-risk MSM who will benefit from it most. © Copyright 2016 Wolters Kluwer Health, Inc. Article	2016	Rosseel, Bergih V.; Callegaro A.P.; Micheli V.; Brurzone B.; Colao G.; Gismondo M.R.; Vicenti I.; Penco G.; Zazzi M.; Rusconi S.	Impact of circulating resistance-associated mutations on HIV pre-exposure prophylaxis (PrEP) efficacy: Modelling from antiretroviral resistance cohort analysis (ARCA) outbreak database	Journal of Clinical Virology	-	-	-	13866532	10.1016/j.jcv.2016.08.293	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84964867965&doi=10.1016%2Fj.jcv.2016.08.293&partnerID=40&md5=5b165f4b59e153af3bd7c9d51180f6f	Background PrEP with FTC/TDF has shown great efficacy in preventing new HIV infections but issues remain (low adherence, high costs, toxicity and resistance development). No data are available about the impact of circulating Resistance-Associated Mutations (RAMs) on its efficacy. Objectives describe the prevalence of TFC and/or TDF-related RAMs in Italian HIV-infected population and their potential impact on PrEP efficacy. Study design ARCA is a national database that collects data about RAMs and epidemiological correlates from sites throughout Italy; it was queried about the prevalence of these RAMs in the last decade. PrEP efficacy was adjusted for a dynamic score based on RAMs prevalence. Absolute and relative risk increases (ARI and RRI) and number needed to harm (NNH) were calculated for each year. Results 21,691 patients were included and 5579 (25.8%) were infected before 2006 (Group 1), 6,662 (30.7%) between 2006 and 2010 (Group 2) and 9450 (43.5%) between 2011 and 2015 (Group 3). Compared to Group 1, lower significant differences were observed in Group 2 (ARI 0.6%, p = 0.0001; RRI 1.4%, p = 0.0001) and 3 (ARI 0.8%, p = 0.0001; RRI 1.8%, p = 0.0001). Relative risk increases (RRI) were 1.4% (exponential MSM), NNH is largely above 10000 except for having receptive anal sex with a HAART-experienced MSM on a failing treatment (NNH = 2). Conclusions According to this model, PrEP may be introduced in Italy without significant increases in the risk of HIV resistance. Article	2016	Schwartz, Sheree R; West, Nora; Pheda, Rebecca; Yende, Nompumelelo; Sanne, Ian; Bassett, Jean; Van Rie, Annelies	Acceptability and preferences for safer conception HIV prevention strategies: a qualitative study.	International Journal of STD & AIDS	-	-	-	1758-1052	10.1177/0956462415604091	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4889511/	Safer conception strategies to reduce the HIV transmission risk include antiretroviral therapy for HIV-positive partners, pre-exposure prophylaxis for HIV-negative partners, condomless sex limited to fertile periods, and home insemination. Recommendations to inform decisions to taking treatment or cohital concerns may limit uptake of strategies and intervention success. Understanding the acceptability and preferences between different approaches is important to optimise service delivery. Between February and July 2013, 42 adults (21 HIV-positive and 21 HIV-negative) receiving primary care at Wilkespoes Health and Wellness Centre in Mossy-spruit, South Africa, participated in focus group discussions or in-depth interviews. Themes were analysed using a grounded theory approach. Acceptability of antiretroviral therapy varied. Concerns over side effects, antiretroviral treatment duration and beliefs that treatment is only for the sick were common barriers; however, desperation for a child was noted as a facilitator for uptake. HIV-negative men and HIV-positive women had favourable attitudes towards self-insemination, though paternity and safety concerns were raised. Self-insemination was generally preferred over pre-exposure prophylaxis by HIV-negative men, and antiretroviral-based strategies were preferred by couples with HIV-negative female partners, despite concerns raised about condomless sex while virally suppressed. Knowledge about the fertile window was low. A strong counselling component will be required for effective uptake and adherence to safer conception services. Article	2016	Scott H.M.; Klausner J.D.	Sexually transmitted infections and pre-exposure prophylaxis: Challenges and opportunities among men who have sex with men in the US	AIDS Research and Therapy	-	-	-	17426405	10.1186/s12981-016-0089-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84955389014&doi=10.1186%2Fs12981-016-0089-8&partnerID=40&md5=03f4964cff04a0f72228ad6ce4e2	Pre-Exposure Prophylaxis (PrEP) has shown high efficacy in preventing human immunodeficiency virus (HIV) infection among men who have sex with men (MSM) in several large clinical trials, and more recently in "real-world" reports of clinical implementation and a PrEP demonstration project. These studies also demonstrated high bacterial sexually transmitted infection (STI) incidence and the discussion of how PrEP may impact STI control efforts, especially in the setting of increasing Neisseria gonorrhoeae antimicrobial resistance and the increase in syphilis cases among MSM. Here, we discuss STIs as a driver of HIV transmission risk among MSM, and the potential opportunities and challenges for STI control afforded by expanded PrEP implementation among high-risk MSM. © 2016 Scott and Klausner. Article	2016	Seidman, DL; Weber, S; Timoney, MT; Ota, KK; Mullins, E; Cohen, DL; Wright, RL	Use of HIV pre-exposure prophylaxis during the preconception, antepartum and postpartum periods at two United States medical centers	American Journal of Obstetrics and Gynecology	-	-	-	0002-9378	10.1016/j.ajog.2016.06.020	https://pubmed.ncbi.nlm.nih.gov/27440959/	BACKGROUND: Pregnancy may increase a woman's susceptibility to HIV. Maternal HIV acquisition during pregnancy and lactation is associated with increased perinatal and lactational HIV transmission. There are no published reports of preexposure prophylaxis use after the first trimester of pregnancy or during lactation. OBJECTIVE: The purpose of this study was to report the use of preexposure prophylaxis and to identify gaps in HIV prevention services for women who were at substantial risk of HIV preconception and during pregnancy and lactation at 2 United States medical centers. STUDY DESIGN: Chart review was performed on women who were identified as "at significant risk" for HIV acquisition preconception (women desiring pregnancy) and during pregnancy and lactation at 2 medical centers in San Francisco and New York from 2010-2015. Women were referred to specialty clinics for women who were living with or were at substantial risk of HIV. RESULTS: Twenty-seven women who were identified had a median age of 27 years. One-half of the women had unstable housing, 22% of the women had ongoing intimate partner violence, and 22% of the women had active substance use. Twenty-two women (81%) were referred for HIV risk reduction counseling, and 15 (56%) were prescribed PrEP. Of the 15 women who were prescribed PrEP, 11 (73%) initiated therapy, and 42% (3/7) had documented viral suppression. Thirty-nine percent (10/26) of patients had known detectable virus, and 19% (5/26) had unknown viral loads. Women were identified by clinicians, health educators, and health departments. Approximately one-third of the women were identified preconception (8/27); the majority of the women were identified during pregnancy (18/27) with a median gestational age of 28 weeks (interquartile range, 11x23), and 1 woman was identified at the postpartum period. None of the pregnant referrals had received safer conception counseling to reduce HIV transmission. Twenty-six percent of all women (7/27) were eligible for postexposure prophylaxis at referral, of whom 57% (4/7) were offered postexposure prophylaxis. In 30% (8/27), the last HIV exposure was not assessed and postexposure prophylaxis was not offered. The median time from identification as "at substantial risk" to consultation was 30 days (interquartile range, 2x62). Two women were lost to follow-up before consultation. One woman who was identified as "at significant risk" was not referred because of multiple pregnancy complications. She remained in obstetrics care and was HIV-negative at delivery but was lost to follow-up. Two women who were referred for preconception counseling (2/8) became pregnant before receiving counseling. Preconception counseling was provided to 6 women (6/26) who chose to take it, which was relatively consistent/similar (between were preconception (5/8), pregnant (10/18), or after delivery (1/1). Median length of fitness preexposure prophylaxis was 30weeks (interquartile range, 20x53). One-half of women (10/20) who were in care at delivery did not attend a postpartum visit. CONCLUSION: Women at 2 United States centers frequently chose to use preexposure prophylaxis for HIV prevention when it was offered preconception and during pregnancy and lactation. Further research and education are needed to close critical gaps in screening for women who are at risk of HIV for pre-and postexposure prophylaxis eligibility and gaps in care linkage before and during pregnancy and lactation. Postpartum women are particularly vulnerable to loss-to-follow-up and miss opportunities for safe and effective HIV prevention. Article	2016	Seidman, Dominika; Carlson, Kimberly; Weber, Shannon; Witt, Jacki; Kelly, Patricia J	United States family planning providers' knowledge of and attitudes towards preexposure prophylaxis for HIV prevention: a national survey.	Contraception	-	-	-	-	1879-0518	10.1016/j.contraception.2015.12.018	https://dx.doi.org/10.1016/j.contraception.2015.12.018	OBJECTIVES: The Centers for Disease Control and Prevention defines HIV prevention as a core family planning service. The HIV community identified family planning visits as key encounters for women to access preexposure prophylaxis (PrEP) for HIV prevention. No studies explore US family planning providers' knowledge of and attitudes towards PrEP. We conducted a national survey of clinicians to understand barriers and facilitators to PrEP implementation in family planning. STUDY DESIGN: Family planning providers recruited via website postings, national meetings, and email completed an anonymous survey in 2015. Descriptive statistics were performed. RESULTS: Among 604 respondents, 495 were eligible for analysis and 342 were potential PrEP prescribers (physicians, nurse practitioners, midwives or physicians assistants). Among potential prescribers, 38% correctly defined PrEP 95% confidence interval (CI): 32.5-42.8, 37% correctly stated the efficacy of PrEP (95% CI: 32.0-42.4), and 36% chose the correct HIV test after a recent exposure (95% CI: 30.6-40.8). Characteristics of those who answered knowledge questions correctly included age less than 35 years, practicing in the Northeast or West, routinely offering HIV testing, providing rectal sexually transmitted infection screening or having seen any PrEP guidelines. Even among providers in the Northeast and West, the proportion of respondents answering questions correctly was less than 50%. Thirty-six percent of respondents had seen any PrEP guidelines. Providers identified lack of training as the main barrier to PrEP implementation; 87% wanted PrEP education. CONCLUSIONS: To offer comprehensive HIV prevention services, family planning providers urgently need training on PrEP and HIV testing. IMPLICATIONS: US family planning providers have limited knowledge about HIV PrEP and HIV testing, and report lack of provider training as the main barrier to PrEP provision. Provider education is needed to ensure that family planning clients access comprehensive HIV prevention methods. Article	2016	Sevelius J.M.; Keatley J.; Calma N.; Arnold E.	I am not a man': Trans-specific barriers and facilitators to PrEP acceptability among transgender women	Global Public Health	-	-	-	-	17441692	10.1080/17441692.2016.1154085	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961211384&doi=10.1080%2f17441692.2016.1154085&partnerID=40&md5=8b9cf5606dc68b97791f4a99e86ffb82	The frequent conflation of transgender ('trans') women with 'men who have sex with men (MSM)' in HIV prevention obscures trans women's unique gender identities, social and behavioural vulnerabilities, and their disproportionally high rates of HIV infection. Pre-exposure prophylaxis (PrEP) is an efficacious biomedical HIV prevention approach. However, trans women are underrepresented in PrEP research, and are often aggregated with MSM without consideration for their unique positions within sociocultural contexts. This study examined PrEP acceptability among trans women via three focus groups and nine individual interviews (total N = 30) in San Francisco. While knowledge of PrEP was low, interest was relatively high once participants were informed. Due to past negative healthcare experiences, ability to obtain PrEP from a trans-competent provider was cited as essential to PrEP uptake and adherence. Participants noted that PrEP could address situations in which trans women experience reduced power to negotiate safer sex, including sex work. Trans-specific barriers included lack of trans-inclusive marketing of PrEP, prioritisation of hormone use, and medical mistrust due to transphobia. Findings underscore the importance of disaggregating trans women from MSM in HIV prevention strategies to mitigate disparate risk among this highly vulnerable population. © 2016 Informa UK Limited, trading as Taylor & Francis Group. Article	2016	Sevelius, Jae M; Deutsch, Madeline B; Grant, Robert	The future of PrEP among transgender women: the critical role of gender affirmation in research and clinical practices.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.19.7.21105	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5071750	INTRODUCTION: Globally, transgender ("trans") women are one of the key populations most disproportionately impacted by HIV. Pre-exposure prophylaxis (PrEP) is the newest and most promising biomedical HIV prevention intervention to date. This paper reviews relevant literature to describe the current state of the science and describes the potential role of PrEP among trans women, including a discussion of unique considerations for maximizing the impact of PrEP for this vulnerable population. METHODS: Available information, including but not limited to existing scientific literature, about trans women and PrEP was reviewed and critiqued based on author expertise, including PrEP clinical trials and rollout. RESULTS: To date, PrEP demonstration projects and clinical trials have largely excluded trans women, or have not included them in a meaningful way. Data collection strategies that fail to identify trans women in clinical trials and research further limit the ability to draw conclusions about trans women's unique needs and devise strategies to meet them. Gender-affirming providers and clinic environments are essential components of any sexual health programme that aims to serve trans women, as they will largely avoid settings that may result in stigmatizing encounters and threats to their identities. While there is currently no evidence to suggest drug-drug interactions between PrEP and commonly used feminizing hormone regimens, community concerns about potential interactions may limit interest in and uptake of PrEP among trans women. CONCLUSIONS: In scaling up PrEP for trans women, it is essential to engage trans communities, utilize trans-inclusive research and marketing strategies and identify and/or train healthcare providers to provide gender-affirming healthcare to trans women, including transition-related care such as hormone provision. PrEP implementation guidelines must consider and address trans women's unique barriers and facilitators to uptake and adherence.	ransgender women, PrEP, HIV prevention	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Sewell, Janey; Speakman, Andrew; Phillips, Andrew N.; Cambiano, Valentina; Lampe, Fiona C.; Gilson, Richard; Asboe, David; Nwokolo, Nneka; Clarke, Amanda; Ogilvy, Ali; Collins, Simon; Rodger, Alison J.	Attitudes to and Understanding of Risk of Acquisition of HIV Over Time: Design and Methods for an Internet-based Prospective Cohort Study Among UK Men Who Have Sex With Men (the AURAH2 Study).	JMIR Research Protocols	-	-	-	-	1929-0748	10.2196/resprot.5582	https://pubmed.ncbi.nlm.nih.gov/27307218/	BACKGROUND: The annual number of new human immunodeficiency virus (HIV) infections among men who have sex with men (MSM) has risen in the United Kingdom and, of those who are HIV positive, the proportion undiagnosed is high. OBJECTIVE: The prospective AURAH2 study aims to assess factors associated with HIV acquisition among MSM in the United Kingdom and to investigate changes over time within individuals in sexual behavior and HIV-testing practices. METHODS: AURAH2 is a prospective study among MSM without diagnosed HIV, aiming to recruit up to 1000 sexually active MSM attending sexual health clinics in London and Brighton in the United Kingdom. Participants complete an initial paper-based questionnaire, followed by online follow-up questionnaires every 4 months collecting sociodemographic, health and behavioral data, including sexual behavior, recreational and other drug use, HIV testing practices, and pre-exposure prophylaxis use, over a planned 3-year period. RESULTS: The study is ongoing. CONCLUSIONS: The results from AURAH2 study will provide important insight into established and emerging risk behaviors that may be associated with acquisition of HIV in MSM in the United Kingdom, changes over time within individuals in sexual behavior, and information on HIV testing practices. These data will be crucial to inform future HIV prevention strategies.	pre-exposure prophylaxis; HIV infection; HIV transmission; men who have sex with men; HIV testing; sexual risk behaviour; HIV negative; chemsex; HIV self-testing; health and well-being; recreational drug use; study design	English	Canada	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2016	Shilaih, Mohaned; Marzel, Alex; Scherrer, Alexandra U.; Braun, Dominique L.; Kovari, Helen; Rougemont, Mathieu; Darling, Katharine; Battegay, Manuel; Hoffmann, Matthias; Bernasconi, Enos; Hirzel, Cedric; Günthard, Huldrych F.; Kouyos, Roger D.	Dually Active HIV/HBV Antiretrovirals as Protection Against Incident Hepatitis B Infections: Potential for Prophylaxis.	The Journal of Infectious Diseases	-	-	-	-	1537-6613 0022-1899	10.1093/infdis/jiw195	https://pubmed.ncbi.nlm.nih.gov/27190182/	BACKGROUND: Hepatitis B virus (HBV) has a detrimental effect on human immunodeficiency virus (HIV) natural course, and HBV vaccination is less effective in the HIV infected. We examine the protective effect of dually active antiretroviral therapy (DAART) for HIV/HBV (tenofovir, lamivudine, and emtricitabine) in a large cohort encompassing heterosexuals, men who have sex with men, and intravenous drug users who are HIV infected yet susceptible to HBV, with comprehensive follow-up data about risky behavior and immunological profiles. METHODS: We defined an incident HBV infection as the presence of any of HBV serological markers (hepatitis B surface antigen, anti-hepatitis B core antibodies, or HBV DNA) after a negative baseline test result for anti-hepatitis B core antibodies. Patients with positive anti-hepatitis B surface antigen serology were excluded. Cox proportional hazards models were used, with an incident case of HBV infection as the outcome variable. RESULTS: We analyzed 1716 eligible patients from the Swiss HIV Cohort Study with 177 incident HBV cases. DAART was negatively associated with incident HBV infection (hazard ratio HR, 0.4; 95% confidence interval CI, .2-.6). This protective association was robust to adjustment (HR, 0.3; 95% CI, .2-.5) for condomless sex, square-root-transformed CD4 cell count, drug use, and patient demographics. Condomless sex (HR, 1.9; 95% CI, 1.4-2.6), being a man who has sex with men (2.7; 1.7-4.2), and being an intravenous drug user (3.8; 2.4-6.1) were all associated with a higher hazard of contracting HBV. CONCLUSIONS: Our study suggests that DAART, independently of CD4 cell count and risky behavior, has a potentially strong public health impact, including pre-exposure prophylaxis of HBV coinfection in the HIV infected. Article	2016	Shrestha R.K.; Sansom S.L.; Purcell D.W.	Assessing HIV acquisition risks among men who have sex with men in the United States of America	Revista Panamericana de Salud Pública/Pan American Journal of Public Health	-	-	-	-	10204989	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85014081854&partnerID=40&md5=cd46c36021ab1bcb8b19df0aab91bbae	Men who have sex with men (MSM) can reduce their risk of acquiring human immunodeficiency virus (HIV) by using various prevention strategies and by understanding the effectiveness of each option over the short- and long-term. Strategies examined were: circumcision; insertive anal sex only; consistent, 100% self-reported condom use; and pre-exposure prophylaxis (PrEP). PrEP efficacy was based on three levels of adherence. The cumulative HIV acquisition risk among MSM over periods of 1 year and 10 years were estimated with and without single and combinations of prevention strategies. A Bernoulli process model was used to estimate risk. In the base case with no prevention strategies, the 1-year risk of HIV acquisition among MSM was 8.8%. In contrast, the 1-year risk associated with circumcision alone was 6.9%; with insertive sex only, 5.5%; with 100% self-reported condom use, 2.7%; and with average, high, and very high PrEP adherence, 5.1%, 2.5%, and 0.7%, respectively. The 10-year risk of HIV acquisition among MSM with no prevention strategy was 60.3%. In contrast, that associated with circumcision alone was 51.1%; with insertive sex only, 43.1%; with 100% self-reported condom use, 24.0%; and with average, high, and very high PrEP adherence, 40.5%, 22.2%, and 7.2%, respectively. While MSM face substantial risk of HIV, there are now a number of prevention strategies that reduce risk. Very high adherence to PrEP alone or with other strategies appears to be the most powerful tool for HIV prevention. Article	2016	Smith D.K.; Maier E.; Betts J.; Gray S.; Kolodziejski B.; Hoover K.W.	What community-based HIV prevention organizations say about their role in biomedical HIV prevention	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2016.28.5.426	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84990841529&doi=10.1521%2faeap.2016.28.5.426&partnerID=40&md5=7e22b51fa1f1455dbcd043c40ec90f58	Community-based organizations (CBOs) are critical to delivery of effective HIV prevention because of their reach to key populations. This online survey of a national sample of CBOs assessed their awareness of, interest in, and resources needed to provide nonoccupational postexposure prophylaxis (nPEP), preexposure prophylaxis (PrEP), and HIV treatment as prevention (TasP). One hundred seventy-five CBOs participated: 87 clinical and 88 nonclinical CBOs. For nPEP, PrEP, and TasP, program managers reported that awareness was high (94%, 90%, 85%), meeting current client need was low (20%, 13%, 18%), and the likelihood of increasing their current provision with additional resources was somewhat high (62%, 64%, 62%). Clinical CBOs were more prepared to support expansion of these biomedical interventions than nonclinical CBOs. Meeting the information, training, and resource needs of CBOs is critical for effective collaboration to reduce the number of new HIV infections through expanded delivery of PrEP, nPEP, and TasP. © 2016 The Guilford Press. Article	2016	Smith D.K.; Mendoza M.C.B.; Stryker J.E.; Rose C.E.	PrEP awareness and attitudes in a national survey of primary care clinicians in the United States, 2009-2015	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0156592	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84973512736&doi=10.1371%2fjournal.pone.0156592&partnerID=40&md5=5d150a8f2b17f2fef2a054442870fd73	Objectives: As trials were assessing the safety and efficacy of daily oral antiretroviral preexposure prophylaxis (PrEP) for the prevention of HIV infection, there was a clear need to understand the evolution of knowledge of, and attitudes toward, PrEP among primary care clinicians. Methods: Physicians and nurse practitioners were surveyed in 2009 (n = 1500), 2010 (n = 1504), 2012 (n = 1503), 2013 (n = 1507), 2014 (n = 1508) and 2015 (n = 1501) to assess their awareness of PrEP, willingness to prescribe PrEP, and whether they support use of public funds to pay for PrEP. Pharmacists (n = 251) were surveyed about PrEP in 2012 only. Descriptive statistics were computed for physician demographics and PrEP-related questions. Prevalence ratios for willingness to prescribe PrEP were computed using Poisson regression analysis. Results: Awareness of PrEP was low among clinicians (2009: 24%, 2010: 29%) but increased after trials reported effectiveness (2012: 49%, 2013: 51%, 2014: 61%, 2015: 66%). Following a description of PrEP with an estimated effectiveness of 75%, across 6 of the study years 91% of clinicians indicated a willingness to prescribe PrEP to at least one group at high risk of HIV acquisition. A smaller majority of clinicians indicated support for public funding of PrEP in 2009: 59%, 2010: 53%, and 2013: 63%. Conclusions: In surveys conducted before and after the release of PrEP trial results, primary care clinicians were largely unaware of PrEP. They indicated high levels of willingness to prescribe it for patients at high risk of HIV acquisition and expressed interest in education about how to deliver this new clinical HIV prevention method. It will be important to continue monitoring clinician knowledge, attitudes, and practices as the use of PrEP increases in the US. © 2016, Public Library of Science. All rights reserved. Article	2016	Smith, Jennifer A.; Anderson, Sarah-Jane; Harris, Kate L.; McGillen, Jessica B.; Lee, Edward; Garnett, Geoff P.; Hallett, Timothy B.	Maximising HIV prevention by balancing the opportunities of today with the promises of tomorrow: a modelling study.	The Lancet HIV	-	-	-	-	2352-3018 2405-4704	10.1016/S2352-3018(16)30036-4	https://pubmed.ncbi.nlm.nih.gov/27365203/	BACKGROUND: Many ways of preventing HIV infection have been proposed and more are being developed. We sought to construct a strategic approach to HIV prevention that would use limited resources to achieve the greatest possible prevention impact through the use of interventions available today and in the coming years. METHODS: We developed a deterministic compartmental model of heterosexual HIV transmission in South Africa and formed assumptions about the costs and effects of a range of interventions, encompassing the further scale-up of existing interventions (promoting condom use, male circumcision, early antiretroviral therapy ART initiation for all including increased HIV testing and counselling activities, and oral pre-exposure prophylaxis PrEP), the introduction of new interventions in the medium term (offering intravaginal rings, long-acting injectable antiretroviral drugs) and long term (vaccine, broadly neutralising antibodies bNAbs). We examined how available resources could be allocated across these interventions to achieve maximum impact, and assessed how this would be affected by the failure of the interventions to be developed or scaled up. FINDINGS: If all interventions are available, the optimum mix would place great emphasis on the following: scale-up of male circumcision and early ART initiation with outreach testing, as these are available immediately and assumed to be low cost and highly efficacious; intravaginal rings targeted to sex workers; and vaccines, as these can achieve a large effect if scaled up even if imperfectly efficacious. The optimum mix would rely less on longer term developments, such as long-acting antiretroviral drugs and bNAbs, unless the costs of these reduced. However, if impossible to scale up existing interventions to the extent assumed, emphasis on oral PrEP, intravaginal rings, and long-acting antiretroviral drugs would increase. The long-term effect on the epidemic is most affected by scale-up of existing interventions and the successful development of a vaccine. INTERPRETATION: With current information, a strategic approach in which limited resources are used to maximise prevention impact would focus on strengthening the scale-up of existing interventions, while pursuing a workable vaccine and developing other approaches that can be used if further scale-up of existing interventions is limited. Article	2016	Solomon, Marc M; Schechter, Mauro; Liu, Albert Y; McManhan, Vanessa M; Guanira, Juan V; Hance, Robert J; Chariyalertsak, Suwat; Mayer, Kenneth H	The Safety of Tenofovir–Emtricitabine for HIV Pre-Exposure Prophylaxis (PrEP) in Individuals With Active Hepatitis B	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1525-4135	https://doi.org/10.1097/qai.0000000000000857	https://escholarship.org/uc/item/5g13b2s4	BackgroundPre-exposure prophylaxis (PrEP) with daily oral emtricitabine and tenofovir disoproxil fumarate (FTC/TDF) prevents HIV infection. The safety and feasibility of HIV PrEP in the setting of hepatitis B virus (HBV) infection were evaluated.MethodsThe Iniciativa Profilaxis Pre-Exposición study randomized 2499 HIV-negative men and transgender women who have sex with men to once-daily oral FTC/TDF versus placebo. Hepatitis serologies and transaminases were obtained at screening and at the time PrEP was discontinued. HBV DNA was assessed by polymerase chain reaction, and drug resistance was assessed by population sequencing. Vaccination was offered to individuals susceptible to HBV infection.ResultsOf the 2499 participants, 12 (0.5%; including 6 randomized to FTC/TDF) had chronic HBV infection. After stopping FTC/TDF, 5 of the 6 participants in the active arm had liver function tests performed at follow-up. Liver function tests remained within normal limits at post-stop visits except for a grade 1 elevation in 1 participant at post-stop week 12 (alanine aminotransferase = 90, aspartate aminotransferase = 61). There was no evidence of hepatic flares. Polymerase chain reaction of stored samples showed that 2 participants in the active arm had evidence of acute HBV infection at enrollment. Both had evidence of grade 4 transaminase elevations with subsequent resolution. Overall, there was no evidence of TDF or FTC resistance among tested genotypes. Of 1633 eligible for vaccination, 1587 (97.2%) received at least 1 vaccine; 1383 (84.7%) completed the series.ConclusionsPrEP can be safely provided to individuals with HBV infection if there is no evidence of cirrhosis or substantial transaminase elevation. HBV vaccination rates at screening were low globally, despite recommendations for its use, yet uptake and efficacy were high when offered. Article	2016	Spieldenner A.	PrEP Whores and HIV Prevention: The Queer Communication of HIV Pre-Exposure Prophylaxis (PrEP)	Journal of Homosexuality	-	-	-	-	918369	10.1080/00918369.2016.1158012	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84966703858&doi=10.1080%2f00918369.2016.1158012&partnerID=40&md5=9602a5638ee6e4f7c75fe5991e983f14	HIV pre-exposure prophylaxis (PrEP) has been introduced as another biomedical tool in HIV prevention. Whereas other such tools—including post-exposure prophylaxis (PEP) and interruption of perinatal transmission—have been embraced by those impacted by HIV, PrEP has been met with more conflict, especially within the gay community and HIV organizations. The "PrEP whore" has come to designate the social value and personal practices of those taking PrEP. This study examines the "PrEP whore" discourse by using queer theory and queer theory. Within these theoretical vantage points, the study explicates four discursive areas: slut shaming, dirty/clean binaries, mourning the loss of condoms, and reclaiming the inner whore. The study illuminates possible discursive strategies that lie outside of the domains of public health and within the individual and community. © 2016 Taylor & Francis. Article	2016	Spinner C.D.; Boesecke C.; Zink A.; Jessen H.; Stellbrink H.-J.; Rockstroh J.K.; Esser S.	HIV pre-exposure prophylaxis (PrEP): a review of current knowledge of oral systemic HIV PrEP in humans	Infection	-	-	-	-	3008126	10.1007/s15010-015-0850-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84944712010&doi=10.1007%2fs15010-015-0850-2&partnerID=40&md5=74f3ea295b548a00d97f615321 0c38f7	Purpose: Despite established HIV prevention strategies and broadly available diagnostic strategies in developed western countries, rates of HIV new infections remain high. Alternative strategies for HIV prevention, particularly among men who have sex with men (MSM), are crucial. HIV pre-exposure prophylaxis (PrEP) has been discussed as one additional option that this review seeks to explore. Methods: An online search identifying PrEP-relevant literature from 1st January 2010 to 1st August, 2015 was performed. Results: The iPrEx study, first published in 2010, demonstrated a reduction in relative risk (RRR) of HIV seroconversion of 44 % for continuous PrEP with tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) in MSM. The efficacy of PrEP has been confirmed for continuous PrEP in the PROUD study and for intermittent PrEP in the IPERGAY study (RRR = 86 % in both studies). The PrEP was well tolerated in all studies, and the evolution of HIV resistance has been low. Compensatory increased sexual risk behavior was not observed in recent studies. In contrast to the high efficacy of risk reduction for HIV transmission in MSM, the results of TDF PrEP and TDF/FTC PrEP studies using microbicidal agents or pills among heterosexual women were different (RRR 6–75 %). Conclusions: Continuous and intermittent PrEP demonstrated high efficacy in preventing HIV seroconversion, notably among MSM. PrEP was well tolerated. Adherence was critical for high efficacy in all studies. Further studies to evaluate implementation strategies and cost-effectiveness in different risk populations are needed as well as drug approval in Europe. © 2015, Springer-Verlag Berlin Heidelberg. Topical delivery of tenofovir disoproxil fumarate and emtricitabine from pod-intravaginal rings protects macaques from multiple SHIV exposures	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0157061	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84975292127&doi=10.1371%2fjournal.pone.0157061&partnerID=40&md5=418c201c27748bbdd019392241702189	Topical preexposure prophylaxis (PrEP) against HIV has been marginally successful in recent clinical trials with low adherence rates being a primary factor for failure. Controlled, sustained release of antiretroviral (ARV) drugs may help overcome these low adherence rates if the product is protective for extended periods of time. The oral combination of tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) is currently the only FDA-approved ARV drug for HIV PrEP. A novel pod-intravaginal ring (IVR) delivering TDF and FTC at independently controlled rates was evaluated for efficacy at preventing SHIV162p3 infection in a rigorous, repeat low-dose vaginal exposure model using normally cycling female pigtailed macaques. Six macaques received pod-IVRs containing TDF (65 mg) and FTC (68 mg) every two weeks, and weekly vaginal exposures to 50 TCID50 of SHIV162p3 began one week after the first pod-IVR insertion. All pod-IVR-treated macaques were fully protected throughout the study (P = 0.0002, Log-rank test), whereas all control animals became infected with a median of 4 exposures to infection. The topical, sustained release of TDF and FTC from the pod-IVR maintained protective drug levels in macaques over four months of virus exposures. This novel and versatile delivery system has the capacity to deliver and maintain protective levels of multiple drugs and the protection observed here warrants clinical evaluation of this pod-IVR design. © 2016, Public Library of Science. Article	2016	Stahlman, Shauna; Beyrer, Chris; Sullivan, Patrick S.; Mayer, Kenneth H.; Baral, Stefan D.	Engagement of Gay Men and Other Men Who Have Sex with Men (MSM) in the Response to HIV: A Critical Step in Achieving an AIDS-Free Generation.	AIDS and Behavior	-	-	-	-	1573-3254 1090-7165	10.1007/s10461-016-1388-8	https://link.springer.com/article/10.1007/s10461-016-1388-8	Men who have sex with men (MSM) continue to be at elevated risk for HIV acquisition and transmission secondary to biological and behavioral characteristics, social and sexual network characteristics, community environmental factors, and structural factors. HIV incidence rates remain high among MSM in both low- and high-income settings, and in both concentrated and more generalized HIV epidemic settings. While data quality tends to be poorer, the best estimates collectively suggest that MSM have up to 20 times the odds of living with HIV as compared to other reproductive aged adults across low- and middle-income countries. Recent prevention strategies to lower biological HIV transmission and acquisition risks, including the early use of antiretrovirals to decrease infectiousness for those living with HIV, and pre-exposure prophylaxis for those at significant risk of HIV acquisition, have demonstrated the potential to change the trajectory of the HIV epidemics among MSM. However, the coverage and effectiveness of these approaches is limited by structural factors including the punitive legal frameworks and institutional discrimination that contribute to limited uptake, challenges to adherence, and suboptimal health-seeking behaviors among MSM. More intensive efforts will be required to reach MSM who do not currently have access to relevant and effective prevention and treatment services or elect not to access these services given enacted and/or perceived stigma. Respect for human rights, including efforts to aggressively confront and combat the forms of stigma that are preventing us from achieving an AIDS-Free generation, are needed for all people including gay men and other MSM.	*Homosexuality, Male; Humans; Male; *Developing Countries; HIV; HIV Infections/epidemiology/*prevention & control; Human Rights; *Community Participation; *Sexual Behavior; *Pre-Exposure Prophylaxis; MSM; Men who have sex with men; Social Stigma; Risk factors; *Epidemics; Epidemic; Acquired Immunodeficiency Syndrome/epidemiology/*prevention & control; *Sexual and Gender Minorities; Social Discrimination	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2016	Sued, Omar; Figueroa, María Inés; Cahn, Pedro	Clinical challenges in HIV/AIDS: Hints for advancing prevention and patient management strategies.	Advanced Drug Delivery Reviews	-	-	-	-	1872-8294 0169-409X	10.1016/j.addr.2016.04.016	https://pubmed.ncbi.nlm.nih.gov/27117711/	Acquired immune deficiency syndrome has been one of the most devastating epidemics of the last century. The current estimate for people living with the HIV is 36.9 million. Today, despite availability of potent and safe drugs for effective treatment, lifelong therapy is required for preventing HIV re-emergence from a pool of latently infected cells. However, recent evidence show the importance to expand HIV testing, to offer antiretroviral treatment to all infected individuals, and to ensure retention through all the cascade of care. In addition, circumcision, pre-exposure prophylaxis, and other biomedical tools are now available for included in a comprehensive preventive package. Use of all the available tools might allow cutting the HIV transmission in 2030. In this article, we review the status of the epidemic, the latest advances in prevention and treatment, the concept of treatment as prevention and the challenges and opportunities for the HIV cure agenda. Article	2016	Sugarman, Jeremy	Ethical considerations regarding oral preexposure prophylaxis in HIV prevention trials.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0000000000000214	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4669881	PURPOSE OF REVIEW: Although substantial evidence supports oral preexposure prophylaxis with tenofovir disoproxil fumarate and emtricitabine (OPTF) for the primary prevention of HIV infection in certain settings, assessing whether other promising HIV prevention interventions are safe and effective as well as determining optimal prevention strategies necessitates research. However, given the established safety and efficacy of OPTF, it is necessary to determine when and how it is ethically acceptable to conduct this research, which is the focus of this review. RECENT FINDINGS: Although they are somewhat intertwined, questions regarding OPTF in research can be considered in two broad categories: use in a comparison arm and as a standard of prevention. Major statements addressing these issues are described and recent literature directed at the particular issue of OPTF in research is reviewed and critiqued. SUMMARY: There is now arguably a rebuttable presumption for the use of OPTF as a comparator or as part of the standard of prevention in much future HIV prevention research. However, making such determinations necessitates taking into account scientific considerations, the modality being evaluated, acceptability, adherence, and the local context. Doing so should be optimized by robust stakeholder engagement.	preexposure prophylaxis, HIV infection, ethics, research ethics, comparator arm, standard of prevention	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2016	Suosu WEI; Huide WEI; Xiaohong HUANG; Hongping PAN; Yi TAN; Guanghe YANG; Jinghong LIU; Wenjuan LYU; Ying WEI; Siqi LAN; Hui LIU; Tengyan WU	Analysis of willingness and influencing factors for usage of pre-exposure prophylaxis among male u-niversity students who have sex with men	Chinese Journal of Behavioral Medicine and Brain Science	-	-	-	-	1674-6554	10.3760/cma.j.issn.1674-6554.2016.12.015	http://dx.doi.org/10.3760/cma.j.issn.1674-6554.2016.12.015	Objective To analyze the willingness and influencing factors for usage of pre-exposure prophylaxis(PrEP) among male students who have sex with men (MSM) in universities of Guangxi. Meth-ods 295 MSM students in universities were recruited by Snow-balling methods. Questionnaires were self-administered to collect social demographic information,AIDS related risky sexual behaviors and willingness for usage of PrEP. Logistic regression was employed for univariate and multivariate analysis. Results Of the 295 MSM,58(19.7%)had ever heard PrEP,265(89.8%) said that they would like to use PrEP. Multivari-ate logistic regression analysis showed that those who had found partners through friends (OR=11.419,95%CI:1.363~95.641), those who would advise his friend to use PrEP (OR=87.946,95%CI:13.660-566.222),those who concerned the convenience to gain the medicine (OR=119.652,95%CI:3.765-3802.184) and those who said that they could take medicine every day (OR=88.245,95%CI:10.237-760.696) were more likely to accept PrEP. The subjects whose partners would be angry if they stick to use condoms(OR=0.106,95%CI:0.019-0.606),and those who suspected the effectiveness of drugs(OR=0.010,95%CI0. 001-0.112) were less likely to accept PrEP. Conclusion The acceptability of PrEP is high in university students'MSM. The safety of drugs and the convenience to gain the medicine are the main influencing factors for usage of PrEP.Using of PrEP should be strengthened to the MSM. Article	2016	Tangmunkongvorakul A.; Chariyalertsak S.; Amico K.R.; Guptarak M.; Saokhieo P.; Sangangamsakun T.; Songsupa R.; McMahan V.; Grant R.	Sexual practices among men who have sex with men in chiang mai, Thailand: Part of the antiretroviral pre-exposure prophylaxis trial	Southeast Asian Journal of Tropical Medicine and Public Health	-	-	-	-	1251562	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84982161857&partnerID=40&md5=97bbc9868ccd073620627121c5648b70	This study aimed to gain a better understanding of the association between participation in a blinded antiretroviral pre-exposure prophylaxis (PrEP) clinical trial and sexual practices among men who have sex with men and transgender women. This study utilized both quantitative and qualitative methodologies. Data included reported PrEP medication adherence and sexual behavior among 114 study participants. Forty-six participants took part in qualitative data collection, 32 were interviewed and 14 participated in one of three focus group discussions. The average percentage of study medication adherence, number of sex partners and rates of sex without a condom were calculated. For qualitative data, content analysis was used to identify repeated normative themes, some of which arose spontaneously from interview interactions. Participants at the Chiang Mai site reported good adherence to the study medication. The sexual risk behavior of these participants had decreased by their final study visit; this was unrelated to level of adherence. Qualitative findings describe sexual practices that were highly contextual; participants used risk assessments to determine sex practices. Condoms were used with casual partners but not necessarily with primary partners. Our findings suggest that while PrEP is an exciting new development for HIV prevention, it must be paired with behavioral interventions to fully address sexual risk among this population. Interventions should provide this population with skills to negotiate condom use with their primary partners as well as in situations in which their sexual partners do not support condom use. © 2017, SEAMEO TROPMED Network. Article	2016	Thomson K.A.; Baeten J.M.; Mugo N.R.; Bekker L.-G.; Celum C.L.; Heffron R.	Tenofovir-based oral preexposure prophylaxis prevents HIV infection among women	Current Opinion in HIV and AIDS	-	-	-	-	1746630X	10.1097/COH.0000000000000207	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84951906477&doi=10.1097%2fCOH.0000000000000207&partnerID=40&md5=07ec0f1adf2bdfcec72256e07714151f	Purpose of review Despite tremendous promise as a female-controlled HIV prevention strategy, implementation of preexposure prophylaxis (PrEP) among women has been limited, in part because of disparate efficacy results from randomized trials in this population. This review synthesizes existing evidence regarding PrEP efficacy for preventing HIV infection in women and considerations for delivering PrEP to women. Recent findings In three efficacy trials, conducted among men and women, tenofovir-based oral PrEP reduced HIV acquisition in subgroups of women by 49â€"79% in intent-to-treat analyses, and by >85% when accounting for PrEP adherence. Two trials did not demonstrate an HIV prevention benefit from PrEP in women, but substantial evidence indicates those results were compromised by very low adherence to the study medication. Qualitative research has identified risk perception, stigma, and aspects of clinical trial participation as influencing adherence to study medication. Pharmacokinetic studies provide supporting evidence that PrEP offers HIV protection in women who are adherent to the medication. Summary Tenofovir-based daily oral PrEP prevents HIV acquisition in women. Offering PrEP as an HIV prevention option for women at high risk of HIV acquisition is a public health imperative and opportunities to evaluate implementation strategies for PrEP for women are needed. Article	2016	Trang T.P.; Dong B.J.; Kojima N.; Klausner J.D.	Drug safety evaluation of oral tenofovir disoproxil fumarate-emtricitabine for pre-exposure prophylaxis for human immunodeficiency virus infection	Expert Opinion on Drug Safety	-	-	-	-	14740338	10.1080/14740338.2016.1211108	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84979520762&doi=10.1080%2f14740338.2016.1211108&partnerID=40&md5=188d2042959c49f63fdf5ed41d6261a9	Introduction: Tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) are nucleoside reverse transcriptase inhibitors approved as pre-exposure prophylaxis (PrEP) against human immunodeficiency virus (HIV). Prophylactic TDF-based regimens have been shown to reduce the risk of HIV infection by 74 to 92% among participants with detectable drug levels. Adverse events observed in clinical trials include nausea, elevated creatinine and liver enzymes, and decreased bone mineral density. Areas covered: This article reviews the pharmacology, pharmacokinetics, and the safety profile of TDF and FTC used as PrEP for HIV infection. Expert opinion: TDF-FTC can have a large impact in preventing HIV infections among high risk individuals when taken daily. Although TDF-FTC is associated with adverse events, they can be minimized with clinician-guided monitoring. © 2016 Informa UK Limited, trading as Taylor & Francis Group.	bone mineral density; creatinine; emtricitabine; HIV; pre-exposure prophylaxis; prevention; renal dysfunction; safety; Tenofovir disoproxil fumarate	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2016	Underhill K.; Morrow K.M.; Colleran C.; Calabrese S.K.; Operario D.; Salovey P.; Mayer K.H.	Explaining the Efficacy of Pre-exposure Prophylaxis (PrEP) for HIV Prevention: A Qualitative Study of Message Framing and Messaging Preferences Among US Men Who have Sex with Men	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-015-1088-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84929208887&doi=10.1007%2fs10461-015-1088-9&partnerID=40&md5=50c5f845825e0f6b307e5993c118e64f	We investigated message comprehension and message framing preferences for communicating about PrEP efficacy with US MSM. We conducted eight focus groups (n = 38) and n = 56 individual interviews with MSM in Providence, RI. Facilitators probed comprehension, credibility, and acceptability of efficacy messages, including percentages, non-numerical paraphrases, efficacy ranges versus point estimates, and success- versus failure-framed messages. Our findings indicated a range of comprehension and operational understandings of efficacy messages. Participants tended to prefer percentage-based and success-framed messages, although preferences varied for communicating about efficacy using a single percentage versus a range. Participants reported uncertainty about how to interpret numerical estimates, and many questioned whether trial results would predict personal effectiveness. These results suggest that providers and researchers implementing PrEP may face challenges in communicating with users about efficacy. Efforts to educate MSM about PrEP should incorporate percentage-based information, and message framing decisions may influence message credibility and overall PrEP acceptability. © 2015, Springer Science+Business Media New York. Article	2016	Unni, Elizabeth J; Lian, Nadia; Kuykendall, William	Understanding community pharmacist perceptions and knowledge about HIV preexposure prophylaxis (PrEP) therapy in a Mountain West state.	Journal of the American Pharmacists Association	-	-	-	-	1544-3450	10.1016/j.japh.2016.05.004	https://dx.doi.org/10.1016/j.japh.2016.05.004	OBJECTIVES: Preexposure prophylaxis (PrEP) therapy is prescribed to HIV-negative individuals who are at high risk of contracting the virus to reduce the risk of transmission. Adherence to therapy is essential for optimal treatment outcome, and community pharmacists have an important role in achieving this through patient counseling. The objectives of this study were to measure pharmacists' actual knowledge about HIV PrEP therapy, perceptions about their HIV PrEP therapy knowledge, and intention to counsel patients about PrEP therapy. METHODS: A cross-sectional survey was conducted among community pharmacists in Utah to measure their actual knowledge and perceptions of knowledge about PrEP therapy based on the basic information from the Centers for Disease Control website. In addition, the pharmacist's intention to counsel patients on PrEP therapy was measured with the use of the validated Godin 12-item tool. Descriptive analyses and t tests identified characteristics based on gender, degree earned, and years of practice in pharmacy. Regression analysis determined significant predictors of the intention to counsel. RESULTS: There were 251 responses (75% PharmD, 61% male, 42% >10 years' experience as a pharmacist). An exploratory factor analysis of the Godin 12-item tool demonstrated 4 domains: beliefs about capabilities, social influence, moral norms, and intention to counsel patients. There was no difference in the intention to counsel based on gender. Pharmacists with a PharmD and less than 10 years of experience had significantly higher knowledge and intention to counsel. The actual knowledge score of the respondents was significantly higher than their perceptions of their knowledge. Multiple regression results showed that the beliefs about capabilities and social influence were significant predictors of intention to counsel. CONCLUSION: Educating community pharmacists on PrEP therapy using pharmacists who are considered to be opinion leaders in the pharmacy profession can affect the social influence and beliefs about capabilities domains, which in turn can increase counseling on PrEP therapy. Article	2016	Vaccher S.; Grulich A.; McAllister J.; Templeton D.J.; Bloch M.; McNulty A.; Holden J.; Poynten I.M.; Prestage G.; Zablotska I.; Carr A.; Cheung C.; Foster R.; Gianacas C.; Guy R.; Holt M.; Kaldor J.; Mackie B.; Mayer K.; Murphy D.; Ooi C.; Pell C.; Ryder N.; De Wit J.; Wright E.	Protocol for an open-label, single-arm trial of HIV pre-exposure prophylaxis (PrEP) among people at high risk of HIV infection: the NSW Demonstration Project PRELUDE	BMJ Open	-	-	-	-	20446055	10.1136/bmjopen-2016-012179	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84976318099&doi=10.1136%2fbmjopen-2016-012179&partnerID=40&md5=28eb527607716dd40a5e8f1775bb4c52	Introduction: Despite a number of HIV prevention strategies, the number of new HIV infections remains high. In Australia, over three-quarters of new HIV diagnoses are in gay and bisexual men (GBM). Pre-exposure prophylaxis (PrEP) has been shown to be effective at preventing new HIV infections in several randomised trials. The PRELUDE study aims to evaluate the implementation of PrEP in healthcare settings in New South Wales (NSW), Australia, among a sample of high-risk adults. Methods and analysis: PRELUDE is an ongoing open-label, single-arm demonstration project, conducted in public and private clinics across NSW, Australia. Enrolment began in November 2014. The study is designed for 300 high-risk participants - mainly GBM and heterosexual women. Participants receive daily oral PrEP, composed of emtricitabine (FTC) and tenofovir disoproxil fumarate (TDF), for up to 2.5 years. Quarterly study visits include testing for HIV and sexually transmitted infections (STIs), assessment of ongoing eligibility and side effects, and self-reported adherence. Following each study visit, online behavioural surveys are administered to collect information on medication adherence, risk behaviours and attitudes. Blood samples will be collected in a subset of patients 1, 6 and 12 months after PrEP initiation to measure FTC/TDF concentrations. Analyses using longitudinal regression models will focus on feasibility, adherence, safety, tolerability and effects of PrEP on behaviour. This study will inform PrEP policy and guide the implementation of PrEP in Australia in people at high risk of HIV. Ethics and dissemination: The study will be conducted in accordance with the Declaration of Helsinki. All patients will provide written informed consent prior to participation in the study. Publications relating to each of the primary end points will be gradually released after 12 months of follow-up is complete. © Published by the BMJ Publishing Group Limited.	gay, homosexual, and other men who have sex with men; implementation research; pre-exposure prophylaxis; Truvada	English	United Kingdom	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Quantitative
Article	2016	Vamvaka, E; Evans, A; Ramessar, K; Krumpe, L R; H; Shattock, R J; O'keefe, B R; Christou, P; Capell, T	Cyanovirin-N produced in rice endosperm offers effective pre-exposure prophylaxis against HIV-1^sub BaL^ infection in vitro	Plant Cell Reports	-	-	-	-	07217714	10.1007/s00299-016-1963-5	https://www.proquest.com/scholarly-journals/cyanovirin-n-produced-rice-endosperm-offers/docview/1788491103/se-2?accountid=8113	Key message Cyanovirin-N produced in rice endosperm provides efficient pre-exposure prophylaxis against HIV-1 BaL infection in vitro. Abstract Cyanovirin-N (CV-N) is a lectin with potent antiviral activity that has been proposed as a component of microbicides for the prevention of infection with Human immunodeficiency virus (HIV). The production of protein-based microbicide components requires a platform that is sufficiently economical and scalable to meet the demands of the large at-risk population, particularly in resource poor developing countries. We, therefore, expressed CV-N in rice endosperm, because the dried seed is ideal for storage and transport and crude extracts could be prepared locally and used as a microbicide component without further purification. We found that crude extracts from rice seeds expressing up to 10 µg CV-N per gram dry seed weight showed dose-dependent gp120 binding activity, confirming that the protein was soluble, correctly folded and active. The recombinant lectin (OSCV-N) reduced the infectivity of HIV-1BaL (an R5 virus strain representing the majority of transmitted infections) by ~90 % but showed only weak neutralization activity against HIV-1RF (representative of X4 virus, rarely associated with transmission), suggesting it would be highly effective for pre-exposure prophylaxis against the vast majority of transmitted strains. Crude extracts expressing OSCV-N showed no toxicity towards human cells at working dilutions indicating that microbicide components produced in rice endosperm are safe for direct application as topical microbicides in humans. Article	2016	van der Straten, A; Brown, ER; Marrazzo, JM; Chirenje, MZ; Liu, K; Gomez, K; Marzinke, MA; Piper, JM; Hendrix, CW	Divergent adherence estimates with pharmacokinetic and behavioural measures in the MTN-003 (VOICE) study	Journal of the International AIDS Society	-	-	-	-	NA	10.7448/IAS.19.1.20642	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01179621/full	INTRODUCTION: In the Microbicide Trial Network MTN-003 (VOICE) study, a Phase IIB pre-exposure prophylaxis trial of daily oral or vaginal tenofovir (TFV), product adherence was poor based on pharmacokinetic (PK) drug detection in a random subsample. Here, we sought to compare behavioural and PK measures of adherence and examined correlates of adherence misreporting. METHODS: We included participants with PK and behavioural data from VOICE random subsample. Behavioural assessments included face-to-face interviews (FTFI), audio computer-assisted self-interviewing (ACASI) and pharmacy-returned product counts (PC). TFV concentrations < 0.31 ng/mL in plasma (oral group) and < 8.5 ng/swab in vaginal group were defined as "PK non-adherent." Logistic regression models were fit to calculate the combined predictive ability of the behavioural measures as summarized by area under the curve (AUC). Baseline characteristics associated with over-reporting daily product use relative to PK measures was assessed using a Generalized Linear Mixed Model. RESULTS: In this random adherence cohort of VOICE participants assigned to active products, (N = 472), PK non-adherence was 69% in the oral group (N = 314) and 65% in the vaginal group (N = 158). Behaviourally, ≤ 10% of the cohort reported low/none use with any behavioural measure and accuracy was low (≤ 43%). None of the regression models had an AUC > 0.65 for any single or combined behavioural measures. Significant (p < 0.05) correlates of over-reporting included being very worried about getting HIV and being unmarried for the oral group; whereas for the vaginal group, being somewhat worried about HIV was associated with lower risk of over-reporting. CONCLUSIONS: PK measures indicated similarly low adherence for the oral and vaginal groups. No behavioural measure accurately predicted PK non-adherence. Accurate real-time measures to monitor product adherence are urgently needed. TRIAL REGISTRATION: ClinicalTrials.gov identifier: NCT00705679. Article	2016	Venter W.D.F.	What does preexposure prophylaxis mean for treatment; What does treatment mean for preexposure prophylaxis?	Current Opinion in HIV and AIDS	-	-	-	-	1746630X	10.1097/COH.0000000000000208	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84951906238&doi=10.1097%2fCOH.0000000000000208&partnerID=40&md5=806e14a29f83867eb5b97f3bf87f3169	Purpose of review Both preexposure prophylaxis (PrEP) and treatment as prevention (TaP) have shown promise in contributing to HIV prevention, in models, observational cohorts and in real-world intervention studies. They share similarities, in that they use the same drugs, toxicity markers and may be focused on the same key populations. How to implement PrEP is still the source of much debate; effective coverage with TaP, with recent data on the positive impact of treatment at high CD4 counts, is still an ongoing challenge. Recent findings Treatment has demonstrated individual benefit even at CD4 counts above 350 cells/ml; PrEP has shown the effectiveness in real-world use. Summary This article discusses the intersection of the two interventions, some programmatic misconceptions and complexities, and argues that PrEP is a nuanced and useful adjunct to HIV programmes. PrEP can be rolled out in a way that complements treatment, possibly even within primary health clinics, and may be required for the many people in whom TaP currently fails. PrEP will need constant adaptation so as to maintain programmatic and costâ€"effectiveness, as the epidemiology of HIV changes with TaP rollout and expansion as CD4 restrictions are lifted. Finally, the article also argues that so-called ethical concerns around competing resources are relatively easily resolved. Copyright © 2015 Wolters Kluwer Health, Inc. Article	2016	Venter, Willem Daniel Francois; Fairlie, Lee; Feldman, Charles; Cleaton-Jones, Peter; Chersich, Matthew	Views of Medical Doctors Regarding the 2013 WHO Adult HIV Treatment Guidelines Indicate Variable Applicability for Routine Patient Monitoring, for Their Family Members and for Themselves, in South-Africa.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0145911	https://wiredspace.wits.ac.za/server/api/core/bitstreams/28ed9285-e60e-4efe-9e34-0e4e290296bd/content	South African doctors (n = 211) experienced in antiretroviral therapy use were asked via an online questionnaire about the WHO 2013 adult antiretroviral integrated guidelines, as well as clinical and personal issues, in three hypothetical scenarios: directing the Minister of Health, advising a family member requiring therapy amidst unstable antiretroviral supplies, and where doctors themselves were HIV-positive. Doctors (54%) favoured the 500 cells/µl WHO initiation threshold if advising the Minister; a third recommended retaining the 350 cells/µl threshold used at the time of the survey. However, they favoured a higher initiation threshold for their family member. Doctors were 4.9 fold more likely to initiate modern treatment, irrespective of their CD4 cell count, for themselves than for public-sector patients (95%CI odds ratio = 3.33-7.33; P<0.001, although fewer if limited to stavudine-containing regimens. Doctors were equally concerned about stavudine-induced lactic acidosis and lipoatrophy. The majority (84%) would use WHO-recommended first-line therapy, with concerns split between tenofovir-induced nephrotoxicity (55%), and efavirenz central nervous system effects (29%). A majority (61%), if HIV-positive, would pay for a pre-initiation resistance test, use influenza-prophylaxis (85%), but not INH-prophylaxis (61%), and treat their cholesterol and blood pressure concerns conventionally (63% and 60%). Over 60% wanted viral loads and creatinine measured six monthly. A third felt CD4 monitoring only necessary if clinically indicated or if virological failure occurred. They would use barrier prevention (83%), but not recommend pre-exposure prophylaxis, if their sexual partner was HIV-negative (68%). A minority would be completely open about their HIV status, but the majority would disclose to their sexual partners, close family and friends. Respondents were overwhelmingly in favour of continued antiretrovirals after breastfeeding. In conclusion, doctors largely supported adult WHO guidelines as public policy, although would initiate treatment at higher CD4 counts for their family and themselves. Resistance to INH-prophylaxis is unexpected and warrants investigation. Article	2016	Veselinovic M.; Yang K.-H.; Sykes C.; Remling-Mulder L.; Kashuba A.D.M.; Akkina R.	Mucosal tissue pharmacokinetics of the integrase inhibitor raltegravir in a humanized mouse model: Implications for HIV pre-exposure prophylaxis	Virology	-	-	-	-	426822	10.1016/j.virol.2015.12.014	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84952919018&doi=10.1016%2fj.virol.2015.12.014&partnerID=40&md5=986a90f47ad92a625b5c3627a89416d2	Orally administered anti-retroviral drugs show considerable promise for HIV/AIDS pre-exposure prophylaxis (PrEP). For the success of these strategies, pharmacokinetic (PK) data defining the optimal concentration of the drug needed for protection in relevant mucosal exposure sites is essential. Here we employed a humanized mouse model to derive comprehensive PK data on the HIV integrase inhibitor raltegravir (RAL), a leading PrEP drug candidate. Under steady state conditions following oral dosing, plasma and multiple mucosal tissues were sampled simultaneously. RAL exhibited higher drug exposure in mucosal tissues relative to that in plasma with one log higher exposure in vaginal and rectal tissue and two logs higher exposure in intestinal mucosa reflecting the trends seen in the human studies. These data demonstrate the suitability of RAL for HIV PrEP and validate the utility of humanized mouse models for deriving important preclinical PK-PD data. © 2015 Elsevier Inc. Article	2016	Wagner, Glenn J.; Woldetsadik, Mahlet A.; Beyeza-Kashesya, Jolly; Goggin, Kathy; Mindry, Deborah; Finocchario-Kessler, Sarah; Khanakwa, Sarah; Wanyenze, Rhoda K.	Multi-level Correlates of Safer Conception Methods Awareness and Attitudes Among Ugandan HIV Clients with Fertility Intentions.	African Journal of Reproductive Health	-	-	-	-	1118-4841	10.29063/ajrh2016/v20i1.4	https://pubmed.ncbi.nlm.nih.gov/28190955/	Many people living with HIV desire childbearing, but low cost safer conception methods (SCM) such as timed unprotected intercourse (TUI) and manual self-insemination (MSI) are rarely used. We examined awareness and attitudes towards SCM, and the correlates of these constructs among 400 HIV clients with fertility intentions in Uganda. Measures included awareness, self-efficacy, and motivation regarding SCM, as well as demographics, health management, partner and provider characteristics. Just over half knew that MSI (53%) and TUI (51%) reduced transmission risk during conception, and 15% knew of sperm washing and pre-exposure prophylaxis. In separate regression models for SCM awareness, motivation, and self-efficacy, nearly all independent correlates were related to the partner, including perceived willingness to use SCM, knowledge of respondent's HIV status, HIV-seropositivity, marriage and equality in decision making within the relationship. These findings suggest the importance of partners in promoting SCM use and partner inclusion in safer conception counselling. Article	2016	Walensky, Rochelle P; Jacobsen, Margo M; Bekker, Linda-Gail; Parker, Robert A; Wood, Robin; Resch, Stephen C; Horstman, N Kaye; Freedberg, Kenneth A; Paltiel, A David	Potential Clinical and Economic Value of Long-Acting Preexposure Prophylaxis for South African Women at High-Risk for HIV Infection.	Journal of Infectious Diseases	-	-	-	-	1537-6613	10.1093/infdis/jiv523	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4837902	BACKGROUND: For young South African women at risk for human immunodeficiency virus (HIV) infection, preexposure prophylaxis (PrEP) is one of the few effective prevention options available. Long-acting injectable PrEP, which is in development, may be associated with greater adherence, compared with that for existing standard oral PrEP formulations, but its likely clinical benefits and additional costs are unknown. METHODS: Using a computer simulation, we compared the following 3 PrEP strategies: no PrEP, standard PrEP (effectiveness, 62%; cost per patient, $150/year), and long-acting PrEP (effectiveness, 75%; cost per patient, $220/year) in South African women at high risk for HIV infection (incidence of HIV infection, 5%/year). We examined the sensitivity of the strategies to changes in key input parameters among several outcome measures, including deaths averted and program cost over a 5-year period; lifetime HIV infection risk, survival rate, and program cost and cost-effectiveness; and budget impact. RESULTS: Compared with no PrEP, standard PrEP and long-acting PrEP cost $580 and $870 more per woman, respectively, and averted 15 and 16 deaths per 1000 women at high risk for infection, respectively, over 5 years. Measured on a lifetime basis, both standard PrEP and long-acting PrEP were cost saving, compared with no PrEP. Compared with standard PrEP, long-acting PrEP was very cost-effective ($150/life-year saved) except under the most pessimistic assumptions. Over 5 years, long-acting PrEP cost $1.6 billion when provided to 50% of eligible women. CONCLUSIONS: Currently available standard PrEP is a cost-saving intervention whose delivery should be expanded and optimized. Long-acting PrEP will likely be a very cost-effective improvement over standard PrEP but may require novel financing mechanisms that bring short-term fiscal planning efforts into closer alignment with longer-term societal objectives. Article	2016	Wall, Kristin M.; Canary, Lauren; Workowski, Kimberly; Lockard, Annie; Jones, Jeb; Sullivan, Patrick; Hills, Katherine; Fofana, Kadija; Stephenson, Rob; Allen, Susan	Acceptability of Couples' Voluntary HIV Testing Among HIV-infected Patients in Care and Their HIV-negative Partners in the United States.	The Open AIDS Journal	-	-	-	-	1874-6136	10.2174/1874613601610010001	https://pubmed.ncbi.nlm.nih.gov/27014393/	INTRODUCTION: Couples' voluntary HIV counseling and testing (CHTC) is an HIV risk reduction strategy not widely available in the US. METHODS: We assessed willingness to participate in CHTC among US HIV-infected clinic patients via tablet-based survey and among HIV-negative persons with HIV-infected partners in care via mixed-method phone interviews. RESULTS: Most of the N=64 HIV-infected partners surveyed were men (89%), on antiretroviral treatment (ART) (92%), and many self-identified homosexual (62%). We observed high levels of willingness to participate in CHTC (64%) among HIV-infected partners. Reasons for not wanting to participate included perceived lack of need (26%), desire to self-disclose their status (26%), and fear of being asked sensitive questions with their partner present (17%). HIV-infected partners were interested in discussing ART (48%), other sexually transmitted infections (STIs) (44%), and relationship agreements like monogamy (31%) during CHTC sessions. All N=15 HIV-negative partners interviewed were men, most identified as homosexual (73%), and about half (54%) reported consistent condom use with HIV-infected partners. We observed high levels of willingness to participate in CHTC (87%) among HIV-negative partners, who were also interested in discussing ART (47%), other STIs (47%), mental health services (40%), and relationship agreements (33%). Most negative partners (93%) indicated that they believed their HIV-infected partner was virally suppressed, but in the event that they were not, many (73%) were willing to take pre-exposure prophylaxis (PrEP). CONCLUSION: These results indicate that CHTC for serodiscordant couples is acceptable and should emphasize aspects most pertinent to these couples, such as discussion of ART/PrEP, STIs, and relationship agreements. Article	2016	Weis J.F.; Baeten J.M.; McCoy C.O.; Warth C.; Donnell D.; Thomas K.K.; Hendrix C.W.; Marzinke M.A.; Mugo N.; Iv F.A.M.; Celum C.; Lehman D.A.	Preexposure prophylaxis-selected drug resistance decays rapidly after drug cessation	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000000915	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84957698480&doi=10.1097%2fQAD.0000000000000915&partnerID=40&md5=b2f363728c96d7b38516f03c2a88c1dc	Objective: Resistance to emtricitabine plus tenofovir disoproxil fumarate (FTC/TDF) or TDF alone used as preexposure prophylaxis (PrEP) has been detected in individuals who initiated PrEP during unrecognized acute HIV infection and, rarely, in PrEP breakthrough infections. PrEP-selected resistance could alter future treatment options, and therefore we sought to determine how long resistance persisted after PrEP cessation. Methods: The Partners PrEP Study was a randomized placebo-controlled trial of FTC/TDF or TDF as PrEP for HIV prevention. We previously reported that PrEP-related mutations (K65R, K70E or M184IV) were detected by 454 sequencing following seroconversion in nine individuals who acquired HIV during the Partners PrEP Study. In the current study, we used 454 sequencing to detect and quantify PrEP-related mutations in HIV RNA-positive plasma samples prior to seroconversion, as well as in plasma from 6, 12, and 24 months after PrEP cessation from these nine individuals. Results: HIV RNA-positive, antibody-negative samples were available prior to seroconversion for four of nine individuals with resistance detected at seroconversion. In all four cases, K65R, K70E and M184IV were not detected prior to seroconversion, suggesting PrEP-related resistance was selected and not transmitted. All PrEP-selected mutations were no longer detectable by 6 months after PrEP cessation and remained undetectable at 12 and 24 months in the absence of antiretroviral therapy. Conclusion: Using highly sensitive assays, PrEP-selected resistance in plasma decays below detection by 6 months following drug cessation and remains undetectable for at least 24 months. Even high levels of resistance mutations during acute infection decay rapidly in the absence of ongoing PrEP exposure. © Copyright 2015 Wolters Kluwer Health, Inc. Article	2016	Whitfield, Thomas; Torkington, Adele; van Halsema, Clare	Profile of cabotegravir and its potential in the treatment and prevention of HIV-1 infection: evidence to date.	HIV AIDS (Auckland)	-	-	-	-	1179-1373	10.2147/HIV.S97920	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5074732	Modern antiretroviral therapy has demonstrated effectiveness in preexposure prophylaxis (PrEP) and treatment of HIV infection. There is a demand for prevention and treatment regimens that could overcome challenges of improving adherence, toxicity, and dosing convenience. Cabotegravir is an integrase strand transfer inhibitor and an analog of dolutegravir. Unlike dolutegravir, cabotegravir has a long half-life and can be formulated into a long-acting nanosuspension for parenteral administration. Initial pharmacokinetic studies in humans have demonstrated adequate drug levels with intramuscular (IM) administration at 4 weekly and 8 weekly intervals, with few interactions with commonly used concomitant medications. Preliminary animal PrEP studies have shown that IM cabotegravir can prevent simian/HIV acquisition from rectal, vaginal, and intravenous challenge. Currently, there are two ongoing Phase II studies assessing cabotegravir as a PrEP agent in humans: ÉCLAIR and HPTN077. Cabotegravir has been studied in combination with rilpivirine as long-acting IM maintenance therapy. The Long-Acting Antiretroviral Treatment Enabling study demonstrated that those switching to oral cabotegravir/rilpivirine once virologically suppressed were more likely to maintain suppression than those continuing standard efavirenz-based therapy (82% vs 71% at 24 weeks). Initial results of the Long-Acting Antiretroviral Treatment Enabling-2 study of parenteral regimens found that 12 weeks after randomization to parenteral or oral regimens, there was no difference in proportions virologically suppressed on cabotegravir/rilpivirine daily orally vs IM every 4 weeks or 8 weeks (91% vs 94% vs 95%). The injections were well tolerated as, although they caused injection site pain in most recipients, most participants reported satisfaction with parenteral therapy. Cabotegravir offers a new member of the integrase strand transfer inhibitor class with potential for alternative mode of delivery. We await Phase III studies to define its efficacy and real-world experience to learn which patient groups stand to benefit most from the novel mode of delivery of treatment and PrEP.	integrase inhibitor, long-acting antiretroviral therapy, preexposure prophylaxis	English	New Zealand	Asia and the Pacific	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Review
Article	2016	Wilton, James; Kain, Taylor; Fowler, Shawn; Hart, Trevor A.; Grennan, Troy; Maxwell, John; Tan, Darrell Hs	Use of an HIV-risk screening tool to identify optimal candidates for PrEP scale-up among men who have sex with men in Toronto, Canada: disconnect between objective and subjective HIV risk.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.19.1.20777	https://onlinelibrary.wiley.com/doi/full/10.7448/IAS.19.1.20777	INTRODUCTION: Identifying appropriate pre-exposure prophylaxis (PrEP) candidates is a challenge in planning for the safe and effective roll-out of this strategy. We explored the use of a validated HIV risk screening tool, HIV Incidence Risk Index for Men who have Sex with Men (HIRI-MSM), to identify "optimal" candidates among MSM testing at a busy sexual health clinic's community testing sites in Toronto, Canada. METHODS: Between November 2014 and April 2015, we surveyed MSM undergoing anonymous HIV testing at community testing sites in Toronto, Canada, to quantify "optimal" candidates for scaling up PrEP roll-out, defined as being at high objective HIV risk (scoring ≥10 on the HIRI-MSM), perceiving oneself at moderate-to-high HIV risk and being willing to use PrEP. Cascades were constructed to identify barriers to broader PrEP uptake. The association between HIRI-MSM score and both willingness to use PrEP and perceived HIV risk were explored in separate multivariable logistic regression analyses. RESULTS: Of 420 respondents, 64.4% were objectively at high risk, 52.5% were willing to use PrEP and 27.2% perceived themselves at moderate-to-high HIV risk. Only 16.4% were "optimal" candidates. Higher HIRI-MSM scores were positively associated with both willingness to use PrEP (aOR=1.7 per 10 score increase, 95%CI=1.3-2.2) and moderate-to-high perceived HIV risk (aOR=1.7 per 10 score increase, 95%CI=1.2-2.3). The proportion of men who were "optimal" candidates increased to 42.9% when the objective HIV risk cut-off was changed to top quartile of HIRI-MSM scores (≥26). In our full cascade, a very low proportion (5.3%) of MSM surveyed could potentially benefit from PrEP under current conditions. The greatest barrier in the cascade was low perception of HIV risk among high-risk men, but considerable numbers were also lost in downstream cascade steps. Of men at high objective HIV risk, 68.3% did not perceive themselves to be at moderate-to-high HIV risk, 23.6% were unaware of PrEP, 40.1% were not willing to use PrEP, 47.6% lacked a family physician with whom they felt comfortable discussing sexual health, and 31.6% had no means to cover the cost of PrEP. CONCLUSIONS: A higher HIRI-MSM cut-off may be helpful for identifying candidates for PrEP scale-up. Improving engagement in the PrEP cascade will require interventions to simultaneously address multiple barriers. Article	2016	Yacoub, Rabi; Nadkarni, Girish N; Weikum, Damian; Konstantinidis, Ioannis; Boueilh, Anna; Grant, Robert M; Mugwanya, Kenneth K; Baeten, Jared M; Wyatt, Christina M	Elevations in Serum Creatinine With Tenofovir-Based HIV Pre-Exposure Prophylaxis: A Meta-Analysis of Randomized Placebo-Controlled Trials.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000000906	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4767606	Pre-exposure prophylaxis (PrEP) with daily tenofovir disoproxil fumarate (TDF), alone or in fixed-dose combination with emtricitabine (FTC/TDF), decreases the risk of sexual transmission of HIV.1-5 In HIV-infected individuals, there is a small risk of acute kidney injury and proximal tubulopathy,6-8 and cumulative TDF exposure has been associated with decreased glomerular filtration rate (eGFR).9,10 In clinical trials of healthy HIV-uninfected adults receiving TDF-containing PrEP, there was no statistically significant increase in renal adverse events; however, the trials were not powered to detect rare safety events.2-5,11-16 Secondary analyses of three large PrEP trials demonstrated small but statistically significant declines in eGFR or calculated creatinine clearance (CrCl) in participants assigned to active PrEP.17-19 We performed a systematic review and meta-analysis of randomized, placebo-controlled trials to assess the risk of renal adverse events in healthy subjects receiving TDF-containing PrEP. This meta-analysis was designed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) checklist.20 Detailed methods are provided in the Supplementary Appendix. We included randomized clinical trials evaluating daily TDF-based PrEP, alone or in combination with FTC. All studies used a graded elevation in serum creatinine as the primary measure of renal adverse events. Most studies used the National Institutes of Health Division of AIDS (DAIDS) toxicity table;21 several studies modified the DAIDS definition (Supplementary Table 1). For the pooled analysis, we defined the endpoint as any Grade 1 or higher elevation in serum creatinine as reported by the study investigators. Analyses were based on the number of participants with at least one graded creatinine elevation, divided by the number at risk as defined by the study investigators. We also considered a modified intention to treat analysis including only HIV-negative participants who were dispensed at least one dose of study drug. Data were analyzed using Stata 11 (Stata Corp LP) and RevMan 5 (The Cochrane Collaboration). We chose a conservative analytic approach using random effects due to differences in patient population, duration of PrEP exposure, loss-to-follow up and adherence, and frequency of creatinine assessment across studies. Results are expressed as the pooled odds ratio (OR); we re-expressed this result as number needed to harm to illustrate the magnitude of risk. Potential heterogeneity in the estimated effect of PrEP versus placebo was explored via random-effects meta-regression. We identified 2657 potential articles, and 10 studies were eligible for inclusion (Supplementary Table 1 and Supplementary Figure 1). Analysis of publication quality is summarized in Supplementary Table 2. The included studies enrolled a total of 19,507 HIV-positive participants, including 17,220 participants randomized to daily oral PrEP (n=9913) versus placebo (n=7307). Eight studies followed participants for 12 months or longer, while two small studies followed participants for only 4 months. No individual study demonstrated a statistically significant difference in the odds of graded creatinine elevation between participants assigned to active PrEP versus placebo (Figure 1). Article	2016	Yang, Zhongrong; Huang, Zhaohui; Dong, Zhengquan; Li, Jing; Zhang, Sichao; Wu, Nanping; Jin, Meihua	Risk Factors for HIV Diagnosis Among Men Who Have Sex with Men: Results of a Case-Control Study in One Sample of Eastern China.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/AID.2016.0031	https://pubmed.ncbi.nlm.nih.gov/27329367/	Substantial increases in human immunodeficiency virus (HIV) have been reported worldwide in recent years, particularly among men who have sex with men (MSM). We conducted a matched case-control study to examine the factors associated with HIV diagnosis among MSM in one sample of eastern China. Between February 2012 and December 2014, we used surveillance records to identify MSM diagnosed with HIV (case participants); we also recruited MSM who did not have HIV (controls) and then matched them (2:1) with control cases in terms of age (±3 years). Multivariate logistic regression models were used to assess the factors associated with HIV diagnosis. According to a multivariate analysis using logistic regression model involving 101 cases and 202 matched controls, a lack of comprehensive knowledge of HIV (adjusted odds ratio OR = 0.40; 95% confidence interval CI = 0.18, 0.89), a monthly income of ≥4,000 RMB (adjusted OR = 2.99; 95% CI = 1.45, 6.16), having at least two male sexual partners in the past 6 months (adjusted OR = 2.85; 95% CI = 1.28, 6.31), participating in at least four anal sex experiences with a man in the past month (adjusted OR = 3.56; 95% CI = 1.64, 7.73), and having a current syphilis infection (adjusted OR = 3.30; 95% CI = 1.06, 10.25) were associated with an increased risk for HIV diagnosis. MSM with a comprehensive knowledge of HIV were at reduced risk of HIV diagnosis, whereas those with more male sexual partners, more male anal sexual experiences (including receptive or/and insertive anal intercourse, rimming, and fisting), and a current syphilis infection were at increased risk of HIV diagnosis. Focus on protection and safer sex behaviors during male sexual activity (i.e., consistent condom use, pre-exposure prophylaxis, closed sexual networks among MSM) would likely be effective for reducing the HIV transmission rate.	*Homosexuality, Male; Adolescent; Adult; Humans; Male; Middle Aged; Young Adult; Risk Factors; HIV; Case-Control Studies; Health Knowledge, Attitudes, Practice; AIDS; China/epidemiology; MSM; men who have sex with men; risk factors; HIV Infections/*diagnosis/*epidemiology; diagnosis	English	United States	Western and Central Europe and North America	China	Asia and the Pacific	China	Asia and the Pacific	Quantitative
Article	2016	Yoong, Deborah; Naccarato, Mark; Sharma, Malika; Wilton, James; Senn, Heather; Tan, Darrell Hs	Preparing for pre-exposure prophylaxis: perceptions and readiness of Canadian pharmacists for the implementation of HIV pre-exposure prophylaxis.	International Journal of STD & AIDS	-	-	-	-	1758-1052	10.1177/0956462415589896	https://dx.doi.org/10.1177/0956462415589896	Pre-exposure prophylaxis (PrEP) has been shown to reduce the risk of HIV transmission but has the potential to cause harm if not used properly. Pharmacists are well-positioned to foster PrEP's efficacy but little is known whether they would endorse it as an HIV prevention tool. The objective of the study was to determine Canadian HIV pharmacists' support for PrEP and to identify current barriers to promoting PrEP. Canadian pharmacists with experience in HIV care were invited to complete an online survey about their experiences, opinions, and learning needs regarding PrEP from December 2012 to January 2013. Among the 59 surveys received, 48 met criteria for final analysis. Overall, 33 (69%) respondents would provide education positively supporting the use of PrEP and 26 (54%) believed Health Canada should approve PrEP for use in Canada. Familiarity with the concept of PrEP and practice characteristics examined did not appear to be significantly associated with support for PrEP in univariable analyses. The principal barriers to promoting PrEP included inadequate drug coverage and insufficient knowledge to educate others. Many Canadian HIV pharmacists would endorse PrEP for high-risk patients; however, wider dissemination of information and lower drug costs may be needed to make PrEP more widely promoted. Article	2016	Young I.; Flowers P.; Mcdaid L.	Can a pill prevent HIV? Negotiating the biomedicalisation of HIV prevention	Sociology of Health and Illness	-	-	-	-	1419889	10.1111/1467-9566.12372	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84960807770&doi=10.1111%2f1467-9566.12372&partnerID=40&md5=f0715c65baa164ec630732bf245a2caf	This article examines how biomedicalisation is encountered, responded to and negotiated within and in relation to new biomedical forms of HIV prevention. We draw on exploratory focus group discussions on pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP) to examine how the processes of biomedicalisation are affected by and affect the diverse experiences of communities who have been epidemiologically framed as 'vulnerable' to HIV and towards whom PrEP and TasP will most likely be targeted. We found that participants were largely critical of the perceived commodification of HIV prevention as seen through PrEP, although this was in tension with the construction of being medical consumers by potential PrEP candidates. We also found how deeply entrenched forms of HIV stigma and homophobia can shape and obfuscate the consumption and management of HIV-related knowledge. Finally, we found that rather than seeing TasP or PrEP as 'liberating' through reduced levels of infectiousness or risk of transmission, social and legal requirements of responsibility in relation to HIV risk reinforced unequal forms of biomedical self-governance. Overall, we found that the stratifying processes of biomedicalisation will have significant implications in how TasP, PrEP and HIV prevention more generally are negotiated. © 2016 Foundation for the Sociology of Health & Illness. Pre-exposure prophylaxis of HIV: A right way to go or a long way to go?	Artificial cells, nanomedicine, and biotechnology	-	-	-	-	2169-1401	https://doi.org/10.3109/21691401.2014.934458	https://escholarship.org/uc/item/8jz33886	Antiretroviral drugs are being tried as candidates for the pre-exposure prophylaxis (PrEP) against HIV for a considerable period, due to their potential for immediate inhibition of viral replication. Discrepancies in the findings called for a critical review of the relevant efforts and their outcomes. A systematic literature search identified 143 eligible articles of which only 5 reported complete findings while another 11 were still on-going. Observed moderate efficacy and good safety profile seemed to identify PrEP as a promising step for minimizing the spread of HIV to relatively unaffected population and controlling the epidemic among high risk population groups. But the duration of this efficacy was found to depend heavily on the availability, adherence and other related issues like cost, political commitment, ethical consideration etc. To prevent potential cultural and behavioral modifications, proper pre-administration counseling also seemed critical for the success of PrEP as a cost-effective intervention with adequate coverage. PrEP implementation in the Asia-Pacific region: Opportunities, implementation and barriers	Journal of the International AIDS Society	-	-	-	-	17582652	10.7448/IAS.19.7.21119	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84995750496&doi=10.7448%2fIAS.19.7.21119&partnerID=40&md5=23a8ba6f62aab6104a7d673551acd4ae	Introduction: HIV epidemics in the Asia-Pacific region are concentrated among men who have sex with men (MSM) and other key populations. Pre-exposure prophylaxis (PrEP) is an effective HIV prevention intervention and could be a potential game changer in the region.We discuss the progress towards PrEP implementation in the Asia-Pacific region, including opportunities and barriers. Discussion: Awareness about PrEP in the Asia-Pacific is still low and so are its levels of use. A high proportion ofMSMwho are aware of PrEP are willing to use it. Key PrEP implementation barriers include poor knowledge about PrEP, limited access to PrEP, weak or non-existent HIV prevention programmes for MSM and other key populations, high cost of PrEP, stigma and discrimination against key populations and restrictive laws in some countries. Only several clinical trials, demonstration projects and a few largerscale implementation studies have been implemented so far in Thailand and Australia. However, novel approaches to PrEP implementation have emerged: researcher-, facility- and community-led models of care, with PrEP services for fee and for free.The WHO consolidated guidelines on HIV testing, treatment and prevention call for an expanded access to PrEP worldwide and have provided guidance on PrEP implementation in the region. Some countries like Australia have released national PrEP guidelines. There are growing community leadership and consultation processes to initiate PrEP implementation in Asia and the Pacific. Conclusions: Countries of the Asia-Pacific region will benefit from adding PrEP to their HIV prevention packages, but for many this is a critical step that requires resourcing. Having an impact on the HIV epidemic requires investment. The next years should see the region transitioning from limited PrEP implementation projects to growing access to PrEP and expansion of HIV prevention programmes. © 2016 World Health Organization; licensee IAS. Article	2016	Zablotska, I; Grulich, AE; Guy, R; Amin, J; Selvey, C; Schmidt, HM; Price, K; Cooper, D; EPIC-NSW Study Grp	Expanded PrEP implementation in communities in NSW, Australia (EPIC-NSW): evidence-based implementation study	Journal of the International AIDS Society	-	-	-	-	1758-2652	NA	https://na.eventscloud.com/file_uploads/0df862a21ba419f3253046cdff3d5190_331_IrynaZablotska.pdf	"Background: The New South Wales (NSW) HIV Strategy 2016-2020 aims to virtually eliminate HIV transmission by 2020. In the NSW context of high testing and treatment coverage, HIV pre-exposure prophylaxis (PrEP) is identified as a key tool. The NSW government, community, research organisations and clinicians have partnered in an innovative approach to rapidly scale-up PrEP. We describe the evidence-based design and roll-out of the NSW PrEP implementation study, EPICNSW. Methods: 3700 people were calculated to meet the high-risk criteria for PrEP eligibility according to the NSW PrEP Guidelines. Based on estimates of HIV risk, daily PrEP use by these people was estimated to directly prevent 150 new HIV infections over one year. The NSW partnership designed the EPIC-NSW study which aims to measure the population-level impact of the rapid roll-out of PrEP to 3700 people on HIV diagnoses in NSW. Results: EPIC-NSW features: 1) large-scale, rapid roll-out (March-December 2016) to ~25 clinics (including sexual health services, hospitals and general practices); 2) real-life implementation, consistent with clinical PrEP guidelines, and innovative models of care; 3) community resource development, education and mobilisation;4) innovative data collection with minimal health service burden (automated extraction of clinical data from patient management systems and brief online self-administered adherence/behavioural questionnaires); 5) assessment of the program's impact on HIV and STI incidence in the cohort and the target population over three years. Enrolment is ongoing, with the enrolment rate exceeding projections. Discussion: The design and results of this trial will provide definitive evidence for the additional role of PrEP in an integrated HIV response to ending HIV transmission. The success of EPIC-NSW relies on strong collaboration across the NSW HIV sector and community mobilisation to achieve rapid roll-out and creative use of available data sources and resources to enable efficient and effective implementation. DISCLOSURE OF INTEREST STATEMENT: Funding for this study was provided by the NSW Ministry of Health and in-kind supply of 2000 person-years of the study drug was provided by Gilead Sciences. The Kirby Institute receives funding from the Australian Government Department of Health. The Kirby Institute is affiliated with the Faculty of Medicine, UNSW Australia. Article	2016	Zalazar V.; Aristegui I.; Kerr T.; Marshall B.D.L.; Romero M.; Sued O.; Socías M.E.	High Willingness to Use HIV Pre-Exposure Prophylaxis among Transgender Women in Argentina	Transgender Health	-	-	-	-	2380193X	10.1089/trgh.2016.0033	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053852505&doi=10.1089%2ftrgh.2016.0033&partnerID=40&md5=b8f421de9c4aa2bf27816713025b6e5f	Purpose: In Argentina, transgender women face a disproportionately high prevalence of HIV infection (34%). Although not currently approved in Argentina, pre-exposure prophylaxis (PrEP) may offer a potential effective HIV prevention tool for this population. In this study, we assessed the willingness to use PrEP among transgender women in Argentina. Methods: Data were drawn from a nationwide cross-sectional survey conducted among transgender women in 2013. Using multivariable logistic regression, we assessed the prevalence of and factors associated with willingness to use PrEP among transgender women with negative or unknown HIV status. Results: This study included 337 transgender women (278 HIV negative and 59 with unknown HIV status), most of whom had a history of sex work involvement (81.8%). Overall, 301 (89.3%) expressed willingness to use PrEP. In a multivariable analysis, having casual sexual partners was positively associated with willingness to use PrEP (adjusted odds ratio AOR=4.26, 95% confidence interval CI 1.73-10.51), while discrimination by healthcare workers was negatively associated (AOR=0.33, 95% CI 0.12-0.88). Conclusion: We found high levels of willingness to use PrEP among transgender women in Argentina, suggesting that there is high perception of HIV risk in this population. However, discrimination by healthcare workers was a strong negative correlate of willingness to use PrEP, suggesting that multilevel interventions that address gender-based stigma in healthcare settings will be critical for the success of PrEP as an HIV prevention strategy in this population. © Virginia Zalazar et al. 2016; Published by Mary Ann Liebert, Inc. 2016.	discrimination; HIV/AIDS; pre-exposure prophylaxis; transgender persons	English	United States	Western and Central Europe and North America	Argentina	Latin America and the Caribbean	Argentina	Latin America and the Caribbean	Quantitative
Article	2016	Zash, Rebecca; Souda, Sajini; Chen, Jennifer Y; Binda, Kelebogile; Dryden-Peterson, Scott; Lockman, Shahin; Mmalane, Mompati; Makhema, Joseph; Essex, Max; Shapiro, Roger	Reassuring Birth Outcomes With Tenofovir/Emtricitabine/Efavirenz Used for Prevention of Mother-to-Child Transmission of HIV in Botswana.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000000847	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4767604	BACKGROUND: Before introduction of tenofovir/emtricitabine/efavirenz (TDF/FTC/EFV), 3-drug antiretroviral therapy (ART) was associated with increased adverse birth outcomes when used for prevention of mother-to-child HIV transmission (PMTCT) in Botswana. METHODS: We extracted obstetric records from all women at the 2 largest maternities in Botswana from 2009-2011 when Botswana National Guidelines recommended zidovudine (ZDV) from 28 weeks gestational age (GA) for CD4 ≥350 and ART for CD4 <350, and again in 2013-2014 after implementation of TDF/FTC/EFV for prevention of mother-to-child HIV transmission regardless of CD4 or GA. We compared the use of TDF/FTC/EFV in pregnancy with other 3-drug ART regimens, and with initiation of ZDV, among women with similar CD4 cell counts. Outcomes included small for gestational age (SGA), preterm delivery (PTD) (<37 weeks GA), and stillbirths (SB). RESULTS: Among 9445 HIV-infected women delivering during the study period, 170 were on TDF/FTC/EFV at conception and 1468 initiated TDF/FTC/EFV during pregnancy. Adverse birth outcomes were high overall (3% SB, 21% PTD, and 18% SGA) and among women receiving TDF/FTC/EFV (3% SB, 22% PTD, and 12% SGA). There was no difference in PTD or SB among women initiating TDF/FTC/EFV compared with ZDV or other 3-drug ART, but initiating TDF/FTC/EFV was associated with fewer SGA infants than other 3-drug ART (adjusted odds ratio: 0.4, 95% confidence interval: 0.2 to 0.7). CONCLUSIONS: Adverse birth outcomes remain high among HIV-infected women. TDF/FTC/EFV was at least as safe as other ART and associated with fewer SGA infants when initiated during pregnancy. Larger studies are needed to evaluate birth outcomes and congenital abnormalities among women on TDF/FTC/EFV at conception. Article	2016	Zhao, Yuqin; Wood, Daniel T.; Kojouharov, Hristo V.; Kuang, Yang; Dimitrov, Dobromir T.	Impact of Population Recruitment on the HIV Epidemics and the Effectiveness of HIV Prevention Interventions.	Bulletin of Mathematical Biology	-	-	-	-	1522-9602 0092-8240	10.1007/s11538-016-0211-z	https://pubmed.ncbi.nlm.nih.gov/27704329/	Mechanistic mathematical models are increasingly used to evaluate the effectiveness of different interventions for HIV prevention and to inform public health decisions. By focusing exclusively on the impact of the interventions, the importance of the demographic processes in these studies is often underestimated. In this paper, we use simple deterministic models to assess the effectiveness of pre-exposure prophylaxis in reducing the HIV transmission and to explore the influence of the recruitment mechanisms on the epidemic and effectiveness projections. We employ three commonly used formulas that correspond to constant, proportional and logistic recruitment and compare the dynamical properties of the resulting models. Our analysis exposes substantial differences in the transient and asymptotic behavior of the models which result in 47 % variation in population size and more than 6 percentage points variation in HIV prevalence over 40 years between models using different recruitment mechanisms. We outline the strong influence of recruitment assumptions on the impact of HIV prevention interventions and conclude that detailed demographic data should be used to inform the integration of recruitment processes in the models before HIV prevention is considered. Article	2017	Adamson, Blythe J S; Carlson, Josh J; Kublin, James G; Garrison, Louis P	The Potential Cost-Effectiveness of Pre-Exposure Prophylaxis Combined with HIV Vaccines in the United States.	Vaccines (Basel)	-	-	-	-	2076-393X	10.3390/vaccines5020013	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5492010	This economic evaluation aims to support policy-making on the combined use of pre-exposure prophylaxis (PrEP) with HIV vaccines in development by evaluating the potential cost-effectiveness of implementation that would support the design of clinical trials for the assessment of combined product safety and efficacy. The target study population is a cohort of men who have sex with men (MSM) in the United States. Policy strategies considered include standard HIV prevention, daily oral PrEP, HIV vaccine, and their combination. We constructed a Markov model based on clinical trial data and the published literature. We used a payer perspective, monthly cycle length, a lifetime horizon, and a 3% discount rate. We assumed a price of $500 per HIV vaccine series in the base case. HIV vaccines dominated standard care and PrEP. At current prices, PrEP was not cost-effective alone or in combination. A combination strategy had the greatest health benefit but was not cost-effective (ICER = $463,448/QALY) as compared to vaccination alone. Sensitivity analyses suggest a combination may be valuable for higher-risk men with good adherence. Vaccine durability and PrEP drug prices were key drivers of cost-effectiveness. The results suggest that boosting potential may be key to HIV vaccine value.	economic evaluation, mathematical modeling, HIV vaccines, pre-exposure prophylaxis, cost-effectiveness	English	Switzerland	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Adimora, Adaora A; Cole, Stephen R; Eron, Joseph J	US Black Women and Human Immunodeficiency Virus Prevention: Time for New Approaches to Clinical Trials.	Clinical Infectious Diseases	-	-	-	-	1537-6591	10.1093/cid/cix313	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5850546	Black women bear the highest burden of human immunodeficiency virus (HIV) infection among US women. Tenofovir/emtricitabine HIV prevention trials among women in Africa have yielded varying results. Ideally, a randomized controlled trial (RCT) among US women would provide data for guidelines for US women's HIV preexposure prophylaxis use. However, even among US black women at high risk for HIV infection, sample size requirements for an RCT with HIV incidence as its outcome are prohibitively high. We propose to circumvent this large sample size requirement by evaluating relationships between HIV incidence and drug concentrations measured among participants in traditional phase 3 trials in high-incidence settings and then applying these observations to drug concentrations measured among at-risk individuals in lower-incidence settings, such as US black women. This strategy could strengthen the evidence base to enable black women to fully benefit from prevention research advances and decrease racial disparities in HIV rates. Article	2017	Afassinou K.; Chirove F.; Govinder K.S.	Pre-exposure prophylaxis and antiretroviral treatment interventions with drug resistance	Mathematical Biosciences	-	-	-	-	255564	10.1016/j.mbs.2017.01.005	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85009468619&doi=10.1016%2fj.mbs.2017.01.005&partnerID=40&md5=3271a820532744f8d1873f8a7d9fbdea	We introduce a model for HIV/AIDS which can be utilized to assess the impact of combining pre-exposure prophylaxis (PrEP) and antiretroviral drugs (ARVs) use interventions (incorporating drug resistance). Mathematical and numerical analyses are carried out to investigate the effects of the combined controls in the presence of PrEP drug resistance. Our results predict a significant decrease in the number of new HIV infections when PrEP and ARVs are concurrently implemented at high levels. The results also reveal that PrEP drug resistance has the potential to slow down or reverse the effects of PrEP, especially at low efficacy levels. © 2017 Elsevier Inc. Article	2017	Akudibillah G.; Pandey A.; Medlock J.	Maximizing the benefits of ART and PrEP in resource-limited settings	Epidemiology and Infection	-	-	-	-	9502688	10.1017/S0950268816002958	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85007504959&doi=10.1017%2fS0950268816002958&partnerID=40&md5=9780466c5e3cefbaf8f1fdddf0986a2d	Antiretroviral therapy (ART) is increasingly being used as an HIV-prevention tool, administered to uninfected people with ongoing HIV exposure as pre-exposure prophylaxis (PrEP) and to infected people to reduce their infectiousness. We used a modelling approach to determine the optimal population-level combination of ART and PrEP allocations required in South Africa to maximize programme effectiveness for four outcome measures: new infections, infection-years, death and cost. We considered two different strategies for allocating treatment, one that selectively allocates drugs to sex workers and one that does not. We found that for low treatment availability, prevention through PrEP to the general population or PrEP and ART to sex workers is key to maximizing effectiveness, while for higher drug availability, ART to the general population is optimal. At South Africa's current level of treatment availability, using prevention is most effective at reducing new infections, infection-years, and cost, while using the treatment as ART to the general population best reduces deaths. At treatment levels that meet the UNAIDS's ambitious new 90-90-90 target, using all or almost all treatment as ART to the general population best reduces all four outcome measures considered. © Cambridge University Press 2016. Article	2017	Allen E.; Gordon A.; Krakower D.; Hsu K.	HIV preexposure prophylaxis for adolescents and young adults	Current Opinion in Pediatrics	-	-	-	-	10408703	10.1097/MOP.0000000000000512	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85020621389&doi=10.1097%2fMOP.0000000000000512&partnerID=40&md5=9c03adf4d165aab303aa1bf1399bfc3c	Purpose of review The review describes the evidence for HIV preexposure prophylaxis (PrEP) with daily combined tenofovir disoproxil fumarate and emtricitabine for adolescents and young adults. Current recommendations are described, as are the unique medical, socioeconomic, and legal considerations regarding the use of PrEP for youth. Recent findings PrEP with daily oral tenofovir disoproxil fumarate-emtricitabine has been shown to help prevent new HIV infection among adults at substantial risk. Evidence suggests a protective benefit of PrEP for youth at risk for HIV, although low adherence is emerging as a barrier to effective use. Summary Effective use of antiretrovirals for PrEP represents a seminal development in HIV prevention efforts. Improving access and adherence to PrEP for youth has the potential to substantially reduce the incidence of HIV in this population. © 2017 Wolters Kluwer Health, Inc. Article	2017	Allotey, John; Marlin, Nadine; Mol, Ben W; Peter Von Dadelszen; Wessel Ganzevoort; Akkermans, Joost; Ahmed, Asif; Daniels, Jane; Deeks, Jon; Ismail, Khaled; Barnard, Ann Marie; Dodds, Julie; Kerry, Sally; Moons, Carl; Khan, Khalid S; Riley, Richard D	Development and validation of prediction models for risk of adverse outcomes in women with early-onset pre-eclampsia: protocol of the prospective cohort PREP study	Diagnostic and Prognostic Research	-	-	-	-	NA	10.1186/s41512-016-0004-8	https://www.proquest.com/scholarly-journals/development-validation-prediction-models-risk/docview/2547513734/se-2?accountid=8113	Background Early-onset pre-eclampsia with raised blood pressure and protein in the urine before 34 weeks' gestation is one of the leading causes of maternal deaths in the UK. The benefits to the child from prolonging the pregnancy need to be balanced against the risk of maternal deterioration. Accurate prediction models of risks are needed to plan management. Methods We aim to undertake a multicentre prospective cohort study (Prediction of Risks in Early onset Pre-eclampsia (PREP)) to develop clinical prediction models in women with early-onset pre-eclampsia, for risk of adverse maternal outcomes by 48 h and by discharge. We will externally validate the models in two independent cohorts with 634 and 216 women. In the secondary analyses, we will assess risk of adverse fetal and neonatal outcomes at birth and by discharge. Discussion The PREP study will quantify the risk of maternal complications at various time points and provide individualised estimates of overall risk in women with early-onset pre-eclampsia to plan the management. Article	2017	Aloysius, I; Savage, A; Zdravkov, J; Korologou-Linden, R; Hill, A; Smith, R; Houghton-Price, V; Boffito, M; Nwokolo, N	InterPrEP. Internet-based pre-exposure prophylaxis with generic tenofovir DF/emtricitabine in London: an analysis of outcomes in 641 patients	Journal of Virus Eradication	-	-	-	-	2055-6640	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5632549/	Introduction: HIV pre-exposure prophylaxis (PrEP) is not available on the National Health Service (NHS) in England. People are buying generic versions of tenofovir disoproxil fumarate (TDF)/emtricitabine (FTC) on the internet, which is legal under UK import laws. Methods: HIV-negative individuals attending our clinic who reported purchasing generic PrEP online were provided with risk-reduction advice and were evaluated for HIV, hepatitis B and C, renal function and sexually transmitted infections (STIs) on their first visit. They were offered regular follow-up visits every 3 months and given risk-reduction advice. Plasma therapeutic drug monitoring (TDM) for tenofovir and FTC was also offered. Results: 641 individuals accessed the service during 2016-2017. Median time on generic PrEP was 202 days. All were MSM, 81% were white, 75% used PrEP daily and 14% on an event-driven basis, and 67% were on generic TDF/FTC manufactured by Cipla Ltd. There were no serious adverse events. Thirty-nine percent of individuals (191/494) reported using recreational drugs in the 12 months before starting PrEP, and 29% (127/443) reported this while taking PrEP. During follow-up, 26% (142/552) of individuals were diagnosed with an STI at one or more follow-up visits. In 336 person-years of follow-up, there were no cases of HIV infection (0%, 95% CI 0%-1.1%). There were no new cases of hepatitis B and two new cases of hepatitis C. Discussion: There were no new cases of HIV in 641 individuals using generic PrEP. At the same centre, new HIV diagnoses fell from 69 per month in October 2015 to 15 per month in June 2017. We believe that our support for individuals taking generic PrEP has contributed to this fall. There was a 10% increase in STI diagnoses during PrEP compared to baseline. Strategies to reduce STIs remain crucial. Article	2017	Amico K.R.; Wallace M.; Bekker L.-G.; Roux S.; Atujuna M.; Sebastian E.; Dye B.J.; Elharrar V.; Grant R.M.	Experiences with HPTN 067/ADAPT Study-Provided Open-Label PrEP Among Women in Cape Town: Facilitators and Barriers Within a Mutuality Framework	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1458-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84975137686&doi=10.1007%2fs10461-016-1458-y&partnerID=40&md5=8516d846658c5a2635750dc73dcd05af	Placebo-controlled trials of pre-exposure prophylaxis (PrEP) have reported challenges with study-product uptake and use, with the greatest challenges reported in studies with young women in sub-Saharan Africa. We conducted a qualitative sub-study to explore experiences with open-label PrEP among young women in Cape Town, South Africa participating in HPTN 067/Alternative Dosing to Augment Pre-Exposure Prophylaxis Pill Taking (ADAPT). HPTN 067/ADAPT provided open label oral FTC/TDF PrEP to young women in Cape Town, South Africa who were randomized to daily and non-daily PrEP regimens. Following completion of study participation, women were invited into a qualitative sub-study including focus groups and in-depth interviews. Interviews and groups followed a semi-structured guide, were recorded, transcribed, and translated to English from isiXhosa, and coded using framework analysis. Sixty of the 179 women enrolled in HPTN 067/ADAPT participated in either a focus group (six groups for a total of 42 participants) or an in-depth interview (n = 18). This sample of mostly young, unmarried women identified facilitators of and barriers to PrEP use, as well as factors influencing study participation. Cross-cutting themes characterizing discourse suggested that women placed high value on contributing to the well-being of one's community (Ubuntu), experienced a degree of skepticism towards PrEP and the study more generally, and reported a wide range of approaches towards PrEP (ranging from active avoidance to high levels of persistence and adherence). A Mutuality Framework is proposed that identifies four dynamics (distrust, uncertainty, alignment, and mutuality) that represent distinct interactions between self, community and study and serve to contextualize women's experiences. Implications for better understanding PrEP use, and non-use, and intervention opportunities are discussed. In this sample of women, PrEP use in the context of an open-label research trial was heavily influenced by underlying beliefs about safety, reciprocity of contributions to community, and trust in transparency and integrity of the research. Greater attention to factors positioning women in the different dynamics of the proposed Mutuality Framework could direct intervention approaches in clinical trials, as well as open-label PrEP scale-up. © 2016, The Author(s). Article	2017	Anand T.; Nitpolprasert C.; Trachunthong D.; Kerr S.J.; Janyam S.; Linjongrat D.; Hightow-Weidman L.B.; Phanuphak P.; Ananworanich J.; Phanuphak N.	A novel Online-To-Offline (O2O) model for pre-exposure prophylaxis and HIV testing scale up	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.20.1.21326	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026865590&doi=10.7448%2fIAS.20.1.21326&partnerID=40&md5=7feee7752f57c09707fd1c0c968eddd9	Introduction: PrEP awareness and uptake among men who have sex with men (MSM) and transgender women (TG) in Thailand remains low. Finding ways to increase HIV testing and PrEP uptake among high-risk groups is a critical priority. This study evaluates the effect of a novel Adam's Love Online-To-Offline (O2O) model on PrEP and HIV testing uptake among Thai MSM and TG and identifies factors associated with PrEP uptake. Methods: The O2O model was piloted by Adam's Love (www.adamslove.org) HIV educational and counselling website. MSM and TG reached online by PrEP promotions and interested in free PrEP and/or HIV testing services contacted Adam's Love online staff, received real-Time PrEP eCounseling, and completed online bookings for receiving services at one of the four sites in Bangkok based on their preference. Auto-generated site-And service-specific e-Tickets and Quick Response (QR) codes were sent to their mobile devices enabling monitoring and check-in by offline site staff. Service uptake and participant's socio-demographic and risk behaviour characteristics were analyzed. Factors associated with PrEP uptake were assessed using multiple logistic regression. Results: Between January 10th and April 11th, 2016, Adam's Love reached 272,568 people online via the PrEP O2O promotions. 425 MSM and TG received eCounseling and e-Tickets. There were 325 (76.5%) MSM and TG who checkedin at clinics and received HIV testing. Nine (2.8%) were diagnosed with HIV infection. Median (IQR) time between receiving the e-Ticket and checking-in was 3 (0-7) days. Of 316 HIV-negative MSM and TG, 168 (53.2%) started PrEP. In a multivariate model, higher education (OR 2.30, 95%CI 1.14-4.66; p = 0.02), seeking sex partners online (OR 2.05, 95%CI 1.19-3.54; p = 0.009), being aware of sexual partners' HIV status (OR 2.37, 95%CI 1.29-4.35; p = 0.008), ever previously using post-exposure prophylaxis (PEP) (OR 2.46, 95%CI 1.19-5.09; p = 0.01), and enrolment at Adam's Love clinic compared to the other three sites (OR 3.79, 95%CI 2.06-6.95; p < 0.001) were independently associated with PrEP uptake. Conclusions: Adam's Love O2O model is highly effective in linking online at-risk MSM and TG to PrEP and HIV testing services, and has high potential to be replicated and scaled up in other settings with high Internet penetration among key populations. © 2017 Anand T et al. Cabotegravir long acting injection protects macaques against intravenous challenge with SIVmac251	AIDS	-	-	-	2699370	10.1097/QAD.0000000000001343	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85000416127&doi=10.1097%2fQAD.0000000000001343&partnerID=40&md5=f3607e3b043d9a8c32aba74739739597	Objective: We evaluated the effectiveness of cabotegravir (CAB; GSK1265744 or GSK744) long acting as preexposure prophylaxis (PrEP) against intravenous simian immunodeficiency virus (SIV) challenge in a model that mimics blood transfusions based on the per-act probability of infection. Design: CAB long acting is an integrase strand transfer inhibitor formulated as a 200 mg/ml injectable nanoparticle suspension that is an effective PrEP agent against rectal and vaginal simian/human immunodeficiency virus transmission in macaques. Methods: Three groups of rhesus macaques (n=8 per group) were injected intramuscularly with CAB long acting and challenged intravenously with 17 animal infectious dose 50% SIVmac251 on week 2. Group 1 was injected with 50 mg/kg on week 0 and 4 to evaluate the protective efficacy of the CAB long acting dose used in macaque studies mimicking sexual transmission. Group 2 was injected with 50 mg/kg on week 0 to evaluate the necessity of the second injection of CAB long acting for protection against intravenous challenge. Group 3 was injected with 25 mg/kg on week 0 and 50 mg/kg on week 4 to correlate CAB plasma concentrations at the time of challenge with protection. Five additional macaques remained untreated as controls. Results: CAB long acting was highly protective with 21 of the 24 CAB long-actingtreated macaques remaining aviremic, resulting in 88% protection. The plasma CAB concentration at the time of virus challenge appeared to be more important for protection than sustaining therapeutic plasma concentrations with the second CAB long acting injection. Conclusion: These results support the clinical investigation of CAB long acting as PrEP in people who inject drugs. © Copyright 2017 Wolters Kluwer Health, Inc. All rights reserved. Article	2017	Arnold, Trisha; Brinkley-Rubinstein, Lauren; Chan, Philip A; Perez-Brumer, Amaya; Bologna, Estefany S; Beauchamps, Laura; Johnson, Kendra; Mena, Leandro; Nunn, Amy	Social, structural, behavioral and clinical factors influencing retention in Pre-Exposure Prophylaxis (PrEP) care in Mississippi.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0172354	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5319650	Pre-exposure prophylaxis (PrEP) is a biomedical intervention that can reduce rates of HIV transmission when taken once daily by HIV-negative individuals. Little is understood about PrEP uptake and retention in care among the populations most heavily impacted by the HIV epidemic, particularly among young men who have sex with men (YMSM) in the Deep South. Therefore, this study explored the structural, social, behavioral, and clinical factors that affect PrEP use and retention in care among YMSM in Jackson, Mississippi. Thirty MSM who were prescribed PrEP at an outpatient primary care clinic were interviewed and included 23 men who had been retained in PrEP care and seven who had not been retained. The mean age of participants was 26.6 years. Most (23) participants were African American. Major factors affecting PrEP use and retention in PrEP care included 1) structural factors such as cost and access to financial assistance for medications and clinical services; 2) social factors such as stigma and relationship status; 3) behavioral factors including sexual risk behaviors; and 4) clinical factors such as perceived and actual side effects. Many participants also discussed the positive spillover effects of PrEP use and reported that PrEP had a positive impact on their health. Four of the seven individuals who had not been retained re-enrolled in PrEP care after completing their interviews, suggesting that case management and ongoing outreach can enhance retention in PrEP care. Interventions to enhance retention in PrEP care among MSM in the Deep South will be most effective if they address the complex structural, social, clinical, and behavioral factors that influence PrEP uptake and retention in PrEP care. Article	2017	Ayieko, J; Koss, C; Owaraganise, A; Mwangwa, F; Kwarisiima, D; Black, D; Clark, T; Kaur, M; Wallenta, J; Charlebois, E; Cohen, C; Bukusi, EA; Kamya, M; Petersen, M; Havlir, D	"Early adopters" of PrEP in SEARCH study in rural Kenya and Uganda	Journal of the International AIDS Society	-	-	-	1758-2652	10.1093/cid/ciy390	https://pubmed.ncbi.nlm.nih.gov/29741594/	Background: Global guidelines recommend preexposure prophylaxis (PrEP) for individuals with substantial human immunodeficiency virus (HIV) risk. Data on PrEP uptake in sub-Saharan Africa outside of clinical trials are limited. We report on "early adopters" of PrEP in the Sustainable East Africa Research in Community Health (SEARCH) study in rural Uganda and Kenya. Methods: After community mobilization and PrEP education, population-based HIV testing was conducted. HIV-uninfected adults were offered PrEP based on an empirically derived HIV risk score or self-identified HIV risk (if not identified by score). Using logistic regression, we analyzed predictors of early PrEP adoption (starting PrEP within 30 days vs delayed/no start) among adults identified for PrEP. Results: Of 21212 HIV-uninfected adults in 5 communities, 4064 were identified for PrEP (2991 by empiric risk score, 1073 by self-identified risk). Seven hundred and thirty nine individuals started PrEP within 30 days (11% of those identified by risk score; 39% of self-identified); 77% on the same day. Among adults identified by risk score, predictors of early adoption included male sex (adjusted odds ratio 1.53; 95% confidence interval, 1.09-2.15), polygamy (1.92; 1.27-2.90), serodiscordant spouse (3.89; 1.18-12.76), self-perceived HIV risk (1.66; 1.28-2.14), and testing at health campaign versus home (5.24; 3.33-8.26). Among individuals who self-identified for PrEP, predictors of early adoption included older age (2.30; 1.29-4.08) and serodiscordance (2.61; 1.01-6.76). Conclusions: Implementation of PrEP incorporating a population-based empiric risk score, self-identified risk, and rapid initiation, is feasible in rural East Africa. Strategies are needed to overcome barriers to PrEP uptake, particularly among women and youth. Article	2017	Bacon, O; Gonzalez, R; Andrew, E; Potter, MB; Iñiguez, JR; Cohen, SE; Liu, AY; Fuchs, JD	Informing Strategies to Build PrEP Capacity Among San Francisco Bay Area Clinicians	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	10.1097/QAI.0000000000001182	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5233589/	A large pool of clinicians are needed to meet the growing demand for HIV preexposure prophylaxis. We surveyed a mixed group of HIV specialists and nonspecialists in the San Francisco Bay Area to determine their attitudes toward and training needs regarding prescribing preexposure prophylaxis to persons at increased risk of HIV infection. Willingness to prescribe was associated with experience in caring for HIV-infected patients (adjusted odds ratio 4.76, 95% confidence interval: 1.43 to 15.76, P = 0.01). Desire for further training was associated with concerns about drug resistance (P = 0.04) and side effects (P = 0.04) and was more common among noninfectious disease specialists. Clinicians favored online and inperson training methods. Article	2017	Bailey J.L.; Molino S.T.; Vega A.D.; Badowski M.	A Review of HIV Pre-Exposure Prophylaxis: The Female Perspective	Infectious Diseases and Therapy	-	-	-	21938229	10.1007/s40121-017-0159-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029505556&doi=10.1007%2fs40121-017-0159-9&partnerID=40&md5=329418590ccfeb797ecb09bbfc3bc188	When taken consistently, pre-exposure prophylaxis (PrEP) against human immunodeficiency virus (HIV) with once daily tenofovir disoproxil fumarate-emtricitabine (TDF-FTC) has been shown to safely reduce the incidence of HIV infection in high-risk individuals by more than 90%. Yet, according to the Centers for Disease Control and Prevention, there were about 2.1 million new cases of HIV reported worldwide in 2015. Undoubtedly, there is significant room for improvement to prevent the transmission of HIV. Research to date has been heavily focused on the high-risk men who have sex with men (MSM) population, yet, many women worldwide remain at high risk of HIV transmission. PrEP offers women a protection method that is discrete, does not require partner consent, and may be compatible with both contraception or conception as desired. However, women often remain under-represented in HIV prevention literature and are reported to have lower real-world uptake in comparison to men. Furthermore, clinical trials that do focus on the female population demonstrate mixed efficacy results that highlight the adherence challenges in this population. It is essential to identify factors that contribute to PrEP non-adherence as well as barriers to preventative treatment. This review will discuss the clinical evidence behind PrEP in women, current barriers to use afflicting this population, pharmacotherapy considerations for the female patient, alternative and future agents, and the current real-world application of PrEP. © 2017, The Author(s). Article	2017	Balzer, Laura; Staples, Patrick; Onnela, Jukka-Pekka; DeGruttola, Victor	Using a network-based approach and targeted maximum likelihood estimation to evaluate the effect of adding pre-exposure prophylaxis to an ongoing test-and-treat trial.	Clinical Trials	-	-	-	1740-7753	10.1177/1740774516679666	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5377920	BACKGROUND: Several cluster-randomized trials are underway to investigate the implementation and effectiveness of a universal test-and-treat strategy on the HIV epidemic in sub-Saharan Africa. We consider nesting studies of pre-exposure prophylaxis within these trials. Pre-exposure prophylaxis is a general strategy where high-risk HIV- persons take antiretrovirals daily to reduce their risk of infection from exposure to HIV. We address how to target pre-exposure prophylaxis to high-risk groups and how to maximize power to detect the individual and combined effects of universal test-and-treat and pre-exposure prophylaxis strategies. METHODS: We simulated 1000 trials, each consisting of 32 villages with 200 individuals per village. At baseline, we randomized the universal test-and-treat strategy. Then, after 3 years of follow-up, we considered four strategies for targeting pre-exposure prophylaxis: (1) all HIV- individuals who self-identify as high risk, (2) all HIV- individuals who are identified by their HIV+ partner (serodiscordant couples), (3) highly connected HIV- individuals, and (4) the HIV- contacts of a newly diagnosed HIV+ individual (a ring-based strategy). We explored two possible trial designs, and all villages were followed for a total of 7 years. For each village in a trial, we used a stochastic block model to generate bipartite (male-female) networks and simulated an agent-based epidemic process on these networks. We estimated the individual and combined intervention effects with a novel targeted maximum likelihood estimator, which used cross-validation to data-adaptively select from a pre-specified library the candidate estimator that maximized the efficiency of the analysis. RESULTS: The universal test-and-treat strategy reduced the 3-year cumulative HIV incidence by 4.0% on average. The impact of each pre-exposure prophylaxis strategy on the 4-year cumulative HIV incidence varied by the coverage of the universal test-and-treat strategy with lower coverage resulting in a larger impact of pre-exposure prophylaxis. Offering pre-exposure prophylaxis to serodiscordant couples resulted in the largest reductions in HIV incidence (2% reduction), and the ring-based strategy had little impact (0% reduction). The joint effect was larger than either individual effect with reductions in the 7-year incidence ranging from 4.5% to 8.8%. Targeted maximum likelihood estimation, data-adaptively adjusting for baseline covariates, substantially improved power over the unadjusted analysis, while maintaining nominal confidence interval coverage. CONCLUSION: Our simulation study suggests that nesting a pre-exposure prophylaxis study within an ongoing trial can lead to combined intervention effects greater than those of universal test-and-treat alone and can provide information about the efficacy of pre-exposure prophylaxis in the presence of high coverage of treatment for HIV+ persons. Theses and Dissertations	2017	Batista, Amanda Trajano	Prevenir ou remediar? atitudes dos profissionais de saúde frente à profilaxia pré exposição ao HIV/AIDS	-	-	Universidade Federal da Paraíba; Programa de Pós-Graduação em Psicologia Social; UFPB; Brasil; Psicologia Social	-	-	NA	https://repositorio.ufpb.br/jspui/handle/123456789/12142	As taxas de novas infecções por HIV continuam elevadas em todo o mundo, trazendo a necessidade da criação de novas estratégias de prevenção. Atualmente, os antirretrovirais (ARV) são utilizados como tratamento, na estratégia de Testar e oferecer Tratamento, como profilaxia após a exposição ao HIV e, mais recentemente, como profilaxia Pré- Exposição (PrEP) indicada para populações-chaves. Esta última, não obstante a eficácia observada, tem levantado questionamentos. Considerando que a implementação e adesão à PrEP é dependente da prescrição pelos profissionais de saúde e tendo como aporte teórico o conceito de atitudes desenvolvido por Fishbein e Ajzen (1975), este estudo teve por objetivo analisar as atitudes dos profissionais da área de saúde sobre a prescrição e utilização da Profilaxia Pré-exposição (PrEP). Tratou-se de um estudo transversal, exploratório e descritivo, de caráter quantitativo e qualitativo. A amostra foi composta por 68 profissionais de saúde. Utilizou-se um questionário sociodemográfico e profissional a fim de caracterizar os participantes e, em seguida, foram realizadas entrevistas individuais, segundo o procedimento de Evocação-Enunciação-Averiguação. Os participantes foram abordados em serviços especializados em Aids, assim como em um evento científico sobre HIV/Aids realizado em João Pessoa/PB. Os dados quantitativos foram analisados por meio de estatísticas descritivas, enquanto os qualitativos por meio de análise de conteúdo. A maioria dos participantes era do sexo feminino (66,2%); com média de idade de 41 anos (DP=11,3); sendo 35,3% enfermeiros e 20,6% psicólogos; com tempo de atuação média nos serviços de 9,5 anos (DP= 6,5). O lócus de atuação mais frequente foi o Serviço de Atenção Especializado (SAE) (33,8%), seguido do Centro de Testagem e Aconselhamento (CTA) (23,5%) e gestão (19,1%). Em relação à intenção de prescrever a PrEP, 45,8% da amostra apresentou intenção positiva; 29,2% apresentaram intenção negativa e 25% se colocaram numa posição de intenção condicional. Já as análises das entrevistas mostraram a presença de duas classes temáticas: A primeira intitulada "Crenças acerca da PrEP" é composta por seis categorias de análise (1-grupo-chave, 2-comportamento de risco, 3- Instrumento de prevenção, 4-Direitos, 5-Paradigma Biomédico, 6- consequências de PrEP), e a segunda "Implantação da PrEP nos Serviços de Saúde" composta por três categorias (1- Qualificação, 2-Organização, 3-Estratégias para implementação). Diante dos dados coletados, pôde-se verificar que, embora parte dos profissionais participantes tenha afirmado intenção de…	CNPQ::CIENCIAS HUMANAS::PSICOLOGIA; HIV/Aids; Profilaxia pré-Exposição; Profissionais de saúde; HIV / AIDS; Pre-exposure prophylaxis; Health professionals	Portuguese	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	-	-	Mixed methods
Article	2017	Bazzi A.R.; Leech A.A.; Biancarelli D.L.; Sullivan M.; Drainoni M.-L.	Experiences Using Pre-Exposure Prophylaxis for Safer Conception among HIV Serodiscordant Heterosexual Couples in the United States	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2017.0098	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026558231&doi=10.1089%2fapc.2017.0098&partnerID=40&md5=eb4fa7ba3742cfb917e7dfbaf45becfa	Antiretroviral pre-exposure prophylaxis (PrEP) is a promising HIV prevention strategy for HIV serodiscordant couples (HIV-infected male, uninfected female) seeking safer conception. However, most research on PrEP for safer conception has focused on couples in sub-Saharan Africa; little is known about the perspectives or experiences of heterosexual couples in the United States. We conducted qualitative interviews with six couples (six women and five of their male partners) receiving PrEP for conception services at an urban safety net hospital in the US Northeast. In-depth interview guides explored couple relationships and contextual factors and attitudes, perceptions, and decision-making processes surrounding PrEP for safer conception. Thematic analyses focused on identifying the following emergent themes. We found that couple relationships were situated within broader social and cultural contexts of immigration, family, and community that shaped their experiences with HIV and serodiscordant relationship status. Despite strong partner support within relationships, HIV stigma and disapproval of serodiscordant relationships contributed to couples' feelings of social isolation and subsequent aspirations to have "normal" families. By enabling "natural" conception through condomless sex, PrEP for safer conception provided a sense of enhanced relationship intimacy. Couples called for increasing public awareness of PrEP through positive messaging as a way to combat HIV stigma. Findings suggest that relationship dynamics and broader social contexts appear to shape HIV serodiscordant couples' fertility desires and motivations to use PrEP. However, increased public awareness of PrEP for safer conception may be needed to combat HIV stigma at the community level. © Copyright 2017, Mary Ann Liebert, Inc.	conception; fertility; heterosexual couples; HIV prevention; pre-exposure prophylaxis; serodiscordant couples	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2017	Bernard, Cora L; Owens, Douglas K; Goldhaber-Fiebert, Jeremy D; Brandeau, Margaret L	Estimation of the cost-effectiveness of HIV prevention portfolios for people who inject drugs in the United States: A model-based analysis.	PLOS Medicine	-	-	-	1549-1676	10.1371/journal.pmed.1002312	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5444347	BACKGROUND: The risks of HIV transmission associated with the opioid epidemic make cost-effective programs for people who inject drugs (PWID) a public health priority. Some of these programs have benefits beyond prevention of HIV-a critical consideration given that injection drug use is increasing across most United States demographic groups. To identify high-value HIV prevention program portfolios for US PWID, we consider combinations of four interventions with demonstrated efficacy: opioid agonist therapy (OAT), needle and syringe programs (NSPs), HIV testing and treatment (Test & Treat), and oral HIV pre-exposure prophylaxis (PrEP). METHODS AND FINDINGS: We adapted an empirically calibrated dynamic compartmental model and used it to assess the discounted costs (in 2015 US dollars), health outcomes (HIV infections averted, change in HIV prevalence, and discounted quality-adjusted life years QALYs), and incremental cost-effectiveness ratios (ICERs) of the four prevention programs, considered singly and in combination over a 20-y time horizon. We obtained epidemiologic, economic, and health utility parameter estimates from the literature, previously published models, and expert opinion. We estimate that expansions of OAT, NSPs, and Test & Treat implemented singly up to 50% coverage levels can be cost-effective relative to the next highest coverage level (low, medium, and high at 40%, 45%, and 50%, respectively) and that OAT, which we assume to have immediate and direct health benefits for the individual, has the potential to be the highest value investment, even under scenarios where it prevents fewer infections than other programs. Although a model-based analysis can provide only estimates of health outcomes, we project that, over 20 y, 50% coverage with OAT could avert up to 22,000 (95% CI: 5,200, 46,000) infections and cost US$18,000 (95% CI: US$14,000, US$24,000) per QALY gained, 50% NSP coverage could avert up to 35,000 (95% CI: 8,900, 43,000) infections and cost US$25,000 (95% CI: US$7,000, US$76,000) per QALY gained, 50% Test & Treat coverage could avert up to 6,700 (95% CI: 1,200, 16,000) infections and cost US$27,000 (95% CI: US$15,000, US$48,000) per QALY gained, and 50% PrEP coverage could avert up to 37,000 (22,000, 58,000) infections and cost US$300,000 (95% CI: US$162,000, US$667,000) per QALY gained. When coverage expansions are allowed to include combined investment with other programs and are compared to the next best intervention, the model projects that scaling OAT coverage up to 50%, then scaling NSP coverage to 50%, then scaling Test & Treat coverage to 50% can be cost-effective, with each coverage expansion having the potential to cost less than US$50,000 per QALY gained relative to the next best portfolio. In probabilistic sensitivity analyses, 59% of portfolios prioritized the addition of OAT and 41% prioritized the addition of NSPs, while PrEP was not likely to be a priority nor a cost-effective addition. Our findings are intended to be illustrative, as data on achievable coverage are limited and, in practice, the expansion scenarios considered may exceed feasible levels. We assumed independence of interventions and constant returns to scale. Extensive sensitivity analyses allowed us to assess parameter sensitivity, but the use of a dynamic compartmental model limited the exploration of structural sensitivities. CONCLUSIONS: We estimate that OAT, NSPs, and Test & Treat, implemented singly or in combination, have the potential to effectively and cost-effectively prevent HIV in US PWID. PrEP is not likely to be cost-effective in this population, based on the scenarios we evaluated. While local budgets or policy may constrain feasible coverage levels for the various interventions, our findings suggest that investments in combined prevention programs can substantially reduce HIV transmission and improve health outcomes among PWID. Article	2017	Beymer M.R.; Weiss R.E.; Sugar C.A.; Bourque L.B.; Gee G.C.; Morisky D.E.; Shu S.B.; Javanbakht M.; Bolan R.K.	Are Centers for Disease Control and Prevention Guidelines for Preexposure Prophylaxis Specific Enough? Formulation of a Personalized HIV Risk Score for Pre-Exposure Prophylaxis Initiation	Sexually Transmitted Diseases	-	-	-	1485717	10.1097/OLQ.0000000000000535	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85000623123&doi=10.1097%2fOLQ.0000000000000535&partnerID=40&md5=74d7a65c8d9c0f34bf648a7cb688e942	Background Preexposure prophylaxis (PrEP) has emerged as a human immunodeficiency virus (HIV) prevention tool for populations at highest risk for HIV infection. Current US Centers for Disease Control and Prevention (CDC) guidelines for identifying PrEP candidates may not be specific enough to identify gay, bisexual, and other men who have sex with men (MSM) at the highest risk for HIV infection. We created an HIV risk score for HIV-negative MSM based on Syndemics Theory to develop a more targeted criterion for assessing PrEP candidacy. Methods Behavioral risk assessment and HIV testing data were analyzed for HIV-negative MSM attending the Los Angeles LGBT Center between January 2009 and June 2014 (n = 9481). Syndemics Theory informed the selection of variables for a multivariable Cox proportional hazards model. Estimated coefficients were summed to create an HIV risk score, and model fit was compared between our model and CDC guidelines using the Akaike Information Criterion and Bayesian Information Criterion. Results Approximately 51% of MSM were above a cutpoint that we chose as an illustrative risk score to qualify for PrEP, identifying 75% of all seroconverting MSM. Our model demonstrated a better overall fit when compared with the CDC guidelines (Akaike Information Criterion Difference = 68) in addition to identifying a greater proportion of HIV infections. Conclusions Current CDC PrEP guidelines should be expanded to incorporate substance use, partner-level, and other Syndemic variables that have been shown to contribute to HIV acquisition. Deployment of such personalized algorithms may better hone PrEP criteria and allow providers and their patients to make a more informed decision prior to PrEP use. © Copyright 2016 American Sexually Transmitted Diseases Association All rights reserved.	3,4 methylenedioxymethamphetaminemethamphetaminenitric acid derivative	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Beymer, Matthew R; Weiss, Robert E; Bolan, Robert K; Kofron, Ryan M; Flynn, Risa P; Pieribone, David L; Kulkarni, Sonali P; Landovitz, Raphael J	Differentiating Nonoccupational Postexposure Prophylaxis Seroconverters and Non-Seroconverters in a Community-Based Clinic in Los Angeles, California.	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1093/ofid/ofx061	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5458294	BACKGROUND: Nonoccupational postexposure prophylaxis (nPEP) is a 28-day regimen of antiretroviral medications taken within 72 hours of human immunodeficiency virus (HIV) exposure to prevent HIV acquisition. Although nPEP has been recommended since 1998, few studies have analyzed the characteristics that distinguish nPEP failures (seroconverters) and successes (non-seroconverters). METHODS: This retrospective study analyzed all nPEP courses prompted by sexual exposure that were prescribed at the Los Angeles LGBT Center between March 2010 and July 2014. Fisher exact tests and logistic regressions were used to determine characteristics that distinguished nPEP seroconverters from non-seroconverters. RESULTS: Of the nPEP courses administered, 1744 had a follow-up visit for HIV testing within 24 weeks of exposure and 17 individuals seroconverted. Seven reported a known re-exposure, 8 self-reported only condom-protected sex subsequent to the initial exposure, and 2 reported abstinence since the exposure. In multivariable analyses, seroconverters were more likely than non-seroconverters to report methamphetamine use, incomplete medication adherence, and nPEP initiation later in the 72-hour window. CONCLUSIONS: Nonoccupational postexposure prophylaxis is an important emergency tool for HIV prevention. Our findings corroborate that timing of the initial nPEP dose is an important predictor of seroconversion. Although the current study did not offer the initial nPEP dose at the beginning of the visit, use of this fast-track dosing schedule will ensure that the first dose is taken as early as possible postexposure and may lower the likelihood for seroconversion. Furthermore, we recommend systematic screening for substance use because these individuals may be well suited for pre-exposure prophylaxis given their sustained risk. Article	2017	Beyrer, Chris	Pre-exposure prophylaxis for people who inject drugs and their sex partners.	Addiction	-	-	-	1360-0443	10.1111/add.13527	https://dx.doi.org/10.1111/add.13527	Background: People who inject drugs (PWID) are at increased risk for HIV infection through sharing contaminated needles and injection equipment, and engaging in condomless sex. Objectives: To qualitatively examine the overlapping nature of these behaviors among PWID in the US Northeast. Methods: We recruited HIV-uninfected PWID and key informants through community-based organizations. Qualitative interviews explored sexual partnerships as they related to sharing contaminated needles and injection equipment, engaging in condomless sex, and associated indications for PrEP among PWID. Results: Among 33 PWID, 66% engaged in condomless vaginal or anal sex in the past 3 months, and 27% had three or more sexual partners in this same time period. Over half engaged in any past month distributive or receptive syringe sharing (64%). We identified three contexts through which overlapping sexual and injection-related HIV risks emerged, including (1) multiple concurrent sexual partnerships; (2) using and injecting drugs with sexual partners (including increase injecting of crystal methamphetamine); and (3) exchanging sex for money or drugs (including among male PWID). Condom use was inconsistent across these contexts. Limited interactions with healthcare providers often resulted in sexual risks being overlooked in light of competing health concerns. Conclusions: Sexual risk for HIV acquisition is complex and multi-faceted among PWID yet may be overlooked by prevention and healthcare providers. Comprehensive HIV prevention efforts must acknowledge the distinct contexts in which overlapping injection and sexual risk behaviors occur. Increased sexual health screening and risk reduction services including PrEP for PWID may help curtail transmission in this population. Article	2017	Biello K.B.; Oldenburg C.E.; Mitty J.A.; Closson E.F.; Mayer K.H.; Safren S.A.; Mimiaga M.J.	The "Safe Sex" Conundrum: Anticipated Stigma From Sexual Partners as a Barrier to PrEP Use Among Substance Using MSM Engaging in Transactional Sex	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1466-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84976428006&doi=10.1007%2fs10461-016-1466-y&partnerID=40&md5=c5e55998c867a63bfb86f45ee9cb530c	Pre-exposure prophylaxis (PrEP) is efficacious for HIV prevention when taken consistently; however, barriers to PrEP use are poorly understood among individuals who could benefit from PrEP, including men who have sex with men (MSM) who engage in transactional sex (i.e., sex exchanged for money or drugs). Two hundred and thirty-seven HIV-uninfected, PrEP-naive MSM reporting concurrent substance dependence and sexual risk completed a questionnaire on PrEP use barriers. Barriers to PrEP use for MSM who engaged in recent transactional sex (22 %) versus those who had not were compared using an ecological framework. Individual (e.g., HIV stigma, substance use) and structural (e.g., economic, healthcare) barriers did not differ (p > 0.05). MSM who recently engaged in transactional sex were more likely to report that anticipated stigma from primary and casual partners would be barriers to PrEP use. Assessing recent transactional sex may help identify men who may need additional counseling to avoid anticipated stigma so they can integrate PrEP into their lives. © 2016, Springer Science+Business Media New York. Article	2017	Bien, Cedric H; Patel, Viraj V; Blackstock, Oni J; Felsen, Uriel R	Reaching Key Populations: PrEP Uptake in an Urban Health Care System in the Bronx, New York	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1663-8	https://www.proquest.com/scholarly-journals/reaching-key-populations-prep-uptake-urban-health/docview/1883470004/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) has been established as an effective HIV prevention tool, but real world studies are limited. To inform dissemination efforts, we sought to describe individuals prescribed PrEP in the largest health care system in the Bronx, New York, an urban region with a high burden of HIV. We used a clinical database and chart review to identify individuals prescribed PrEP between 2011 and 2015 (n = 108). A majority were Black and Hispanic, half were men who have sex with men, and nearly a third were cisgender women who have sex with men. Primary care settings were the most common site of PrEP prescription and PrEP prescription rates increased over time. Despite reaching a diverse patient population, PrEP prescribing rates were low, underscoring the urgent need for PrEP scale-up. Article	2017	Blackstock O.J.; Moore B.A.; Berkenblit G.V.; Calabrese S.K.; Cunningham C.O.; Fiellin D.A.; Patel V.V.; Phillips K.A.; Tetrault J.M.; Shah M.; Edelman E.J.	A Cross-Sectional Online Survey of HIV Pre-Exposure Prophylaxis Adoption Among Primary Care Physicians	Journal of General Internal Medicine	-	-	-	8848734	10.1007/s11606-016-3903-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84992200939&doi=10.1007%2fs11606-016-3903-z&partnerID=40&md5=30a2663a3980af5e9ca9197606910323	Background: Among health care providers, prescription of HIV pre-exposure prophylaxis (PrEP) has been low. Little is known specifically about primary care physicians (PCPs) with regard to PrEP awareness and adoption (i.e., prescription or referral), and factors associated with adoption. Objective: To assess PrEP awareness, PrEP adoption, and factors associated with adoption among PCPs. Design: Cross-sectional online survey conducted in April and May 2015. Respondents: Members of a national professional organization for academic primary care physicians (n = 266). Main Measures: PrEP awareness, PrEP adoption (ever prescribed or referred a patient for PrEP yes/no), provider and practice characteristics, and self-rated knowledge, attitudes, and beliefs associated with adoption. Key Results: The survey response rate was 8.6 % (266/2093). Ninety-three percent of respondents reported prior awareness of PrEP. Of these, 34.9 % reported PrEP adoption. In multivariable analysis of provider and practice characteristics, compared with non-adopters, adopters were more likely to provide care to more than 50 HIV-positive patients (vs. 0, aOR = 6.82, 95 % CI 2.06–22.52). Compared with non-adopters, adopters were also more likely to report excellent, very good, or good self-rated PrEP knowledge (15.1 %, 33.7 %, 30.2 % vs. 2.5 %, 18.1 %, 23.8 %, respectively; p < 0.001) and to perceive PrEP as extremely safe (35.1 % vs. 10.7 %; p = 0.002). Compared with non-adopters, adopters were less likely to perceive PrEP as being moderately likely to increase risk behaviors ("risk compensation") (12.8 % vs. 28.8 %, p = 0.02). Conclusions: While most respondents were aware of PrEP, only one-third of PrEP-aware PCPs reported adoption. Adopters were more likely to have experience providing HIV care and to perceive PrEP as extremely safe, and were less likely to perceive PrEP use as leading to risk compensation. To enhance PCP adoption of PrEP, educational efforts targeting PCPs without HIV care experience should be considered, as well as training those with HIV care experience to be PrEP "clinical champions". Concerns about safety and risk compensation must also be addressed. © 2016, Society of General Internal Medicine. Article	2017	Blackstock, Oni J; Patel, Viraj V; Felsen, Uriel; Park, Connie; Jain, Sachin	Pre-exposure prophylaxis prescribing and retention in care among heterosexual women at a community-based comprehensive sexual health clinic.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2017.1286287	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5514312	In the United States, heterosexual women account for 20% of new HIV infections. As a user-controlled HIV prevention method, pre-exposure prophylaxis (PrEP) has substantial potential to reduce new infections among women. However, among women, PrEP is vastly underutilized. To guide efforts to increase women-at-risk's PrEP use, we sought to describe the characteristics of women prescribed PrEP as well as their retention in PrEP care. We conducted a chart review of women who received care at a comprehensive sexual health clinic within a large urban health care system. Referral sources included the health care system's clinics and HIV testing program, as well as local community-based organizations. From 1 December 2014 to 5 August 2016, 554 women received care at the clinic. During this period, 21 heterosexual women (3.8%) received at least one prescription for daily oral PrEP. For women prescribed PrEP, median age was 35 years old (range: 20-52). The majority (66.7%) were either Latina or non-Latina Black and most (81.2%) had public health insurance. The most common PrEP indication was being in a known sero-discordant partnership (85.7%). Of women in such partnerships, 83.3% reported their male partner was currently taking antiretroviral medications (ARVs) and 16.7% reported trying to conceive with their partner (not mutually exclusive). Of women with ARV-using partners, 66.7% reported that their partners were virally suppressed. Retention in PrEP care at three months was 61.1% and, at six months, 37.5%. Further study is necessary to expand PrEP to women whose risk factors extend beyond being in a known sero-discordant partnership, and to understand the reasons for the observed drop-off in PrEP care visits in real-world settings. Article	2017	Blaizot S.; Huerga H.; Riche B.; Ellman T.; Shroufi A.; Etard J.-F.; Ecochard R.	Combined interventions to reduce HIV incidence in KwaZulu-Natal: A modelling study	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-017-2612-5	https://bmcinfectdis.biomedcentral.com/articles/10.1186/s12879-017-2612-5	Background: Combined prevention interventions, including early antiretroviral therapy initiation, may substantially reduce HIV incidence in hyperendemic settings. Our aim was to assess the potential short-term impact of combined interventions on HIV spreading in the adult population of Mbongolwane and Eshowe (KwaZulu-Natal, South Africa) using sex- and age-specific scenarios, and age-targeted interventions. Methods: A mathematical model was used with data on adults (15-59 years) from the Mbongolwane and Eshowe HIV Impact in Population Survey to compare the effects of various interventions on the HIV incidence rate. These interventions included increase in antiretroviral therapy (ART) coverage with extended eligibility criteria, increase in voluntary medical male circumcision (VMMC), and implementation of pre-exposure prophylaxis (PrEP) among women. Results: With no additional interventions to the ones in place at the time of the survey (ART at CD4 < 350 and VMMC), incidence will decrease by 24% compared to the baseline rate. The implementation of "ART at CD4<500" or "ART for all" would reduce further the incidence rate by additional 8% and 15% respectively by 4 years and 20% and 34% by 10 years. Impacts would be higher with age-targeted scenarios than without. Conclusions: In Mbongolwane and Eshowe, implementation of the new South African guidelines, recommending ART initiation regardless of CD4 count, would accelerate incidence reduction. In this setting, combining these guidelines, VMMC, and PrEP among young women could be an effective strategy in reducing the incidence to low levels. © 2017 The Author(s). Article	2017	Bourne, Adam; Cassolato, Matteo; Thuan Wei, Clayton Koh; Wang, Bangyuan; Pang, Joselyn; Lim, Sin How; Azwa, Iskandar; Yee, Ilias; Mburu, Gitau	Willingness to use pre-exposure prophylaxis (PrEP) for HIV prevention among men who have sex with men (MSM) in Malaysia: findings from a qualitative study	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.20.1.21899	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5577697	BACKGROUND: Men who have sex with men (MSM) continue to be disproportionately affected by HIV in Malaysia. Recent success has been observed within demonstration projects examining the efficacy of HIV pre-exposure prophylaxis (PrEP), an antiretroviral -based medication taken by HIV-negative men to prevent sero-conversion. In order for such promising findings to be translated in real-world settings, it is important to understand the acceptability of PrEP, including perceived barriers to access or uptake. METHODS: As part of a larger mixed-methods study exploring acceptability and willingness to use PrEP among MSM in Malaysia, 19 men took part in audio-recorded focus group discussions hosted by a community-based HIV organization and facilitated by a trained researcher. Discussions focussed on awareness and potential information management, general perceptions of PrEP and potential motivations or barriers to the use of PrEP, including those at the personal, social, health system or structural level. Data were transcribed verbatim and underwent a detailed thematic analysis. RESULTS: Rather than perceiving PrEP as a replacement for condoms in terms of having safer sex, many participants viewed it as an additional layer protection, serving as a crucial barrier to infection on occasions where condom use was intended, but did not occur. It was also perceived as more valuable to "at-risk" men, such as those in HIV sero-discordant relationships or those with a higher number of sexual partners. Elements of discussion tended to suggest that some men taking PrEP may be subject to stigma from others, on the assumption they may be promiscuous or engage in high-risk sexual behaviours. CONCLUSIONS: This qualitative study indicates that, broadly speaking, PrEP may be acceptable to MSM in Malaysia. However, in order for its potential to be realized, and uptake achieved, educative interventions are required to inform the target population as to the efficacy and potential, positive impact of PrEP. Given concerns for how those taking it may be stigmatized, it is crucial that the use of PrEP is presented as a responsible course of action, and one of a range of strategies that men can use to keep themselves safe from HIV. Institutional	2017	Brasil. Ministério da Saúde. Secretaria de Ciência, Tecnologia e Insumos Estratégicos	Tenofovir associado a entricitabina (TDF/FTC 300/200mg) como profilaxia pré-exposição (PrEP) para populações sob maior risco de adquirir o vírus da imunodeficiência humana (HIV)	-	-	-	-	-	NA	http://conitec.gov.br/images/Relatorios/2017/Recomendacao/Relat%C3%B3rio_TenofovirEntricitabina_PREP_Recomendacao_2017.pdf	CONTEXTO: A resposta brasileira à epidemia de aids é resultante de um longo processo de atuação do governo brasileiro que garante desde 1996 acesso universal ao tratamento antirretroviral. Contudo, apesar dos inúmeros avanços ocorridos na redução da morbimortalidade nos últimos anos, o número de novos casos de aids vem se mantendo praticamente inalterado. No Brasil, a epidemia de aids é concentrada em determinados segmentos populacionais, que apresentam uma maior prevalência de infecção pelo HIV, quando comparados à população em geral, e respondem pela maioria de casos novos da infecção. Assim, para essas populações sob maior risco de infecção pelo HIV faz-se necessário a construção de estratégias de prevenção focalizadas como forma de impactar a epidemia. TECNOLOGIA: Profilaxia pré-exposição (PrEP) oral, na forma de tenofovir associado a entricitabina (TDF/FTC 300/200mg). Consiste no uso de antirretrovirais previamente à exposição de risco. INDICAÇÃO: Redução de risco em adquirir a infecção pelo HIV, entre pessoas sob risco aumentado. PERGUNTA: O uso de tenofovir associado a entricitabina (TDF/FTC 300/200mg) quando comparado ao uso de placebo reduz o risco de infecção pelo HIV entre pessoas sob alto risco? EVIDÊNCIAS CIENTÍFICAS: As evidências científicas disponíveis demostram que o uso de PrEP reduz o risco de infecção pelo HIV, comparado a placebo, com eficácia >70% (RR=0,30, 95% IC: 0,21-0,45, p= 0,001). Sua eficácia está diretamente relacionada à adesão ao medicamento. Os eventos adversos foram similares entre o grupo placebo e o que usou PrEP. Casos de resistência aos medicamentos foram encontrados entre aqueles que iniciaram PrEP durante a fase aguda da infecção, mas a incidência de resistência durante o uso de PrEP foi baixa. Não foi encontrada associação entre uso de PrEP e mudanças no comportamento sexual. O uso de PrEP demonstrou segurança e eficácia, para a redução de risco em adquirir a infecção pelo HIV, entre pessoas sob risco aumentado, quando comparado ao uso de placebo. RECOMENDAÇÃO DA CONITEC: A CONITEC recomendou a incorporação da associação de tenofovir e entricitabina (TDF/FTC 300/200mg) como profilaxia pré-exposição (PrEP) para populações sob risco aumentado de infecção pelo HIV no SUS, condicionada à aprovação do registro na ANVISA para essa indicação e à apresentação de um plano de acompanhamento anual das pessoas que receberão a profilaxia, de forma que sua incorporação possa ser reavaliada dentro de um prazo de tempo de, no máximo, 2 anos. CONSULTA PÚBLICA: Por meio da Consulta Pública nº 05 foram recebidas 147 contribuições distribuídas entre os formulários destinados a experiência e opinião e os para contribuições técnico-científicas. O nível de concordância com a recomendação inicial favorável à incorporação do medicamento como profilaxia pré-exposição (prep) para populações sob risco aumentado de adquirir o vírus da imunodeficiência humana (HIV) no SUS foi alto, abrangendo quase a totalidade das contribuições técnico-científica e 77% das contribuições de experiência e opinião. Entre as discordantes ou parcialmente concordantes não foram identificadas contribuições que trouxessem evidências científicas novas às já incluídas nesse parecer técnico-científico ou contestações às evidências científicas identificadas e que embasam a proposta de incorporação do medicamento com finalidade profilática. A maioria das experiências profissionais relatadas convergem com a proposta de incorporação elaborada nesse parecer. RECOMENDAÇÃO FINAL: Deliberou-se por unanimidade recomendar a incorporação da associação de tenofovir e entricitabina (TDF/FTC 300/200mg) como profilaxia pré-exposição (prep) para populações sob risco aumentado de adquirir o vírus da imunodeficiência humana (HIV) no SUS, condicionada à aprovação da inclusão da indicação para profilaxia pré-exposição ao HIV no registro do medicamento pela ANVISA e reavaliação do plano de acompanhamento anual das pessoas que receberão a profilaxia, em até 2 anos. DECISÃO: Incorporar o tenofovir associado a entricitabina (TDF/FTC 300/200mg) como profilaxia pré-exposição (PrEP) para populações sob maior risco de adquirir o vírus da imunodeficiência humana (HIV), no âmbito do Sistema Único de Saúde - SUS, dada pela Portaria nº 21, publicada no DOU nº 101, do dia 29 de maio de 2017, seção 1, pág. 73.(AU)	NA	Portuguese	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	-	-	Other

Article	2017	Brisson J.; Nguyen V.-K.	Science, technology, power and sex: PrEP and HIV-positive gay men in Paris	Culture, Health & Sexuality	-	-	-	13691058	10.1080/13691058.2017.1291994	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85013455977&doi=10.1080%2f13691058.2017.1291994&partnerID=40&md5=5cd6f8e35d357718194291521ced6a79	The pre-exposure prophylaxis (PrEP) drug Truvada is a new HIV prevention technology that is predominantly promoted as relevant to HIV-negative gay men. This paper explores what PrEP represents for HIV-positive gay men living in Paris, based upon data collected through interviews and ethnographic research. While HIV-positive gay men do not directly consume Truvada through PrEP, they nonetheless hold opinions and understandings of this drug, specifically as it relates to their own sexuality. This paper expands the representations and meanings of this new technology in a different light through the voices of gay men living with HIV in Paris. The main argument of this article is that PrEP as an additional HIV prevention tool blurs the lines between science, technologies and human sexuality. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Fall in new HIV diagnoses among men who have sex with men (MSM) at selected London sexual health clinics since early 2015: Testing or treatment or pre-exposure prophylaxis (PrEP)?	Eurosurveillance	-	-	-	1025496X	10.2807/1560-7917.ES.2017.22.25.30553	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021739568&doi=10.2807%2f1560-7917.ES.2017.22.25.30553&partnerID=40&md5=f1b53d08aff5f716a11cf9677c48c0df	Since October 2015 up to September 2016, HIV diagnoses fell by 32% compared with October 2014- September 2015 among men who have sex with men (MSM) attending selected London sexual health clinics. This coincided with high HIV testing volumes and rapid initiation of treatment on diagnosis. The fall was most apparent in new HIV testers. Intensified testing of high-risk populations, combined with immediately received anti-retroviral therapy and a pre-exposure prophylaxis (PrEP) programme, may make elimination of HIV achievable. © 2017, European Centre for Disease Prevention and Control (ECDC). Article	2017	Buttolph, Jasmine; Inwani, Irene; Agot, Kawango; Cleland, Charles M; Cherutich, Peter; Kiarie, James N; Osoti, Alfred; Celum, Connie L; Baeten, Jared M; Nduati, Ruth; Kinuthia, John; Hallett, Timothy B; Alsallaq, Ramzi; Kurth, Ann E	Gender-Specific Combination HIV Prevention for Youth in High-Burden Settings: The MP3 Youth Observational Pilot Study Protocol.	JMIR Research Protocols	-	-	-	1929-0748	10.2196/resprot.5833	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5434770	BACKGROUND: Nearly three decades into the epidemic, sub-Saharan Africa (SSA) remains the region most heavily affected by human immunodeficiency virus (HIV), with nearly 70% of the 34 million people living with HIV globally residing in the region. In SSA, female and male youth (15 to 24 years) are at a disproportionately high risk of HIV infection compared to adults. As such, there is a need to target HIV prevention strategies to youth and to tailor them to a gender-specific context. This protocol describes the process for the multi-staged approach in the design of the MP3 Youth pilot study, a gender-specific, combination, HIV prevention intervention for youth in Kenya. OBJECTIVE: The objective of this multi-method protocol is to outline a rigorous and replicable methodology for a gender-specific combination HIV prevention pilot study for youth in high-burden settings, illustrating the triangulated methods undertaken to ensure that age, sex, and context are integral in the design of the intervention. METHODS: The mixed-methods, cross-sectional, longitudinal cohort pilot study protocol was developed by first conducting a systematic review of the literature, which shaped focus group discussions around prevention package and delivery options, and that also informed age- and sex- stratified mathematical modeling. The review, qualitative data, and mathematical modeling created a triangulated evidence base of interventions to be included in the pilot study protocol. To design the pilot study protocol, we convened an expert panel to select HIV prevention interventions effective for youth in SSA, which will be offered in a mobile health setting. The goal of the pilot study implementation and evaluation is to apply lessons learned to more effective HIV prevention evidence and programming. RESULTS: The combination HIV prevention package in this protocol includes (1) offering HIV testing and counseling for all youth; (2) voluntary medical circumcision and condoms for males; (3) pre-exposure prophylaxis (PrEP), conditional cash transfer (CCT), and contraceptives for females; and (4) referrals for HIV care among those identified as HIV-positive. The combination package platform selected is mobile health teams in an integrated services delivery model. A cross-sectional analysis will be conducted to determine the uptake of the interventions. To determine long-term impact, the protocol outlines enrolling selected participants in mutually exclusive longitudinal cohorts (HIV-positive, PrEP, CCT, and HIV-negative) followed by using mobile phone text messages (short message service, SMS) and in-person surveys to prospectively assess prevention method uptake, adherence, and risk compensation behaviors. Cross-sectional and sub-cohort analyses will be conducted to determine intervention packages uptake. CONCLUSIONS: The literature review, focus groups, and modeling indicate that offering age- and gender- specific combination HIV prevention interventions that include biomedical, behavioral, and structural interventions can have an impact on HIV risk reduction. Implementing this protocol will show the feasibility of delivering these services at scale. The MP3 Youth study is one of the few combination HIV prevention intervention protocols incorporating youth- and gender-specific interventions in one delivery setting. Lessons learned from the design of the protocol can be incorporated into the national guidance for combination HIV prevention for youth in Kenya and other high-burden SSA settings. Article	2017	Buttram, Mance E; Kurtz, Steven P	Preliminary evidence of HIV seroconversion among HIV-negative men who have sex with men taking non-prescribed antiretroviral medication for HIV prevention in Miami, Florida, USA	Sexual Health	-	-	-	14485028	10.1071/SH16108	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85017165845&doi=10.1071%2fSH16108&partnerID=40&md5=c9a018a3b84b096c99edcd9a42734232	Background Limited information suggests that men who have sex with men (MSM) are informally obtaining antiretroviral medication (ARVs) and using them for HIV pre-exposure prophylaxis (PrEP). Methods: Data are drawn from an on-going study examining the use of non-prescribed ARVs for PrEP. To date, 24 qualitative interviews have been conducted with HIV-negative, substance-using MSM living in Miami, Florida, USA. Data are presented from two participants who reported HIV seroconversion while using non-prescribed ARVs for PrEP. Results: Preliminary data indicate that some young MSM: (i) lack awareness of and accurate information about the efficacious use of PrEP; (ii) obtain non-prescribed ARVs from HIV-positive sex partners and use these medications for PrEP in a way that does not provide adequate protection against HIV infection or cohere with established guidelines; and (iii) engage in multiple HIV transmission risk behaviours, including condomless anal sex and injection drug use. Conclusions: The informal, non-prescribed and non-medically supervised use of ARVs for HIV prevention has the potential to undermine the protective benefits of PrEP and leave men unprotected against HIV transmission and at risk for ARV resistance. © CSIRO 2017. Theses and Dissertations	2017	Cabral, Alejandra	Partner violence and self-reported pre-exposure prophylaxis (PrEP) interruptions among HIV negative partners in HIV serodiscordant couples in Kenya and Uganda.	-	-	University of Washington	-	-	NA	https://digital.lib.washington.edu/researchworks/handle/1773/39800	Abstract: Background: Pre-exposure prophylaxis (PrEP) is effective for HIV prevention among diverse populations and studies of PrEP delivery are investigating ways to deliver PrEP with high adherence. In many settings with high HIV burden, where PrEP is an important intervention, intimate partner violence (IPV) is reported often. We examined the role of IPV to influence interruptions in PrEP use. Methods: We analyzed data from 1,013 serodiscordant heterosexual couples enrolled in a large PrEP demonstration project in Kenya and Uganda, the Partners Demonstration Project. At quarterly study visits, HIV negative participants receiving PrEP self-reported interruptions in their PrEP use and experiences with IPV. The association of IPV and PrEP interruptions was analyzed using multivariate generalized estimating equations. Results: Of 1,013 HIV negative people who used PrEP during the study, 67% were male and the median age was 30 (interquartile range IQR 26-36). Interruptions in PrEP use were reported at 328 visits (7.1% of all visits). The median length of PrEP interruption was 28 days (interquartile range IQR: 7-45). At baseline and follow up there were 53 reports of abuse by HIV negative partners, including physical, economic, verbal, or other types of abuse. The frequency of PrEP interruption among people who experienced IPV was 23.8% and those without IPV was 6.9%. The crude odds ratio for PrEP interruption was 3.83 (95% CI 1.8-8.0) and remained significant after adjustment for age, and frequency of intercourse (aOR=2.64, 95% CI 1.17-6.00). Conclusion: IPV was more likely to be reported at visits when PrEP interruptions were also reported, which may have implications for successful adherence to PrEP. Within PrEP delivery, there may be opportunities to assess and intervene on IPV in order to bolster adherence. Article	2017	Cahill, Sean; Taylor, S Wade; Elsesser, Steven A; Mena, Leandro; Hickson, DeMarc; Mayer, Kenneth H	Stigma, medical mistrust, and perceived racism may affect PrEP awareness and uptake in black compared to white gay and bisexual men in Jackson, Mississippi and Boston, Massachusetts.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2017.1300633	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5595632	Gay and bisexual men and other men who have sex with men (MSM) account for more than two thirds of new HIV infections in the U.S., with Black MSM experiencing the greatest burden. Antiretroviral pre-exposure prophylaxis (PrEP) can reduce MSM's vulnerability to HIV infection. Uptake of PrEP has been limited, particularly among racial and ethnic minority MSM. Four semi-structured focus groups with gay and bisexual men and other MSM at risk for HIV infection were convened in Boston and Jackson in late 2013. The analysis plan utilized a within-case, across-case approach to code and analyze emerging themes, and to compare results across the two cities. Participants recruited in Jackson were primarily Black gay men, while Boston participants were mostly non-Hispanic White gay men. Participants in both sites shared concerns about medication side effects and culturally insensitive health care for gay men. Jackson participants described stronger medical mistrust, and more frequently described experiences of anti-gay and HIV related stigma. Multiple addressable barriers to PrEP uptake were described. Information about side effects should be explicitly addressed in PrEP education campaigns. Providers and health departments should address medical mistrust, especially among Black gay and bisexual men and other MSM, in part by training providers in how to provide affirming, culturally competent care. Medicaid should be expanded in Mississippi to cover low-income young Black gay and bisexual men and other MSM. Article	2017	Calabrese S.K.; Krakower D.S.; Mayer K.H.	Integrating HIV preexposure prophylaxis (PrEP) into routine preventive health care to avoid exacerbating disparities	American Journal of Public Health	-	-	-	900036	10.2105/AJPH.2017.304061	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85033608482&doi=10.2105%2fAJPH.2017.304061&partnerID=40&md5=61e69636ee750dccf04f937fb4c7d45a	More than 3 decades since its emergence in the United States, HIV continues to spread and disproportionately affect socially marginalized groups. Preexposure prophylaxis (PrEP), a highly effective prevention strategy federally approved since 2012, could fundamentally alter the course of the epidemic. However, PrEP's potential has not been fully realized, in part because health care providers have been slow to adopt PrEP in clinical practice and have been selective in their discussion of PrEP with patients. This nonstandardized approach has constrained PrEP access. PrEP access has not only been inadequate but also inequitable, with several groups in high need showing lower rates of uptake than do their socially privileged counterparts. Recognizing these early warning signs that current approaches to PrEP implementation could exacerbate existing HIV disparities, we call on health professionals to integrate PrEP into routine preventive health care for adult patients—particularly in primary care, reproductive health, and behavioral health settings. Drawing on the empirical literature, we present 4 arguments for why doing so would improve access and access equity, and we conclude that the benefits clearly outweigh the challenges. Article	2017	Calabrese S.K.; Underhill K.; Mayer K.H.	HIV preexposure prophylaxis and condomless sex: Disentangling personal values from public health priorities	American Journal of Public Health	-	-	-	900036	10.2105/AJPH.2017.303966	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029479967&doi=10.2105%2fAJPH.2017.303966&partnerID=40&md5=6a4fd164c4b33d09a049b5f524bb0b5f	Daily HIV preexposure prophylaxis (PrEP) is an effective form of HIV protection that remains unknown and inaccessible for many people in the United States despite receiving federal approval over five years ago. PrEP is supported by the public health community, but forgoing condoms while taking PrEP has proven controversial; this controversy may be contributing to the lag in PrEP uptake. We argue that limiting PrEP access based on anticipated or actual sexual behavior contradicts the goals of public health research andpractice and is not scientifically justified. As evidence for the effectiveness of novel forms of biomedicalHIV protection emerges, public health professionals need to accept new definitions of "protected sex" and ensure that their personal values do not override empirical evidence when determining public health priorities. Article	2017	Calabrese, Sarah K.; Magnus, Manya; Mayer, Kenneth H.; Krakower, Douglas S.; Eldahan, Adam I.; Hawkins, Lauren A. Gaston; Underhill, Kristen; Hansen, Nathan B.; Kershaw, Trace S.; Betancourt, Joseph R.; Dovidio, John F.	"Support Your Client at the Space That They're in": HIV Pre-Exposure Prophylaxis (PrEP) Prescribers' Perspectives on PrEP-Related Risk Compensation	AIDS Patient Care and STDs	-	-	-	1557-7449 1087-2914	10.1089/apc.2017.0002	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5404273	Despite the demonstrated effectiveness of HIV pre-exposure prophylaxis (PrEP) and evidence that most PrEP users do not engage in risk compensation (i.e., increased risk behavior due to a perceived decrease in HIV susceptibility), some healthcare providers report patient risk compensation to be a deterrent to prescribing PrEP. Overcoming this barrier is essential to supporting PrEP access and uptake among people at risk for HIV. To inform such efforts, this qualitative study explored PrEP-related risk compensation attitudes among providers with firsthand experience prescribing PrEP. US-based PrEP providers (n = 18), most of whom were HIV specialists, were recruited through direct outreach and referral from colleagues and other participants. Individual 90-min semistructured interviews were conducted by phone or in person from September 2014 through February 2015, transcribed, and thematically analyzed. Three attitudinal themes emerged: (1) providers' role is to support patients in making informed decisions, (2) risk behavior while taking PrEP does not fully offset PrEP's protective benefit (i.e., PrEP confers net protection, even with added behavioral risk), and (3) PrEP-related risk compensation is unduly stigmatized within and beyond the healthcare community. Participants were critical of other healthcare providers' negative judgment of patients and reluctance to prescribe PrEP due to anticipated risk compensation. Several providers also acknowledged an evolution in their thinking toward greater acceptance of PrEP and PrEP-related behavior change. PrEP providers' insights about risk compensation may help to address unsubstantiated concerns about PrEP-related risk compensation and challenge the acceptability of withholding PrEP on these grounds. Article	2017	Carballo-Diéguez, Alex; Balán, Ivan C; Brown, William; Giguere, Rebecca; Dolezal, Curtis; Leu, Cheng-Shiun; Marzinke, Mark A; Hendrix, Craig W; Piper, Jeanna M; Richardson, Barbra A; Grossman, Cynthia; Johnson, Sherri; Gomez, Kailazarid; Horn, Stephanie; Kunjara Na Ayudhya, Ratiya Pamela; Patterson, Karen; Jacobson, Cindy; Bekker, Linda-Gail; Chariyalertsak, Suwat; Chitwarakorn, Anupong; Gonzales, Pedro; Holtz, Timothy H; Liu, Albert; Mayer, Kenneth H; Zorrilla, Carmen; Lama, Javier; McGowan, Ian; Cranston, Ross D	High levels of adherence to a rectal microbicide gel and to oral Pre-Exposure Prophylaxis (PrEP) achieved in MTN-017 among men who have sex with men (MSM) and transgender women.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0181607	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5531503	Trials to assess microbicide safety require strict adherence to prescribed regimens. If adherence is suboptimal, safety cannot be adequately assessed. MTN-017 was a phase 2, randomized sequence, open-label, expanded safety and acceptability crossover study comparing 1) daily oral emtricitabine/tenofovir disoproxil fumarate (FTC/TDF), 2) daily use of reduced-glycerin 1% tenofovir (RG-TFV) gel applied rectally, and 3) RG-TFV gel applied before and after receptive anal intercourse (RAI)-if participants had no RAI in a week, they were asked to use two doses of gel within 24 hours. Product use was assessed by mixed methods including unused product return count, text messaging reports, and qualitative plasma TFV pharmacokinetic (PK) results. Convergence interviews engaged participants in determining the most accurate number of doses used based on product count and text messaging reports. Client-centered adherence counseling was also used. Participants (N = 187) were men who have sex with men and transgender women enrolled in the United States (42%), Thailand (29%), Peru (19%) and South Africa (10%). Mean age was 31.4 years (range 18-64 years). Based on convergence interviews, over an 8-week period, 94% of participants had ≥80% adherence to daily tablet, 41% having perfect adherence; 83% had ≥80% adherence to daily gel, 29% having perfect adherence; and 93% had ≥80% adherence to twice-weekly use during the RAI-associated gel regimen, 75% having perfect adherence and 77% having ≥80% adherence to gel use before and after RAI. Only 4.4% of all daily product PK results were undetectable and unexpected (TFV concentrations <0.31 ng/mL) given self-reported product use near sampling date. The mixed methods adherence measurement indicated high adherence to product use in all three regimens. Adherence to RAI-associated rectal gel use was as high as adherence to daily oral PrEP. A rectal microbicide gel, if efficacious, could be an alternative for individuals uninterested in daily oral PrEP. Article	2017	Carballo-Diéguez, Alex; Giguere, Rebecca; Dolezal, Curtis; Leu, Cheng-Shiun; Balán, Iván C; Brown, William; Rael, Christine; Richardson, Barbra A; Piper, Jeanna M; Bekker, Linda-Gail; Chariyalertsak, Suwat; Chitwarakorn, Anupong; Gonzales, Pedro; Holtz, Timothy H; Liu, Albert; Mayer, Kenneth H; Zorrilla, Carmen D; Lama, Javier R; McGowan, Ian; Cranston, Ross D	Preference of Oral Tenofovir Disoproxil Fumarate/Emtricitabine Versus Rectal Tenofovir Reduced-Glycerin 1% Gel Regimens for HIV Prevention Among Cisgender Men and Transgender Women Who Engage in Receptive Anal Intercourse with Men.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-017-1969-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5856109	Oral pre-exposure prophylaxis (PrEP) can prevent HIV transmission. Yet, some may prefer not to take systemic daily medication. MTN-017 was a 3-period, phase 2 safety and acceptability study of microbicide gel applied rectally either daily or before and after receptive anal intercourse (RAI), compared to daily oral tablet. At baseline, cisgender men and transgender women who reported RAI (N = 187) rated the daily oral regimen higher in overall liking, ease of use, and likelihood of future use than the gel regimens. After trying all three, 28% liked daily oral the least. Gel did not affect sexual enjoyment (88%) or improved it (7-8%). Most partners had no reaction to gel use. Ease of gel use improved significantly between the first and the last few times of daily use. A rectal gel used before and after RAI may constitute an attractive alternative to daily tablet. Experience with product use may increase acceptability.	acceptability, gel, PrEP, microbicide, rectal	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Book Section	2017	Carnes N.A.; Malone J.; Helms J.	HIV prevention: Treatment as prevention (TasP), Occupational Postexposure Prophylaxis (oPEP), Nonoccupational Postexposure Prophylaxis (nPEP), and Pre-exposure Prophylaxis (PrEP)	-	HIV/AIDS in Rural Communities: Research, Education, and Advocacy	-	978-331956239-1	-	10.1007/978-3-319-56239-1_5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055160334&doi=10.1007%2f978-3-319-56239-1_5&partnerID=40&md5=7b94e3ae8aae34bab0e7963bb06748a8	In this chapter, we review selected literature reflecting on biomedical interventions that prevent HIV infection, and regarding treatment as prevention (TasP), also assist those living with HIV given its goal to effectively reduce infectivity by reducing people living with HIV's viral load to an undetectable level. Unfortunately, in context to rural health care, little empirical data exists on these interventions, as standalone or combined approaches. What we know about TasP, occupational postexposure prophylaxis (oPEP), nonoccupational postexposure prophylaxis (nPEP), and pre-exposure prophylaxis (PrEP) is that they work, at least in clinical trials they worked. Theoretically, each poses significant potential to reduce HIV transmissions in all geographical settings. Realizing their potential in real-world settings, including rural areas, will require more resources that have yet to be allocated for large-scale implementation, especially concerning nPEP and PrEP. Ideally, our response system should consider developing integrated approaches that include all these interventions, in all jurisdictions. All the more critical, it will be essential to mobilize biomedical (e.g. medications and condoms), behavioral (e.g. cleaning needles prior to use or not sharing needles), and structural (e.g. eliminating stigma attached to HIV infection) interventions to achieve large-scale HIV prevention. In sum, since the discovery of HIV over three and a half decades ago, we have gained considerable knowledge that can and has improved our efforts to prevent (and treat) HIV. Now is the time to make this knowledge work to our advantage with a vision to end HIV transmissions. Whether TDF-containing antiretroviral therapy (ART) reduces HSV-2 acquisition is unknown. Design: Secondary analysis of AIDS Clinical Trials Group A5175, a randomized, open-label study of 3 ART regimens among 1571 participants. Methods: HSV-2 serostatus was assessed at baseline, at study exit, and before a change in ART regimen. Results: Of 365 HSV-2-seronegative persons, 68 acquired HSV-2, with 24 receiving TDF-containing ART and 44 receiving ART without TDF (HSV-2 seroconversion incidence, 6.42 and 6.63 cases/100 person-years, respectively; hazard ratio, 0.89; 95% confidence interval, .55-1.44). Conclusions: HSV-2 acquisition was not reduced in HIV-infected, HSV-2-uninfected persons during TDF-containing ART. Article	2017	Cerdeira C.R.; Blanco E. S.; Blanco B. S.; Gregorio M. C.	Sexually transmitted infections in the PReP Era. are family doctors ready to give advice?	Open Dermatology Journal	-	-	-	18743722	10.2174/1874372201711010035	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85043772712&doi=10.2174%2f1874372201711010035&partnerID=40&md5=1c9dd4ffe9bdabd91ded7de40c62d9ce	Background: Pre-exposure prophylaxis (PrEP) for human immunodeficiency virus (HIV) as a method of HIV prevention is not without controversy, and there has been concern that it may lead its users to think that they no longer need other preventive measures such as condoms. Thus, healthcare providers are convinced that PrEP decreases condom use and increases sexually transmitted infections (STIs). This treatment has been studied in men who have sex with men, and men and women in heterosexual HIV-discordant couples, and heterosexual men and women. Objective: The objective of this study was to review the current state of evidence on the association of PrEP with condom use, the incidence of STIs, and the change in sexual behaviours in populations with risky practices. Materials and Methods: PubMed (National Center for Biotechnology Information, Bethesda, MD, USA), Science Direct (Elsevier Ltd., Oxford, UK), and Google Scholar (Google Inc., Mountain View, CA, USA) search engines were used during the study. We used the terms HIV, PrEP, sexually transmitted infections (STIs), MSM, condom, heterosexual men / women to search the databases. Results: Here, we present evidence that daily oral treatment is safe and effective in these populations studied, especially when medication adherence is high. STI testing should include extra-genital testing regardless of PrEP use to prevent health deficits and onward transmission. Conclusion: Despite this safety and efficacy, we strongly advise that patients continue to use condoms as a prophylactic measure against other sexually transmitted diseases. This update addresses the benefits and precautions that must be taken when establishing PrEP treatment, focusing mainly on family doctorswho are best positioned to provide follow-up and advice to patients and their relatives. © 2017 Rodríguez Cerdeira et al. Article	2017	Chan, Chi N; Trinité, Benjamin; Levy, David N	Potent Inhibition of HIV-1 Replication in Resting CD4 T Cells by Resveratrol and Pterostilbene	Antimicrobial Agents and Chemotherapy	-	-	-	1098-6596	10.1128/AAC.00408-17	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5571302	HIV-1 infection of resting CD4 T cells plays a crucial and numerically dominant role during virus transmission at mucosal sites and during subsequent acute replication and T cell depletion. Resveratrol and pterostilbene are plant stilbenoids associated with several health-promoting benefits. Resveratrol has been shown to inhibit the replication of several viruses, including herpes simplex viruses 1 and 2, papillomaviruses, severe acute respiratory syndrome virus, and influenza virus. Alone, resveratrol does not inhibit HIV-1 infection of activated T cells, but it does synergize with nucleoside reverse transcriptase inhibitors in these cells to inhibit reverse transcription. Here, we demonstrate that resveratrol and pterostilbene completely block HIV-1 infection at a low micromolar dose in resting CD4 T cells, primarily at the reverse transcription step. The anti-HIV effect was fully reversed by exogenous deoxynucleosides and Vpx, an HIV-1 and simian immunodeficiency virus protein that increases deoxynucleoside triphosphate (dNTP) levels. These findings are consistent with the reported ability of resveratrol to inhibit ribonucleotide reductase and to lower dNTP levels in cells. This study supports the potential use of resveratrol, pterostilbene, or related compounds as adjuvants in anti-HIV preexposure prophylaxis (PrEP) formulations.	resting CD4 T cells, human immunodeficiency virus, pterostilbene, resveratrol, reverse transcription, stilbenoid, PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Chard, Anna N; Metheny, Nicholas; Stephenson, Rob	Perceptions of HIV Seriousness, Risk, and Threat Among Online Samples of HIV-Negative Men Who Have Sex With Men in Seven Countries.	JMIR Public Health and Surveillance	-	-	-	2369-2960	10.2196/publichealth.7546	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5497068	BACKGROUND: Rates of new HIV infections continue to increase worldwide among men who have sex with men (MSM). Despite effective prevention strategies such as condoms and pre-exposure prophylaxis (PrEP), low usage of both methods in many parts of the world hinder prevention efforts. An individual's perceptions of the risk of acquiring HIV and the seriousness they afford to seroconversion are important drivers of behavioral risk-taking. Understanding the behavioral factors suppressing the uptake of HIV prevention services is a critical step in informing strategies to improve interventions to combat the ongoing HIV pandemic among MSM. OBJECTIVE: The study aimed to examine cross-national perceptions of HIV/AIDS seriousness, risk, and threat and the association between these perceptions and sociodemographic characteristics, relationships, and high-risk sexual behaviors among MSM. METHODS: Participants in Australia, Brazil, Canada, Thailand, South Africa, the United Kingdom, and the United States were recruited for a self-administered survey via Facebook (N=1908). Respondents were asked to rate their perceived seriousness from 1 (not at all serious) to 5 (very serious) of contracting HIV, their perceived risk from 1 (no risk) to 10 (very high risk) of contracting HIV based on their current behavior, and their perception of the threat of HIV-measured as their confidence in being able to stay HIV-negative throughout their lifetimes-on a scale from 1 (will not have HIV by the end of his lifetime) to 5 (will have HIV by the end of his lifetime). Covariates included sociodemographic factors, sexual behavior, HIV testing, drug use, and relationship status. Three ordered logistic regression models, one for each outcome variable, were fit for each country. RESULTS: Contracting HIV was perceived as serious (mean=4.1-4.6), but perceptions of HIV risk (mean=2.7-3.8) and threat of HIV (mean=1.7-2.2) were relatively low across countries. Older age was associated with significantly lower perceived seriousness of acquiring HIV in five countries (Australia: odds ratio, OR 0.97, 95% CI 0.94-0.99; Brazil: OR 0.95, 95% CI 0.91-0.98; Canada: OR 0.96, 95% CI 0.93-0.98; South Africa: OR 0.96, 95% CI 0.94-0.98; United Kingdom: OR 0.95, 95% CI 0.92-0.98). Being in a male-male sexual relationship was associated with significantly lower perceived risk of HIV in four countries (Australia: OR 0.47, 95% CI 0.30-0.75; Canada: OR: 0.54, 95% CI 0.35-0.86; United Kingdom: OR 0.38, 95% CI 0.24-0.60; United States: OR 0.5, 95% CI 0.31-0.82). Drug use in the previous year was associated with greater threat of contracting HIV in two countries (Canada: OR 1.81, 95% CI 1.13-2.91; United Kingdom: OR 1.7, 95% CI 1.06-2.74). CONCLUSIONS: Few measures of behavioral or sexual risk-taking were significantly associated with perceived HIV seriousness, risk, or threat across countries. Overall, low levels of reported risk were identified, and results illustrate important gaps in the understanding of risk among MSM across societies that could be addressed through culturally-tailored prevention messaging. Hepatitis a outbreak in HIV-infected MSM and in PrEP-using MSM despite a high level of immunity, Lyon, France, January to June 2017	Eurosurveillance	-	-	-	1025496X	10.2807/1560-7917.ES.2017.22.48.17-00742	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037335232&doi=10.2807%2f1560-7917.ES.2017.22.48.17-00742&partnerID=40&md5=c8a19e44a4ea130cee3de679459e7420	Since 2016, an increase in the number of hepatitis A cases affecting mainly men who have sex with men (MSM) has been reported in low endemic countries in Europe. We calculated the attack rate in Lyon, France, in populations considered at high-risk: HIV-infected MSM and HIV-negative MSM receiving HIV pre-exposure prophylaxis (PrEP). In these populations, high level of immunity did not prevent the outbreak, indicating that vaccination should be reinforced, particularly in younger individuals. © 2017, European Centre for Disease Prevention and Control (ECDC). Article	2017	Chen, Iris; Zhang, Yinfeng; Cummings, Vanessa; Cloherty, Gavin A; Connor, Matthew; Beauchamp, Geetha; Griffith, Sam; Rose, Scott; Gallant, Joel; Scott, Hyman M; Shoptaw, Steven; Del Rio, Carlos; Kuo, Irene; Mannheimer, Sharon; Tieu, Hong-Van; Hurt, Christopher B; Fields, Sheldon D; Wheeler, Darrell P; Mayer, Kenneth H; Koblin, Beryl A; Eshleman, Susan H	Analysis of HIV Integrase Resistance in Black Men Who Have Sex with Men in the United States.	AIDS Research and Human Retroviruses	-	-	-	1931-8405	10.1089/aid.2017.0005	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5512295	Resistance to reverse transcriptase and protease inhibitors was frequently detected in HIV from black men who have sex with men (MSM) enrolled in the HIV prevention trials network (HPTN) 061 study. In this study, integrase strand transfer inhibitor (INSTI) resistance was analyzed in black MSM enrolled in HPTN 061 (134 infected at enrollment and 23 seroconverters) and a follow-up study, HPTN 073 (eight seroconverters). The ViroSeq HIV-1 Integrase Genotyping Kit (Abbott Molecular) was used for analysis. Major INSTI resistance mutations were not detected in any of the samples. HIV from 14 (8.4%) of the 165 men, including 4 (12.9%) of 31 seroconverters, had accessory or polymorphic INSTI-associated mutations. The most frequently detected mutation was E157Q. These findings are promising because INSTI-based regimens are now recommended for first-line antiretroviral treatment and because long-acting cabotegravir is being evaluated for pre-exposure prophylaxis.	: HIV integrase, integrase inhibitor, drug resistance, men who have sex with men	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Chen, Yea-Hung; McFarland, Willi; Raymond, Henry F; Scott, Hyman M; Vittinghoff, Eric; Porco, Travis C	Distribution of Behavioral Patterns Before Infection Among San Francisco Men Who Have Sex With Men Newly Infected With HIV in 2014.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001439	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5649625	BACKGROUND: Despite continued reductions in the number of HIV cases reported among San Francisco men who have sex with men (MSM) and the HIV-prevention potential offered by pharmaceutical tools such as pre-exposure prophylaxis (PrEP), there are uncertainties, particularly given reported decreases in consistent condom use. A key uncertainty is what groups of MSM should be targeted. This study estimates the distribution of behavioral patterns before infection among San Francisco MSM newly infected with HIV in 2014. METHODS: We used a novel modeling approach. The approach uses estimates from the National HIV Behavioral Surveillance System for MSM, the Medical Monitoring Project, 2 trials of PrEP, and a meta-analysis of per-act risks of HIV infection. RESULTS: The modeling study suggests that 76% of newly HIV-infected MSM in 2014 were individuals with no discernible strategy in the 6 months before infection: that is, they had condomless receptive anal intercourse with one or more partners not perceived to be HIV uninfected. An estimated 7% of newly infected MSM were serosorters before infection. CONCLUSIONS: Prevention efforts in San Francisco must reach HIV-uninfected MSM with no discernible behavioral strategy, a group that constitutes 8% of HIV-uninfected MSM in the city. Our study suggests that if all HIV-uninfected, San Francisco MSM with no discernible strategy had been on PrEP in 2014, there would have been 70% fewer HIV infections among San Francisco MSM. Uncertainty analysis suggests that PrEP's impact may be maximized by encouraging PrEP persistence and concomitant reductions in sexual risk behaviors. Theses and Dissertations	2017	Christianson, Adam	The Mutable Dynamics of HIV-Prevention: Insights from Ontarian MSM on Pre-Exposure Prophylaxis (PrEP)	-	-	Carleton University	-	-	NA	https://repository.library.carleton.ca/concern/etds/76537215t	Pre-exposure prophylaxis or "PrEP," is a cluster of methods that keep HIV-negative persons from contacting the virus. Effectively PrEP allows members of "high risk" communities a form of immunity against the virus. This thesis examines how PrEP is interpreted by men who have sex with men (MSM) PrEP users and non-users from south-east Ontario. Comparing the accounts of MSM users and interested non-users of PrEP, I examine barriers to implementation and how PrEP interacts with established methods of sexual hygiene and prophylactic preference. I examine how HIV-stigma is challenged by PrEP and challenges PrEP's viability as a technology. I discuss how a successful implementation of PrEP as a mainstay of HIV prevention technologies stands to significantly impact HIV stigma and allows for forms of intimacy not afforded by current HIV technologies or safer sex practices. Article	2017	Coleman, Rosalind; Prins, Maria	Options for affordable pre-exposure prophylaxis (PrEP) in national HIV prevention programmes in Europe	Eurosurveillance	-	-	-	1025496X	10.1071/SH18147	https://www.proquest.com/scholarly-journals/options-affordable-pre-exposure-prophylaxis-prep/docview/1980993170/se-2?accountid=8113	Coleman and Prins offer options for affordable pre-exposure prophylaxis (PrEP) in national HIV prevention programmes in Europe. Such programmes can enable and motivate people with a high risk of HIV infection to come for testing, encourage those who test negative to consider PrEP, support their effective adherence and deliver collateral benefits such as increased screening and treatment of other sexually transmitted infections (STIs). All PrEP programmes need to address persistent barriers and doubts including the need for an estimate of the number of people eligible for PrEP, the price of the PrEP medication, the risk of drug resistance, a potential increase in STI diagnoses via risk compensation and increased testing, achieving effective adherence to PrEP and limited engagement with PrEP by certain members of key populations and certain healthcare providers. Article	2017	Collier, Kate L.; Colarossi, Lisa G.; Sanders, Kim	Raising Awareness of Pre-Exposure Prophylaxis (PrEP) among Women in New York City: Community and Provider Perspectives	Journal of Health Communication	-	-	-	10810730	10.1080/10810730.2016.1261969	https://www.proquest.com/scholarly-journals/raising-awareness-pre-exposure-prophylaxis-prep/docview/1873376531/se-2?accountid=8113	This study explored the knowledge, attitudes, and perceived facilitators and barriers to adoption of HIV pre-exposure prophylaxis (PrEP) among black women and Latinas in the Bronx, NY. Data were collected in focus group discussions (FGDs) held separately with staff (n = 21) and black and Latina female clients aged 18 to 50 (n = 23) of four organizations providing health and social services. Participants were also asked to give feedback about four action messages regarding PrEP for a social marketing campaign. Transcripts were analyzed by two researchers using grounded theory. We found that the majority of clients (74%) and staff (57%) had not heard about PrEP before participating in the FGDs. Following brief educational messaging about PrEP, participants identified potential facilitators and barriers to PrEP uptake among women, and expressed enthusiasm for more widespread efforts to raise awareness about PrEP as an HIV prevention option. Participants preferred an action message that was brief, referred to PrEP as a pill, and did not mention condoms or STD testing. These findings demonstrate the need to raise awareness about PrEP among women and build the capacity of women-serving organizations to educate, screen, and refer or provide PrEP services. Article	2017	Collins, Shane P.; McMahan, Vanessa M.; Stekler, Joanne D.	The Impact of HIV Pre-exposure Prophylaxis (PrEP) Use on the Sexual Health of Men Who Have Sex with Men: A Qualitative Study in Seattle, WA	International Journal of Sexual Health	-	-	-	19317611	10.1080/19317611.2016.1206051	https://www.proquest.com/scholarly-journals/impact-hiv-pre-exposure-prophylaxis-prep-use-on/docview/1870005577/se-2?accountid=8113	This study explores the impacts of HIV pre-exposure prophylaxis (PrEP) use on the sexual health of men who have sex with men (MSM). The authors conducted in-depth interviews with MSM who use PrEP (n = 14). Data was analyzed using interpretative phenomenological analysis. PrEP use reduced fear and shame associated with sex and facilitated greater sexual satisfaction and intimacy. Although participants generally viewed PrEP as empowering and beneficial, they also experienced PrEP-related stigma. The authors' analysis emphasizes the importance of understanding the reasons MSM use PrEP and highlights opportunities for reducing harm and fostering sexual health among MSM who are using or considering PrEP. Article	2017	Copeland, Raniyah M; Wilson, Phill; Betancourt, Gabriela; Garcia, David; Penner, Murray; Abravanel, Rebecca; Wong, Eric Y; Parisi, Lori D	Disparities in HIV knowledge and attitudes toward biomedical interventions among the non-medical HIV workforce in the United States.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2017.1317323	https://dx.doi.org/10.1080/09540121.2017.1317323	Non-medical, community-based workers play a critical role in supporting people living with (or at risk of acquiring) HIV along the care continuum. The biomedical nature of promising advances in HIV prevention, such as pre-exposure prophylaxis and treatment-as-prevention, requires frontline workers to be knowledgeable about HIV science and treatment. This study was developed to: measure knowledge of HIV science and treatment within the HIV non-medical workforce, evaluate workers' familiarity with and attitudes toward recent biomedical interventions, and identify factors that may affect HIV knowledge and attitudes. A 62-question, web-based survey was completed in English or Spanish between 2012 and 2014 by 3663 US-based employees, contractors, and volunteers working in AIDS service organizations, state/local health departments, and other community-based organizations in a non-medical capacity. Survey items captured the following: respondent demographics, HIV science and treatment knowledge, and familiarity with and attitudes toward biomedical interventions. An average of 61% of HIV knowledge questions were answered correctly. Higher knowledge scores were associated with higher education levels, work at organizations that serve people living with HIV/AIDS or who are at a high risk of acquiring HIV, and longer tenure in the field. Lower knowledge scores were associated with non-Hispanic Black or Black race/ethnicity and taking the survey in Spanish. Similarly, subgroup analyses showed that respondents who were non-Hispanic Black or Hispanic (versus non-Hispanic white), as well as those located in the South (versus other regions) scored significantly lower. These subpopulations were less familiar with and had less positive attitudes toward newer biomedical prevention interventions. Respondents who took the survey in Spanish (versus English) had lower knowledge of, but generally less positive attitudes toward, biomedical interventions. In summary, low knowledge scores suggest the need for additional capacity-building efforts and training for non-medical HIV workers, particularly those who provide services in the communities most affected by HIV.	:VIH/SIDAenquetetrabalhadoresconhecimentointervenções biomédicasatitudes	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Corado, Katya C; Daar, Eric S	Emtricitabine + tenofovir alafenamide for the treatment of HIV.	Expert Opinion on Pharmacotherapy	-	-	-	1744-7666	10.1080/14656566.2017.1288720	https://dx.doi.org/10.1080/14656566.2017.1288720	INTRODUCTION: Tenofovir alafenamide is a new oral prodrug of tenofovir resulting in relatively low plasma levels and rapid uptake into peripheral blood mononuclear cells in its active form. The United States Food and Drug Administration has now approved this drug coformulated with elvitegravir/cobicistat/emtricitabine, rilpivirine/emtricitabine and emtricitabine. United States guidelines now list this formulation as one of the preferred components of a variety of antiretroviral regimens, and is included as an alternative in other international guidelines, with the notable exception of the World Health Organization, mostly due to limited availability. Areas covered: This review covers pre-clinical and clinical data searched through PubMedà up to August 2016. Expert opinion: Tenofovir alafenamide is effective as part of an antiretroviral regimen. There is also compelling data that it has less adverse effects on bone mineral density and possibly kidneys than tenofovir disoproxil fumarate. Although approved for use in those with estimated glomerular filtration rates as low as 30 mL/min, data is somewhat limited in this group. While there are few reasons to not use tenofovir alafenamide as a substitute for tenofovir disoproxil fumarate, the former should not be used with rifamycins, is not yet recommended in pregnancy and needs to be studied further before it can be considered as part of a pre-exposure prophylaxis regimen.	: Antiretroviral therapy; Integrase strand transfer inhibitor; Long-term; Renal safety; Bone safety	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2017	Coulibaly, Fohona S.; Ezoulin, Miezan J. M.; Purohit, Sudhaunshu S.; Ayon, Navid J.; Oyler, Nathan A.; Youan, Bi-Botti C.	Layer-by-Layer Engineered Microbicide Drug Delivery System Targeting HIV-1 gp120: Physicochemical and Biological Properties.	Molecular Pharmaceutics	-	-	-	1543-8392 1543-8384	10.1021/acs.molpharmaceut.7b00555	https://pubmed.ncbi.nlm.nih.gov/28830144/	The purpose of this study was to engineer a model anti-HIV microbicide (tenofovir) drug delivery system targeting HIV-1 envelope glycoprotein gp120 (HIV-1 g120) for the prevention of HIV sexual transmission. HIV-1 g120 and mannose responsive particles (MRP) were prepared through the layer-by-layer coating of calcium carbonate (CaCO(3)) with concanavalin A (Con A) and glycogen. MRP average particle size ranged from 881.7 ± 15.45 nm to 1130 ± 15.72 nm, depending on the number of Con A layers. Tenofovir encapsulation efficiency in CaCO(3) was 74.4% with drug loading of 16.3% (w/w). MRP was non-cytotoxic to Lactobacillus crispatus, human vaginal keratinocytes (VK2), and murine macrophage RAW 264.7 cells and did not induce any significant proinflammatory nitric oxide release. Overall, compared to control, no statistically significant increase in proinflammatory cytokine IL-1α, IL-1β, IL-6, MKC, IL-7, and interferon γ-inducible protein 10 (IP10) levels was observed. Drug release profiles in the presence of methyl α-d-mannopyranoside and recombinant HIV-1 envelope glycoprotein gp120 followed Hixson-Crowell and Hopfenberg kinetic models, indicative of a surface-eroding system. The one Con A layer containing system was found to be the most sensitive (∼2-fold increase in drug release vs control SFS:VFS) at the lowest HIV gp120 concentration tested (25 μg/mL). Percent mucoadhesion, tested ex vivo on porcine vaginal tissue, ranged from 10% to 21%, depending on the number of Con A layers in the formulation. Collectively, these data suggested that the proposed HIV-1 g120 targeting, using MRP, potentially represent a safe and effective template for vaginal microbicide drug delivery, if future preclinical studies are conclusive. Article	2017	Coutinho, Catarina; Sarmento, Bruno; das Neves, José	Targeted microbicides for preventing sexual HIV transmission.	Journal of Controlled Release	-	-	-	1873-4995	10.1016/j.jconrel.2017.09.030	https://dx.doi.org/10.1016/j.jconrel.2017.09.030	Sexual transmission remains one of the most significant hurdles in the fight against HIV infection. The use of vaginal or rectal microbicides has been proposed for topical pre-exposure prophylaxis but available results from clinical trials of candidate products have been, at best, less than optimal. While waiting for the first product to get regulatory approval, novel approaches are being explored in order to enhance efficacy, as well as to assure safety. Strategies involving specific delivery of antiviral agents to key players involved in the early steps of sexual transmission have the potential to help achieving such purposes. Engineering systems that allow targeting cells, tissues or other biological structures of interest may provide a way to modulate local pharmacokinetics of promising microbicide molecules and, thus, maximize protection. This concise review discusses the identification and use of potential targets for such purpose, while detailing on several examples of targeted systems engineered as potential microbicide candidates. Furthermore, remaining challenges and hints for future work in the field of targeted microbicides are addressed.	Drug carriers; Drug delivery; Drug targeting; Nanomedicine; Pre-exposure prophylaxis. Article	2017	Cremin I.; McKinnon L.; Kimani J.; Cherutich P.; Gakii G.; Muriuki F.; Kripke K.; Hecht R.; Kiragu M.; Smith J.; Hinsley W.; Gelmon L.; Hallett T.B.	PrEP for key populations in combination HIV prevention in Nairobi: a mathematical modelling study	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(17)30021-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85013490497&doi=10.1016%2fS2352-3018%2817%2930021-8&partnerID=40&md5=456440306ad3794cbee6812e8344a682	Background The HIV epidemic in the population of Nairobi as a whole is in decline, but a concentrated sub-epidemic persists in key populations. We aimed to identify an optimal portfolio of interventions to reduce HIV incidence for a given budget and to identify the circumstances in which pre-exposure prophylaxis (PrEP) could be used in Nairobi, Kenya. Methods A mathematical model was developed to represent HIV transmission in specific key populations (female sex workers, male sex workers, and men who have sex with men MSM) and among the wider population of Nairobi. The scale-up of existing interventions (condom promotion, antiretroviral therapy, and male circumcision) for key populations and the wider population as have occurred in Nairobi is represented. The model includes a detailed representation of a PrEP intervention and is calibrated to prevalence and incidence estimates specific to key populations and the wider population. Findings In the context of a declining epidemic overall but with a large sub-epidemic in MSM and male sex workers, an optimal prevention portfolio for Nairobi should focus on condom promotion for male sex workers and MSM in particular, followed by improved antiretroviral therapy retention, earlier antiretroviral therapy, and male circumcision as the budget allows. PrEP for male sex workers could enter an optimal portfolio at similar levels of spending to when earlier antiretroviral therapy is included; however, PrEP for MSM and female sex workers would be included only at much higher budgets. If PrEP for male sex workers cost as much as US$500, average annual spending on the interventions modelled would need to be less than $3·27 million for PrEP for male sex workers to be excluded from an optimal portfolio. Estimated costs per infection averted when providing PrEP to all female sex workers regardless of their risk of infection, and to high-risk female sex workers only, are $65 160 (95% credible interval CrI $43 520–$90 250) and $10 920 (95% CrI $4700–$51 560), respectively. Interpretation PrEP could be a useful contribution to combination prevention, especially for under-served key populations in Nairobi. An ongoing demonstration project will provide important information regarding practical aspects of implementing PrEP for key populations in this setting. Article	2017	Cressey, Tim R; Siriprakaisil, Oraphan; Klinbuayaem, Virat; Quame-Amaglo, Justice; Kubiak, Rachel W; Sukrakanchana, Pra-Ornsuda; Than-In-At, Kanchana; Baeten, Jared; Sirirungsi, Wasna; Cressey, Ratchada; Drain, Paul K	A randomized clinical pharmacokinetic trial of Tenofovir in blood, plasma and urine in adults with perfect, moderate and low PrEP adherence: the TARGET study.	BMC Infectious Diseases	-	-	-	1471-2334	10.1186/s12879-017-2593-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5513124	BACKGROUND: Tenofovir disoproxil fumarate (TDF) is key component of pre-exposure prophylaxis (PrEP) and antiretroviral therapy (ART) for HIV, but existing tools to monitor drug adherence are often inaccurate. Detection of tenofovir (TFV) in accessible biological samples, such as fingerprick blood, urine or oral fluid samples could be a novel objective measure of recent TDF adherence. To measure TFV concentrations associated with different levels of TDF adherence, we designed a randomized clinical trial to assess the blood, urine and oral fluid concentrations of TFV in adults with perfect, moderate and low drug adherence. METHODS/DESIGN: A randomized, open-label, clinical pharmacokinetic study of tenofovir in healthy adult volunteers without HIV or Hepatitis B infection in Thailand. Consenting, eligible participants are randomized (1:1:1) among three groups to receive a controlled number of TDF (300 mg) doses in a combination pill with emtricitabine (FTC, 200 mg) for six weeks. Participants in Group 1 receive a single TDF/FTC tablet once daily (Perfect adherence); Group 2 receive a single TDF/FTC tablet 4 times/week (Moderate adherence); and Group 3 receive a single TDF/FTC tablet 2 times/week (Low adherence). Blood, plasma, urine and oral fluid samples are collected for drug measurement during three study phases: (i) initial 6-week treatment phase; (ii) intensive 24-h blood sampling phase after 6 weeks; (iii) 4-week washout phase. Thirty adults with evaluable pharmacokinetic samples (10 per group) will be enrolled based on ensuring 25% precision in pharmacokinetic parameter estimates. Pre-dose drug concentrations during the treatment phase will be descriptive and comparisons between groups performed using a Kruskal-Wallis test. A non-compartmental pharmacokinetic analysis will be performed on the intensive sampling data at Week 7 and the time course of TFV washout in the difference biological matrices will be reported based on the detected concentrations following drug cessation. DISCUSSION: The results of this randomized trial will define the target concentration thresholds of TFV in blood, urine and oral fluid that can distinguish between different levels of TDF adherence. Such adherence 'benchmarks' can be applied to real-time drug testing and novel point-of-care tests to identify individuals with poor PrEP or ART adherence. Article	2017	Crosby, Richard A.	Dealing with pre-exposure prophylaxis-associated condom migration: changing the paradigm for men who have sex with men.	Sexual Health	-	-	-	1448-5028	10.1071/SH16128	https://pubmed.ncbi.nlm.nih.gov/27585107/	The behavioural aspects of pre-exposure prophylaxis (PrEP) are challenging, particularly the issue of condom migration. Three vital questions are: (1) at the population-level, will condom migration lead to increases in non-viral sexually transmissible infections?; (2) how can clinic-based counselling best promote the dual use of condoms and PrEP?; and (3) in future PrEP trials, what are the 'best practices' that should be used to avoid type 1 and type 2 errors that arise without accounting for condom use behaviours? This communication piece addresses each question and suggests the risk of a 'PrEP only' focus to widening health disparities.	*Homosexuality, Male; Humans; Male; Patient Compliance; HIV Infections/*prevention & control; Risk Reduction Behavior; Risk-Taking; Sexual Behavior; Sexual Partners; Health Knowledge, Attitudes, Practice; *Condoms; Sexually Transmitted Diseases, Viral/*prevention & control; *Pre-Exposure Prophylaxis; *Bisexuality	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review

Article	2017	Curlin, Marcel E; Gvetadze, Roman; Leelawiwat, Wanna; Martin, Michael; Rose, Charles; Niska, Richard W; Segolodi, Tebogo M; Choopanya, Kachit; Tongtoyai, Jaray; Holtz, Timothy H; Samandari, Taraz; McNicholl, Janet M	Analysis of False-Negative Human Immunodeficiency Virus Rapid Tests Performed on Oral Fluid in 3 International Clinical Research Studies.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/cix228	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6502462	BACKGROUND.: The OraQuick Advance Rapid HIV-1/2 Test is a point-of-care test capable of detecting human immunodeficiency virus (HIV)-specific antibodies in blood and oral fluid. To understand test performance and factors contributing to false-negative results in longitudinal studies, we examined results of participants enrolled in the Botswana TDF/FTC Oral HIV Prophylaxis Trial, the Bangkok Tenofovir Study, and the Bangkok MSM Cohort Study, 3 separate clinical studies of high-risk, HIV-negative persons conducted in Botswana and Thailand. METHODS.: In a retrospective observational analysis, we compared oral fluid OraQuick (OFOQ) results among participants becoming HIV infected to results obtained retrospectively using enzyme immunoassay and nucleic acid amplification tests on stored specimens. We categorized negative OFOQ results as true-negative or false-negative relative to nucleic acid amplification test and/or enzyme immunoassay, and determined the delay in OFOQ conversion relative to the estimated time of infection. We used log-binomial regression and generalized estimating equations to examine the association between false-negative results and participant, clinical, and testing-site factors. RESULTS.: Two-hundred thirty-three false-negative OFOQ results occurred in 80 of 287 seroconverting individuals. Estimated OFOQ conversion delay ranged from 14.5 to 547.5 (median, 98.5) days. Delayed OFOQ conversion was associated with clinical site and test operator (P < .05), preexposure prophylaxis (P = .01), low plasma viral load (P < .02), and time to kit expiration (P < .01). Participant age, sex, and HIV subtype were not associated with false-negative results. Long OFOQ conversion delay time was associated with antiretroviral exposure and low plasma viral load. CONCLUSIONS.: Failure of OFOQ to detect HIV-1 infection was frequent and multifactorial in origin. In longitudinal trials, negative oral fluid results should be confirmed via testing of blood samples. Article	2017	Cutrell A.; Donnell D.; Dunn D.T.; Glidden D.V.; Grobler A.; Hanscom B.; Stancil B.S.; Meyer R.D.; Wang R.; Cuffe R.L.	HIV prevention trial design in an era of effective pre-exposure prophylaxis	HIV Clinical Trials	-	-	-	15284336	10.1080/15284336.2017.1379676	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037979946&doi=10.1080%2f15284336.2017.1379676&partnerID=40&md5=51b6a5aa76975078bf871ba6fb916aff	Pre-exposure prophylaxis (PrEP) has demonstrated remarkable effectiveness protecting at-risk individuals from HIV-1 infection. Despite this record of effectiveness, concerns persist about the diminished protective effect observed in women compared with men and the influence of adherence and risk behaviors on effectiveness in targeted subpopulations. Furthermore, the high prophylactic efficacy of the first PrEP agent, tenofovir disoproxil fumarate/emtricitabine (TDF/FTC), presents challenges for demonstrating the efficacy of new candidates. Trials of new agents would typically require use of non-inferiority (NI) designs in which acceptable efficacy for an experimental agent is determined using pre-defined margins based on the efficacy of the proven active comparator (i.e. TDF/FTC) in placebo-controlled trials. Setting NI margins is a critical step in designing registrational studies. Under- or over-estimation of the margin can call into question the utility of the study in the registration package. The dependence on previous placebo-controlled trials introduces the same issues as external/historical controls. These issues will need to be addressed using trial design features such as re-estimated NI margins, enrichment strategies, run-in periods, crossover between study arms, and adaptive re-estimation of sample sizes. These measures and other innovations can help to ensure that new PrEP agents are made available to the public using stringent standards of evidence. © 2017 The Author(s). Article	2017	Davey, Dvora Joseph; Wall, Kristin M; Kilembe, William; Naw, Htee Khu; Brill, Ilene; Vwalika, Bellington; Chomba, Elwyn; Mulenga, Joseph; Tichacek, Amanda; Javanbakt, Marjan; Gorbach, Pamina M; Allen, Susan A	HIV Incidence and Predictors of HIV Acquisition From an Outside Partner in Serodiscordant Couples in Lusaka, Zambia.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001494	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5597474	OBJECTIVE: Evaluate the incidence and predictors of HIV acquisition from outside partners in serodiscordant couples. METHODS: Demographic, behavioral, and clinical exposures were measured quarterly in a cohort of serodiscordant cohabiting couples in Zambia from 1995 to 2012 (n = 3049). Genetic analysis classified incident infections as those acquired from the study partner (linked) or acquired from an outside partner (unlinked). Factors associated with time to unlinked HIV infection were evaluated using multivariable Cox proportional hazards regression stratified by sex. RESULTS: There were 100 unlinked infections in couples followed for a median of 806 days. Forty-five infections occurred in women 1.85/100 couple-years; 95% confidence interval (CI): 1.35 to 2.47. Risk of female unlinked infection (vs. nonseroconverting females) was associated with reporting being drunk weekly/daily vs. moderate/nondrinkers at baseline adjusted hazard ratio (aHR) = 5.44; 95% CI: 1.03 to 28.73, genital ulcers (aHR = 6.09; 95% CI: 2.72 to 13.64), or genital inflammation (aHR = 11.92; 95% CI: 5.60 to 25.37) during follow-up adjusting for age, years cohabiting, income, contraceptive use, previous pregnancies, history of sexually transmitted infections, and condomless sex with study partner. Fifty-five infections occurred in men (1.82/100 couple-years; 95% CI: 1.37 to 2.37). Risk of male unlinked infection was associated with genital inflammation (aHR = 8.52; 95% CI: 3.82 to 19.03) or genital ulceration (aHR = 2.31; 95% CI: 2.05 to 8.89), reporting ≥1 outside sexual partner (aHR = 3.86; 95% CI: 0.98 to 15.17) during follow-up, and reporting being drunk weekly/daily vs. moderate/nondrinkers at baseline (aHR = 3.84; 95% CI: 1.28 to 11.55), controlling for age, income, circumcision status, and history of sexually transmitted infection. CONCLUSIONS: Predictors of unlinked infection in serodiscordant relationships were alcohol use, genital inflammation, and ulceration. Causes of genital inflammation and ulceration should be screened for and treated in HIV-negative individuals. Counseling on risk of alcohol use and sex with outside partners should be discussed with couples where 1 or both are HIV-negative, including in counseling on use of pre-exposure prophylaxis to prevent HIV acquisition in the HIV-negative partner (when feasible and affordable).	serodiscordant, unlinked infection, couples, Zambia, HIV transmission, HIV acquisition	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	de Baetselier I.; Reyniers T.; Nöstlinger C.; Wouters K.; Fransen K.; Crucitti T.; Kenyon C.; Buyze J.; Schurmans C.; Laga M.; Vuylsteke B.	Pre-exposure prophylaxis (PrEP) as an additional tool for HIV prevention among men who have sex with men in Belgium: The be-prep-ared study protocol	JMIR Research Protocols	-	-	-	19290748	10.2196/resprot.6767	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85030761141&doi=10.2196%2fresprot.6767&partnerID=40&md5=bc7288951141495e1594bf65ab0b6f9b	Background: Pre-exposure prophylaxis (PrEP) is a promising and effective tool to prevent HIV. With the approval of Truvada as daily PrEP by the European Commission in August 2016, individual European Member states prepare themselves for PrEP implementation following the examples of France and Norway. However, context-specific data to guide optimal implementation is currently lacking. Objective: With this demonstration project we evaluate whether daily and event-driven PrEP, provided within a comprehensive prevention package, is a feasible and acceptable additional prevention tool for men who have sex with men (MSM) at high risk of acquiring HIV in Belgium. The study's primary objective is to document the uptake, acceptability, and adherence to both daily and event-driven PrEP, while several secondary objectives have been formulated including impact of PrEP use on sexual behavior. Methods: The Be-PrEP-ared study is a phase 3, single-site, open-label prospective cohort study with a large social science component embedded in the trial. A total of 200 participants choose between daily or event-driven PrEP use and may switch, discontinue, or restart their regimen at the 3-monthly visits for a duration of 18 months. Data are collected on several platforms: an electronic case report form, a Web-based tool where participants register their sexual behavior and pill use, a more detailed electronic self-administered questionnaire completed during study visits on a tablet computer, and in-depth interviews among a selected sample of participants. To answer the primary objective, the recruitment rate, (un)safe sex behavior during the last 6 months, percentage of reported intention to use PrEP in the future, retention rates in different regimens, and attitudes towards PrEP use will be analyzed. Adherence will be monitored using self-reported adherence, pill count, tenofovir drug levels in blood samples, and the perceived skills to adhere. Results: All participants are currently enrolled, and the last study visit is planned to take place around Q3 2018. Conclusions: As PrEP is not yet available in Belgium for use, this study will provide insights into how to optimally implement PrEP within the current health care provision and will shape national and European guidelines with regard to the place of PrEP in HIV prevention strategies. © Irith De Baetselier, Thijs Reyniers, Christiana Nöstlinger, Kristien Wouters, Katrien Fransen, Tania Crucitti, Chris Kenyon, Jozefien Buyze, Céline Schurmans, Marie Laga, Bea Vuylsteke, Be-PrEP-Ared Study Group. Article	2017	Deeks E.D.; Lyseng-Williamson K.; Plosker G.L.	Emtricitabine/tenofovir disoproxil fumarate in HIV-1 pre-exposure prophylaxis: a guide to its once-daily use in the EU	Drugs and Therapy Perspectives	-	-	-	11720360	10.1007/s40267-016-0363-9	https://link.springer.com/article/10.1007/s40267-016-0363-9	The fixed-dose combination of emtricitabine/tenofovir disoproxil fumarate (tenofovir DF) Truvada® is approved in the EU for pre-exposure prophylaxis, in conjunction with safer sex practices, to reduce the risk of sexually-acquired HIV-1 infection in adults at high risk. Once-daily administration of emtricitabine/tenofovir DF was effective in preventing HIV-1 infection in clinical trials in high-risk populations, including men who have sex with men, heterosexual HIV-1-serodiscordant couples, and heterosexual men and women. As adherence to the regimen correlates with the risk of HIV-1 infection, it is important that patient adhere to pre-exposure prophylaxis. Pre-exposure prophylaxis with the combination was generally well tolerated. © 2016, Springer International Publishing Switzerland. Article	2017	Delaugerre C.; Antoni G.; Mahjoub N.; Pialoux G.; Cua E.; Pasquet A.; Hall N.; Tremblay C.; Cotte L.; Capitant C.; Chaix M.-L.; Meyer L.; Molina J.-M.	Assessment of HIV screening tests for use in preexposure prophylaxis programs	Journal of Infectious Diseases	-	-	-	221899	10.1093/infdis/jix297	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029223683&doi=10.1093%2finfdis%2fjix297&partnerID=40&md5=5fd7b17f2b5780cd9cd1ada3f42a72d2	Preexposure prophylaxis programs involve frequent human immunodeficiency virus (HIV) testing. We evaluated the sensitivity of 2 antigen/antibody immunoassays (Architect and Bioplex), 2 antibody-based rapid tests (Vikia-HIV-1/2 and Autotest-VIH), and 1 antigen/antibody rapid test (Alere HIV Combo) for the diagnosis of HIV infection. Among the 31 HIV-1-infected participants in the ANRS-IPERGAY trial, HIV-1 RNA was detected alone in only 2. The sensitivities of the Architect and Bioplex assays were 83% (95% confidence interval CI, 76%-99%) and 82% (95% CI, 63%-94%), respectively. The sensitivities of the Vikia, Autotest, and Alere tests were 54% (95% CI, 34%-72%), 50% (95% CI, 31%-69%), and 78% (95% CI, 58%-91%), respectively. Antigen/antibody tests should be preferred to avoid missing cases of acute HIV infection and to decrease the related risks of viral transmission and emergence of drug resistance. © The Author 2017. Article	2017	Desai, Monica; Field, Nigel; Grant, Robert; McCormack, Sheena	Recent advances in pre-exposure prophylaxis for HIV	BMJ: British Medical Journal	-	-	-	na	10.1136/bmj.j5011	https://www.proquest.com/scholarly-journals/recent-advances-pre-exposure-prophylaxis-hiv/docview/1975474697/se-2?accountid=8113	Abstract Although pre-exposure prophylaxis (PrEP)-the use of antiretroviral drugs by non-infected people to prevent the acquisition of HIV-is a promising preventive option, important public health questions remain. Daily oral emtricitabine (FTC)-tenofovir disoproxil fumarate (TDF) is highly efficacious in preventing the acquisition of HIV in people at risk as a result of a range of different types of sexual exposure. There is good evidence of efficacy in women and men, and when men who have sex with men use event based dosing. Studies have been conducted in several countries and epidemics. Because adherence to this treatment varies greatly there are questions about its public health benefit. Oral FTC-TDF is extremely safe, with minimal impact on kidney, bone, or pregnancy outcomes, and there is no evidence that its effectiveness has been reduced by risk compensation during open label and programmatic follow-up. It is too early to assess the impact of this treatment on the incidence of sexually transmitted infections (STIs) at a population level. Many challenges remain. Access to pre-exposure prophylaxis is limited and disparities exist, including those governed by race and sex. Different pricing and access models need to be explored to avoid further widening inequalities. The optimal combination prevention program needs to be defined, and this will depend on local epidemiology, service provision, and cost effectiveness. This review updates the evidence base for pre-exposure prophylaxis regarding its effectiveness, safety, and risk compensation. Article	2017	Desrosiers, Aimee; Zumer, Maria; Levy, Matt; Dright, Aurnell; Jallah, Nikardi; Kuo, Irene; Magnus, Manya; Siegel, Marc	Client-Centered Counseling-Based Resource Center Increased Uptake of HIV Pre-Exposure Prophylaxis (PrEP) in a Randomized Controlled Trial of Young Black Men who have Sex with Men	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1093/ofid/ofx163.1116	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5631387/	Abstract Background New US HIV infections are increasingly concentrated among young Black men who have sex with men (BMSM). Although oral PrEP is recommended by the CDC and WHO, uptake has been low among young BMSM. We evaluated the effect of a resource center offering a client-centered counseling approach to address the psychosocial, health care, and HIV prevention needs of young BMSM on the uptake of PrEP Methods BMSM aged 16–25 were randomized on a 1:1 basis to (1) standard of care PrEP referral or (2) standard of care PrEP referral + counseling-based PrEP resource center at enrollment with ongoing phone- and texting-based support. Subjects were asked to follow up at 3 months. We evaluated the number of subjects who were started on PrEP in the community and the number of new sexually transmitted infections (STIs) over the course of the study Results 50 HIV- BMSM were enrolled. Median age was 22 years. 43 subjects had seen a doctor in the last 12 months but only 13 had discussed PrEP and only 1 subject had taken PrEP before. 80% of subjects reported unprotected anal sex in the 3 months prior to enrollment, 31% with a man who was HIV-positive or of unknown HIV status. 42 subjects completed the study, 22 in the intervention and 20 in the control arm. 21 subjects saw a medical profession over the study period, of whom 14 discussed PrEp. 6 subjects, all of whom were in the intervention arm, started PrEP and 4 were still taking PrEP at the end of the study (P = 0.012). At baseline 1 subject was diagnosed with syphilis, 4 with gonorrhea and 10 with Chlamydia. At the 3-month visit, 1 subject was diagnosed with syphilis, 5 with gonorrhea, and 5 with Chlamydia. 2 subjects, 1 in the intervention and 1 in the control arm, tested positive for HIV at the 3-month mark. Neither subject was taking PrEP. There was no difference in the incidence of new STIs between the 2 groups. Fewer subjects reported unprotected anal intercourse both over the study period compared with prior to the study (64% vs. 80%), as well as with men who were HIV-positive or of unknown HIV status (31% vs. 19%) Conclusion The large number of STIs over the study period (34 STIs in 21 subjects) highlights that this population is at high risk for HIV acquisition and would greatly benefit from PrEP. Our study shows that a resource center is an effective intervention to increase the uptake of PrEP in this patient population Disclosures All authors: No reported disclosures. PrEP in Italy: The time may be ripe but who's paying the bill? A nationwide survey on physicians' attitudes towards using antiretrovirals to prevent HIV infection	PLOS One	-	-	-	19326203	10.1371/journal.pone.0181433	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026238824&doi=10.1371%2fjournal.pone.0181433&partnerID=40&md5=657786fefc7636f44fefbcdd595d0db6	Several studies have demonstrated the efficacy of the oral pre-exposure prophylaxis (PrEP) with tenofovir (with or without emtricitabine) on preventing HIV-negative partners of HIV infected patients to become infected through sexual contacts. PrEP is already available in the United States and now is approved by European Medicine Agency. In this setting we would like to gauge physicians' knowledge, acquaintance with and attitude to include PrEP in their clinical practice. A cross sectional survey was conducted among Italian physicians expert on antiretroviral therapy. Out of 146 physicians, 35% of participants declared to be familiar with PrEP but only 46% of them believed that, currently, there are not enough reasons to make it available in Italy. 51% of physicians have already been attracted to prescribe it and 63.4% have been openly asked about PrEP. The main concerns noticed were: the risk of acquire other sexual transmitted diseases (STDs) (70% of physicians feared that PrEP could favor STDs spread), the potential harmful of PrEP if not adequately implemented and, especially the risk of possible side effects if not properly used. Nevertheless, 55.9% of participants believed that Health Authorities face an ethical obligation to make PrEP available as part of the strategies to protect from HIV transmission and half of the respondents asked for further researches to better define the role for PrEP. Attitudes regarding PrEP impact on Italian National Health Organization were also very interesting: 57.5% of participants did not believe that investing in PrEP would be an appropriate use of healthcare resources, while 70.6% affirmed that PrEP's financial coverage should not be funded by the Italian National System of Health (SSN). This survey showed a high awareness of PrEP potential among Italian physicians coupled with a great deal of skepticism about how and if implementing it in clinical practice. © 2017 Di Biagio et al. Article	2017	Distefano A.S.; Takeda M.	HIV Pre-Exposure Prophylaxis and Postexposure Prophylaxis in Japan: Context of Use and Directions for Future Research and Action	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2016.0160	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85012216642&doi=10.1089%2fapc.2016.0160&partnerID=40&md5=156e225c76fe8e6dded32a2ccfb611c7	Biomedical HIV prevention strategies are playing an increasingly prominent role in addressing HIV epidemics globally, but little is known about their use in Japan, where persistent HIV disparities and a recently stable, but not declining, national epidemic indicate the need for evolving approaches. We conducted an ethnographic study to determine the context of pre-exposure prophylaxis (PrEP) and postexposure prophylaxis (PEP) use and to identify directions for future research and action in Japan. We used data from observational fieldwork in the Kansai region and Tokyo Metropolitan Area (n = 178 persons observed), qualitative interviews (n = 32), documents and web-based data sources (n = 321), and email correspondences (n = 9) in the period 2013-2016. Drug approvals by Japan's regulatory agencies, insurance coverage for medications, and policies by healthcare institutions and government agencies were the main factors affecting PrEP and PEP legality, use, and awareness. Awareness and the observable presence of PrEP and PEP were very limited, particularly at the community level. PrEP and PEP held appeal for Japanese scientists and activists, and for study participants who represented various other stakeholder groups; however, significant concerns prevented open endorsements. Japanese health officials should prioritize a national discussion, weigh empirical evidence, and strongly consider formal approval of antiretroviral (ARV) medications for use in PrEP and both occupational and nonoccupational PEP. Once approved, social marketing campaigns can be used to advertise widely and increase awareness. Future research would benefit from theoretical grounding in a diffusion of innovations framework. These findings can inform current and future ARV-based prevention strategies at a critical time in the international conversation. © Copyright 2017, Mary Ann Liebert, Inc. 2017.	biomedical prevention; ethnographic; HIV; Japan; PEP; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2017	Doblecki-Lewis, Susanne; Liu, Albert; Feaster, Daniel; Cohen, Stephanie E; Cardenas, Gabriel; Bacon, Oliver; Andrew, Erin; Kolber, Michael A	Healthcare Access and PrEP Continuation in San Francisco and Miami After the US PrEP Demo Project.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001236	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5340616	BACKGROUND: Pre-exposure prophylaxis (PrEP) for prevention of HIV infection has demonstrated efficacy in randomized controlled trials and in demonstration projects. For PrEP implementation to result in significant reductions in HIV incidence for men who have sex with men in the United States, sufficient access to PrEP care and continued engagement outside of demonstration projects is required. METHODS: We report the results of a follow-up survey of 173 former participants from the Miami and San Francisco sites of the US PrEP Demo Project, administered 4-6 months after study completion. RESULTS: Survey respondents continued to frequently access medical care and had a high incidence of sexually transmitted infections after completion of the Demo Project, indicating ongoing sexual risk behavior. Interest in continuing PrEP was high with 70.8% indicating that they were "very interested" in continuing PrEP. Among respondents, 39.9% reported continuation of PrEP after completion of the Demo Project, largely through their primary care providers and frequently at low or no cost. Variability in access and engagement was seen, with participants from the San Francisco site, those with medical insurance, and those with a primary care provider at the end of the Demo Project more likely to successfully obtain PrEP medication. Two respondents reported HIV seroconversion in the period between study completion and the follow-up survey. CONCLUSIONS: Additional effort to increase equitable access to PrEP outside of demonstration projects is needed to realize the potential impact of this evidence-based prevention intervention.	1 a 18	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Donnell, D; Ramos, E; Celum, C; Baeten, J; Dragavon, J; Tappero, J; Lingappa, JR; Ronald, A; Fife, K; Coombs, RW	The effect of oral preexposure prophylaxis on the progression of HIV-1 seroconversion	AIDS	-	-	-	na	10.1097/QAD.0000000000001577	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01395874/full	Objective: To investigate whether oral preexposure prophylaxis (PrEP) alters timing and patterns of seroconversion when PrEP use continues after HIV-1 infection. Design: Retrospective testing of the timing of Fiebig stage HIV-1 seroconversion in the Partners PrEP Study, a randomized placebo-controlled clinical trial of PrEP conducted in Kenya and Uganda. Methods: Specimens from 138 seroconverters were collected every 3 months and when HIV-1 infection was suspected based on monthly rapid HIV-1 tests. Progression of seroconversion was compared between randomized groups (PrEP versus placebo) and per-protocol groups (placebo versus PrEP participants with detectable tenofovir during the seroconversion period) using laboratory assessment of Fiebig stage. Delay in site-detection of seroconversion and association with PrEP drug-regimen resistant virus were assessed using logistic regression. Analysis of time to each Fiebig stage used maximum likelihood estimation with a parametric model to accommodate the varying lengths of HIV-infection intervals. Results: There was a significant increase in delayed site detection of infection associated with PrEP (odds ratio==3.49, P==0.044). Delay in detection was not associated with increased risk of resistance in the PrEP arm (odds ratio==0.93, P==0.95). Estimated time to each Fiebig stage was elongated in seroconverters with evidence of ongoing PrEP use, significantly for only Stage 5 (28 versus 17 days, P==0.05). Adjusted for Fiebig stage, viral RNA was ~2/3 log lower in those assigned to PrEP compared with placebo; no differences were found in Architect signal to cut-off at any stage. Conclusion: Ongoing PrEP use in seroconverters may delay detection of infection and elongate seroconversion, although the delay does not increase risk of resistance.	*Human immunodeficiency virus 1 infection; *Seroconversion; *pre-exposure prophylaxis; *seroconversion; Administration, Oral; Adult; Anti-HIV Agents *administration & dosage; Architect; Clinical trial; Controlled clinical trial; Controlled study; Disease model; Double-Blind Method; Drug resistance; Drug therapy; Female; HIV Infections *prevention & control; HIV test; HIV-1 *immunology; Human; Human tissue; Humans; Kenya; Logistic regression analysis; Longitudinal Studies; Male; Maximum likelihood method; Placebo; Placebos administration & dosage; Pre-Exposure Prophylaxis *methods; Randomized controlled trial; Retrospective Studies; Statistical model; Tenofovir; Time Factors; Uganda; Virus RNA	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2017	Draper, Bridget L; Fowkes, Freya J I; Oo, Zaw Min; Thein, Zaw Win; Aung, Poe Poe; Veronese, Vanessa; Ryan, Claire; Thant, Myo; Hughes, Chad; Stoové, Mark	Willingness to use HIV pre-exposure prophylaxis among gay men, other men who have sex with men and transgender women in Myanmar.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.20.1.21885	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5577714	INTRODUCTION: HIV pre-exposure prophylaxis (PrEP) has emerged as a key component of contemporary HIV combination prevention strategies. To explore the local suitability of PrEP, country-specific acceptability studies are needed to inform potential PrEP implementation. In the context of Myanmar, in addition to resource constraints, HIV service access by gay men, other men who have sex with men, and transgender women (GMT) continues to be constrained by legislative and community stigma and marginalization. We aimed to determine PrEP acceptability among GMT in Myanmar and explore the factors associated with willingness to use PrEP. METHODS: GMT were recruited in Yangon and Mandalay through local HIV prevention outreach programmes in November and December 2014. Quantitative surveys were administered by trained peer educators and collected data on demographics, sexual risk, testing history and PrEP acceptability. A modified six-item PrEP acceptability scale classified self-reported HIV undiagnosed GMT as willing to use PrEP. Multivariable logistic regression identified factors associated with willingness to use PrEP. RESULTS: Among 434 HIV undiagnosed GMT, PrEP awareness was low (5%). PrEP acceptability was high, with 270 (62%) GMT classified as willing to use PrEP. GMT recruited in Mandalay (adjusted odds ratio (aOR) = 1.79; 95%CI = 1.05-3.03), who perceived themselves as likely to become HIV positive (aOR = 1.82; 95%CI = 1.10-3.02), who had more than one recent regular partner (aOR = 2.94; 95%CI = 1.41-6.14), no regular partners (aOR = 2.05; 95%CI = 1.10-3.67), more than five casual partners (aOR = 2.05; 95%CI = 1.06-3.99) or no casual partners (aOR = 2.25; 95%CI = 1.23-4.11) were more likely to be willing to use PrEP. The association between never or only occasionally using condoms with casual partners and willingness to use PrEP was marginally significant (aOR = 2.02; 95%CI = 1.00-4.10). GMT who reported concern about side effects and long-term use of PrEP were less likely (aOR = 0.35; 95%CI = 0.21-0.59) to be willing to use PrEP. CONCLUSIONS: This is the first study to assess PrEP acceptability in Myanmar. Findings suggest PrEP is an acceptable prevention option among GMT in Myanmar, providing they are not required to pay for it. Implementation/demonstration projects are needed to explore the feasibility and cost-effectiveness of PrEP as a prevention option for GMT in Myanmar. Article	2017	Eakle R.; Bourne A.; Jarrett C.; Stadler J.; Larson H.	Motivations and barriers to uptake and use of female-initiated, biomedical HIV prevention products in sub-Saharan Africa: An adapted meta-ethnography	BMC Public Health	-	-	-	14712458	10.1186/s12889-017-4959-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038447678&doi=10.1186%2fs12889-017-4959-3&partnerID=40&md5=85f639f72628f2bbe23b6f724eaf4b4a	Background: Women bear a disproportionate burden of HIV throughout the world prompting extensive research into HIV prevention products for women which has met with varied success. With an aim of informing future policy and programming, this review examines the barriers and motivations to the uptake and use of female initiated products in sub-Saharan countries. Methods: We conducted a systematic review as an adapted meta-ethnography of qualitative data focused on actual use of products. After deduplication, 10,581 and 3861 papers in the first and second round respectively were screened. Following the PRISMA guidance, 22 papers were selected and synthesized using Malpass's definitions of first, second, and third order constructs. First order constructs, consisting of participant data published in the selected papers, were extracted and categorised by second and third order constructs for analysis. A weight of evidence review was conducted to compare and assess quality across the papers. Results: The 22 papers selected span 11 studies in 13 countries. We derived 23 s order constructs that were translated into seven overarching third order constructs: Sexual Satisfaction, Trust, Empowerment and Control, Personal Well-being, Product use in the social-cultural environment, Practical Considerations, Risk Reduction, and Perceptions of Efficacy. Relationships and trust were seen to be as or more important for product use as efficacy. These constructs reveal an inherent inter-relationality where decision making around HIV prevention uptake and use cannot be binary or mono-faceted, but rather conducted on multiple levels. We developed a framework illustrating the central and proximal natures of constructs as they relate to the decision-making process surrounding the use of prevention products. Conclusions: Health systems, structural, and individual level HIV prevention interventions for women should adopt a holistic approach. Interventions should attend to the ways in which HIV prevention products can serve to reduce the likelihood of HIV transmission, as well as help to protect partnerships, enhance sexual pleasure, and take into account woman's roles in the social environment. Stigma, as well as sexuality, is likely to continue to influence product uptake and use and should be prominently taken into account in large-scale interventions. Trial registration: Not applicable. © 2017 The Author(s). Article	2017	Eakle R.; Gomez G.B.; Naicker N.; Bothma R.; Mbogua J.; Cabrera Escobar M.A.; Saayman E.; Moorhouse M.; Venter W.D.F.; Rees H.	HIV pre-exposure prophylaxis and early antiretroviral treatment among female sex workers in South Africa: Results from a prospective observational demonstration project	PLOS Medicine	-	-	-	15491277	10.1371/journal.pmed.1002444	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85036560031&doi=10.1371%2fjournal.pmed.1002444&partnerID=40&md5=dde05212212245bef082271e8c16d239	Background: Operational research is required to design delivery of pre-exposure prophylaxis (PrEP) and early antiretroviral treatment (ART). This paper presents the primary analysis of programmatic data, as well as demographic, behavioural, and clinical data, from the TAPS Demonstration Project, which offered both interventions to female sex workers (FSWs) at 2 urban clinic sites in South Africa. Methods and findings: The TAPS study was conducted between 30 March 2015 and 30 June 2017, with the enrolment period ending on 31 July 2016. TAPS was a prospective observational cohort study with 2 groups receiving interventions delivered in existing service settings: (1) PrEP as part of combination prevention for HIV-negative FSWs and (2) early ART for HIV-positive FSWs. The main outcome was programme retention at 12 months of follow-up. Of the 947 FSWs initially seen in clinic, 692 were HIV tested. HIV prevalence was 49%. Among those returning to clinic after HIV testing and clinical screening, 93% of the women who were HIV-negative were confirmed as clinically eligible for PrEP (n = 224/241), and 41% (n = 110/270) of the women who were HIV-positive had CD4 counts within National Department of Health ART initiation guidelines at assessment. Of the remaining women who were HIV-positive, 93% were eligible for early ART (n = 148/160). From those eligible, 98% (n = 219/224) and 94% (n = 139/148) took up PrEP and early ART, respectively. At baseline, a substantial fraction of women had a steady partner, worked in brothels, and were born in Zimbabwe. Of those enrolled, 22% on PrEP (n = 49/219) and 60% on early ART (n = 83/139) were seen at 12 months; we observed high rates of loss to follow-up: 71% (n = 156/219) and 30% (n = 42/139) in the PrEP and early ART groups, respectively. Little change over time was reported in consistent condom use or the number of sexual partners in the last 7 days, with high levels of consistent condom use with clients and low use with steady partners in both study groups. There were no seroconversions on PrEP and 7 virological failures on early ART among women remaining in the study. Reported adherence to PrEP varied over time between 70% and 85%, whereas over 90% of participants reported taking pills daily while on early ART. Data on provider-side costs were also collected and analysed. The total cost of service delivery was approximately US$126 for PrEP and US$406 for early ART per person-year. The main limitations of this study include the lack of a control group, which was not included due to ethical considerations; clinical study requirements imposed when PrEP was not approved through the regulatory system, which could have affected uptake; and the timing of the implementation of a national sex worker HIV programme, which could have also affected uptake and retention. Conclusions: PrEP and early ART services can be implemented within FSW routine services in high prevalence, urban settings. We observed good uptake for both PrEP and early ART; however, retention rates for PrEP were low. Retention rates for early ART were similar to retention rates for the current standard of care. While the cost of the interventions was higher than previously published, there is potential for cost reduction at scale. The TAPS Demonstration Project results provided the basis for the first government PrEP and early ART guidelines and the rollout of the national sex worker HIV programme in South Africa. © 2017 Eakle et al.	na	English	United States	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Clinical
Article	2017	Eaton L.A.; Matthews D.D.; Driffin D.D.; Bukowski L.; Wilson P.A.; Stall R.D.	A Multi-US City Assessment of Awareness and Uptake of Pre-exposure Prophylaxis (PrEP) for HIV Prevention Among Black Men and Transgender Women Who Have Sex with Men	Prevention Science	-	-	-	13894986	10.1007/s11121-017-0756-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85009786986&doi=10.1007%2fs11121-017-0756-6&partnerID=40&md5=7ce5b2144e84efbf129776e3d7529e0f	The HIV epidemic among Black men and transgender women who have sex with men (BMTW) demands an urgent public health response. HIV point prevalence among this population ranges from 25 to 43%—a rate far exceeding any other group. Pre-exposure prophylaxis (PrEP) for HIV prevention is a very promising prevention tool; however, its full potential to slow the epidemic has yet to be realized. For the current study, random time-location sampling at Black Gay Pride Events was used to collect data from N = 1274 BMTW, from five US cities, reporting HIV-negative/unknown status. In-field HIV testing was also provided to participants. Participants were assessed on awareness and use of PrEP, health care factors, HIV testing history, psychosocial variables, and sex behaviors. About one third of participants were aware of PrEP (39%), and a small percentage of participants were users of PrEP (4.6%). In multivariable analyses, being in a relationship, testing for HIV in the past 6 months, and others being aware of one's sexuality were positively associated with PrEP awareness. Higher levels of internalized homophobia and greater numbers of female sex partners were positively associated with PrEP use, while education and condom use were negatively associated. Based on study findings, messaging and uptake of PrEP needs greater expansion and requires novel approaches for scale-up. Improving linkage to HIV testing services is likely critical for engaging BMTW with PrEP. The potential for PrEP to slow the HIV epidemic is high; however, we must strengthen efforts to ensure universal availability and uptake. © 2017, Society for Prevention Research. Editorial	2017	Eaton, Lisa A	What Can We Do or Change to Encourage People to Seek Out Preexposure Prophylaxis?	American Journal of Public Health	-	-	-	1541-0048	10.2105/AJPH.2017.304149	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5678417	Many prevention and treatment successes have been observed in the course of the HIV epidemic. We have seen great strides made in behavioral change interventions, law and policy change interventions, sexually transmitted infection treatment programs, needle exchange programs, programs focusing on the prevention of perinatal HIV transmission, blood supply testing and monitoring services, male circumcision programs, and other initiatives.1 More recently, major advances have occurred in biomedical antiretroviral-based prevention, with treatment as prevention and preexposure prophylaxis (PrEP) demonstrating efficacy in preventing transmission of HIV. Much anticipation and excitement exist around the potential for treatment as prevention and PrEP to effectively halt the HIV epidemic, both domestically and internationally.2 And there is good reason for this positive response: antiretroviral-based prevention, when adhered to, will prevent HIV transmission.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Other
Article	2017	Eaton, Lisa A; Kalichman, Seth C; Price, Devon; Finneran, Stephanie; Allen, Aerielle; Maksut, Jessica	Stigma and Conspiracy Beliefs Related to Pre-exposure Prophylaxis (PrEP) and Interest in Using PrEP Among Black and White Men and Transgender Women Who Have Sex with Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1690-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85009841218&doi=10.1007%2fs10461-017-1690-0&partnerID=40&md5=5026d66db49c32130da7469fdcac5f1b	The HIV/AIDS epidemic in the US continues to persist, in particular, among race, sexual orientation, and gender minority populations. Pre-exposure prophylaxis (PrEP), or using antiretroviral medications for HIV prevention, is an effective option, but uptake of PrEP has been slow. Sociocultural barriers to using PrEP have been largely underemphasized, yet have the potential to stall uptake and, therefore, warrant further understanding. In order to assess the relationships between potential barriers to PrEP (i.e., PrEP stigma and conspiracy beliefs), and interest in PrEP, Black men and transgender women who have sex with men (BMTW, N = 85) and White MTW (WMTW, N = 179) were surveyed at a gay pride event in 2015 in a large southeastern US city. Bivariate and multivariate logistic regression analyses were completed to examine factors associated with PrEP interest. Among the full sample, moderate levels of PrEP awareness (63%) and low levels of use (9%) were observed. Believing that PrEP is for people who are promiscuous (stigma belief) was strongly associated with lack of interest in using PrEP, and individuals who endorsed this belief were more likely to report sexual risk taking behavior. Conspiracy beliefs related to PrEP were reported among a large minority of the sample (42%) and were more frequently reported among BMTW than WMTW. Given the strong emphasis on the use of biomedical strategies for HIV prevention, addressing sociocultural barriers to PrEP access is urgently needed and failure to do so will weaken the potential benefits of biomedical prevention. © 2017, Springer Science+Business Media New York. Article	2017	Edelman E.J.; Moore B.A.; Calabrese S.K.; Berkenblit G.; Cunningham C.; Patel V.; Phillips K.; Tetrault J.M.; Shah M.; Fiellin D.A.; Blackstock O.	Primary Care Physicians' Willingness to Prescribe HIV Pre-exposure Prophylaxis for People who Inject Drugs	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1612-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84997703667&doi=10.1007%2fs10461-016-1612-6&partnerID=40&md5=cf3eed70e9f0e0ee213839100ecb395e	Pre-exposure prophylaxis for HIV (PrEP) is recommended for people who inject drugs (PWID). Despite their central role in disease prevention, willingness to prescribe PrEP to PWID among primary care physicians (PCPs) is largely understudied. We conducted an online survey (April–May 2015) of members of a society for academic general internists regarding PrEP. Among 250 respondents, 74% (n = 185) of PCPs reported high willingness to prescribe PrEP to PWID. PCPs were more likely to report high willingness to prescribe PrEP to all other HIV risk groups (p's < 0.03 for all pair comparisons). Compared with PCPs delivering care to more HIV-infected clinic patients, PCPs delivering care to fewer HIV-infected patients were more likely to report low willingness to prescribe PrEP to PWID (Odds Ratio 95% CI = 6.38 1.48–27.47). PCP and practice characteristics were not otherwise associated with low willingness to prescribe PrEP to PWID. Interventions to improve PCPs' willingness to prescribe PrEP to PWID are needed. © 2017, Springer Science+Business Media New York. Theses and Dissertations	2017	Erguiza, Randulf Villaneuva; Jillson, Irene	Effect of Pre-Exposure Prophylaxis (PrEP) Education on Sexual Behaviors of Gay and Bisexual Men	-	-	Universidade de Georgetown	-	na	NA	https://www.proquest.com/dissertations-theses/effect-pre-exposure-prophylaxis-prep-education-on/docview/2006981709/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) is a drug that prevents the transmission of human-immunodeficiency virus (HIV), but not the transmission of other sexually-transmitted infections (STIs). Studies of PrEP use to prevent the transmission of HIV among gay and bisexual men (GBM) have demonstrated high risks for engagement in risk-compensating sexual behaviors, which increase their susceptibility to STIs. This study's aims were to elicit understanding of the effect of PrEP education on sexual behaviors and STI rates of GBM, and to inform the development of evidence-based PrEP education. The quasi-experimental intervention study was based on Pender's Health Promotion Model (HPM) as the theoretical framework and comprised two phases: a pre-post intervention assessment and a three-month follow-up. The knowledge, attitudes, and practices (KAP) of a purposive sample of GBM were measured in both phases, through in-person semi-structured interviews, an STI-PrEP Knowledge Questionnaire™, Sexual Risk Cognition Questionnaire (SRCQ), and self-reported STI status. The intervention comprised two brief Centers for Disease Control and Prevention (CDC) educational videos. Quantitative analyses included descriptive statistics and non-parametric tests. Analysis of open-ended questions was based on the hierarchical, editing style to generate categories and themes. Eight GBM participated in the first phase and four of them (50%) in the second, follow-up phase. Comparing the STI-PrEP questionnaire scores, there was a significant difference in scores between pre-intervention (Median = 13.50) and both post-intervention (Median = 15.00) and three-month follow-up (Median = 14.75), p = .023, demonstrating that the improvement in STI-PrEP questionnaire scores was maintained at follow-up. The SRCQ yielded no significant change in sexual cognition between pre-intervention and follow-up, p = .461. There was a 25% decrease in the self-reported STI rate from baseline at pre-intervention to follow-up. Thematic analysis of the qualitative responses showed that PrEP use motivators include sexual pleasure, condom-less sex, and PrEP's efficacy; PrEP education effects include improved informed decision-making and PrEP compliance. PrEP education improved knowledge, reduced STI rates, and had an effect on sexual intentions. Strengthened PrEP education in healthcare may improve sexual behaviors and STI rates utilizing the HPM and a multidisciplinary approach in implementing multimodal strategies in addressing sexual behaviors. Article	2017	Eriksen, Jaran; Albert, Jan; Blaxhult, Anders; Carlander, Christina; Flamholc, Leo; Gisslén, Magnus; Josephson, Filip; Karlström, Olof; Navér, Lars; Svedhem, Veronica; Yilmaz, Aylin; Sönnerborg, Anders	Antiretroviral treatment for HIV infection: Swedish recommendations 2016.	Infection (Lond)	-	-	-	2374-4243	10.1080/23744235.2019.1707867	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-27804313	The Swedish Medical Products Agency and the Swedish Reference Group for Antiviral Therapy (RAV) have jointly published recommendations for the treatment of HIV infection on seven previous occasions (2002, 2003, 2005, 2007, 2009, 2011 and 2014). In February 2016, an expert group under the guidance of RAV once more revised the guidelines. The most important updates in the present guidelines are as follows: Tenofovir alafenamide (TAF) has recently been registered. TAF has several advantages over tenofovir disoproxilfumarate (TDF) and is recommended instead of TDF in most cases. First-line treatment for previously untreated individuals includes dolutegravir, boosted darunavir or efavirenz with either abacavir/lamivudine or tenofovir (TDF/TAF)/emtricitabine. Pre-exposure prophylaxis (PrEP) is recommended for high-risk individuals. As in the case of the previous publication, recommendations are evidence-graded in accordance with the Oxford Centre for Evidence Based Medicine (http://www.cebm.net/oxford-centre-evidence-based-medicine-levels-evidence-march-2009/) (Table 1). This document does not cover treatment of opportunistic infections and tumours. Table: see text. Theses and Dissertations	2017	Escudero, Daniel J	The Use of Antiretrovirals for Preventing HIV Among People who Inject Drugs	-	-	Brown University	-	na	NA	https://repository.library.brown.edu/studio/item/bdr:730632/	The purpose of this dissertation work was to assess limitations and effectiveness of antiretroviral-based prevention methods among people who use drugs (PWID), specifically pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP). Each of these prevention strategies has been shown to have potential to prevent population-level HIV transmission and acquisition among PWID. The implementation of these prevention methods, however, has been limited in settings throughout the world. The research herein used literature review, cohort data, and agent-based modeling to examine the implementation and potential barriers to the successful deployment of these prevention methods in varying settings. Specifically, we used a literature review to summarize the existing scientific evidence for PrEP implementation and effectiveness among PWID. We then assessed the willingness of PWID in Vancouver, BC, to use PrEP, and used multivariate logistic regression to examine the independent correlates of willingness to use PrEP within this community. To better understand the limitations of TasP, we used agent-based modeling to estimate the proportion of all HIV transmission events arising from PWID that were attributable to acute HIV infection—a period early in HIV infection that may thwart TasP effectiveness in certain environments. Finally, we used a similar agent-based modeling technique to estimate the proportion of HIV transmission arising from PWID at each step of the HIV care continuum, a theoretical construct used to assess the diagnosis and treatment status of HIV positive individuals. Although our findings suggest that there are significant barriers to the long-term effectiveness of these prevention strategies, our results also suggest that these limitations are surmountable, and likely amenable to specific efforts within the HIV prevention community. Article	2017	Falcao J.; Zerbe A.; Lahuerta M.; Buggaley R.; Abreu L.; Dimetto P.; Morales F.; Ramiro I.; El-Sadr W.M.	Factors Associated with Use of Short-Term Pre-Exposure Prophylaxis for HIV among Female Partners of Migrant Miners in Mozambique	AIDS Patient Care and STDs	-	-	-	-	10.1089/apc.2017.0179	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85030227863&doi=10.1089%2Fapc.2017.0179&partnerID=40&md5=ae79212d613da3c0f4a3698ba9ce92a3	Effective interventions tailored to specific types of behaviors and contexts are needed for women at risk for HIV acquisition. Oral pre-exposure prophylaxis (PrEP) is an efficacious HIV prevention intervention that uses antiretroviral drugs to reduce the risk of acquiring HIV infection. In Mozambique, HIV remains a major public health concern, with a national prevalence of 13%. Studies have demonstrated that the migration of male miners between southern provinces of Mozambique and South Africa is contributing to the HIV epidemic in Mozambique. This increased risk is associated with the engagement of male miners, while separated from their partners, in sexual relationships with other women, including transactional sex workers, in a hyperendemic setting in South Africa. We conducted 25 in-depth interviews with a subset of female partners in a stable relationship with migrant miners participating in a prospective cohort study to assess the feasibility, acceptability, and adherence to daily oral short-term PrEP. Drug levels were available for the participants, as reported in an earlier study. Interviews were recorded, transcribed, and submitted for qualitative thematic analysis. The major themes identified were the benefits of taking PrEP, the ease of taking daily PrEP, the reluctance to disclose PrEP use to partners, the lack of changes in sexual behavior, and prevailing gender dynamics and how they impact women's ability to access PrEP and other HIV prevention interventions. © Copyright 2017, Mary Ann Liebert, Inc.	-	-	-	HIV; Mozambique; PrEP; Qualitative; Women	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative

We conducted a cross-sectional study to assess the willingness of migrant miners and female partners of miners to take short-term pre-exposure prophylaxis (PrEP) for prevention of HIV acquisition. The study was conducted in Gaza Province, Mozambique, between September and October 2015. A total of 111 male miners and their partners of male miners completed a questionnaire. Subsequently, 40 in-depth interviews among male miners and female partners of miners and 3 focus-group discussions (FGDs) among female partners of miners were conducted. Questions were tabulated and analyzed. A structured coding scheme was developed and qualitative data were analyzed using Atlas.ti. Most participants (94%) were willing to take PrEP for short-term use. Facilitating factors for willingness to use PrEP were concerns about partner's sexual behaviour, desire for pregnancy and men's own sexual behaviour. The main barriers to PrEP use were concerns regarding side-effects, perceived difficulty adhering to daily pill taking and concern about family disapproval. Overall, participants saw potential barriers for PrEP as minor obstacles that could be overcome. The male partner's influence on PrEP use was significant. Article	2017	Fallon S.A.; Park J.N.; Ogbue C.P.; Flynn C.; German D.	Awareness and Acceptability of Pre-exposure HIV Prophylaxis Among Men Who have Sex with Men in Baltimore	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1619-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84968660768&doi=10.1007%2Fs10461-016-1619-z&partnerID=40&md5=85ed5cab9f34c17859f1ec3e8f565ba4	This paper assessed characteristics associated with awareness of and willingness to take pre-exposure prophylaxis (PrEP) among Baltimore men who have sex with men (MSM). We used data from BESURE-MSM3, a venue-based cross-sectional HIV surveillance study conducted among MSM in 2011. Multivariate regression was used to identify characteristics associated with PrEP knowledge and acceptability among 599 participants. Eleven percent had heard of PrEP, 49% would be willing to use PrEP, and none had previously used it. In multivariable analysis, black race and perceived peer/friend disapproval of PrEP use with HIV were significantly associated with decreased awareness, and those who perceived higher HIV discrimination reported higher acceptability of PrEP. Our findings indicate a need for further education about the potential utility of PrEP in addition to other prevention methods among MSM. HIV prevention efforts should address the link between discrimination and potential PrEP use, especially among men of color. © 2016, Springer Science+Business Media New York. Article	2017	Farhat D.; Greene E.; Paige M.Q.; Kobin B.A.; Frye V.	Knowledge, Stereotyped Beliefs and Attitudes Around HIV Chemoprophylaxis in Two High HIV Prevalence Neighborhoods in New York City	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1426-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84968263758&doi=10.1007%2Fs10461-016-1426-6&partnerID=40&md5=a08b7a4f0046d1067df2fd2f15e9c224e1	HIV chemoprophylaxis (PrEP/PEP) has emerged as a transformative prevention tool to reduce infection rates and decrease disease burden. However, uptake is low, and efficacy depends upon adherence. To maximize impact, potential barriers to uptake and adherence must be identified and understood. Using univariate and logistic regression analytic methods, we assessed associations among potential barriers to uptake and adherence, including HIV chemoprophylaxis knowledge, negative stereotyped beliefs about people who use it and negative attitudes towards HIV chemoprophylaxis use by vignettes among 513 residents of two high HIV prevalence neighborhoods in New York City. About a quarter of respondents knew about HIV chemoprophylaxis and over 50 % endorsed negative stereotyped beliefs about users; yet, approximately two-thirds had positive attitudes toward its use among a male or female relative. Young age, having lesbian or gay friends/family members and low levels of homophobia were associated with not endorsing negative stereotyped beliefs. Negative stereotyped beliefs were not associated with negative attitudes toward HIV chemoprophylaxis use among relatives. Implications for PrEP discrimination are discussed. © 2016, Springer Science+Business Media New York. Article	2017	Fisher C.B.; Fried A.L.; Desmond M.; Macapagal K.; Mustanski B.	Facilitators and barriers to participation in prep hiv prevention trials involving transgender male and female adolescents and emerging adults	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2017.29.3.205	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021334562&doi=10.1521%2Faeap.2017.29.3.205&partnerID=40&md5=2ac7db7594f3571cd057b0f2fb8f0b6c	Despite the disproportionate burden of HIV facing transgender youth, they continue to be under-represented in studies to provide an empirical basis for pre-exposure prophylaxis (PrEP) programs that can meet the unique needs of this population. This study examined facilitators and barriers to participation in a PrEP adherence study, determined through an online survey administered to 90 transgender male and 60 transgender female 14–21-year-olds attracted to ingredder male sexual partners. Approximately 50% reported likely to participate in the PrEP study. Participation facilitators included prior sexual and health service experiences and study access to PrEP and health services. Participation barriers included lack of concern about HIV, potential medication side effects, the logistics of quarterly meetings, remembering to take PrEP daily, and reluctance to discuss gender identity with study staff. Results suggest that successful recruitment and retention of transgender youth in PrEP prevention studies warrant protocols designed to address these barriers. © 2017 The Guilford Press.	adolescentadultArticleattitudescommunity participationfriendsgender identityhealth servicesHIV testhomosexual orientationhumansHuman immunodeficiency virus infectionsmaleMinnesotaMinnesota participantsexpressive prophylaxispreventionsexual orientationsexualityrisk effectstransgenderyoung adultsthetitude to healthhealth care delivery(HIV Infectionsmale homosexualitymotivationparticipant attitudepsychologicalpsychometricsreceiver operating characteristicsexual behaviorstatistics and numerical data	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Flash C.A.; Dale S.K.; Krakower D.S.	Pre-exposure prophylaxis for HIV prevention in women: Current perspectives	International Journal of Women's Health	-	-	-	-	11791411	10.2147/IJWH.S113675	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85022197005&doi=10.2147%2FIJWH.S113675&partnerID=40&md5=19de2c2d9f2416b1f4375884cb9498e2	There are ~900,000 new HIV infections among women every year, representing nearly half of all new HIV infections globally. In the US, nearly one-fifth of all new HIV infections occur among women, and women from racial and ethnic minority communities experience disproportionately high rates of new HIV infections. Thus, there is a need to develop and implement effective HIV prevention strategies for women. Oral pre-exposure prophylaxis (PrEP) is highly effective at preventing HIV infection among men who have sex with men and people who inject drugs, but data on its use and antiretroviral medications by HIV-uninfected persons to prevent HIV acquisition, can reduce HIV incidence among women who are adherent to PrEP. However, to date, awareness and uptake of PrEP among women have been very limited, suggesting a need for innovative strategies to increase the knowledge of and access to PrEP among women in diverse settings. This narrative review summarizes the efficacy and safety data of PrEP in women, discusses considerations related to medication adherence for women who use PrEP, and highlights behavioral, social, and structural barriers to maximize the effectiveness of PrEP in women. It also reviews novel modalities for PrEP in women which are being developed and tested, including topical formulations and long-acting injectable agents that may offer advantages as compared to oral PrEP and proposes a community-oriented, social networking framework to increase awareness of PrEP among women. If women are provided with access to PrEP and support to overcome social and structural barriers to adhere to PrEP, this prevention strategy holds great promise to impact the HIV epidemic among women in the US and globally. © 2017 Flash et al. NA	-	-	-	-	10.1596/978-1-4648-0524-0_ch7	https://pubmed.ncbi.nlm.nih.gov/30212104/	Because of the severe health consequences of human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS) and the costs of lifelong treatment, inexpensive and effective HIV prevention is bound to be cost-effective. But what constitutes HIV prevention, and can it be affordable and effective? The use of condoms that cost a few cents and prevent a young adult from acquiring a chronic and fatal disease will, over time, be cost-saving. Avoiding sex with someone who is infected with HIV/AIDS will be even more so. What can be done to get condoms to those who need them? What can be done to facilitate the avoidance of risky sexual encounters? Additional efficacious biomedical tools have become available, but similar questions persist: What can be done to get young women at risk to use oral tenofovir effectively as pre-exposure prophylaxis (PrEP) and to get young men at risk to be circumcised? The answers to these questions will determine what packages of prevention are essential, how much prevention programs should cost, and how cost-effective they can be. This chapter reviews current evidence about the efficacy, effectiveness, and costs of HIV/AIDS prevention products, programs, and approaches. Article	2017	Garrison, Lindsey E; Haberer, Jessica E	Technological methods to measure adherence to antiretroviral therapy and preexposure prophylaxis.	Current Opinion in HIV and AIDS	-	-	-	-	17464338	10.1097/COH.0000000000000393	https://ds.doi.org/10.1097/COH.0000000000000393	PURPOSE OF REVIEW: The WHO's Consolidated Guidelines (2016) call for research on improved methods to proactively monitor adherence and identify those individuals who have the most need for adherence support. This review aims to elucidate the latest technologies available to measure adherence to HIV antiretroviral therapy and preexposure prophylaxis against HIV infection and present their utility in various settings and populations. RECENT FINDINGS: Within the last few years, advances have been made in the features of existing technology to measure adherence (real-time adherence measurements), additional approaches have been developed (digital medicine systems) and improved (short message service surveys), and point of care testing for pharmacokinetic measures are under development. SUMMARY: Technology advances in adherence measurement are promising for improved accuracy and, in some cases, the ability to intervene with adherence challenges in real time. This progress will greatly further our understanding of adherence behavior, as well as the ability to effectively link interventions with individuals who need them, thus maximizing the clinical and public health benefits of both antiretroviral therapy and preexposure prophylaxis. Potential for immune-driven viral polymorphisms to compromise antiretroviral-based preexposure prophylaxis for prevention of HIV-1 infection	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001575	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021286614&doi=10.1097%2FQAD.0000000000001575&partnerID=40&md5=a3a66fe0f9702fa1d9e8cf3e49403bc8	OBJECTIVES: Long-acting rilpivirine is a candidate for preexposure prophylaxis (PrEP) for prevention of HIV-1 infection. However, rilpivirine resistance mutations at reverse transcriptase codon 138 (E138K) occur naturally in a minority of HIV-1-infected persons, in particular those expressing human leukocyte antigen (HLA)-B 18-positive reverse transcriptase E138K mutations as an immune escape mutation. We investigate the global prevalence, B 18-linkage and replicative cost of reverse transcriptase E138K and its regional implications for rilpivirine PrEP. Methods: We analyzed linked reverse transcriptase-integrase E138K/A/G/R sequences from 1574 antiretroviral-naive persons with HLA data from 42 countries (Spearman's R = 0.74, P = 1e-01 to 0 and 1e-324 for 2 to longer 1-41 after dosing, respectively. The median C24 of tenofovir and emtricitabine was 40 and 63 μg/L, respectively. The median PBMC tenofovir diphosphate and emtricitabine triphosphate levels were 12.2 and 16.7 fmol/106 cells and 2060 and 2000 fmol/106 cells at 2 and 24 h after dosing, respectively. Seven plasma AUC0-24 ratios were 2% and 17% for tenofovir and emtricitabine, respectively. Emtricitabine was detected in rectal tissue 30 min after dosing, whereas tenofovir was only detectable at 24 h. Ex vivo HIV infectibility assays of rectal biopsies showed partial protection after dosing (P = 0.07). DISCUSSION: A single high dose of oral tenofovir disoproxil fumarate/emtricitabine provides rapid and high blood levels of tenofovir and emtricitabine, with rapid diffusion of emtricitabine in saliva and rectal tissue. Article	2017	Fonsart, Julien; Sarogoni, Sotiroh; Tassi, Mikel; Peytavin, Gilles; Bushman, Lane; Chervenn, Isabelle; Hance, Allan; Goldwirt, Lauriane; Morel, Stéphane; Martreau, Fabrice; Lesa, Blotchkie; Capitant, Catherine; Clavel, François; Malfoyb, Nadia; Meyer, Laurence; Andersen, Peter L; Delmgerry, Constance; Molina, Jean-Michel	Single-dose pharmacokinetics and pharmacodynamics of oral tenofovir and emtricitabine in blood, saliva and rectal tissue: a sub-study of the ANRS IPERGAY trial.	Journal of Antimicrobial Chemotherapy	-	-	-	-	1466-2091	10.1093/jac/dkw412	https://dx.doi.org/10.1093/jac/dkw412	OBJECTIVES: In the ANRS IPERGAY pre-exposure prophylaxis (PrEP) trial, a single dose of tenofovir disoproxil fumarate and emtricitabine was taken orally 2–24 h before sexual intercourse. A sub-study was conducted to assess the pharmacokinetics of tenofovir and emtricitabine in blood, saliva and rectal tissue following this initial oral intake. METHODS: Plasma, PBMC, saliva and rectal tissue sampling was performed over 24 h in 12 seronegative men before enrolment in the ANRS IPERGAY trial, following a single dose of 600 mg tenofovir disoproxil fumarate/400 mg emtricitabine. Ex vivo HIV infectibility of rectal biopsies was also assessed. RESULTS: The median plasma Tmax of tenofovir (median Cmax: 401 μg/L) and emtricitabine (median Cmax: 2098 μg/L) was obtained 1 h (range: 0.5–6 and 2 h (range: 1–6) after dosing, respectively. The median C24 of tenofovir and emtricitabine was 40 and 63 μg/L, respectively. The median PBMC tenofovir diphosphate and emtricitabine triphosphate levels were 12.2 and 16.7 fmol/106 cells and 2060 and 2000 fmol/106 cells at 2 and 24 h after dosing, respectively. Saliva/plasma AUC0-24 ratios were 2% and 17% for tenofovir and emtricitabine, respectively. Emtricitabine was detected in rectal tissue 30 min after dosing, whereas tenofovir was only detectable at 24 h. Ex vivo HIV infectibility assays of rectal biopsies showed partial protection after dosing (P = 0.07). Article	2017	Georgescu, Anca; Egarievla, Cesar; Schaff, Spencer; Fisher, Julie; Smith, Shannon; Florita, Catalin; Gaido, Alyssa; Klotz, Stephen	PrEP Uptake and Emergent HIV infections in Southern Arizona: Is There A Disconnect?	Open Forum Infectious Diseases	-	-	-	-	2328-8957	10.1093/ofid/ofx163.1111	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5631111/	Abstract Background Despite expansion of antiretroviral therapy in recent years and growing evidence for PrEP (pre exposure prophylaxis) efficacy, HIV incidence has continued to rise while PrEP uptake has remained low, particularly in populations at risk. Our goal is to compare these populations and further identify discrepancies in populations at risk in Southern Arizona. Methods We retrospectively reviewed the electronic medical records of patients who were diagnosed with HIV infection between January 2015 and December 2016 at the Kino Clinic, a Ryan White clinic in Tucson/suburbs for PrEP. Results We identified 147 patients with an HIV diagnosis and 43 patients evaluated for PrEp. 63% of the newly diagnosed HIV were of Hispanic, African American or American Indian descend (46%, 14% and 3% respectively) while the majority of PrEP patients were White (58%) with a statistically significant difference between the groups ($P = 0.006$). There was no significant difference between the age groups 20 (19%) of the HIV and 13 (20%) of the PrEP were 18–24 or gender (88% of people accessing HIV care were men, 91% men newly PrEP). Insurance information at the time of presentation was available for 145 HIV and 64 PrEP patients with statistically significant differences between the groups. 31(21%) newly diagnosed HIV had no insurance and 71 (49%) had a Medicaid plan while 48 (74%) of PrEP patients has a private insurance plan ($P < 0.001$). None of the people accessing PrEP reported to prior drug use as a risk factor compared with 16 (11%) of the newly diagnosed ($P = 0.005$). Retention in care at 3 months was similar (76% of HIV and 75% of PrEP). The predominant risk categories were MSM with multiple partners and/or condomless anal sex for both groups (88% and 98% respectively). Conclusion Despite the similar risk profiles, there are disparities in a border region of the Southwestern US, which is home to a large Hispanic minority population. Our findings suggest that low income minority populations, such as Hispanic, African American and American Indian in this region continue to have a higher risk for HIV acquisition and highlights the ongoing need to expand research on how these populations perceive their risk for HIV and navigate complex systems, such as health insurance, when seeking clinical services for PrEP. Article	2017	Girometti N.; Gutierrez A.; Nwokolo N.; McOwan A.; Whitlock G.	High HIV incidence in men who have sex with men following an early syphilis diagnosis: Is there room for pre-exposure prophylaxis as a prevention strategy?	Sexually Transmitted Infections	-	-	-	-	13684973	10.1136/sextrans-2016-052865	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85025127907&doi=10.1136%2Fsextrans-2016-052865&partnerID=40&md5=7829271745f68dbaab1d1588ecca15	OBJECTIVES: Pre-exposure prophylaxis (PrEP) is becoming a pivotal strategy for HIV prevention. Understanding the impact of risk factors for HIV transmission to identify those at highest risk would favour the implementation of PrEP, currently limited by costs. In this service evaluation, we estimated the incidence of bacterial STIs in men who have sex with men (MSM) diagnosed with early syphilis attending a London sexual health clinic according to their HIV status. In addition, we estimated the incidence of HIV infection in HIV-negative MSM, following a diagnosis of early syphilis. Methods We undertook a retrospective case note review of all MSM patients diagnosed with early syphilis between January and June 2014. A number of sexual health screens and diagnoses of chlamydia, gonorrhoea and HIV were prospectively analysed following early syphilis diagnosis. Results 206 MSM were diagnosed with early syphilis. 110 (53%) were HIV-negative at baseline, 96 (47%) were HIV-positive. Age (37 vs 32 years, p=0.0005) was significantly different according to HIV status of MSM at baseline. In HIV-negative versus HIV-positive MSM, incidence of rectal chlamydia infection at follow-up was 27 cases in 50/100 person-years (95% CI 18 to 39) versus 9 cases in 100/100 person-years (95% CI 5 to 17) (p=0.0003). Incidence of rectal gonorrhoea was 20 (p=0.0046) for syphilis reinfections, respectively. Trend follow-up for 110 HIV-negative MSM was 144 person-years. HIV incidence was 8.3/100 PYFU (CI 4.2 to 14). Conclusions A diagnosis of early syphilis carries a high risk of consequent HIV seroconversion and should warrant prioritised access to prevention measures such as PrEP and regular STI screening to prevent HIV transmission. © Published by the BMJ Publishing Group Limited. Article	2017	Glidden, David V.; Mulligan, Kathleen; McMahan, Vanessa; Anderson, Peter L.; Guanira, Juan; Chariyalertsak, Suwat; Buchbinder, Susan P.; Bekker, Linda Gail; Schechter, Mauro; Grinsztejn, Beatriz; Grant, Robert M.	Recovery of Bone Mineral Density Following Dx Tenofovir-Based HIV Pre-Exposure Prophylaxis	JAIDS Journal of Acquired Immune Deficiency Syndrome	-	-	-	-	1525-4135	10.1097/QAI.0000000000001475.	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5536955/	Background—Oral tenofovir disoproxil fumarate (TDF) for HIV prevention and treatment is associated with decreases in bone mineral density (BMD). Previous reports suggest that these changes may be reversible after discontinuation of TDF. Setting—A metabolic substudy of 498 participants in a randomized, placebo-controlled HIV prevention trial of oral co-formulated TDF with emtricitabine (TDF/FTC, Truvada®) for HIV pre-exposure prophylaxis (PrEP) enrolling 4,758 men and transgender women. Methods—Participants underwent dual X-ray absorptiometry to quantify bone mineral density (BMD) in the hip and spine during PrEP and at 2 visits after stopping (median of 23 and 78 weeks post-PrEP, respectively). Results are stratified by pharmacologic measure of TDF/FTC adherence. Results—There was no significant difference in change in hip/spine BMD at any timepoint between placebo and those with low adherence. Adherent participants had a mean (standard error) BMD change at TDF/FTC discontinuation of -1.02% (0.24) at the hip and -1.86% (0.36) in the spine. After stop, unmodified BMD increases of 1.13% per year (0.27) in hip and 1.81% per year (0.36) in spine were observed. Modeling BMD recovery using a mixed effects model, 95% (21) in the placebo group, 95% (21) in the low adherence group, and 100% (21) in the adherent group (p=0.005) had recovered to baseline by 1 year after PrEP stop. Recovery was consistent across age, baseline BMD z-score and treatment duration. Conclusions—Mean BMD returns to baseline levels within 12–18 months after TDF-based PrEP discontinuation in both hip and spine with consistency across participant subgroups. Article	2017	Goedel, William C; Hagen, Daniel; Halkitis, Perry N; Greene, Richard E; Griffin-Tomas, Marybec; Brooks, Forrest A; Hickson, DeMarc; Duncan, Dustin T	Post-exposure prophylaxis awareness and use among men who have sex with men in London who use geosocial-networking smartphone applications	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2016.1259655	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85008961062&doi=10.1080%2F09540121.2016.1259655&partnerID=40&md5=717fa5367893ca3782581a3e681ce72	The number of new HIV infections continues to be on the rise in many high-income countries, most notably among men who have sex with men (MSM). Despite recent attention to the use of antiretroviral medications as pre-exposure prophylaxis (PrEP) among populations disproportionately affected by HIV, considerably less research has been diversely conducted on awareness and use of post-exposure prophylaxis (PEP). Based on a convenience sample of 179 self-reported HIV-uninfected MSM using a geosocial-networking smartphone application, this study is among the first to examine the awareness and use of PEP and their demographic and behavioral correlates among MSM in London. Most respondents (98.3%) had heard of PEP, where 27.4% reported having used it. In multivariable models, the disclosure of one's sexual orientation to their general practitioner (Prevalence ratio PR: 3.49; 95% confidence interval (CI): 1.34, 10.76; p = .029) and reporting one's HIV status as negative (rather than unknown) (PR: 11.49; 95% CI: 1.68, 76.92; p = .013) were associated with higher likelihood of PEP use. The recent use of club drugs (PR: 3.02; 95% CI: 1.42, 6.43; p = .004) was associated with having ever used PEP. High awareness and use in this sample suggest that PEP is a valuable risk-reduction strategy that should be capitalized on, be it in addition to or in the absence of PrEP. © 2016 Informa UK Limited, trading as Taylor & Francis Group. Article	2017	Golub, Sarit A.; Gamarel, Kristi E.; Surace, Anthony	Demographic Differences in PrEP-Related Stereotypes: Implications for Implementation.	AIDS and Behavior	-	-	-	-	1573-3254 1090-7165	10.1007/s10461-015-1129-4	https://pubmed.ncbi.nlm.nih.gov/26143247/	Qualitative interviews about pre-exposure prophylaxis (PrEP) stereotypes were conducted with a subsample of 160 MSM who participated in a PrEP messaging study. Negative stereotypes about PrEP users were identified by 80 % of participants. Two types of stereotypes were most common: PrEP users are HIV-infected (and lying about it), and PrEP users are promiscuous and resistant to condom use. Participants' identification of these stereotype categories differed significantly by demographic factors (i.e., race/ethnicity, education). Expanding access to PrEP requires recognizing potential differences in the experience or anticipation of PrEP-related stereotypes that might impact willingness to discuss PrEP with providers, friends, or partners.	-	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2017	Golub, Sarit A; Gamarel, Kristi E; Lelutiu-weinberger, Corina	The Importance of Sexual History Taking for PrEP Comprehension Among Young People of Color	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1512-9	https://www.proquest.com/scholarly-journals/importance-sexual-history-taking-prep/docview/1883409090/se-2?accountid=9133	Despite demonstrated efficacy, uptake of pre-exposure prophylaxis (PrEP) remains low, especially among highest priority populations. This study examined four PrEP messaging factors hypothesized to impact comprehension of PrEP educational information: (1) modality (video versus in-person message delivery); (2) frame (risk versus health focus); (3) specificity (gist versus verbatim efficacy information); and (4) sexual history (administered either before or after PrEP education). We examined message comprehension among 157 young people of color (YPoC) eligible for PrEP, using a series of multiple choice questions. Overall, 63.6 % (n = 103) got all message comprehension questions correct. In multivariate analyses, engaging in a sexual history before receiving PrEP education was associated with increased odds of message comprehension (aOR 2.23; 95 % CI 1.06-4.72). This effect was even stronger among those who received PrEP education via video (aOR 3.53; 95 % CI 1.16-10.81) compared to via health focus. This research underscores the importance of sexual history-taking as part of PrEP education and clinical practice for YPoC, and suggests that engaging patients in a sexual history prior to providing them with PrEP education may be key to increasing comprehension. Article	2017	Goparaju, Lakshmi; Praschan, Nathan C; Warren-Jeanpiere, Lari; Experton, Laure S; Young, Mary A; Kassaye, Seble	Stigma, Partners, Providers and Costs: Potential Barriers to PrEP Uptake among US Women.	Journal of AIDS & Clinical Research	-	-	-	2155-6113	10.4172/2155-6113.1000730	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5708581	BACKGROUND: Pre-Exposure Prophylaxis (PrEP) use has remained low among US women while significantly increasing among men who have sex with men. Besides lack of awareness, women face several social and structural barriers in gaining access to and using PrEP. METHODS: Four focus group discussions with 20 HIV-negative women who live in the Washington DC metropolitan area. RESULTS: The women expressed concerns about social and structural barriers to PrEP use. They were afraid that stigma related to using "HIV medicines" could affect PrEP use as well. They are worried that family and friends may question their reasons for taking anti-retrovirals and suspect that they were HIV-positive. They expected hostile reactions from male partners, including accusations of infidelity and introducing mistrust in their relationships. Communicating with health care providers about sexual matters in general and their need for PrEP in particular were identified as further barriers. Women reported that providers rarely ask about risk behaviors related to HIV acquisition; that short visits hinder establishing a trusting relationship to discuss sensitive matters. They were concerned that disclosure of risk behaviors may result in judgmental responses and harsh treatment from providers. Lastly, women were concerned that PrEP costs, including insurance coverage and copays, would keep PrEP out of their reach. While cognizant of the potential barriers, women were unwavering in their determination to find ways to circumvent challenges to PrEP access. CONCLUSION: Social and structural barriers may impede women's access to PrEP despite their own reported interest. Continued efforts to reduce HIV stigma, improve patient-provider relationships and ensure affordability of PrEP may increase the likelihood that women will use this important prevention modality. Article	2017	Govender E.; Mansoor L.; MacQueen K.; Abdool Karim Q.	Secrecy, empowerment and protection: positioning PrEP in KwaZulu-Natal, South Africa	Culture, Health & Sexuality	-	-	-	13691058	10.1080/13691058.2017.1309682	https://www.jstor.org/stable/26787821	The release of World Health Organisation guidelines recommending the prophylactic use of daily Truvada® for all populations at high risk of acquiring HIV opens the way for implementation of oral pre-exposure prophylaxis (PrEP). The impact of new prevention technologies is, however, dependent on demand creation strategies such as user awareness, acceptability and access, which in turn are influenced by sociocultural and gender norms. This study was conducted in three locations in KwaZulu-Natal, urban, rural and peri-urban, with six participatory workshops. Knowledge, desirable features of a product and demand positioning for PrEP were assessed using a participatory action media research process which included art-based activities and group discussion using a semi-structured interview schedule. The data were analysed using thematic analysis. The key themes that emerged in relation to product adoption were: ability to maintain secrecy of product use; the need for agency with personal choices around HIV prevention; and an increased desire for HIV protection. Findings reaffirm the influence of user engagement in understanding the sociocultural dynamics that influence demand creation for PrEP adoption. © 2017 Informa UK Limited, trading as Taylor & Francis Group.	action media; demand creation; HIV prevention; Pre-exposure prophylaxis; South Africa; women	English	United Kingdom	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Qualitative
Article	2017	Govender E.M.; Mansoor L.E.; Abdool Karim Q.	Influences of geo-spatial location on pre-exposure prophylaxis use in South Africa: positioning microbicides for better product uptake	AIDS Care	-	-	-	9540121	10.1080/09540121.2016.1248349	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84994065446&doi=10.1080%2f09540121.2016.1248349&partnerID=40&md5=1675ee51b47a15cfd6fa21ded6d793fb	Young women bear a disproportionately high burden of HIV infection in sub-Saharan Africa, prioritising pre-exposure prophylaxis (PrEP) can be an integral part of HIV prevention combination strategies. Women initiated HIV prevention technology options will require consistent adherence, an imperative for product effectiveness. With several PrEP clinical trials underway; exploring women's acceptability to advances in HIV prevention technologies can better facilitate demand creation for future PrEP roll out. This study utilised the opportunity of post-trial access to CAPRISA 008 women (trial) and non-trial women from three geo-spatial settings (urban, rural and peri-urban) to identify microbicide acceptability and how product associations of microbicides can influence future HIV prevention choices. Six participatory workshops using participatory action research with art-based activities and discussion groups were conducted in KwaZulu-Natal with 104 women from various geo-spatial locations and social status to understand microbicide acceptability and product associations. The data were analysed using thematic analysis. The study found that women's acceptability and product association of the tenofovir gel microbicide differed according to rural and urban areas. Most urban women identified confidence, sexiness and classiness as key associations that will encourage microbicide acceptability and use, while rural women identified respect, responsibility and confidence as the key product associations, with increased focus on the individual and collective family/community benefits of product acceptance and use. Urban–rural differences suggest a market segmentation that is contextualised to be locally responsive to promote HIV prevention technologies. Various sexual encounters further determined the types of HIV prevention technologies women would consider. In line with WHO's recommendation that PrEP should be an additional prevention choice for people at risk of HIV, this study underscores the importance of user engagement, understanding product associations and how this can influence product acceptability and promotion of HIV prevention technologies. © 2016 Informa UK Limited, trading as Taylor & Francis Group.	market segmentation; participatory research; Pre-exposure prophylaxis	English	United Kingdom	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Clinical
Article	2017	Grant, Hannah; Mukandavire, Zindoga; Eakle, Robyn; Prudden, Holly; B Gomez, Gabriela; Rees, Helen; Watts, Charlotte	When are declines in condom use while using PrEP a concern? Modelling insights from a Hillbrow, South Africa case study.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.20.1.21744	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5640310	INTRODUCTION: Oral pre-exposure prophylaxis (PrEP) is a promising new prevention approach for those most at risk of HIV infection. However, there are concerns that behavioural disinhibition, specifically reductions in condom use, might limit PrEP's protective effect. This study uses the case of female sex workers (FSWs) in Johannesburg, South Africa, to assess whether decreased levels of condom use following the introduction of PrEP may limit HIV risk reduction. METHOD: We developed a static model of HIV risk and compared HIV-risk estimates before and after the introduction of PrEP to determine the maximum tolerated reductions in condom use with regular partners and clients for HIV risk not to change. The model incorporated the effects of increased STI exposure owing to decreased condom use. Noting that condom use with regular partners is generally low, we also estimated the change in condom use tolerated with clients only, to still achieve 50 and 90% risk reduction on PrEP. The model was parameterized using data from Hillbrow, Johannesburg. Sensitivity analyses were performed to ascertain the robustness of our results. RESULTS: Reductions in condom use could be tolerated by FSWs with lower baseline condom use (65%). For scenarios where 75% PrEP effectiveness is attained, 50% HIV-risk reduction on PrEP would be possible even with 100% reduction in condom use from consistent condom use as high as 70% with clients. Increased exposure to STIs through reductions in condom use had limited effect on the reductions in condom use tolerated for HIV risk not to increase on PrEP. CONCLUSIONS: PrEP is likely to be of benefit in reducing HIV risk, even if reductions in condom use do occur. Efforts to promote consistent condom use will be critical for FSWs with high initial levels of condom use, but with challenges in adhering to PrEP. Article	2017	Greene G.J.; Swann G.; Fought A.J.; Carballo-Diéguez A.; Hope T.J.; Kiser P.F.; Mustanski B.; D'Aquila R.T.	Preferences for Long-Acting Pre-exposure Prophylaxis (PrEP), Daily Oral PrEP, or Condoms for HIV Prevention Among U.S. Men Who Have Sex with Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1565-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84992154227&doi=10.1007%2fs10461-016-1565-9&partnerID=40&md5=5d6e330eede3a818fef83f0af540a042	HIV prevention method preferences were evaluated among 512 U.S. men who have sex with men (MSM; median age: 22 years). Approximately 90 % consistently preferred one option across pairwise comparisons of condoms, daily oral pre-exposure prophylaxis (PrEP), and long-acting PrEP delivered via either an injectable or one of two types of PrEP implants differing in visibility. Condoms were most frequently preferred (33.8 %), followed by non-visible implants (21.5 %), and oral PrEP (17.0 %); HIV risk was reported by more choosing implants. In a follow-up question comparing the four PrEP options only, daily oral pills and non-visible implants were most frequently preferred (35.5 and 34.3 %, respectively), followed by injections (25.2 %) and visible implants (4.3 %). An inductive, open-coding approach determined that convenience, duration of protection, and privacy were the most commonly cited reasons for a PrEP method choice, and associated with self-report of HIV risk. Tailoring PrEP product development to privacy and other concerns important to those at highest HIV risk may improve HIV prevention. © 2016, Springer Science+Business Media New York. Article	2017	Grippo, Jessica; Smallwood, Stacy; Pincura, Katherine; Wright, Tamara; Mase, William	Physician Attitudes Toward the Ethics of Pre-exposure Prophylaxis (PrEP): Cost, Safety, and Resource Allocation	Journal of the Georgia Public Health Association	-	-	-	2471-9773	https://doi.org/10.21633/jgpha.7.104	https://www.researchgate.net/publication/346856915_Physician_Attitudes_Toward_the_Ethics_of_Pre-exposure_Prophylaxis_PrEP_Cost_Safety_and_Resource_Allocation	Background: In the United States, human immunodeficiency virus (HIV) remains a substantial public health issue. There is evidence that the use of antiretroviral medications such as pre-exposure prophylaxis (PrEP) can be a safe and effective primary prevention strategy to reduce new cases of HIV infection. Provider practice behavior as it relates to prescribing PrEP and the potential impact on specific vulnerable populations needs increased attention. Few studies have evaluated the attitudes of physicians towards ethical issues related to prescribing PrEP. Methods: The purpose of the present literature review was to evaluate provider attitudes toward the ethics of prescribing PrEP for individuals at risk of acquiring HIV infection. Searches of the PubMed and Cochrane databases were conducted. Three reviewers independently assessed the relevance of articles and discarded those not directly related to the attitudes of physicians toward ethics of the cost, safety, and resource allocation of PrEP. A total of twenty-one articles were included in the review. Results: Provider attitudes and perceptions focused on three areas: resource allocation, cost, and safety or effectiveness of PrEP. Providers who were hesitant in prescribing PrEP were concerned with the availability of resources, patient adherence, risk of drug resistance, and toxicity. In the studies reviewed, few providers had prescribed PrEP; however, prescribing practices trended upward with time and awareness. Conclusions: Realization of the benefits of PrEP will require a utilitarian ethical approach to identifying the populations that will benefit most, monitoring for adverse effects, addressing costs, and educating and training providers to prescribe PrEP responsibly. Ensuring that PrEP fulfills its potential as part of a combination regimen for HIV prevention requires identification of additional evidence, education, support services, and resources that are needed, as well as the regulatory framework and cost scenarios for access to PrEP. Key words: HIV, pre-exposure prophylaxis, ethics, utilitarianism, PrEP, physician	Pre-exposure prophylaxis; Family medicine; Human immunodeficiency virus (HIV); hiv; Public aspects of medicine; RA1-1270; Resource allocation; prep; ethics; physician; Utilitarianism	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2017	Guillamet, Laia Jimena Vazquez; Moll, Anthony P; Kacin, Alexa; Madi, Jabulile; Ndlovu, Ntombi; Shenoi, Sheela	Perceptions of HIV Pre-exposure prophylaxis (PrEP) among young pregnant women from KwaZulu-Natal, South Africa	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1089/apc.2018.0242	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6531897/	Abstract Background Pre-exposure prophylaxis (PrEP) is effective for HIV prevention with good adherence. In high HIV prevalence settings, young women ages 18–24 are at high risk of HIV acquisition, particularly during pregnancy and the postpartum period, and would potentially benefit from PrEP. More information is needed to achieve successful implementation of PrEP in this population. Methods The study was performed in Tugela Ferry, one of the poorest subdistricts of South Africa. From June-August 2016,the study team interviewed 187 HIV negative pregnant women ages 18–24 anonymously at health care facilities. Interviews collected data on demographics, HIV and PrEP knowledge, HIV risk and readiness for oral PrEP. Results Among 187 pregnant women, the mean age was 20.3 years (SD1.97), 179 (95.7%) were unemployed, 93 (49.7%) completed secondary school, and 137 (73.3%) reported one partner in the last month. None reported having ever being paid for sex. While 185 (98%) knew that HIV can be transmitted through sex, only 117 (62.5%) knew that a woman can transmit HIV to her child, and only 95 (51%) knew that HIV can be transmitted through breastmilk. Sixty-eight (36.4%) women believed that a sexual partner had been sexually active with another person in the last month, though 182 (97.3%) had difficulty negotiating condom use with their partner, and only 7 (3.7%) women reported consistent use of condoms. The vast majority (97%) would start PrEP if a doctor recommended it though 100 (53.5%) were concerned about being mistaken for HIV positive. Conclusion Pregnant young women in rural South Africa are at risk for HIV acquisition and are interested in PrEP. Knowledge of risks of HIV lags, particularly with regard to mother to child transmission. Young pregnant women are not able to negotiate consistent condom use and need a HIV prevention tool that is within their control. Stigma may be a barrier to effective PrEP use among these women. Further research is needed to guide potential PrEP implementation in pregnant women. Disclosures All authors: No reported disclosures. Article	2017	Guise A.; Albers E.R.; Strathdee S.A.	'PrEP is not ready for our community, and our community is not ready for PrEP': pre-exposure prophylaxis for HIV for people who inject drugs and limits to the HIV prevention response	Addiction	-	-	-	9652140	10.1111/add.13437	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84973526743&doi=10.1111%2fadd.13437&partnerID=40&md5=74832191d294586ec6d3cb43d4dc6002	Background and aims: Pre-exposure prophylaxis for HIV, or 'PrEP', is the use of antiretroviral medicines by people who are HIV-negative to protect themselves against acquiring HIV. PrEP has shown efficacy for preventing HIV acquisition. Despite the potential, many concerns have been voiced by people who inject drugs (PWID) and their organizations. There is a need to engage with these views and ensure their integration in to policy and strategy. This paper presents PWID views on PrEP to foster the uptake of these opinions into scientific and policy debate around PrEP. Methods: Critical analysis of a report of a community consultation led by the International Network of People who Use Drugs (INPUD). Results: The INPUD report highlights enthusiasm from PWID for PrEP, but also three main concerns: the feasibility and ethics of PrEP, its potential use as a substitute for other harm reduction strategies and how a focus on PrEP heralds a re-medicalization of HIV. Each concern relates to evidenced gaps in essential services or opposition to harm reduction and PWID human rights. Conclusions: People who use drugs have fundamental concerns about the potential impacts of pre-exposure prophylaxis for HIV which reflect a 'fault line' in HIV prevention: a predominance of biomedical approaches over community perspectives. Greater community engagement in HIV prevention strategy is needed, or we risk continuing to ignore the need for action on the underlying structural drivers and social context of the HIV epidemic. © 2016 Society for the Study of Addiction	Biomedical; community; HIV; injection drug use; PrEP; prevention	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Qualitative

Maraviroc (MVC) is a candidate for human immunodeficiency virus (HIV) pre-exposure prophylaxis. Methods. Phase 2 48-week safety/tolerability study was conducted, comparing 4 regimens: MVC alone, MVC plus emtricitabine (FTC), MVC plus tenofovir disoproxil fumarate (TDF), and TDF plus FTC. Eligible participants were HIV-uninfected men and transgender women reporting condomless anal intercourse with >= 1 HIV-infected or unknown-serostatus man within 90 days. At each visit, assessments, laboratory testing, and counseling were done. Analyses were intention to treat. Results. Among 406 participants, 84% completed follow-up, 7% stopped early, and 9% were lost to follow-up; 9% discontinued their regimen early. The number discontinuing and the time to discontinuation did not differ among study regimens (P = .60). Rates of grade 3-4 adverse events did not differ among regimens (P = .37). In a randomly selected subset, 77% demonstrated detectable drug concentrations at week 48. Five participants acquired HIV infection (4 MVC alone, 1 MVC + TDF; overall annualized incidence, 1.4% 95% confidence interval, .5%-3.3%, without differences by regimen; P = .32); 2 had undetectable drug concentrations at every visit, 2 had low concentrations at the seroconversion visit, and 1 had variable concentrations. Conclusions. MVC-containing regimens were safe and well tolerated compared with TDF + FTC; this study was not powered for efficacy. Among those acquiring HIV infection, drug concentrations were absent, low, or variable. MVC-containing regimens may warrant further study for pre-exposure prophylaxis. Article	2017	Gulick, Roy M; Wilkin, Timothy J; Chen, Ying Q; Landovitz, Raphael J; Amico, K Rivet; Young, Alicia M; Richardson, Paul; Marzinke, Mark A; Hendrix, Craig W; Eshleman, Susan H; McGowan, Ian; Cottle, Leslie M; Andrade, Adriana; Marcus, Cheryl; Klingman, Karin L; Chege, Wairimu; Rinehart, Alex R; Rooney, James F; Andrew, Philip; Salata, Robert A; Siegel, Marc; Manabe, Yukari C; Frank, Ian; Ho, Ken; Santana, Jorge; Stekler, Joanne D; Swaminathan, Shobha; McCauley, Marybeth; Hodder, Sally; Mayer, Kenneth H	Safety and Tolerability of Maraviroc-Containing Regimens to Prevent HIV Infection in Women: A Phase 2 Randomized Trial.	Annals of Internal Medicine	-	-	-	1539-3704	10.7326/M17-0520	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5667908	BACKGROUND: Maraviroc (MVC) is a candidate drug for HIV preexposure prophylaxis (PrEP). OBJECTIVE: To assess the safety and tolerability of MVC-containing PrEP over 48 weeks in U.S. women at risk for HIV infection. DESIGN: Phase 2 randomized, controlled, double-blinded study of 4 antiretroviral regimens used as PrEP. (ClinicalTrials.gov: NCT01505114). SETTING: 12 clinical research sites of the HIV Prevention Trials Network and AIDS Clinical Trials Group. PARTICIPANTS: HIV-uninfected women reporting condomless vaginal or anal intercourse with at least 1 man with HIV infection or unknown serostatus within 90 days. INTERVENTION: MVC only, MVC-emtricitabine (FTC), MVC-tenofovir disoproxil fumarate (TDF), and TDF-FTC (control). MEASUREMENTS: At each visit, clinical and laboratory (including HIV) assessments were done. Primary outcomes were grade 3 and 4 adverse events and time to permanent discontinuation of the study regimen. All randomly assigned participants were analyzed according to their original assignment. RESULTS: Among 188 participants, 85% completed follow-up, 11% withdrew early, and 4% were lost to follow-up; 19% discontinued their regimen prematurely. The number discontinuing and the time to discontinuation did not differ among regimens. Grade 3 or 4 adverse events occurred in 5 (MVC), 13 (MVC-FTC), 9 (MVC-TDF), and 8 (TDF-FTC) participants; rates did not differ among regimens. One death (by suicide) occurred in the MVC-TDF group but was judged not to be related to study drugs. Of available plasma samples at week 48 (n = 126), 60% showed detectable drug concentrations. No new HIV infections occurred. LIMITATIONS: Participants were not necessarily at high risk for HIV infection. The regimen comprised 3 pills taken daily. The study was not powered for efficacy. CONCLUSION: Maraviroc-containing PrEP regimens were safe and well-tolerated compared with TDF-FTC in U.S. women. No new HIV infections occurred, although whether this was due to study drugs or low risk in the population is uncertain. Maraviroc-containing PrEP for women may warrant further study. Article	2017	Haakma T.A.; Luder S.; Müller E.; Somaini B.	Transition from HIV control to HIV elimination in Switzerland	Journal of Public Health (Germany)	-	-	-	9431853	10.1007/s10389-017-0819-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85034738389&doi=10.1007%2fs10389-017-0819-y&partnerID=40&md5=a1aa8912a47c68740498e7736757d781	Purpose: This article proposes a strategy for Switzerland to change the goal from HIV control to HIV elimination. In Switzerland, HIV treatment is well organized and available for all with good access. Methods: An important challenge that obstructs prevention is the new infections originating from people who are unaware of their status. Since the majority of new infections in Switzerland are within the group of men who have sex with men (MSM), this strategy targets MSM who do not know their HIV status and engage in risky sexual behavior. Results: The strategy focuses on three pillars: collaboration and leadership, key actions and important indicators. To guide this effort, we proposed a task force to be responsible for leading this strategy. Its actions are centered around four aspects: learn from MSM, promote and facilitate testing, and include PrEP and PEP in the prevention package together with partner information. This article also provides important indicators that must be measured to inform the task force and to adapt or strengthen the strategy to reach the goal. Conclusion: Reaching the right persons and offering the right "prevention package" are the key challenges for Switzerland to be among the first countries to eliminate HIV transmission. © 2017, Springer-Verlag GmbH Germany. Article	2017	Haberer J.E.; Ngure K.; Muwonge T.; Mugo N.; Katabira E.; Heffron R.; Musinguzi N.; Bangsberg D.R.; Celum C.; Baeten J.M.	Context matters: PrEP adherence is associated with sexual behavior among HIV serodiscordant couples in East Africa	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001548	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037690146&doi=10.1097%2fQAI.0000000000001548&partnerID=40&md5=08bd54d0c0fb7c271f2363f0aa314240	Background: Short message service (SMS) surveys are a promising tool for understanding whether preexposure prophylaxis (PrEP) adherence aligns with risk for HIV acquisition - a concept known as prevention-effective adherence. Methods: The Partners Demonstration Project was an open-label study of integrated PrEP and antiretroviral therapy (ART) delivery among high-risk HIV serodiscordant couples in East Africa. HIV-uninfected partners were offered PrEP until their HIV-infected partner had taken ART for ≥6 months. At 2 study sites, HIV-uninfected partners were offered enrollment into the Partners Mobile Adherence to PrEP (PMAP) substudy based on ongoing PrEP use, personal cell phone ownership, and ability to use SMS. SMS surveys asked about PrEP adherence and sexual activity in the previous 24 hours; these surveys were sent daily for the 7 days before and 7 days after routine study visits in the Partners Demonstration Project. Results: The PMAP substudy enrolled 373 HIV-uninfected partners; 69% were men and mean age was 31 years. Participants completed 17,030 of 23,056 SMS surveys sent (74%) with a mean of 47 surveys per participant over 9.8 months of follow-up. While HIV-infected partner use of ART was,6 months, mean reported PrEP adherence was 92% on surveys concurrently reporting sex within the serodiscordant partnership, and 84% on surveys reporting no sex (P < 0.001). Discussion: SMS surveys provided daily assessment of concurrent PrEP adherence and sexual behavior. Higher PrEP adherence was temporally associated with increased risk for HIV acquisition. Article	2017	Haberer, Jessica E; Kidoguchi, Lara; Heffron, Renee; Mugo, Nelly; Bukusi, Elizabeth; Katabira, Elly; Asiimwe, Stephen; Thomas, Katherine K; Celum, Connie; Baeten, Jared M	Alignment of adherence and risk for HIV acquisition in a demonstration project of pre-exposure prophylaxis among HIV serodiscordant couples in Kenya and Uganda: A prospective analysis of prevention-effective adherence	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.20.1.21842	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037577659&doi=10.7448%2fIAS.20.1.21842&partnerID=40&md5=190c076772a90da18e07a683bf679271	Introduction: Adherence is essential for pre-exposure prophylaxis (PrEP) to protect against HIV acquisition, but PrEP use need not be life-long. PrEP is most efficient when its use is aligned with periods of risk - a concept termed prevention-effective adherence. The objective of this paper is to describe prevention-effective adherence and predictors of adherence within an open-label delivery project of integrated PrEP and antiretroviral therapy (ART) among HIV serodiscordant couples in Kenya and Uganda (the Partners Demonstration Project). Methods: We offered PrEP to HIV-uninfected participants until the partner living with HIV had taken ART for ≥6 months (a strategy known as "PrEP as a bridge to ART"). The level of adherence sufficient to protect against HIV was estimated in two ways: ⩾4 and ⩾6 doses/week (per electronic monitoring). Risk for HIV acquisition was considered high if the couple reported sex with <100% condom use before six months of ART, low if they reported sex but had 100% condom use and/or six months of ART and very low if no sex was reported. We assessed prevention-effective adherence by cross-tabulating PrEP use with HIV risk and used multivariable regression models to assess predictors of ≥4 and ≥6 doses/week. Results: A total of 985 HIV-uninfected participants initiated PrEP; 67% were male, median age was twenty-nine years, and 67% reported condomless sex in the month before enrolment. An average of ≥4 doses and ≥6 doses/week were taken in 81% and 67% of participant-visits, respectively. Adherence sufficient to protect against HIV acquisition was achieved in 75-88% of participant-visits with high HIV risk. The strongest predictor of achieving sufficient adherence was reporting sex with the study partner who was living with HIV; other statistically significant predictors included no concerns about daily PrEP, pregnancy or pregnancy intention, females aged >25 years, older male partners and desire for relationship success. Predictors of not achieving sufficient adherence were no longer being a couple, delayed PrEP initiation, >6 months of follow-up, ART use >6 months by the partner living with HIV and problem alcohol use. Conclusions: Over three-quarters of participant-visits by HIV-uninfected partners in serodiscordant couples achieved prevention-effective adherence with PrEP. Greater adherence was observed during months with HIV risk and the strongest predictor of achieving sufficient adherence was sexual activity. © 2017 Haberer J E et al; licensee International AIDS Society.	pre-exposure prophylaxis; PrEP; prevention-effective adherence	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Hacker, Elizabeth; Cohn, Jonathan; Golden, Matthew R; Heumann, Christine	HIV Pre-Exposure Prophylaxis (PrEP) Uptake, Initiation, and Persistence in the Detroit Public Health STD Clinic	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1093/ofid/ofx163.1107	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5631394/	Abstract Background HIV pre-exposure prophylaxis (PrEP) is an effective HIV prevention tool; however, little is known about PrEP uptake, initiation, and persistence among patients prescribed PrEP in STD clinics. Methods Between July 2016 and March 2017, STD clinic staff compiled reports detailing the eligibility and initiation of PrEP in the Detroit STD Clinic. Staff called all patients prescribed PrEP to determine whether they had started PrEP, were still on PrEP, and their reasons for never initiating or discontinuing PrEP. We used chi-square tests to evaluate differences in PrEP initiation and discontinuation by age and race, calculated the population's mean duration on PrEP (persistence), and used proportional hazards regression to assess differences in persistence by age and race. Results A total of 161 STD clinic patients were eligible for PrEP, of whom 71 (44%) were prescribed PrEP. Of the 71 patients prescribed PrEP, staff successfully interviewed 45 (63%) a median of 113 days following their receipt of prescription. Thirty-four (76%) interviewed patients had initiated PrEP, of whom 17 (50%) had subsequently discontinued their medication a mean of 92 days (95% confidence interval CI: ± 23.8) following receipt of a prescription. Figure 1 illustrates the PrEP care continuum for our clinic: There was no significant difference in PrEP initiation or discontinuation by age or race. There was no significant difference in persistence by race. Ages 18–24 had the shortest mean persistence (62 days, 95% CI: ±37.5), while those ages 35–44 had the longest mean persistence (146 days, 95% CI: ± 47.3) though this was not a significant difference (hazard ratio 0.39, P = 0.28). The most common reason for not initiating or discontinuing PrEP was concern about side effects (29%). Conclusion Clinicians in the Detroit STD clinic prescribed PrEP for less than half of PrEP-eligible patients, only 76% of those prescribed PrEP ever filled their first prescription, and the mean duration of use among those who filled a first prescription was under 6 months. Our findings highlight the need for further evaluation of why eligible patients are not prescribed PrEP, intensified support services to encourage PrEP persistence, and improved patient counseling about potential side effects. Article	2017	Hampel B.; Kusejko K.; Braun D.L.; Harrison-Quintana J.; Kouyos R.; Fehr J.	Assessing the need for a pre-exposure prophylaxis programme using the social media app Grindr®	HIV Medicine	-	-	-	14642662	10.1111/hiv.12521	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85031494560&doi=10.1111%2fhiv.12521&partnerID=40&md5=e30ef494061c2e086f5423e7a6c28670	Objectives: HIV pre-exposure prophylaxis (PrEP) is not approved in Switzerland and therefore must be paid for by the users themselves. We conducted a survey to find out whether men who have sex with men (MSM) in Switzerland are already taking PrEP, or are considering using it, and whether it is being taken under medical supervision or not. Methods: Grindr® is a geosocial networking app for MSM. Between 5 and 24 January 2017, users of the app who were located in Switzerland by a global positioning system (GPS) were asked to participate in a ten-question survey on PrEP use. Results: Of the 2455 people who took part in the survey, 1893 were included in the analysis. Eighty-two participants (4.3%) reported that they were currently taking PrEP, 64 of whom (78%) said that they were under medical supervision. Seven PrEP users (9%) declared that they had not taken an HIV test within the previous 12 months. Nine hundred and forty-four (49.9%) were considering taking PrEP in the next 6 months, and 1474 (77.9%) were considering taking it at some point in the future. Conclusions: In an online survey carried out among sexually active MSM in Switzerland, only a minority of the individuals approached responded that they were currently using PrEP. However, the majority of participants were considering taking PrEP in the future. We identified a substantial proportion of PrEP users taking PrEP outside a medical setting. Hence, a national programme facilitating access to medical care and providing PrEP is urgently needed. © 2017 The Authors. Theses and Dissertations	2017	Han, Hannah H.	CHARACTERIZING THE SAUTI vAGYW HIV RISK ASSESSMENT TOOL TO MEASURE VULNERABILITY OF ADOLESCENT GIRLS AND YOUNG WOMEN IN TANZANIA	-	-	Johns Hopkins University	-	NA	10.1371/journal.pone.0248153	http://jhir.library.jhu.edu/handle/1774.2/40768	Background: Improved strategies to address the disproportionate burden of HIV in adolescent girls and young women (AGYW) remains as a crucial component of an effective HIV response. To best serve AGYW with personalized, evidence-based HIV intervention packages, validated risk stratification tools are needed. The aim of this study was to characterize the reliability and validity of the Sauti vAGYW HIV risk assessment tool using exploratory factor analysis. Methods: A 20-item scale was developed and administered to 6,526 out-of-school AGYW aged 15-24 in five regions of Tanzania August 2015 to June 2016. Exploratory factor analysis was used to assess the underlying construct of HIV vulnerability among AGYW. Factors were extracted based on Kaiser's criterion, eigenvalues, scree plots, Horn's test, and interpretability. Items were included if the factor loadings were within the range of 0.3 and 0.9 with no cross-loadings. Cronbach's alpha, item-rest and item-test correlations were used to test reliability of the scale. Construct validity was assessed using point-biserial correlations and multivariate logistic regression between the scale and HIV-related health outcomes. Results: Twelve items were retained in the final scale, representing three factors. Cronbach's alpha of the overall scale and Factor 1 were 0.76 and 0.72, respectively, suggesting high internal consistency. Factor 2 (α=0.47) and Factor 3 (α=0.65) had relatively lower Cronbach's alpha, potentially influenced by the small number of items loaded onto these factors. The item-test correlations of the twelve items ranged from 0.40 to 0.63, whereas the item-rest correlations ranged from 0.26 to 0.52. Risk scores were significantly associated with history of HIV test, history of childbirth, and the use of alcohol during sex in the past 30 days. The odds of having ever taken an HIV test (OR: 2.04; 95% CI: 1.40, 2.98), given birth to a child (OR: 1.50; 95% CI: 1.01, 2.22), and use of alcohol when having sex in the past 30 days (OR: 2.57; 95% CI: 1.13, 5.85) were significantly higher comparing the very high risk group to the low risk group. However, the associations with other risk levels did not reach the level of statistical significance. Conclusions: The Sauti vAGYW HIV risk assessment tool reliably stratifies out-of-school AGYW in Tanzania based on individual and structural HIV risks. Scaling implementation of this risk stratification tool may support better HIV prevention specification ranging from enhanced counseling and education to HIV pre-exposure prophylaxis. Article	2017	Hankins, Catherine A; Koulla-Shiro, Sinata; Kilmarx, Peter; Ferrari, Guido; Schechter, Mauro; Kane, Coumba Touré; Venter, François; Boucher, Charles Ab; Ross, Anna-Laura; Zewdie, Debrework; Eholié, Serge Paul; Katabira, Elly	Ending AIDS as a public health threat by 2030: Scientific Developments from the 2016 INTEREST Conference in Yaoundé, Cameroon.	Antiviral Therapy	-	-	-	2040-2058	10.3851/IMP3165	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5542813	The underpinning theme of the 2016 INTEREST Conference held in Yaoundé, Cameroon, 3-6 May 2016 was ending AIDS as a public health threat by 2030. Focused primarily on HIV treatment, pathogenesis and prevention research in resource-limited settings, the conference attracted 369 active delegates from 34 countries, of which 22 were in Africa. Presentations on treatment optimization, acquired drug resistance, care of children and adolescents, laboratory monitoring and diagnostics, implementation challenges, HIV prevention, key populations, vaccine and cure, hepatitis C, mHealth, financing the HIV response and emerging pathogens, were accompanied by oral, mini-oral and poster presentations. Spirited plenary debates on the UNAIDS 90-90-90 treatment cascade goal and on antiretroviral pre-exposure prophylaxis took place. Joep Lange career guidance sessions and grantspersonship sessions attracted early career researchers. At the closing ceremony, the Yaoundé Declaration called on African governments; UNAIDS; development, bilateral, and multilateral partners; and civil society to adopt urgent and sustained approaches to end HIV by 2030. Article	2017	Hanson, Brent M; Dorais, Jessie A	Reproductive considerations in the setting of chronic viral illness.	American Journal of Obstetrics and Gynecology	-	-	-	1097-6868	10.1016/j.ajog.2017.02.012	https://dx.doi.org/10.1016/j.ajog.2017.02.012	Special considerations must be taken when patients with human immunodeficiency virus (HIV), hepatitis B, or hepatitis C desire to become pregnant. Patients with chronic viral illnesses desire to have children at rates similar to the general population, and options are available to decrease both vertical transmission and viral transmission between partners. Preconception counseling or consultation with fertility specialists is imperative in patients with HIV, hepatitis B, and hepatitis C so that reproductive goals can be addressed and optimized. In couples in which one partner has HIV, the use of highly active antiretroviral therapy or preexposure prophylaxis can significantly reduce the risk of transmission between serodiscordant partners. The use of density gradient sperm-washing techniques and intrauterine insemination or in vitro fertilization results in an apparent lack of transmission of HIV between partners when the male partner is HIV-positive. Vertical transmission of HIV from mother to child can be reduced by use of highly active antiretroviral therapy regimens throughout pregnancy or by cesarean delivery in the setting of high maternal viral load. Transmission of hepatitis B between partners can be eliminated by vaccinating the uninfected partner. Vertical transmission from a hepatitis B-infected mother to a child can be reduced by vaccinating neonates with the standard hepatitis B vaccine series as well as hepatitis B immune globulin. Recent data have shown the antiviral medication tenofovir to be an effective way to reduce vertical transmission in the setting of high maternal viral load or the presence of hepatitis B e antigen. There are multiple antiviral medications available to treat chronic hepatitis C, although access to these medications often is limited by cost. Similar to HIV-positive patients, in settings in which the male partner is infected with hepatitis C, density gradient sperm washing can be used before intrauterine insemination or in vitro fertilization to reduce transmission of hepatitis C between partners. No safe and effective method exists to reduce vertical transmission of hepatitis C once a woman becomes pregnant, highlighting the importance of treatment of hepatitis C before pregnancy.	assisted reproduction chronic viral illness hepatitis B hepatitis C human immunodeficiency virus (HIV) intrauterine insemination (IUI) in vitro fertilization (IVF)	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Theses and Dissertations	2017	Hartley, Alice	PrEPared Against HIV: 2.0	-	-	University of Canterbury	-	NA	NA	http://dx.doi.org/10.26021/4171	In 2016, there were 244 new HIV infections in New Zealand; this is the fifth consecutive year of rising infection rates, and the largest number of new diagnoses reported since records began in 1985. In New Zealand, men who have sex with men (MSM) can account for up to 80% of new HIV diagnoses yearly. Until now, HIV prevention has focused on behavioural methods, such as condom use, abstinence, and serosorting. However, recent trials show that a new biomedical method, pre-exposure prophylaxis (PrEP), is more than 90% effective at preventing HIV acquisition among HIV-negative, at-risk individuals when taken daily. Unfortunately, PrEP is not a silver bullet for HIV, as cited complexities associated with PrEP include potential antiretroviral resistance, side effects, cost, stigmatisation, and risk compensation. Therefore, this research aimed to answer the following questions: Do MSM from Canterbury feel that PrEP has a place in New Zealand's public health system, and how could a policy be developed to minimise the difficulties regarding implementation faced overseas? Following Carol H. Weiss's problem-solving model, this thesis uses a multiple, mixed-methods approach to reduce uncertainty regarding HIV prevention and treatment attitudes (specifically regarding PrEP) among a particular cohort (MSM) and thus, informs more effective future policies. The methods used are a survey, interviews, and document analysis. The first research question was answered using an anonymous, online, Likert scale survey. Participants were recruited using non-probability purposive sampling. 42 MSM from the Canterbury region were surveyed to measure their attitudes towards HIV, PrEP and condom use. 100% of participants agreed that taking PrEP is a good way to reduce their chances of HIV infection, 100% of participants agreed that PrEP is a worthwhile prevention method for MSM, and 97.5% believed that PrEP should be subsidised for MSM. Building upon the preliminary data, I propose PrEPared Against HIV: 2.0 as a solution to the second research question that follows Weiss's problem-solving model. This policy is designed specifically to fit within New Zealand's public health system and is informed by the grassroots input and empirical evidence collected through interviews with HIV experts, survey data, and document analysis. PrEPared Against HIV: 2.0 pays specific attention to 'PrEP problem areas' such as developing adequate clinical guidelines, ensuring PrEP providers receive adequate support, encouraging adherence, and reducing stigmatisation linked to PrEP use. This research shows there is a need for greater investment in HIV prevention rather than costly HIV treatment. PrEP can reduce future HIV infections and there is obvious support from both HIV experts and MSM for a PrEP policy in New Zealand. However, PrEP needs to be one plank in a multi-faceted policy for wider HIV prevention to ensure that it can have a positive impact on the HIV epidemic in New Zealand. Article	2017	Hassan, Adiba; Blumenthal, Jill; Dube, Michael; Ellorin, Eric; Corado, Katya; Moore, David	Effect of Rectal Hygiene on Sexually Transmitted Infections Among HIV-Negative Men Who Have Sex with Men (MSM)	Infectious Diseases	-	-	-	2328-8957	https://doi.org/10.1093/ofid/ofx163.092	https://escholarship.org/uc/item/0010b61j	Abstract Background Rectal gonorrhea (NG) and chlamydia (Connecticut) infections are common among men who have sex with men (MSM). Rectal douching/enema (RDE) is a common practice among MSM that can affect the rectal microbiome. It is unclear if this practice is associated with acquiring rectal infections (RI) with either NG or CT. Methods From 2013–2015, 398 adult HIV-negative MSM and transwomen were enrolled in a randomized controlled study on text messaging for adherence to pre-exposure prophylaxis (PrEP). Participants were surveyed on sexual behavior, frequency of RDE, drug use, and nutritional habits in conjunction with routine sexually transmitted infection testing. Pearson's χ 2 and two sample t-tests were used to measure significance of RDE and other risk factors with RI. Multivariable logistic regression model was used to control for confounding and assess the association of RDE with RIs. Confounders (i.e., age, number anal receptive sex, number sex partners) were selected a priori for inclusion in the final model based on a causal model and statistical significance. Results Of 397 participants, 262 (67%) performed RDE and 132 (33%) had at least one NG or CT rectal infection over 48 weeks. Number of condomless anal receptive sex acts (mean = 19, P < 0.001), condom use for anal receptive sex (P = 0.017), number of male sex partners in past 3 months (mean = 14, P = 0.001), and the use of poppers (P < 0.001) were associated with RI. There was no significant association between nutritional habits, probiotic foods or supplements and RI, with the exception of energy bars (P = 0.029). Controlling for confounders, RI was associated with RDE less than weekly with OR = 1.02 (95% CI 0.52–1.99) while RDE weekly or more had OR = 2.08 (95% CI 1.03–4.17). Stratified by number of partners, MSMs with more than the median (>6) number of partners had OR = 4.96 (95% CI 1.29–19.03) if performing RDE less than weekly, and OR = 6.03 (95% CI 1.55–23.49) if weekly or more. Conclusion Rectal hygiene with douching/enemas is a common practice among MSMs on PrEP, which increases the odds of acquiring rectal NG and/or CT. This finding is suggestive for the use of rectal hygiene products/practices as potential targets for sexually transmitted infection prevention. Disclosures All authors: No reported disclosures. Article	2017	Havens P.L.; Stephensen C.B.; Van Loan M.D.; Schuster G.U.; Woodhouse L.R.; Flynn P.M.; Gordon C.M.; Pan C.G.; Rutledge B.; Liu N.; Wilson C.M.; Hazra R.; Hosek S.G.; Anderson P.L.; Seifert S.M.; Kapogiannis B.G.; Mulligan K.	Decline in bone mass with tenofovir disoproxil fumarate/emtricitabine is associated with hormonal changes in the absence of renal impairment when used by HIV-uninfected adolescent boys and young men for HIV preexposure prophylaxis	Clinical Infectious Diseases	-	-	-	10584838	10.1093/cid/ciw765	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026913214&doi=10.1093%2fcid%2fciw765&partnerID=40&md5=84a79c73524ae7587a2d05a72b7b39cf	Background. We aimed to define the relative importance of renal and endocrine changes in tenofovir disoproxil fumarate (TDF)-related bone toxicity. Methods. In a study of daily TDF/emtricitabine (FTC) preexposure prophylaxis (PrEP) in human immunodeficiency virus (HIV)-uninfected young men who have sex with men, we measured changes from baseline in blood and urine markers of the parathyroid hormone (PTH)-vitamin D-fibroblast growth factor 23 (FGF23) axis, creatinine, and renal tubular reabsorption of phosphate (TRP). We explored the relationship of those variables to changes in bone mineral density (BMD). Tenofovir-diphosphate (TFV-DP) in red blood cells was used to categorize participants into high and low drug exposure groups. Results. There were 101 participants, median age 20 years (range 15 to 22). Compared with low drug exposure, high-exposure participants showed increase from baseline in PTH and decline in FGF23 by study week 4, with no differences in creatinine, phosphate, or TRP. At 48 weeks, the median (interquartile range) percent decline in total hip BMD was greater in those with high- compared to low- exposure (-1.59 2.77 vs +1.54 3.34 %, respectively; P = .001); in high-exposure participants, this correlated with week 4 TFV-DP (inversely; r = -0.60, P = .002) and FGF23 (directly; r = 0.42; P = .039) but not other variables. Conclusions. These findings support the short-term renal safety of TDF/FTC PrEP in HIV-seronegative young men and suggest that endocrine disruption (PTH-FGF23) is a primary contributor to TDF-associated BMD decline in this age group. Article	2017	Heffron R.; McClelland R.S.; Balkus J.E.; Celum C.; Cohen C.R.; Mugo N.; Bukusi E.; Donnell D.; Lingappa J.; Kiarie J.; Fiedler T.; Munch M.; Fredricks D.N.; Baeten J.M.; Coombs R.W.; Frenkel L.; Hendrix C.W.; McElrath M.J.; Fife K.; Were E.; Tumwesigye E.; Ndase P.; Katabira E.; Ronald A.; Wangisi J.; Campbell J.; Tappero J.; Farquhar C.; John-Stewart G.; Mugo N.R.	Efficacy of oral pre-exposure prophylaxis (PrEP) for HIV among women with abnormal vaginal microbiota: a post-hoc analysis of the randomised, placebo-controlled Partners PrEP Study	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(17)30110-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85024889467&doi=10.1016%2fS2352-3018%2817%2930110-8&partnerID=40&md5=c777187b9583ddf2e9b1c47c75989a4d	Background Daily oral tenofovir-based pre-exposure prophylaxis (PrEP) is high efficacious for HIV prevention among women with high adherence. However, the effect of abnormal vaginal microbiota on PrEP efficacy is of concern. We investigated whether bacterial vaginosis modified the efficacy of oral PrEP. Methods We used prospectively collected data from women in the Partners PrEP Study, a placebo-controlled trial of daily oral PrEP (either tenofovir monotherapy or a combination of tenofovir and emtricitabine) in HIV serodiscordant couples aged 18 years or older in Kenya and Uganda that showed high efficacy in women. We used Cox proportional hazards regression to assess PrEP efficacy among subgroups of women defined by bacterial vaginosis status based on yearly microscopy and Nugent scoring (0–3 indicated healthy microbiota, 4–6 intermediate, and 7–10 bacterial vaginosis). In separate efficacy analyses, we also investigated individual components of the score (ie, detection of Gardnerella vaginalis or Bacteroides spp and non-detection of Lactobacillus spp) as markers of abnormal microbiota. Findings Of 1470 women (median age 33 years), 357 (24%) had bacterial vaginosis at enrolment. 45 women seroconverted to HIV. The HIV prevention efficacy of PrEP did not differ significantly among women with healthy microbiota (incidence 0·6 per 100 person years in PrEP group and 2·5 per 100 person-years in the placebo group; efficacy 76·55% 95% CI 43·09 to 90·37), intermediate microbiota (HIV incidence 1·8 per 100 person-years in the PrEP group and 3·5 per 100 person-years in the placebo group; efficacy 62·72% 95% CI −66·59 to 91·66), or bacterial vaginosis (HIV incidence 0·9 per 100 person-years in the PrEP group and 3·5 per 100 person-years in the placebo group; efficacy 72·50% 95% CI 5·98 to 91·95; pinteraction=0·871). PrEP efficacy was not significantly different between women with G vaginalis or Bacteroides spp morphotypes and those without these morphotypes (efficacy 68·62% vs 76·72%; pinteraction=0·652); or between those with Lactobacillus spp morphotypes and those without (70·48% vs 74·08%; pinteraction=0·86). Interpretation Among African women with a high prevalence of bacterial vaginosis and high adherence to PrEP, the efficacy of daily oral PrEP for HIV prevention did not differ significantly among women with abnormal versus healthy vaginal microbiota as defined by Nugent score. These data are reassuring that oral PrEP delivery to women can continue without the need for concurrent testing for bacterial vaginosis or vaginal dysbiosis. Article	2017	Heffron, Renee; Ngure, Kenneth; Odoyo, Josephine; Bulya, Nulu; Tindimwebwa, Edna; Hong, Ting; Kidoguchi, Lara; Donnell, Deborah; Mugo, Nelly R; Bukusi, Elizabeth A; Katabira, Elly; Asiimwe, Stephen; Morton, Jennifer; Morrison, Susan; Haugen, Harald; Mujugira, Andrew; Haberer, Jessica E; Ware, Norma C; Wyatt, Monique A; Marzinke, Mark A; Frenkel, Lisa M; Celum, Connie; Baeten, Jared M	Pre-exposure prophylaxis for HIV-negative persons with partners living with HIV: Uptake, use, and effectiveness in an open-label demonstration project in East Africa	Gates Open Research	-	-	-	25724754	10.12688/gatesopenres.12752.2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073291106&doi=10.12688%2fgatesopenres.12752.2&partnerID=40&md5=b2e103fadc8b99a67b9b52ee2a37f7ab	Background: Pre-exposure prophylaxis (PrEP) can provide high protection against HIV infection and is a recommended intervention for HIV-negative persons with substantial HIV risk. Demonstration projects conducted in diverse settings worldwide illustrate practical examples of how PrEP can be delivered. This manuscript presents estimates of effectiveness and patterns of PrEP use within a two-year demonstration project of PrEP for HIV-negative members of heterosexual HIV serodiscordant couples in East Africa. Methods: The PrEP delivery model integrated PrEP into HIV treatment services, prioritizing PrEP use for HIV-negative partners within serodiscordant couples before and during the first 6 months after the partner living with HIV initiated antiretroviral therapy (ART). We measured PrEP uptake through pharmacy records and adherence to PrEP through medication event monitoring system (MEMS) bottle caps and quantification of tenofovir in plasma among a random sample of participants. We estimated HIV infections prevented using a counterfactual cohort simulated from the placebo arm of a previous PrEP clinical trial. Results: We enrolled 1,010 HIV serodiscordant couples that were naïve to ART and PrEP. Ninety-seven percent of HIV-negative partners initiated PrEP. Objective measures suggest high adherence: 71% of HIV-negative participants took ≥80% of expected doses, as recorded via MEMS, and 81% of plasma samples had tenofovir detected. Four incident HIV infections were observed (incidence rate=0.24 per 100 person-years), a 95% reduction (95% CI 86-98%, p<0.0001) in HIV incidence, relative to estimated HIV incidence for the population in the absence of PrEP integrated into HIV treatment services. Conclusions: PrEP uptake and adherence were high and incident HIV was rare in this PrEP demonstration project for African HIV-negative individuals whose partners were known to be living with HIV. Delivery of PrEP to HIV-negative partners within HIV serodiscordant couples was feasible and should be prioritized for wide-scale implementation. © 2018 Heffron R et al. Article	2017	Henrich, Timothy J; Hatano, Hiroyu; Bacon, Oliver; Hogan, Louise E; Rutishauser, Rachel; Hill, Alison; Kearney, Mary F; Anderson, Elizabeth M; Buchbinder, Susan P; Cohen, Stephanie E; Abdel-Mohsen, Mohamed; Pohlmeyer, Christopher W; Fromentin, Remi; Hoh, Rebecca; Liu, Albert Y; McCune, Joseph M; Spindler, Jonathan; Metcalf-Pate, Kelly; Hobbs, Kristen S; Thanh, Cassandra; Gibson, Erica A; Kuritzkes, Daniel R; Siliciano, Robert F; Price, Richard W; Richman, Douglas D; Chomont, Nicolas; Siliciano, Janet D; Mellors, John W; Yukl, Steven A; Blankson, Joel N; Liegler, Teri; Deeks, Steven G	HIV-1 persistence following extremely early initiation of antiretroviral therapy (ART) during acute HIV-1 infection: An observational study.	PLOS Medicine	-	-	-	-	1549-1676	10.1371/journal.pmed.1002417	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5675377	BACKGROUND: It is unknown if extremely early initiation of antiretroviral therapy (ART) may lead to long-term ART-free HIV remission or cure. As a result, we studied 2 individuals recruited from a pre-exposure prophylaxis (PrEP) program who started prophylactic ART an estimated 10 days (Participant A; 54-year-old male) and 12 days (Participant B; 31-year-old male) after infection with peak plasma HIV RNA of 220 copies/mL and 3,343 copies/mL, respectively. Extensive testing of blood and tissue for HIV persistence was performed, and PrEP Participant A underwent analytical treatment interruption (ATI) following 32 weeks of continuous ART. METHODS AND FINDINGS: Colorectal and lymph node tissues, bone marrow, cerebral spinal fluid (CSF), plasma, and very large numbers of peripheral blood mononuclear cells (PBMCs) were obtained longitudinally from both participants and were studied for HIV persistence in several laboratories using molecular and culture-based detection methods, including a murine viral outgrowth assay (mVOA). Both participants initiated PrEP with tenofovir/emtricitabine during very early Fiebig stage I (detectable plasma HIV-1 RNA, antibody negative) followed by 4-drug ART intensification. Following peak viral loads, both participants experienced full suppression of HIV-1 plasma viremia. Over the following 2 years, no further HIV could be detected in blood or tissue from PrEP Participant A despite extensive sampling from ileum, rectum, lymph nodes, bone marrow, CSF, circulating CD4+ T cell subsets, and plasma. No HIV was detected from tissues obtained from PrEP Participant B, but low-level HIV RNA or DNA was intermittently detected from various CD4+ T cell subsets. Over 500 million CD4+ T cells were assayed from both participants in a humanized mouse outgrowth assay. Three of 8 mice infused with CD4+ T cells from PrEP Participant B developed viremia (50 million input cells/surviving mouse), but only 1 of 10 mice infused with CD4+ T cells from PrEP Participant A (53 million input cells/mouse) experienced very low level viremia (201 copies/mL); sequence confirmation was unsuccessful. PrEP Participant A stopped ART and remained aviremic for 7.4 months, rebounding with HIV RNA of 36 copies/mL that rose to 59,805 copies/mL 6 days later. ART was restarted promptly. Rebound plasma HIV sequences were identical to those obtained during acute infection by single-genome sequencing. Mathematical modeling predicted that the latent reservoir size was approximately 200 cells prior to ATI and that only around 1% of individuals with a similar HIV burden may achieve lifelong ART-free remission. Furthermore, we observed that lymphocytes expressing the tumor marker CD30 increased in frequency weeks to months prior to detectable HIV-1 RNA in plasma. This study was limited by the small sample size, which was a result of the rarity of individuals presenting during hyperacute infection. CONCLUSIONS: We report HIV relapse despite initiation of ART at one of the earliest stages of acute HIV infection possible. Near complete or complete loss of detectable HIV in blood and tissues did not lead to indefinite ART-free HIV remission. However, the small numbers of latently infected cells in individuals treated during hyperacute infection may be associated with prolonged ART-free remission. Article	2017	Hermanussen R.	HIV pre-exposure prophylaxis (PrEP); Pre-expositieprofylaxe tegen hiv (PrEP)	Huisarts en Wetenschap	-	-	-	-	187070	10.1007/s12445-017-0167-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85020769520&doi=10.1007%2fs12445-017-0167-8&partnerID=40&md5=beb60f959a990009bb0ac9ac8fba2c31	De Nederlandse hiv-behandelcentra zien nog steeds ongeveer duizend nieuwe patiënten per jaar. Dat aantal is gedaald door voorlichtingscampagnes, condoomgebruik en snellere behandeling, maar kan nog verder worden teruggebracht door pre-expositieprofylaxe (PrEP) bij hoogrisicogroepen, met name mannen die seks hebben met mannen. PrEP, een combinatie van de twee antiretrovirale middelen emtricitabine en tenofovir, is toegelaten door de EMA en mag door de huisarts worden voorgeschreven. Het middel werkt goed, heeft weinig bijwerkingen en kan kosteneffectief zijn, maar is duur en wordt in Nederland niet vergoed. Veel gebruikers kiezen daarom voor illegaal internetgebruik. Huisartsen zouden ook deze groep gebruikers moeten begeleiden. De in 2016 verschenen Nederlandse PrEP-richtlijn geeft aanwijzingen voor indicatiestelling, begeleiding en gebruik. De gebruiker moet vooraf gecontroleerd worden op hiv om resistentieontwikkeling te voorkomen. Ook soa's, hepatitis B en C en de nierfunctie moeten gecontroleerd worden in verband met mogelijke bijwerkingen. Daarna is driemaandelijkse controle op soa's, hiv en nierafwijkingen geboden. Article	2017	Hidalgo-Tenorio, Carmen; Gil-Anguita, Concepción; Ramírez-Taboada, Jessica; Esquivias, Javier; López-Ruz, Miguel A; Balgahata, Omar Mohamed; Javier-Martinez, Rosario; Pasquau, Juan	Risk factors for infection by oncogenic human papillomaviruses in HIV-positive MSM patients in the ART era (2010-2016).	Medicine (United States)	-	-	-	-	1536-5964	10.1097/MD.0000000000008109	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5626276	Squamous cell carcinoma of anus (SCCA) is one of the most frequent non-AIDS-defining diseases in HIV patients, mainly in men who have sex with men (MSM), and it is associated with human papillomavirus (HPV) infection.To determine the prevalence of high-risk HPV (HR-HPV) genotypes, premalignant lesions (HSIL) and SCCA in a cohort of HIV-positive MSM; to study the distribution of HPV genotypes according to anal histology results; and to analyze risk factors for this infection.This prospective single-center study was conducted between May 2010 and September 2016. At the study visit, cotton swabs were used to collect anal samples for cytology study in ThinPrep Pap Test liquid medium (Thin Prep Processor 2000, Hologic Corp, USA), and for HPV PCR (Linear Array HPV Genotyping Test). After, high-resolution anoscopy (HRA) (Zeiss 150 fc) was carried out. Logistic regression analysis was performed to identify risk factors for HR-HPV infection.The study included 319 patients, with mean age of 36.7 years; HR-HPV was detected in 81.3%. The prevalence of HSIL was 13.5% and SCCA was 0.3%. With regard to the distribution of HPV genotypes according to histology results, HPV 16 was the most frequent genotype in normal anal mucosa (26.7%), in LSILs (36.9%), and in HSILs (38%). In multivariate analysis, CD4 nadir<200cells/μL was the factor associated with infection by HR-HPV (OR 3.66, 95% CI 1.05%-12.75%).HIV-positive MSM showed a high prevalence of HSIL+ lesions and of infection by oncogenic HPV, which appears to be favored by a deficient immune system. HPV 16 was the most frequently isolated genotype in anal mucosa, regardless of lesion type.	high-risk human papillomavirus, HIV, HSIL, men who have sex with men, squamous cell carcinoma of anus	English	United States	Western and Central Europe and North America	Spain	Western and Central Europe and North America	Spain	Western and Central Europe and North America	Quantitative
Article	2017	Hidalgo-Tenorio, Carmen; Ramírez-Taboada, Jessica; Gil-Anguita, Concepción; Esquivias, Javier; Omar-Mohamed-Balgahata, Mohamed; SamPedro, Antonio; Lopez-Ruz, Miguel; Pasquau, Juan	Safety and immunogenicity of the quadrivalent human papillomavirus (qHPV) vaccine in HIV-positive Spanish men who have sex with men (MSM).	AIDS Research and Therapy	-	-	-	-	1742-6405	10.1186/s12981-017-0160-0	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5516305	BACKGROUND: Safety and immunogenicity of the quadrivalent human papillomavirus (qHPV) vaccine were evaluated in HIV-positive Spanish MSM. The prevalence of High Squamous Intraepithelial Lesions (HSIL) and genotypes of high-risk human papillomavirus (HR-HPV) were also determined, as well as risk factors associated with the presence of HR-HPV in anal mucosa. METHODS: This is a randomised, double blind, placebo-controlled trial of the quadrivalent HPV (qHPV) vaccine. The study enrolled from May 2012 to May 2014. Vaccine and placebo were administered at 0, 2 and 6 months (V1, V2, V3 clinical visits). Vaccine antibody titres were evaluated at 7 months. Cytology (Thin Prep® Pap Test), HPV PCR genotyping (Linear Array HPV Genotyping Test), and high-resolution anoscopy (Zeiss 150 fc© colposcope) were performed at V1. RESULTS: Patients (n = 162; mean age 37.9 years) were screened for inclusion; 14.2% had HSIL, 73.1% HR-HPV and 4.5% simultaneous infection with HPV16 and 18. Study participants (n = 129) were randomized to qHPV vaccine or placebo. The most common adverse event was injection-site pain predominating in the placebo group the first dose (83.6% vs. 56.1%; p = 0.0001; the second dose (87.8% vs. 98.4%; p = 0.0001); the third dose (67.7% vs. 91.9%; p = 0.0001). The vaccine did not influence either the viral load of HIV or the levels of CD4. Of those vaccinated, 76% had antibodies to HPV vs. 30.2% of those receiving placebo (p = 0.0001). In the multivariate analysis, Older age was associated with lower HR-HPV infection (RR 0.97; 95% CI 0.96-0.99), and risk factor were viral load of HIV >200 copies/μL (RR 1.42 95% CI 1.17-1.73) and early commencement of sexual activity (RR 1.35; 95% CI 1.001-1.811). CONCLUSIONS: This trial showed significantly higher anti-HR-HPV antibody titres in vaccinated individuals than in unvaccinated controls. There were no serious adverse events attributable to the vaccine. In our cohort, 1 of every 7 patients had HSIL and the prevalence of combined infection by genotypes 16 and 18 was low. This suggests that patients could benefit from receiving qHPV vaccine. Older age was the main protective factor against HR-HPV infection, and non-suppressed HIV viremia was a risk factor. Article	2017	Hill, BJ; Bak, T; VandeVusse, A; Rosentel, K	Reporting pre-exposure prophylaxis use in Craigslist personal advertisements among men seeking sex with men in the United States	Sexual Health	-	-	-	-	1448-5028	10.1071/SH16221	https://pubmed.ncbi.nlm.nih.gov/28501046/	This study describes the self-reported use of pre-exposure prophylaxis (PrEP) in the personal advertisements of men seeking sex with men in the United States on the online classified advertisement site, Craigslist. Overall self-reported PrEP use was low (0.20%; 95% confidence interval (CI) = 0.18-0.22). However, PrEP use in personal ads was described in conjunction with seeking sexual risk behaviours including 'bareback' sex (22.7%; 95% CI = 17.7-27.7%) and sex with substance use (26.8%; 95% CI = 21.5-32.1%). Only 4.0% of personal ads sought safe sex (3.3%; 95% CI = 1.2-5.4%) or required condoms (0.7%; 95% CI = -0.3-1.7%). Our findings underscore the need for increased public PrEP awareness, particularly among men seeking sex with men, as well as the importance of healthcare providers emphasising sexually transmissible infection prevention behaviours (i. e. condom use) used in conjunction with PrEP. This cross-sectional study describes PrEP awareness and willingness and associated factors among MSM and transvestite/transgender women (trans women) pre-screened for the PrEP Brasil study. Awareness was reported by 61.3 % of the participants and was associated with age, education, site, study period and prior HIV testing. Most participants (82.1 %) were willing to use PrEP, which was associated with site, study period, number of male condomless anal sexual partners and anal sex with HIV positive/unknown partners. PrEP information is need among young and less educated individuals. Willingness to use PrEP was high and future studies should be conducted to confirm PrEP acceptability and the characteristics of the population who chose to adopt this intervention. Article	2017	Hoagland, Brenda; Moreira, Ronaldo I; De Boni, Raquel B; Kallas, Esper G; Madruga, José Valdez; Vasconcelos, Ricardo; Goulart, Silvia; Torres, Thiago S; Marins, Luana M S; Anderson, Peter L; Luz, Paula M; Costa Leite, Iuri da; Liu, Albert Y; Veloso, Valdilea G; Grinsztejn, Beatriz	High pre-exposure prophylaxis uptake and early adherence among men who have sex with men and transgender women at risk for HIV Infection: the PrEP Brasil demonstration project.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.20.1.21472	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5515021	INTRODUCTION: The efficacy of pre-exposure prophylaxis (PrEP) in preventing sexual acquisition of human immunodeficiency virus (HIV) is well established. Little is known about the feasibility of PrEP implementation in middle-income settings with concentrated epidemics among men who have sex with men (MSM) and transgender women (TGW). METHODS: PrEP Brasil is a prospective, multicentre, open-label demonstration project assessing PrEP delivery in the context of the Brazilian Public Health System. HIV-uninfected MSM and TGW in 3 referral centres in Rio de Janeiro and São Paulo were evaluated for eligibility and offered 48 weeks of daily emtricitabine/tenofovir for PrEP. Concentrations of tenofovir diphosphate in dried blood spot samples (DBS) at week 4 after enrolment (early adherence) were measured. Predictors of drug levels were assessed using ordinal logistic regression models considering the DBS drug level as a 3 level variable (<350 fmol/punch, ≥350-699 fmol/punch and ≥700 fmol/punch). RESULTS: 1,270 individuals were assessed for participation; n = 738 were potentially eligible and n = 450 were offered PrEP (PrEP uptake was 60.9%). Eligible but not enrolled individuals were younger, had lower HIV risk perception and had lower PrEP awareness. At week 4, 424 participants (of the 450 enrolled) had DBS TFV-DP concentrations, 94.1% in the protective range (≥350 fmol/punch, consistent with ≥2 pills per week), and 78% were in the highly protective range (≥700 fmol/punch, ≥4 pills per week). Participants with ≥12 years of schooling had 1.9 times the odds (95%CI 1.10-3.29) of a higher versus lower drug level than participants with <12 years of schooling. Condomless receptive anal intercourse in the prior 3 months was also associated with higher drug levels (adjusted OR = 1.78; 95% CI 1.08-2.94). CONCLUSION: The high uptake and early adherence indicate that PrEP for high-risk MSM and TGW can be successfully delivered in the context of the Brazilian Public Health System. Interventions to address disparities on PrEP awareness and HIV risk perception among the younger and less educated are urgently needed in order to maximize the impact of this prevention strategy on the reduction of HIV infection among MSM and TGW in Brazil. Theses and Dissertations	2017	Hojilla, J. Carlo; Carrico, Adam W.; Vlahov, David	Optimizing the Delivery of HIV Pre-Exposure Prophylaxis (PrEP): An Evaluation of Risk Compensation, Disengagement, and the PrEP Cascade	-	-	University of California	University of California	-	NA	NA	https://www.proquest.com/dissertations-theses/optimizing-delivery-hiv-pre-exposure-prophylaxis/docview/1947499844/se-2?accountid=8113	Introduction To inform the optimal implementation of HIV pre-exposure prophylaxis (PrEP), we conducted three studies that evaluated serodisclosure, identified correlates of PrEP disengagement, and characterized the PrEP cascade of care. Methods Study 1 examined the association of PrEP use with participant non-disclosure and lack of knowledge of partner HIV status in the iPrEx Open Label Extension (OLE). Study 2 examined the effects of stimulant use and binge drinking (i.e., ≥5 drinks on one occasion) on PrEP disengagement in a nested case-cohort in OLE. PrEP disengagement was defined as failure to show for a follow-up visit or tenofovir drug levels <700fmol/punch. Study 3 characterized the PrEP cascade (i.e., seeking services, initiating PrEP, and retention in care) and identified predictors of non-retention among those who started PrEP in a clinic-based cohort of men who have sex with men in San Francisco. Results We analyzed data from 1,184 participants in Study 1. PrEP use was not significantly associated with non-disclosure or lack of knowledge of partner status in adjusted analyses (p-values≥.16). However, relationship characteristics were significantly associated with both outcomes. Of the 330 MSM and transgender women included in Study 2, 16% used stimulants and 22% reported binge drinking in the previous three months. Stimulant users had more than 5-fold greater odds of PrEP disengagement (adjusted odds ratio aOR=5.24, 95% CI 1.64-16.76). Binge drinking was not significantly associated with PrEP disengagement after adjusting for stimulant use and baseline confounders (aOR=0.78 0.33-1.88). Of the 344 men who sought PrEP services in Study 3, 268 (78%) initiated PrEP. Cost was the most commonly cited reason for not starting. Among patients who initiated PrEP, cumulative incidence of non-retention at 13 months was 38%. Men with an STI diagnosis at enrollment had a 79% greater rate of non-retention (adjusted hazard ratio aHR=1.79 1.06-3.01). Conclusion We found no evidence to suggest that PrEP use is associated with non-disclosure or not knowing partner status. Comprehensive prevention approaches that enhance uptake, reduce stimulant use, and support PrEP adherence and persistence are needed to address the heightened risk of HIV infection of those who use stimulants and those with STI diagnoses. Article	2017	Holloway I.W.; Dougherty R.; Gildner J.; Beougher S.C.; Pulsipher C.; Montoya J.A.; Plant A.; Leibowitz A.	PrEP Uptake, Adherence, and Discontinuation among California YMSM Using Geosocial Networking Applications	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001164	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84983320085&doi=10.1097%2fQAI.0000000000001164&partnerID=40&md5=c4926b95e93d213413639479f252dc08	We investigated pre-exposure prophylaxis (PrEP) uptake, adherence, and discontinuation among young app-using men who have sex with men in California (N = 761). Approximately, 9.7% of participants had ever used PrEP; 87% of those deemed good candidates for screening (indicated by a Centers for Disease Control and Prevention risk index score ≥10) were not current or past users. PrEP use was associated with higher income adjusted odds ratio (aOR): 4.13; confidence interval (CI): 1.87 to 9.12, receptive condomless anal sex (aOR: 3.41; CI: 1.71 to 6.78), HIV-positive sex partners (aOR: 2.87; CI: 1.53 to 5.38), popper use (aOR: 3.47; CI: 1.96 to 6.13), and recent sexually transmitted infection diagnosis (aOR: 2.90; CI: 1.64 to 5.13). Some users (41.5%) wanted help remembering to take PrEP. The top reason for discontinuation was concern about long-term side effects (33.0%). Young men who have sex with men app users are prime candidates for PrEP, despite low uptake. Apps may be useful tools for PrEP information dissemination, adherence monitoring, and support. Article	2017	Holloway I.W.; Tan D.; Gildner J.L.; Beougher S.C.; Pulsipher C.; Montoya J.A.; Plant A.; Leibowitz A.	Facilitators and Barriers to Pre-Exposure Prophylaxis Willingness among Young Men Who Have Sex with Men Who Use Geosocial Networking Applications in California	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2017.0082	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038560299&doi=10.1089%2fapc.2017.0082&partnerID=40&md5=3104b41894621fd48c68833aa239db33	While correlates of pre-exposure prophylaxis (PrEP) uptake have been explored among older men who have sex with men (MSM), less is known about the facilitators and barriers that encourage uptake among younger MSM (YMSM). This study explores the association between willingness to take PrEP and demographic characteristics, sexual risk, and substance use, and attitudinal factors among YMSM in California who use geosocial networking applications (GSN apps). Based on survey data from YMSM recruited through GSN apps (n = 687), PrEP willingness was positively associated with Hispanic ethnicity adjusted odds ratio (aOR): 1.73; confidence interval (CI): 1.01-2.98; p = 0.046, concerns about drug effects (aOR: 0.46; CI: 0.33-0.65; p < 0.001), medical mistrust (aOR: 0.71; CI: 0.53-0.96; p < 0.001), and concerns about adherence (aOR: 0.65; CI: 0.49-0.89; p = 0.005). PrEP willingness was positively associated with medium (aOR: 1.87; CI: 1.14-3.07; p = 0.014) and high concern (aOR: 1.84; CI: 1.13-3.01; p < 0.001) about contracting HIV and perceived benefits of taking PrEP (aOR: 2.59; CI: 1.78-3.78; p < 0.001). In addition to emphasizing the benefits of using PrEP, campaigns that address concerns regarding adherence and side effects may increase interest in and demand for PrEP among YMSM. More opportunities are needed to educate YMSM about PrEP, including addressing their concerns about this new prevention strategy. Providers should speak openly and honestly to YMSM considering PrEP about what to do if side effects occur and how to handle missed doses. Outreach using GSN apps for PrEP education and screening may be an effective way to reach YMSM. © Copyright 2017, Mary Ann Liebert, Inc. Article	2017	Holt M.; Lea T.; Schmidt H.-M.; Kolstee J.; Ellard J.; Murphy D.; Truong H.-H.; De Wit J.	Willingness to use and have sex with men taking HIV pre-exposure prophylaxis (PrEP): Results of online surveys of Australian gay and bisexual men, 2011-2015	Sexually Transmitted Infections	-	-	-	-	13684973	10.1136/sextrans-2016-052774	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85011106118&doi=10.1136%2fsextrans-2016-052774&partnerID=40&md5=67b29b6b754732dcffe3c124ea2078a9	Objective Assess willingness to use HIV pre-exposure prophylaxis (PrEP), support for others using it and willingness to have sex with partners using PrEP among Australian gay and bisexual men (GBM). Methods National, online cross-sectional surveys of Australian GBM were conducted in 2011, 2013 and 2015. Scales measuring support for and willingness to have sex with men using PrEP were developed in 2015 using factor analysis. Trends and associations with key measures were analysed using multivariate logistic regression. Results During 2011-2015, 3850 surveys were completed by GBM. Willingness to use PrEP among HIV-negative and untested men did not change between 2011 (28.2%) and 2015 (31.7%, p=0.13). In 2015, willingness to use PrEP was independently associated with younger age, having an HIV-positive regular partner, recent condomless anal intercourse with casual male partners (CAIC), more than 10 male sex partners in the previous 6months, ever having taken postexposure prophylaxis and having fewer concerns about using PrEP. In 2015, 54.5% of GBM supported other GBM taking PrEP and 39% were willing to have sex with men using PrEP. Support for and willingness to have sex with PrEP users were both associated with being HIV-positive, having a university degree and having two or more male partners in the previous 6months. Willingness to have sex with men on PrEP was also associated with recent CAIC and using party drugs for sex, but was less likely among men who consistently used or had a positive experience using condoms. Discussion Interest in and support for using PrEP are concentrated among men who engage in higher risk practices and who know more about living with HIV. This is consistent with the targeting of PrEP in Australia. © Published by the BMJ Publishing Group Limited. Article	2017	Holt M.; Murphy D.A.	Individual versus community-level risk compensation following preexposure prophylaxis of HIV	American Journal of Public Health	-	-	-	-	900036	10.2105/AJPH.2017.303930	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029507735&doi=10.2105%2fAJPH.2017.303930&partnerID=40&md5=eed3a9166bf4c5ceaba22829131dd933	Weanalyzed the concept of risk compensation and how it has been applied in HIV prevention, paying particular attention to the strategyofHIVpreexposure prophylaxis (PrEP). In risk compensation, reduced perceptions of risk after the introduction of a preventative intervention lead to more frequent risktaking behavior. Such a change may undermine the intervention's protective benefits. We found that many studies purporting to investigate risk compensation do not assess or report changes in perceptions of risk, instead relying on behavioral measures. Our analysis suggests a complex and sometimes counterintuitive relationship between the introduction of a new prevention intervention, perceptions of HIV risk, and subsequent changes in behavior. As PrEP is introduced, we believe comprehensiveassessment of community-level risk compensation- that is, changes in risk perceptions and behavior as a result of increased optimism about avoiding HIV among people not directly protected by PrEP-should not be omitted. We therefore suggest ways to assess prevention optimism and community-level risk compensation. Article	2017	Holt, Martin	Progress and Challenges in Ending HIV and AIDS in Australia	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1642-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85006975007&doi=10.1007%2fs10461-016-1642-0&partnerID=40&md5=dc1c46a849dc57f2f746a5982b5d4f33	This review considers Australia's progress towards the elimination of HIV and AIDS, as specified in international targets. In particular, it considers the reaction to recent media reports that Australia has 'ended AIDS' and evaluates progress towards reducing HIV transmission. Recent surveillance data and research show significant improvements in HIV testing and treatment, but countervailing trends such as increased condomless sex between gay and other men who have sex with men. Pre-exposure prophylaxis (PrEP) is being implemented at scale in some jurisdictions, with the hope that this will significantly alter the trajectory of Australia's HIV epidemic, which has been stable for the last five years (at around 1000–1100 infections per year). The ongoing challenge in maintaining investment, while also considering how to respond to the diversification of the local epidemic, means that Australia has entered a critical period in which evidence of PrEP's impact is eagerly awaited. © 2016, Springer Science+Business Media New York. Article	2017	Holt, Martin; Lea, Toby; Mao, Limin; Zablotska, Iryna; Lee, Evelyn; de Wit, John B F; Prestage, Garrett	Adapting behavioural surveillance to antiretroviral-based HIV prevention: reviewing and anticipating trends in the Australian Gay Community Periodic Surveys.	Sexual Health	-	-	-	-	1448-5028	10.1071/SH16072	https://dx.doi.org/10.1071/SH16072	Background In Australia, the preventative use of antiretroviral drugs pre-exposure prophylaxis (PrEP) and treatment as prevention is being embraced to protect individuals at high risk of HIV and reduce onward transmission. METHODS: The adaptation of a behavioural surveillance system, the Gay Community Periodic Surveys, was reviewed to monitor the uptake and effect of new prevention strategies in Australia's primary HIV-affected population (gay and bisexual men, GBM). The national trends in key indicators during 2000-15 were reviewed and a new measure to take account of antiretroviral-based prevention was developed. RESULTS: Between 2000 and 2015, there were significant increases (P<0.001) in annual HIV testing (56.1-64.8%), condomless sex with casual partners (26.8-38.8%) and the proportion of HIV-positive men on HIV treatment (72.5-88.4%) and with an undetectable viral load (73.7-94.7%). The proportion of casual partners who were HIV negative, not on PrEP and who engaged in receptive condomless sex also increased between 2000 and 2015 from 12.8 to 19.3%. Two scenarios anticipating the effect of PrEP highlighted the need to target GBM who engage in receptive condomless sex while also sustaining condom use at a population level. CONCLUSIONS: Behavioural surveillance can be successfully adapted to follow the effect of antiretroviral-based prevention. It is anticipated that HIV testing and HIV treatment will continue to increase among Australian GBM, but to prevent new infections, intervention in the growing proportion of GBM who have condomless sex with casual partners is needed. For PrEP to have its desired effect, condom use needs to be sustained.	NA	English	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review
Article	2017	Hoornenborg E.; Krakower D.S.; Prins M.; Mayer K.H.	Pre-exposure prophylaxis for MSM and transgender persons in early adopting countries	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001627	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85030786078&doi=10.1097%2fQAD.0000000000001627&partnerID=40&md5=be9d719bca282d8b2d919904630d4c03	Pre-exposure prophylaxis (PrEP) is a potent and underutilized HIV prevention tool. In this paper we review the state of knowledge regarding PrEP implementation for men who have sex with men and transgender persons in early adopting countries. We focus on implementation of PrEP in demonstration projects and clinical care, and describe the status of PrEP availability and uptake. We report on approaches to identifying appropriate PrEP candidates in real-world settings and on best practices for clinical monitoring. This includes the exclusion of undiagnosed HIV infection prior to PrEP initiation and longitudinal measurement of renal function, in light of safety data. Since adherence is the primary factor moderating the effectiveness of PrEP, we discuss effective adherence support interventions. Additionally, we review the evidence for risk compensation with PrEP use and opportunities to provide PrEP as part of comprehensive and inclusive preventive health programs. We summarize cost-effectiveness studies, including their variable conclusions because of differing underlying assumptions, and discuss the importance of budgetary impact for public health programs and health care insurers. Further, we emphasize a need for greater engagement of health care providers in PrEP to increase access. We conclude with recommendations for ways to improve future efforts at implementing PrEP. © 2017 Wolters Kluwer Health, Inc. Article	2017	Hoornenborg E.; Prins M.; Achterbergh R.C.A.; Woittiez L.R.; Cornelissen M.; Jurriaans S.; Kootstra N.A.; Anderson P.L.; Reiss P.; de Vries H.J.C.; Prins J.M.; de Bree G.J.	Acquisition of wild-type HIV-1 infection in a patient on pre-exposure prophylaxis with high intracellular concentrations of tenofovir diphosphate: a case report	The Lancet HIV	-	-	-	-	23523018	10.1016/S2352-3018(17)30132-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029440818&doi=10.1016%2fS2352-3018%2817%2930132-7&partnerID=40&md5=f422ff3eca5a7cfd8bd7d6ab594c7e4d	Background Pre-exposure prophylaxis (PrEP) with emtricitabine and tenofovir disoproxil fumarate is highly effective against acquisition of HIV infection, and only two cases of infection with a multidrug-resistant virus have been reported under adequate long-term adherence, as evidenced by tenofovir diphosphate concentrations in dried blood spots. We report a case of wild-type HIV-1 infection despite consistent use of emtricitabine and tenofovir disoproxil fumarate. Methods The patient participated in the Amsterdam PrEP project, a demonstration project of daily and event-driven PrEP. We did extensive testing for HIV, including plasma HIV RNA and nested PCR on bulk peripheral blood mononuclear cells (PBMCs) and sigmoid biopsies after seroconversion. Findings A 50-year-old man who has sex with men and had been on daily emtricitabine and tenofovir disoproxil fumarate for 8 months presented with fever, urinary tract infection caused by Escherichia coli, anal lymphogranuloma venereum infection, and a positive fourth-generation HIV test. We found an atypical seroconversion pattern, with initially only gp160 antibodies detected in the western blot. HIV RNA could not be detected in plasma, and nested PCR for HIV RNA and DNA on bulk PBMCs and sigmoid biopsies were negative. PrEP was discontinued; 3 weeks later HIV RNA was detected in plasma. No drug-resistant mutations were detected. Tenofovir diphosphate concentrations in dried blood spots were stable and high. Interpretation To our knowledge, this is the first detailed case report suggesting wild-type HIV infection despite good adherence, evidenced by repeatedly high concentrations of tenofovir diphosphate in dried blood spots. PrEP providers need to be aware that infection can occur despite good adherence. Regular HIV testing and awareness of atypical patterns of seroconversion is highly recommended. Article	2017	Hoornenborg, Elske; Achterbergh, Roel C A; Schim van der Loeff, Maarten F; Davidovich, Udi; Hogewoning, Arjan; de Vries, Henry J C; Schinkel, Janke; Prins, Maria; van de Laar, Thijs J W	MSM starting preexposure prophylaxis are at risk of hepatitis C virus infection.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0000000000001522	https://dx.doi.org/10.1097/QAD.0000000000001522	OBJECTIVES AND DESIGN: Hepatitis C virus (HCV) has been recognized as an emerging sexually transmitted infection (STI) among HIV-positive MSM. However, HIV-negative MSM at high risk for HIV might also be at increased risk for HCV. We studied the HCV prevalence in HIV-negative MSM who start preexposure prophylaxis (PrEP) in Amsterdam. Phylogenetic analysis was used to compare HCV strains obtained from HIV-negative and HIV-positive MSM. METHODS: At enrolment in the Amsterdam PrEP demonstration project, HIV-negative MSM were tested for the presence of HCV antibodies and HCV RNA. If positive for HCV RNA, an HCV NS5B gene fragment (709âbp) was sequenced and compared with HCV isolates from HIV-positive MSM (nâ=â223) and risk groups other than MSM (nâ=â153), using phylogenetic analysis. RESULTS: Of 375 HIV-negative MSM enrolled in Amsterdam PrEP, 18 (4.8%, 95% confidence interval 2.9-7.5%) of participants were anti-HCV and/or HCV RNA positive at enrolment; 15 of 18 (83%) had detectable HCV RNA. HCV genotyping showed genotype 1a (73%), 4d (20%), and 2b (7%). All HCV-positive MSM starting PrEP were part of MSM-specific HCV clusters containing MSM with and without HIV. CONCLUSION: HCV prevalence among HIV-negative MSM who started PrEP was higher than previously reported. All HIV-negative HCV-positive MSM were infected with HCV strains already circulating among HIV-positive MSM. The increasing overlap between sexual networks of HIV-positive and HIV-negative MSM might result in an expanding HCV-epidemic irrespective of HIV-status. Hence, routine HCV testing should be offered to MSM at high risk for HIV, especially for those enrolling in PrEP programs. Article	2017	Hosek S.G.; Landovitz R.J.; Kapogiannis B.; Siberry G.K.; Rudy B.; Rutledge B.; Liu N.; Harris D.R.; Mulligan K.; Zimet G.; Mayer K.H.; Anderson P.; Kiser J.J.; Lally M.; Brothers J.; Bojan K.; Rooney J.; Wilson C.M.	Safety and feasibility of antiretroviral preexposure prophylaxis for adolescent men who have sex with men aged 15 to 17 years in the United States	JAMA Pediatrics	-	-	-	-	21686203	10.1001/jamapediatrics.2017.2007	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85034748192&doi=10.1001%2fjamapediatrics.2017.2007&partnerID=40&md5=f41860d8a0436219b07b81728ea2ec2d	IMPORTANCE: Adolescents represent a key population for implementing preexposure prophylaxis (PrEP) interventions worldwide, yet tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) for PrEP is only licensed for adults. OBJECTIVE: To examine the safety of and adherence to PrEP along with changes in sexual risk behavior among adolescent men who have sex with men (MSM). DESIGN, SETTING, AND PARTICIPANTS: Adolescent Medicine Trials Network for HIV/AIDS Interventions 113 (Project PrEPare) was a PrEP demonstration project that evaluated the safety, tolerability, and acceptability of TDF/FTC and patterns of use, rates of adherence, and patterns of sexual risk behavior among healthy young MSM aged 15 to 17 years. Participants were recruited from adolescent medicine clinics and their community partners in 6 US cities, had negative test results for human immunodeficiency virus (HIV) but were at high risk for acquiring an infection, and were willing to participate in a behavioral intervention and accept TDF/FTC as PrEP. EXPOSURES: All participants completed an individualized evidence-based behavioral intervention and were provided with daily TDF/FTC as PrEP for 48 weeks. MAIN OUTCOMES AND MEASURES: The main objectives were to: (1) provide additional safety data regarding TDF/FTC use among young MSM who had negative test results for HIV; (2) examine the acceptability, patterns of use, rates of adherence, and measured levels of tenofovir diphosphate in dried blood spots; and (3) examine patterns of risk behavior when young MSM were provided with a behavioral intervention in conjunction with open-label TDF/FTC. RESULTS: Among 2864 individuals screened (from August 2013 to September 2014), 260 were eligible and 78 were enrolled (mean SD age, 16.5 0.73 years), of whom 2 (3%) were Asian/Pacific Islander, 23 (29%) were black/African American, 11 (14%) were white, 16 (21%) were White Hispanic, and 26 (33%) were other/mixed race/ethnicity. Over 48 weeks of PrEP use, 23 sexually transmitted infections were diagnosed in 12 participants. The HIV seroconversion rate was 6.4 (95% CI: 1.3-18.7) per 100 person-years. Tenofovir diphosphate levels consistent with a high degree of anti-HIV protection (>700 fmol/punch) were found in 42 (54%), 37 (47%), 38 (49%), 22 (28%), 13 (17%), and 17 (22%) participants at weeks 4, 8, 12, 24, 36, and 48, respectively. CONCLUSIONS AND RELEVANCE: Adolescent Medicine Trials Network for HIV/AIDS Interventions 113 enrolled a diverse sample of adolescent MSM at risk for HIV who consented to study participation. Approximately half achieved protective drug levels during the monthly visits, but adherence decreased with quarterly visits. Youth may need additional contact with clinical staff members to maintain high adherence. TRIAL REGISTRATION: clinicaltrials.gov Identifier: NCT01769456. © 2017 American Medical Association. Article	2017	Hosek S.G.; Rudy B.; Landovitz R.; Kapogiannis B.; Siberry G.; Rutledge B.; Liu N.; Brothers J.; Mulligan K.; Zimet G.; Lally M.; Mayer K.H.; Anderson P.; Kiser J.; Rooney J.F.; Wilson C.M.	An HIV Preexposure Prophylaxis Demonstration Project and Safety Study for Young MSM	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001179	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84987916837&doi=10.1097%2fQAI.0000000000001179&partnerID=40&md5=7ffc8c9ba8277fff1542c08207de15fe	Background: Young men who have sex with men (YMSM) are a key population for implementation of preexposure prophylaxis (PrEP) interventions. This open-label study examined adherence to PrEP and assessed sexual behavior among a diverse sample of YMSM in 12 US cities. Methods: Eligible participants were 18- to 22-year-old HIV-uninfected MSM who reported HIV transmission risk behavior in the previous 6 months. Participants were provided daily tenofovir disoproxil fumarate/emtricitabine (Truvada). Study visits occurred at baseline, monthly through week 12, and then quarterly through week 48. Dried blood spots were serially collected for the quantification of tenofovir diphosphate (TFV-DP). Results: Between March and September 2013, 2186 individuals were approached and 400 were found to be preliminarily eligible. Of those 400, 277 were scheduled for an in-person screening visit and 200 were enrolled (mean age = 20.2; 54.5% black, 26.5% Latino). Diagnosis of sexually transmitted infections, including urethral and rectal chlamydial/gonococcal infection and syphilis, at baseline was 22% and remained high across visits. At week 4, 56% of participants had TFV-DP levels consistent with ≥4 pills per week. By week 48, 34% of participants had TFV-DP levels consistent with ≥4 pills per week, with a noticeable drop-off occurring at week 24. Four HIV seroconversions occurred on study (3.29/100 person-years). Condomless sex was reported by >80% of participants, and condomless anal sex with last partner was associated with higher TFV-DP levels. Conclusions: Acceptability of PrEP was high, and most participants achieved protective drug levels during monthly visits. As visit frequency decreased, so did adherence. YMSM in the United States may need PrEP access in youth-friendly settings with tailored adherence support and potentially augmented visit schedules. Copyright © 2016 Wolters Kluwer Health, Inc. Article	2017	Hubach, Randolph D.; Currin, Joseph M.; Sanders, Carissa A.; Durham, André R.; Kavanaugh, Katherine E.; Wheeler, Denna L.; Croff, Julie M.	Barriers to Access and Adoption of Pre-Exposure Prophylaxis for the Prevention of HIV Among Men Who Have Sex With Men (MSM) in a Relatively Rural State.	AIDS Education and Prevention	-	-	-	-	1943-2755 0899-9546	10.1521/aeap.2017.29.4.315	https://guilfordjournals.com/doi/10.1521/aeap.2017.29.4.315	Biomedical intervention approaches, including antiretroviral pre-exposure prophylaxis (PrEP), have been demonstrated to reduce HIV incidence among several at-risk populations and to be cost effective. However, there is limited understanding of PrEP access and uptake among men who have sex with men (MSM) residing in relatively rural states. Twenty semistructured interviews were conducted (August-November 2016) to assess opinions of and perceived barriers to accessing and adopting PrEP among MSM residing in Oklahoma. Participants perceived substantial barriers to accessing PrEP including a stigmatizing environment and less access to quality, LGBT-sensitive medical care. Overall, geographic isolation limits access to health providers and resources that support sexual health for Oklahoma MSM. Addressing stigma situated across ecological levels in an effort to increase adoption of PrEP by MSM residing in rural states remains necessary. Without this, social determinants may continue to negatively influence PrEP adoption and sexual health outcomes. Article	2017	Hughes A.J.; Chen Y.-H.; Scheer S.	Condomless Anal Sex Among HIV-Positive Men Who Have Sex with Men: Biomedical Context Matters	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-017-1852-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85023170659&doi=10.1007%2fs10461-017-1852-0&partnerID=40&md5=36a815111c7baa4b20ebfb5e6c88dd2a	Data from Medical Monitoring Project was used to determine if partner type is associated with condomless anal sex (CAS) and insertive condomless anal sex (ICAS) among HIV-positive men who have sex with men. Participants reported HIV status and PrEP use of up to five anal sex partners. Partner type was categorized as HIV-positive, HIV status unknown, HIV-negative on PrEP or HIV-negative not on PrEP. To account for correlation of multiple observations per participant, generalized estimating equations were used to calculate adjusted prevalence ratios and 95% confidence intervals of CAS and ICAS. Condom use during anal sex and insertive anal sex varied based on partner type. There was a higher prevalence of CAS and ICAS in partnerships with HIV-positive partners or HIV-negative partners on PrEP compared to HIV-negative partners not on PrEP. © 2017, Springer Science+Business Media, LLC. Editorial	2017	Hull, M; Tan, Dhs	Setting the stage for expanding HIV pre-exposure prophylaxis use in Canada.	Canada Communicable Disease Report	-	-	-	-	1188-4169	https://doi.org/10.14745%2Fccdr.v43i12a05	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5937069	Human immunodeficiency virus (HIV) infection continues to disproportionately affect vulnerable populations in Canada; particularly men who have sex with men (MSM). Novel HIV prevention strategies have recently expanded from the use of non-occupational post-exposure prophylaxis (nPEP) after high risk exposures to the use of pre-exposure prophylaxis (PrEP) in which individuals reduce risk of HIV infection through use of combination antiretrovirals taken prior to risk exposure. With approval of tenofovir/emtricitabine (TDF/FTC) for use as PrEP only in early 2016, and with limited public funding to date, uptake in Canada is in its preliminary stages. These biomedical prevention strategies have proven efficacy for MSM, and they have potential for other at-risk populations. With generic formulations of TDF/FTC now available in Canada, there is an opportunity for widespread implementation. Expanding knowledge of health care providers across Canada on how best to assess, refer for or prescribe and monitor PrEP will contribute to the current efforts to reach the global goal of eliminating new HIV infections. Article	2017	Husnik, Marla J; Brown, Elizabeth R; Marzinke, Mark; Livant, Edward; Palanee-Phillips, Thesla; Hendrix, Craig W; Matovu Kiweewa, Flavia; Nair, Gonasagrie; Soto-Torres, Lydia E; Schwartz, Katie; Hillier, Sharon L; Baeten, Jared M	Implementation of a Novel Adherence Monitoring Strategy in a Phase III, Blinded, Placebo-Controlled, HIV-1 Prevention Clinical Trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000001503	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5634926	BACKGROUND: Placebo-controlled HIV-1 prevention trials of pre-exposure prophylaxis (PrEP) have not generally used concurrent measurement of adherence because of the potential risk of unblinding. However, several pre-exposure prophylaxis trials for HIV-1 prevention among women failed to show effectiveness because of low product adherence. Evaluation of product adherence objectively during a study provides the opportunity for strengthening adherence activities at sites having low adherence. METHODS: During MTN-020/ASPIRE, a phase III, placebo-controlled trial of the dapivirine intravaginal ring, we implemented an adherence monitoring system. Monitoring began in quarter 1 (Q1) 2013 and continued through the conclusion of the trial. Blood plasma was collected quarterly and tested for dapivirine concentrations while maintaining blinding among study team members involved in participant management. Dapivirine concentrations >95 pg/mL, reflecting >8 hours of continuous use, were assessed as signaling product use. Study leadership monitored results on a monthly basis and provided feedback to site investigators. Experiences were shared across sites to motivate staff and counsel participants to strive toward higher adherence levels. RESULTS: An upward trend in adherence was observed (P < 0.0001); the proportion of samples from subjects in the active arm with dapivirine >95 pg/mL increased from 63% in Q1 2013 to 84% by Q1 2015. CONCLUSIONS: Ongoing drug level testing as a marker of adherence in MTN-020/ASPIRE demonstrates the feasibility of real-time adherence monitoring while maintaining study blinding at the level of participants, sites, and study leadership. This approach is novel for large-scale effectiveness studies for HIV-1 prevention. Article	2017	Imp, Brandon; Allen, Elaine; Volk, Jonathan; Bhowmick, Tanaya	Medical Students Have Limited Awareness, Knowledge, Beliefs, and Experiences of Pre-exposure Prophylaxis (PrEP) for HIV Prevention	Open Forum Infectious Diseases	-	-	-	-	2328-8957	https://doi.org/10.1093%2Fofid%2Fofx162.035	https://pmc.ncbi.nlm.nih.gov/articles/PMC5632042/	Background While studies of healthcare professionals have shown increasing awareness, knowledge, positive beliefs, and prescribing practices of emtricitabine/tenofovir pre-exposure prophylaxis (PrEP) for HIV prevention, PrEP is still underutilized in clinical practice. PrEP knowledge is associated with increased prescription so early education of healthcare professionals is recommended, but the extent of PrEP education in medical school is unknown. In this analysis, we describe medical students' awareness, knowledge, beliefs, and experiences regarding PrEP. Methods Medical students at 18 US allopathic medical schools completed a survey on knowledge, beliefs, and experiences of PrEP in May–June 2016. Knowledge was assessed with a 10-question quiz on PrEP facts. No incentives to complete the survey were offered. Data were summarized by frequency (%) for categorical variables and with means (SD) for continuous variables. Chi-squared tests were used to examine differences between knowledge of PREP and other categorical variables. Results The study population (N = 1588) included women (53%), non-Caucasians (27%), and non-heterosexuals (15%). Median age was 25 (range 21–53). Forty-eight home states, including D.C., and 21 home countries were represented. 18% of fourth-year students were never taught about PrEP in medical school, compared with 40% of first-year students (P < 0.001). Overall, 28% of students were unaware of PrEP. Those unaware believed patients without HIV will not adhere to PrEP (P < 0.001). Awareness was associated with knowing someone with HIV besides a patient and experience caring for HIV-infected, intravenous drug-using, and LGBTQ people (P < 0.001). Higher knowledge scores were associated with confidence in determining a patient's candidacy for PrEP and, for third- and fourth-year students, having recommended PrEP in the clinical setting (P < 0.001). Overall, 57% believed that behavioral intervention should be tried before prescribing PrEP, 45% believed that patients would not adhere to PrEP, and 22% worried that PrEP is not effective. Conclusion We show in an 18-site study that medical students have limited awareness, knowledge, positive beliefs, and experiences of PrEP. Given these findings and the underutilization of PrEP by current practitioners, we recommend increasing the inclusion of PrEP in medical student education.	clinical medicine; general & internal medicine; medical and health sciences; Medicine; Pre-exposure prophylaxis; engineering and technology; Human immunodeficiency virus (HIV); Abstracts; Clinical psychology; Medical education; electrical engineering electronic engineering information engineering; medical informatics; Students medical	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Quantitative
Article	2017	Jaspal, Rusi; Nerlich, Brigitte	Polarised press reporting about HIV prevention: Social representations of pre-exposure prophylaxis in the UK press.	Health	-	-	-	-	1461-7196	10.1177/1363459316649763	https://dx.doi.org/10.1177/1363459316649763	Pre-exposure prophylaxis is a novel biomedical HIV prevention option for individuals at high risk of HIV acquisition. Although pre-exposure prophylaxis has yielded encouraging results in various clinical trials, opponents argue that pre-exposure prophylaxis poses a number of risks to human health and to sexually transmitted infection prevention efforts. Using qualitative thematic analysis and social representation theory, this article explores coverage of pre-exposure prophylaxis in the UK print media between 2008 and 2015 in order to chart the emerging social representations of this novel HIV prevention strategy. The analysis revealed two competing social representations of pre-exposure prophylaxis: (1) as a positive development in the 'battle' against HIV (the hope representation) and (2) as a medical, social and psychological setback in this battle, particularly for gay/bisexual men (the risk representation). These social representations map onto the themes of pre-exposure prophylaxis as a superlatively positive development; pre-exposure prophylaxis as a weapon in the battle against HIV/AIDS; and risk, uncertainty and fear in relation to pre-exposure prophylaxis. The hope representation focuses on taking (individual and collective) responsibility, while the risk representation focuses on attributing (individual and collective) blame. The implications for policy and practice are discussed. Article	2017	Jenness S.M.; Sharma A.; Goodreau S.M.; Rosenberg E.S.; Weiss K.M.; Hoover K.W.; Smith D.K.; Sullivan P.	Individual HIV risk versus population impact of risk compensation after HIV preexposure prophylaxis initiation among men who have sex with men	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0169484	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85009816974&doi=10.1371%2fjournal.pone.0169484&partnerID=40&md5=71804b6530630c2a2ccd28bca7e1ef34	Objectives: Risk compensation (RC) could reduce or offset the biological prevention benefits of HIV pre-exposure prophylaxis (PrEP) among those at substantial risk of infection, including men who have sex with men (MSM). We investigated the potential extent and causal mechanisms through which RC could impact HIV transmission at the population and individual levels. Methods: Using a stochastic network-based mathematical model of HIV transmission dynamics among MSM in the United States, we simulated RC as a reduction in the probability of condom use after initiating PrEP, with heterogeneity by PrEP adherence profiles and partnership type in which RC occurred. Outcomes were changes to population-level HIV incidence and individual-level acquisition risk. Results: When RC was limited to MSM highly/moderately adherent to PrEP, 100% RC (full replacement of condoms) resulted in a 2% relative decline in incidence compared to no RC, but an 8% relative increase in infection risk for MSM on PrEP. This resulted from confounding by indication: RC increased the number of MSM indicated for PrEP as a function of more condomless anal intercourse among men otherwise not indicated for PrEP; this led to an increased PrEP uptake and subsequent decline in incidence. Conclusions: RC is unlikely to decrease the prevention impact of PrEP, and in some cases RC may be counterintuitively beneficial at the population level. This depended on PrEP uptake scaling with behavioral indications. Due to the increased acquisition risk associated with RC, however, clinicians should continue to support PrEP as a supplement rather than replacement of condoms. © 2017, Public Library of Science. Article	2017	Jenness, Samuel M; Weiss, Kevin M; Goodreau, Steven M; Gift, Thomas; Chesson, Harrell; Hoover, Karen W; Smith, Dawn K; Liu, Albert Y; Sullivan, Patrick S; Rosenberg, Eli S	Incidence of Gonorrhea and Chlamydia Following Human Immunodeficiency Virus Preexposure Prophylaxis Among Men Who Have Sex With Men: A Modeling Study.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/cix439	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5848234	Background: Preexposure prophylaxis (PrEP) is highly effective for preventing human immunodeficiency virus (HIV) infection, but risk compensation (RC) in men who have sex with men (MSM) raises concerns about increased sexually transmitted infections (STIs). The Center for Disease Control and Prevention's (CDC's) PrEP guidelines recommend biannual STI screening, which may reduce incidence by treating STIs that would otherwise remain undiagnosed. We investigated these two counteracting phenomena. Methods: With a network-based mathematical model of HIV, Neisseria gonorrhoeae (NG), and Chlamydia trachomatis (CT) transmission dynamics among MSM in the United States, we simulated PrEP uptake following the prescription indications and HIV/STI screening recommendations in the CDC guidelines. Scenarios varied PrEP coverage (the proportion of MSM indicated for PrEP who received it), RC (a reduction in the per-act probability of condom use), and the STI screening interval. Results: In our reference scenario (40% coverage, 40% RC), 42% of NG and 40% of CT infections would be averted over the next decade. A doubling of RC would still result in net STI prevention relative to no PrEP. STIs declined because PrEP-related STI screening resulted in a 17% and 16% absolute increase in the treatment of asymptomatic and rectal STIs, respectively. Screening and timely treatment at quarterly vs biannual intervals would reduce STI incidence an additional 50%. Conclusions: Implementation of the CDC PrEP guidelines while scaling up PrEP coverage could result in a significant decline in STI incidence among MSM. Our study highlights the design of PrEP not only as antiretroviral medication but as combination HIV/STI prevention incorporating STI screening. Article	2017	John S.A.; Rendina H.J.; Grov C.; Parsons J.T.	Home-based pre-exposure prophylaxis (PrEP) services for gay and bisexual men: An opportunity to address barriers to PrEP uptake and persistence	PLOS One	-	-	-	19326203	10.1371/journal.pone.0189794	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85039712269&doi=10.1371%2fjournal.pone.0189794&partnerID=40&md5=d0a9f2277624b8302281805d1bb2502b	Gay, bisexual, and other men who have sex with men (GBM) are disproportionately affected by the HIV epidemic. Despite the promise of pre-exposure prophylaxis (PrEP) in reducing HIV transmission risk, barriers for uptake and persistence exist. We sought to identify whether GBM in a nationwide cohort who have not yet initiated PrEP (n = 906) would prefer to get PrEP-related care from a primary care provider (PCP) compared to a specialist clinic or provider. We then sought to identify their level of interest and factors associated with preferences for using home-based PrEP services (i.e., HB-PrEP), defined to participants as conducting HIV/STI self-testing from home with PrEP prescription mailing after an initial in-person clinic visit. We examined the associations of demographics, sexual HIV transmission risk, concern about frequent medical checkups associated with PrEP, health care access, and PrEP intentions with preferences for healthcare provider type and HB-PrEP. Concern about frequent medical checkups were associated with preferring a PCP for PrEP-related care, but men who perceived a barrier to bringing up the topic of PrEP with a doctor preferred a specialist clinic or provider more than a PCP. HB-PrEP was more appealing for younger men and those engaged in sexual HIV transmission risk, suggesting HB-PrEP could help reach GBM most vulnerable to HIV and in need of PrEP. HB-PrEP expansion has potential to increase PrEP uptake and persistence among GBM, particularly for men with barriers to clinic-based care and higher intentions to initiate PrEP. Clinical guidelines regarding HB-PrEP are needed to expand its use. © 2017 John et al. Editorial	2017	Jones A.S.K.; Petrie K.J.	I Can See Clearly Now: Using Active Visualisation to Improve Adherence to ART and PrEP	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1611-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84996598806&doi=10.1007%2fs10461-016-1611-7&partnerID=40&md5=092bfc13f042f65066e35837dfa26f18	Non-adherence remains a perplexing issue in HIV treatment. After decades of research supporting the efficacy of antiretroviral therapy, non-adherence to medication remains an important issue. For patients who are non-adherent to anti-retroviral therapy (ART), there appears to be a mismatch between their model of illness and the necessity for ART treatment. We propose that 'active visualisation' is a technique that could be utilised to improve understanding of treatment and subsequently adherence for both individuals living with HIV and those at-risk of infection. We discuss the theoretical background and highlight the initial evidence suggesting the utility of active visualisation. We then discuss how active visualisation could be utilised in a live demonstration to improve adherence to ART and pre-exposure prophylaxis medications. © 2016, Springer Science+Business Media New York. Article	2017	Jones, Jeb; Hoenigl, Martin; Siegler, Aaron J; Sullivan, Patrick S; Little, Susan; Rosenberg, Eli	Assessing the Performance of 3 Human Immunodeficiency Virus Incidence Risk Scores in a Cohort of Black and White Men Who Have Sex With Men in the South.	Sexually Transmitted Diseases	-	-	-	1537-4521	10.1097/OLQ.0000000000000596	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5407317	BACKGROUND: Risk scores have been developed to identify men at high risk of human immunodeficiency virus (HIV) seroconversion. These scores can be used to more efficiently allocate public health prevention resources, such as pre-exposure prophylaxis. However, the published scores were developed with data sets that comprise predominantly white men who have sex with men (MSM) collected several years prior and recruited from a limited geographic area. Thus, it is unclear how well these scores perform in men of different races or ethnicities or men in different geographic regions. METHODS: We assessed the predictive ability of 3 published scores to predict HIV seroconversion in a cohort of black and white MSM in Atlanta, GA. Questionnaire data from the baseline study visit were used to derive individual scores for each participant. We assessed the discriminatory ability of each risk score to predict HIV seroconversion over 2 years of follow-up. RESULTS: The predictive ability of each score was low among all MSM and lower among black men compared to white men. Each score had lower sensitivity to predict seroconversion among black MSM compared to white MSM and low area under the curve values for the receiver operating characteristic curve indicating poor discriminatory ability. CONCLUSIONS: Reliance on the currently available risk scores will result in misclassification of high proportions of MSM, especially black MSM, in terms of HIV risk, leading to missed opportunities for HIV prevention services. Article	2017	Jotwani, Vasantha; Atta, Mohamed G; Estrella, Michelle M	Kidney Disease in HIV: Moving beyond HIV-Associated Nephropathy.	Journal of the American Society of Nephrology	-	-	-	1533-3450	10.1681/ASN.2017040468	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5661296	In developed countries, remarkable advances in antiretroviral therapy have transformed HIV infection into a chronic condition. As a result, HIV-associated nephropathy, the classic HIV-driven kidney lesion among individuals of African descent, has largely disappeared in these regions. However, HIV-positive blacks continue to have much higher rates of ESRD than HIV-positive whites, which could be attributed to the APOL1 renal risk variants. Additionally, HIV-positive individuals face adverse consequences beyond HIV itself, including traditional risk factors for CKD and nephrotoxic effects of antiretroviral therapy. Concerns for nephrotoxicity also extend to HIV-negative individuals using tenofovir disoproxil fumarate-based pre-exposure prophylaxis for the prevention of HIV infection. Therefore, CKD remains an important comorbid condition in the HIV-positive population and an emerging concern among HIV-negative persons receiving pre-exposure prophylaxis. With the improved longevity of HIV-positive individuals, a kidney transplant has become a viable option for many who have progressed to ESRD. Herein, we review the growing knowledge regarding the APOL1 renal risk variants in the context of HIV infection, antiretroviral therapy-related nephrotoxicity, and developments in kidney transplantation among HIV-positive individuals.	health disparitiesHIV preventionMSMPrEPqualitative research methods	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2017	Kalichman S.C.; Eaton L.	Alcohol-antiretroviral interactive toxicity beliefs as a potential barrier to HIV pre-exposure prophylaxis among men who have sex with men	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.20.1.21534	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037563056&doi=10.7448%2fIAS.20.1.21534&partnerID=40&md5=4a3a1a7528ca5740a0fc58f44b3067d6	Introduction: Pre-exposure prophylaxis (PrEP) offers as much as 90% protection against HIV transmission. However, the effectiveness of PrEP depends on uptake and adherence to even intermittent dosing. Along with intoxication leading to unintentional non-adherence, believing that alcohol mixed with pharmaceuticals is harmful (i.e., interactive toxicity beliefs) may lead to poor uptake and intentional non-adherence. Methods: HIV-negative sexually active men who have sex with men (N = 272) at a large Gay Pride event in Atlanta, GA, completed anonymous surveys of demographic characteristics, sexual behaviour, alcohol use and PrEP-related alcohol interactive toxicity beliefs. Results: A total of 118 (43%) men surveyed had two or more male sex partners and condomless anal sex in the previous six months. Alcohol use was reported by over 90% of men and it was common for participants to believe that mixing alcohol and antiretrovirals is toxic; 75% endorsed at least one interactive toxicity belief. Among the 118 men who had engaged in condomless anal sex and had multiple sex partners, one in three stated that they were not interested in PrEP and men not interested in PrEP were significantly more likely to binge drink and hold interactive toxicity beliefs. Conclusions: These results mirror studies that find interactive toxicity beliefs are a potent predictor of intentional antiretroviral non-adherence among people living with HIV and suggest interactive toxicity beliefs may impede PrEP uptake and adherence. Messages to increase PrEP awareness and adherence may also take steps to counter erroneous beliefs about mixing alcohol with antiretrovirals in the context of PrEP. © 2017 Kalichman S C et al; licensee International AIDS Society. Article	2017	Kapewangolo, Petrina; Kandawa-Schulz, Martha; Meyer, Debra	Anti-HIV Activity of Ocimum labiatum Extract and Isolated Pheophytin-a.	Molecules	-	-	-	1420-3049	10.3390/molecules22111763	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6150305	Ocimum plants are traditionally used to manage HIV/AIDS in various African countries. The effects of Ocimum labiatum extract on HIV-1 protease (PR) and reverse transcriptase (RT) is presented here along with characterization of an identified bioactive compound, achieved through ^{1}H- and 13C-NMR. The extract's effect on HIV-1 replication was assessed by HIV-1 p24 antigen capture. Cytotoxicity of samples was evaluated using tetrazolium dyes and real-time cell electronic sensing (RT-CES). Ocimum labiatum inhibited HIV-1 PR with an IC50 value of 49.8 ± 0.4 μg/mL and presented weak inhibition (21%) against HIV-1 RT. The extract also reduced HIV-1 replication in U1 cells at a non-cytotoxic concentration (25 μg/mL). The CC50 value of the extract in U1 cells was 42.0 ± 0.13 μg/mL. The HIV-1 PR inhibiting fraction was purified using prep-HPLC and yielded a chlorophyll derivative, pheophytin-a (phy-a). Phy-a inhibited HIV-1 PR with an IC50 value of 44.4 ± 1.5 μg/mL (51 ± 1.7 μM). The low cytotoxicity of phy-a in TZM-bl cells was detected by RT-CES and the CC50 value in U1 cells was 51.3 ± 1.0 μg/mL (58.9 ± 1.2 μM). This study provides the first in vitro evidence of anti-HIV activity of O. labiatum and isolated phy-a, supporting further investigation of O. labiatum for lead compounds against HIV-1. Theses and Dissertations	2017	Karki, Pramila	Acceptability and Correlates of Pre-Exposure Prophylaxis Use for HIV Prevention among High-Risk Drug Users in Treatment	-	-	University of Connecticut	-	NA	NA	https://opencommons.uconn.edu/gs_theses/1165 https://opencommons.uconn.edu/context/gs_theses/article/2260/viewcontent/auto_convert.pdf	Background Although people who use drugs (PWUD) are a key population recommended to receive pre-exposure prophylaxis (PrEP) to prevent HIV, few data are available to guide PrEP delivery in this underserved group. We therefore examined the willingness to initiate PrEP, the anticipation of HIV risk reduction while on PrEP, and the acceptability of PrEP based on a number of known PrEP attributes among high-risk PWUD. Methods In a cross-sectional study of 400 HIV-negative, opioid dependent individuals enrolled in a methadone program and reporting recent risk behaviors, we examined independent correlates of being willing to initiate PrEP. Participants also ranked the eight hypothetical PrEP program scenarios with varied combinations of six attributes related to PrEP (cost, dosing, efficacy, side-effects, treatment setting, and frequency of HIV testing). Results While only 72 (18%) were aware of PrEP, after being given a description of it, 251 (62.7%) were willing to initiate PrEP. Willingness to initiate PrEP was associated with having neurocognitive impairment (aOR=3.184, p=0.004) and higher perceived HIV risk (aOR=8.044, p Conclusions Our findings showed high acceptability of PrEP in response to different PrEP program scenarios with different attribute profiles. While willingness to initiate PrEP was high and correlated with being at elevated risk for HIV and having NCI, anticipated higher risk behaviors in this group even while on PrEP suggests that the next generation of HIV prevention approaches may need to combine biomedical and behavioral components to improve adherence to PrEP and to sustain HIV risk reduction over time. Article	2017	Kasaie, Parastu; Pennington, Jeff; Shah, Maunank S; Berry, Stephen A; German, Danielle; Flynn, Colin P; Beyrer, Chris; Dowdy, David W	The Impact of Preexposure Prophylaxis Among Men Who Have Sex With Men: An Individual-Based Model.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001354	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5488295	OBJECTIVES: Preexposure prophylaxis (PrEP) is recommended for preventing HIV infection among individuals at high risk, including men who have sex with men (MSM). Although its individual-level efficacy is proven, questions remain regarding population-level impact of PrEP implementation. DESIGN: We developed an agent-based simulation of HIV transmission among MSM, accounting for demographics, sexual contact network, HIV disease stage, and use of antiretroviral therapy. We use this framework to compare PrEP delivery strategies in terms of impact on HIV incidence and prevalence. RESULTS: The projected reduction in HIV incidence achievable with PrEP reflects both population-level coverage and individual-level adherence (as a proportion of days protected against HIV transmission). For example, provision of PrEP to 40% of HIV-negative MSM reporting more than one sexual partner in the last 12 months, taken with sufficient adherence to provide protection on 40% of days, can reduce HIV incidence by 9.5% (95% uncertainty range: 8%-11%) within 5 years. However, if this could be increased to 80% coverage on 80% of days (eg, through mass campaigns with a long-acting injectable formulation), a 43% (42%-44%) reduction in HIV incidence could be achieved. Delivering PrEP to MSM at high risk for HIV acquisition can augment population-level impact up to 1.8-fold. CONCLUSIONS: If highly ambitious targets for coverage and adherence can be achieved, PrEP can substantially reduce HIV incidence in the short-term. Although the reduction in HIV incidence largely reflects the proportion of person-years protected, the efficiency of PrEP delivery can be enhanced by targeting high-risk populations. Theses and Dissertations	2017	Kauss, Bruno Silv	Novas tecnologias, sexualidade e direitos em tempos de risco : um estudo sobre a implementação da profilaxia pós-exposição ao HIV/AIDS pelos trabalhadores da linha de frente das políticas públicas	-	-	UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL	-	-	NA	http://hdl.handle.net/10183/207038	Novas tecnologias biomédicas de prevenção à infecção por HIV têm sido incorporadas às políticas públicas de HIV e Aids no Brasil. A Profilaxia Pós-Exposição ao HIV ou simplesmente PEP consiste num método de prevenção antirretroviral, que implica no uso de medicamentos antirretrovirais, após uma situação de exposição de risco para o HIV e Aids. O objetivo do presente trabalho é investigar como a PEP, nos casos de exposição sexual consensual, é implementada pelos profissionais de saúde, no cotidiano de um Serviço de Assistência Especializada em IST/HIV/Aids de Porto Alegre, estado do Rio Grande do Sul, Brasil. Trata-se de uma análise de implementação de políticas públicas, a qual possui como parâmetro a atuação de profissionais de saúde na implementação da PEP. Com base numa abordagem qualitativa, o estudo privilegiou as técnicas da observação de cunho etnográfico e de entrevistas em profundidade. No referencial teórico, estabeleceu-se um diálogo entre os campos das Políticas Públicas, da Sexualidade, dos Direitos Sexuais e da Biopolítica. Na análise de dados, observaram-se quatro fatores do processo de implementação: a) o contexto no qual os profissionais estão inseridos; b) os fatores institucionais e organizacionais; c) fatores individuais e relacionais; e, por fim, d) a discricionariedade administrativa. A partir da análise realizada, apontaram-se elementos que provocam dificuldades e elementos facilitadores da implementação da PEP no serviço estudado. Entre os elementos que causam dificuldades estão: (a) concentração de atividades em poucos profissionais no SAE; (b) o baixo conhecimento sobre o Protocolo de PEP; (c) o não alinhamento institucional entre os serviços SAE e CTA; (d) as percepções negativas sobre PEP e, também, sobre o comportamento dos sujeitos que acessam a PEP; e (e) não implementação da estratégia, com base no atributo da discricionariedade. Entre os elementos facilitadores, destacaram-se: (a) a percepção da importância da PEP pela maioria dos profissionais; (b) o atendimento de PEP como uma emergência médica no SAE; (c) o aconselhamento realizado pelos profissionais de Enfermagem no SAE; (d) o reconhecimento da coordenação do serviço sobre a necessidade de mudanças para a efetividade da PEP. Os elementos negativos podem trazer consequências no acesso à estratégia, trazendo prejuízos ao cuidado de si, à preservação da autonomia do sujeito e ao exercício de direitos sexuais. Não obstante a presença de elementos facilitadores, estes devem ser aprimorados no contexto de implementação, por meio de mecanismos de gestão e planejamento dos recursos disponíveis, para fins de alcançar a efetividade da estratégia. Conclui-se que, para além de uma execução técnica, os profissionais de saúde na "linha de frente das políticas públicas" exercem uma execução simbólica, informados pelo contexto em que estão inseridos, pelas percepções, pela cultura organizacional e pelas interações cotidianas com os demais colegas e usuários. Nesse sentido, há de se fomentar os estudos qualitativos sobre o cotidiano dos profissionais de saúde, na busca de maior efetividade das estratégias de prevenção antirretrovirais, e, de modo geral, no aprimoramento das políticas públicas de HIV e Aids, do cuidado de si e do exercício de direitos sexuais. Theses and Dissertations	2017	Kennedy, Brandon	Perception of PrEP (Pre-Exposure Prophylaxis) amongst adults age 18 & older	-	-	The California State University	-	NA	10.1136/bmjopen-2021-054121	http://hdl.handle.net/10211.3/193115	The purpose of this research project was to measure the current perceptions of PrEP (Truvada/Pre-Exposure Prophylaxis) by the community at large since its FDA (Food and Drug Administration) and CDC (Centers for Disease Control and Prevention) approvals for HIV (Human Immunodeficiency Virus)-prevention within an adult age population 18 and older. I hypothesized that participants who identify as homosexual males will show the highest education levels and knowledge surrounding PrEP, regardless of their city location, ethnicity, nor age. Along with that, I hypothesized that the heterosexual population consisting of predominantly women, are the least aware of PrEP and also do not utilize it. This research was conducted by utilizing the snowball and convenient sample methods for finding participants and then posing questions to them through a survey in which they had an option to choose to answer or skip questions as they moved along in the process. Some of the survey questions were logic-based and therefore prompted different questions based off qualifying answers. California State University, Northridge. Department of Social Work. Theses and Dissertations	2017	Kesler, Maya A.	The Impact of Sexual Behaviours, Risk Perceptions and the Criminalization of HIV Non-Disclosure on HIV Transmission among HIV-Negative and HIV-Positive Men Who Have Sex With Men in Toronto	-	-	University of Toronto	-	NA	NA	http://hdl.handle.net/1807/79008	Background: Men who have sex with men (MSM) continue to have disproportionately high rates of human immunodeficiency virus (HIV), even though risk factors for HIV acquisition are known and antiretroviral treatment has reduced transmission. Objectives: To characterize the sexual behaviours and risk perceptions of HIV transmission among HIV-negative and HIV-positive MSM. Methods: 150 HIV-negative and 292 HIV-positive MSM participated in the STI/HIV Co-Infection Study between September 2010 and June 2012. Participants were recruited from the Maple Leaf Medical Clinic, a primary and HIV-related care centre in Toronto. Multivariable logistic regression (MLR) models quantified the relationships between actualsexual HIV risk, HIV incidence risk index for MSM (HIRI-MSM), perceived HIV risk and willingness to take pre-exposure prophylaxis (PrEP) among HIV-negative MSM. MLR and flow chart models were used to estimate the potential impact of HIV non-disclosure laws on HIV testing rates and transmission among HIV-negative MSM, and on condom use, HIV status disclosure and proportion at risk for criminal prosecutions among HIV-positive MSM. Results: As condom use frequency with HIV-positive regular partners decreased, perceived HIV risk (Odds Ratio (OR):18.33, 95% Confidence Interval (CI):1.65-203.45) and willingness to take PrEP (OR:27.11, 95% CI:1.33-554.43) increased. Condom use frequency with casual or HIV-unknown status regular partners and the HIRI-MSM index were not associated with perceived HIV risk or PrEP willingness. The 7% (9/124) reduction in HIV testing due to fear of prosecution found in this study could increase community HIV transmission by 18.5%; the majority of transmission being driven by the unmet needs of undiagnosed HIV-positive MSM. Almost half of HIV-positive MSM were more likely to use condoms and/or disclose their HIV-positive status due to fear of prosecution and 8.6% (25/292) could be at risk for non-disclosure prosecutions given their condom use, viral load and disclosure rates. Conclusions: HIV-negative MSM using condoms less frequently with HIV-positive partners but not with HIV-unknown status or casual partners accurately gauged their sexual risk behaviour and were willing to take PrEP. HIV non-disclosure laws may incentivize safer sex practices among HIV-positive MSM; however, they may also deter HIV testing which impedes HIV prevention efforts and increases community HIV transmission . Article	2017	Khan S.; Funk C.A.; Corado K.; Morris S.; Dube M.P.	Tenofovir Disoproxil Fumarate-Associated Fanconi Syndrome in an Human Immunodeficiency Virus (HIV)-Uninfected Man Receiving HIV Pre-Exposure Prophylaxis	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/OFID/OFX149	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85128226154&doi=10.1093%2fOFID%2fOFX149&partnerID=40&md5=28ae863bb9a9415f77e14eea6325de07	Tenofovir disoproxil fumarate (TDF) has been used worldwide in antiretroviral regimens of human immunodeficiency virus (HIV)-infected patients since being approved by the US Food and Drug Administration in 2001. Tenofovir disoproxil fumarate can cause renal tubular dysfunction and reduced renal function [1]. In its fully developed form, TDF renal dysfunction is associated with hypophosphatemia, renal phosphate wasting, and other features of Fanconi syndrome [1]. Cases of TDF-associated Fanconi syndrome have been reported predominantly among patients with HIV infection [1]. There has been no excess risk of renal tubular toxicity with TDF-emtricitabine (TDF-FTC) detected in large, placebo-controlled trials of HIV pre-exposure prophylaxis (PrEP) [2, 3]. One other well documented likely Fanconi syndrome has been reported in an online supplement to the latter paper [3]. In this study, we report an additional case of this previously described phenomenon. Article	2017	Khan, Tehseen; Kieslich, Katharina; Littlejohns, Peter	Why was a judicial review required to allow the English National Health Service to commission pre-exposure prophylaxis for HIV?	The Lancet	-	-	-	01406736	10.1016/S0140-6736(17)32940-9	https://www.proquest.com/scholarly-journals/why-was-judicial-review-required-allow-english/docview/1973126948/se-2?accountid=8113	Background: Following research trial evidence, pre-exposure prophylaxis (PrEP), consisting of the drug combination tenofovir disoproxil and emtricitabine taken daily or episodically, was licensed to prevent HIV in high-risk individuals. In 2014, an NHS England (NHSE) HIV Clinical Reference Group outlined the position for commissioning PrEP. Despite stakeholders' belief that NHSE would adopt PrEP as a prevention strategy, NHSE announced in March 2016, that it did not have the legal authority to do so owing to the 2012 Health and Social Care Act, which devolved sexual health services to local authorities. This decision was met with criticism, and a judicial review was brought against NHSE by activists, which NHSE lost. This interview study explored the reasons for NHSE's original decision not to commission PrEP and the implications this has for commissioning prevention strategies. The transparency of NHSE's decision-making process, and the effect of recent health-care reforms were also explored. Article	2017	Khandalavala, Karl; Mandal, Subhra; Pham, Rachel; Destache, Christopher J; Shibata, Annemarie	Nanoparticle Encapsulation for Antiretroviral Pre-Exposure Prophylaxis.	Journal of Nanotechnology & Materials Science	-	-	-	2377-1372	10.15436/2377-1372.17.1583	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5987555	HIV continues to be one of the greatest challenges facing the global health community. More than 36 million people currently live with HIV and, in 2015 2.1 million new infections were reported globally. Pre-Exposure Prophylaxis (PrEP) prevents HIV infection by inhibiting viral entry, replication, or integration at the primary site of pathogenic contraction. Failures of large antiretroviral drug (ARV) PrEP clinical trials indicate the current insufficiencies of PrEP for women in high-risk areas, such as sub-Saharan Africa. A combination of social, adherence, and drug barriers create these insufficiencies and limit the efficacy of ARV. Nanotechnology offers the promise of extended drug release and enhances bioavailability of ARVs when encapsulated in polymeric nano-particles. Nanoparticle encapsulation has been evaluated in vitro in comparative studies to drug solutions and exhibit higher efficacy and lower cytotoxicity profiles. Delivery systems for nanoparticle PrEP facilitate administration of nano-encapsulated ARVs to high-risk tissues. In this mini-review, we summarize the comparative nanoparticle and drug solution studies and the potential of two delivery methods: thermosensitive gels and polymeric nanoparticle films for direct prophylactic applications. Article	2017	Khanna A.S.; Schumm P.; Schneider J.A.	Facebook network structure and awareness of preexposure prophylaxis among young men who have sex with men	Annals of Epidemiology	-	-	-	10472797	10.1016/j.annepidem.2016.11.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85008656606&doi=10.1016%2fj.annepidem.2016.11.006&partnerID=40&md5=8eb7fccf9102c2c3688975732e275330	Background Young Black men who have sex with men (YBMSM) are the only population in the United States who have experienced rising human immunodeficiency virus incidence over the past decade. Consistent pre-exposure prophylaxis (PrEP) use can substantially reduce the risk of human immunodeficiency virus acquisition. What differentiates those who become aware of PrEP, and those who do not, remains largely unknown. Methods The social networks of YBMSM can impact their awareness of PrEP; to examine this impact, we used two waves of Facebook data from "uConnect"–a longitudinal cohort study of YBMSM in Chicago (n = 266). Results While PrEP awareness increased from 45% at baseline to 75% at follow-up, its use remained low (4% and 6%). There were 88 PrEP-unaware individuals at baseline who became aware (BA) by follow-up, and 56 who remained persistently unaware. While the persistently unawares had a higher median number of total Facebook friends, the BAs had a higher median numbers of friends who participated in uConnect, who were PrEP-aware, and who practiced behaviors previously found to be associated with individual-level awareness of PrEP at baseline. The BAs also had substantially more "influential" friends. Conclusion These findings demonstrate the potential of social networks in raising PrEP awareness and use among YBMSM. © 2016 Elsevier Inc. Article	2017	Klein, Charles H; Kuhn, Tamara; Huxley, Danielle; Kennel, Jamie; Withers, Elizabeth; Lomonaco, Carmela G	Preliminary Findings of a Technology-Delivered Sexual Health Promotion Program for Black Men Who Have Sex With Men: Quasi-Experimental Outcome Study.	JMIR Public Health and Surveillance	-	-	-	2369-2960	10.2196/publichealth.7933	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5676034	BACKGROUND: Human immunodeficiency virus (HIV) disproportionately affects black men who have sex with men (MSM), yet there are few evidence-based interventions specifically designed for black MSM communities. In response, the authors created Real Talk, a technology-delivered, sexual health program for black MSM. OBJECTIVE: The objective of our study was to determine whether Real Talk positively affected risk reduction intentions, disclosure practices, condom use, and overall risk reduction sexual practices. METHODS: The study used a quasi-experimental, 2-arm methodology. During the first session, participants completed a baseline assessment, used Real Talk (intervention condition) or reviewed 4 sexual health brochures (the standard of care control condition), and completed a 10-minute user-satisfaction survey. Six months later, participants from both conditions returned to complete the follow-up assessment. RESULTS: A total of 226 participants were enrolled in the study, and 144 completed the 6-month follow-up. Real Talk participants were more likely to disagree that they had intended in the last 6 months to bottom without a condom with a partner of unknown status (mean difference=-0.608, P=.02), have anal sex without a condom with a positive man who was on HIV medications (mean difference=-0.471, P=.055), have their partner pull out when bottoming with a partner of unknown HIV status (mean difference=-0.651, P=.03), and pull out when topping a partner of unknown status (mean difference=-0.644, P=.03). Real Talk participants were also significantly more likely to disagree with the statement "I will sometimes lie about my HIV status with people I am going to have sex with" (mean difference=-0.411, P=.04). In terms of attitudes toward HIV prevention, men in the control group were significantly more likely to agree that they had less concern about becoming HIV positive because of the availability of antiretroviral medications (mean difference=0.778, P=.03) and pre-exposure prophylaxis (PReP) (mean difference=0.658, P=.05). There were, however, no significant differences between Real Talk and control participants regarding actual condom use or other risk reduction strategies. CONCLUSIONS: Our findings suggest that Real Talk supports engagement on HIV prevention issues. The lack of behavior findings may relate to insufficient study power or the fact that a 2-hour, standalone intervention may be insufficient to motivate behavioral change. In conclusion, we argue that Real Talk's modular format facilitates its utilization within a broader array of prevention activities and may contribute to higher PReP utilization in black MSM communities. Article	2017	Kludze M.	Preexposure prophylaxis—a new addition to the armamentarium against human immunodeficiency virus	Clinical Medicine Insights: Therapeutics	-	-	-	1179559X	10.1177/1179559X17715241	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85045007847&doi=10.1177%2f1179559X17715241&partnerID=40&md5=13aac65d5fa2bb498613f2230b5e7b81	At the end of 2015, 36.7 million people worldwide were living with human immunodeficiency virus (HIV)/AIDS with 2.1 million newly diagnosed. The development of antiretroviral therapy was a remarkable milestone that vastly transformed the manner in which HIV/ AIDS patients were managed. The introduction of preexposure prophylaxis (PrEP) ushers in a new era that could again redefine the course of this global epidemic. Daily administration of oral combination tenofovir disoproxil fumarate-emtricitabine (TDF-FTC) and TDF alone as PrEP has demonstrated efficacy in preventing new HIV cases in a number of trials. The results of these studies represent major advances in preventing HIV acquisition and provide convincing evidence that widespread use of daily oral TDF-FTC by heterosexuals, men, women, and intravenous drug users and use of vaginal TDF is safe and effective. Low adherence has been cited as reason for failures in a few studies and poses a significant challenge when implementing PrEP in the real world in highly diverse communities. Several studies investigating a variety of strategies for PrEP delivery are underway to mitigate treatment challenges. Emerging strategies include the use of alternative antiretrovirals, novel formulations, and routes of administration, as well as dosing regimens. This article reviews literature on prior studies, current concerns and challenges, and future strategies for implementing effective PrEP. © The Author(s) 2017. Article	2017	Knopf A.S.; Ott M.A.; Liu N.; Kapogiannis B.G.; Zimet G.D.; Fortenberry J.D.; Hosek S.G.	Minors' and Young Adults' Experiences of the Research Consent Process in a Phase II Safety Study of Pre-exposure Prophylaxis for HIV	Journal of Adolescent Health	-	-	-	1054139X	10.1016/j.jadohealth.2017.06.013	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029906897&doi=10.1016%2fj.jadohealth.2017.06.013&partnerID=40&md5=6921718d1a741e0c2477cb3e1342459d	Purpose There is a persistent HIV epidemic among sexual and gender minority adolescents in the U.S. Oral pre-exposure prophylaxis (PrEP) is an efficacious prevention strategy, but not yet approved for minors. Minors' access to biomedical HIV prevention technologies is impeded by the ethical and legal complexities of consent to research participation. We explore autonomous consent and study experiences among minor and adult participants in Project PrEPare, a Phase II safety study of PrEP for HIV prevention. Methods Data for this mixed-methods descriptive study were collected via self-administered web-survey and in-depth telephone interviews in early 2016. Eligible participants were previously enrolled in Project PrEPare. We attempted to contact 191 participants; 74 were reached and expressed interest in participating and 58 enrolled. Results Participants nearly universally felt well informed, understood the study, and freely volunteered with the clear understanding they could withdraw any time. All felt supported by study staff, but a small minority wished for more support during enrollment. Minors were more likely than adults to indicate a wish for more support in decision-making, and adults expressed higher satisfaction with their decision compared to minors. There was no association between elements of consent and Project PrEPare study outcomes. Conclusions Participants had an overwhelmingly positive experience in a Phase II safety study of PrEP for HIV prevention. Some minors wished for more support during the decision-making process, but none consulted their parents about the decision. Our results support the inclusion of decisional supports in consent processes for adolescents, while also protecting their privacy. © 2017 Society for Adolescent Health and Medicine	Biomedical ethics; Consent; HIV; LGBTQ; Pre-exposure prophylaxis; Prevention	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
Article	2017	Koechlin F.M.; Fonner V.A.; Dalglish S.L.; O'Reilly K.R.; Baggaley R.; Grant R.M.; Rodolph M.; Hodges-Mameletzis I.; Kennedy C.E.	Values and Preferences on the Use of Oral Pre-exposure Prophylaxis (PrEP) for HIV Prevention Among Multiple Populations: A Systematic Review of the Literature	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1627-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85000785127&doi=10.1007%2fs10461-016-1627-z&partnerID=40&md5=cc47a59dd09f09c723e4cc32da4467ca	Daily oral pre-exposure prophylaxis (PrEP) is the use of antiretroviral drugs by HIV-negative people to prevent HIV infection. WHO released new guidelines in 2015 recommending PrEP for all populations at substantial risk of HIV infection. To prepare these guidelines, we conducted a systematic review of values and preferences among populations that might benefit from PrEP, women, heterosexual men, young women and adolescent girls, female sex workers, serodiscordant couples, transgender people and people who inject drugs, and among healthcare providers who may prescribe PrEP. A comprehensive search strategy reviewed three electronic databases of articles and HIV-related conference abstracts (January 1990–April 2015). Data abstraction used standardised forms to categorize by population groups and relevant themes. Of 3068 citations screened, 76 peer-reviewed articles and 28 conference abstracts were included. Geographic coverage was global. Most studies (N = 78) evaluated hypothetical use of PrEP, while 26 studies included individuals who actually took PrEP or placebo. Awareness of PrEP was low, but once participants were presented with information about PrEP, the majority said they would consider using it. Concerns about safety, side effects, cost and effectiveness were the most frequently cited barriers to use. There was little indication of risk compensation. Healthcare providers would consider prescribing PrEP, but need more information before doing so. Findings from a rapidly expanding evidence base suggest that the majority of populations most likely to benefit from PrEP feel positively towards it. These same populations would benefit from overcoming current implementation challenges with the shortest possible delay. © 2016, The Author(s). Article	2017	Koenig H.C.; Mounzer K.; Daughtridge G.W.; Sloan C.E.; Lalley-Chareczko L.; Moorthy G.S.; Conyngham S.C.; Zuppa A.F.; Montaner L.J.; Tebas P.	Urine assay for tenofovir to monitor adherence in real time to tenofovir disoproxil fumarate/emtricitabine as pre-exposure prophylaxis	HIV Medicine	-	-	-	14642662	10.1111/hiv.12518	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85018358644&doi=10.1111%2fhiv.12518&partnerID=40&md5=564becb5fc6e95f07d892d837b3b8e9b	Objectives: Tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) is approved for pre-exposure prophylaxis (PrEP) against HIV infection. Adherence is critical for the success of PrEP, but current adherence measurements are inadequate for real-time adherence monitoring. We developed and validated a urine assay to measure tenofovir (TFV) to objectively monitor adherence to PrEP. Methods: We developed a urine assay using high-performance liquid chromatography coupled to tandem mass spectrometry with high sensitivity/specificity for TFV that allowed us to determine TFV concentrations in log10 categories between 0 and 10 000 ng/mL. We validated the assay in three cohorts: (1) HIV-positive subjects with undetectable viral loads on a TDF/FTC-based regimen, (2) healthy HIV-negative subjects who received a single dose of TDF/FTC, and (3) HIV-negative subjects receiving daily TDF/FTC as PrEP for 24 weeks. Results: The urine assay detected TFV with greater sensitivity than plasma-based measures and with a window of measurements within 7 days of the last TDF/FTC dose. Based on the urine log-linear clearance after the last dose and its concordance with all detectable plasma levels, a urine TFV concentration > 1000 ng/mL was identified as highly predictive of the presence of TFV in plasma at > 10 ng/mL. The urine assay was able to distinguish high and low adherence patterns within the last 48 h (> 1000 ng/mL versus 10–1000 ng/mL), as well as nonadherence (< 10 ng/mL) extended over at least 1 week prior to measurement. Conclusions: We provide proof of concept that a semiquantitative urine assay measuring levels of TFV could be further developed into a point-of-care test and be a useful tool to monitor adherence to PrEP. © 2017 British HIV Association	adherence; HIV prevention; pre-exposure prophylaxis; Truvada; urine tenofovir assay	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Koester K.; Amico R.K.; Gilmore H.; Liu A.; McMahan V.; Mayer K.; Hosek S.; Grant R.	Risk, safety and sex among male PrEP users: time for a new understanding	Culture, Health & Sexuality	-	-	-	13691058	10.1080/13691058.2017.1310927	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85017664898&doi=10.1080%2f13691058.2017.1310927&partnerID=40&md5=de1e620d7ffb7d6a9c0ec9714050247b	Recent advances in biomedical HIV prevention have led to optimistic projections of a dramatic worldwide reduction of new infections by 2030. This optimism is counterbalanced by concerns that the protective benefits of one such technology, HIV pre-exposure prophylaxis (PrEP), may be negated by increases in other behaviours that offset these benefits (risk compensation). To contribute to a deeper understanding of concepts of safety and risk in the context of HIV PrEP, we draw on the narrative accounts of 61 male PrEP users who participated in the inaugural PrEP demonstration project: the iPrEx open-label extension study. We conducted in-depth interviews with a purposeful sample of iPrEx participants. Overall, participants did not report significant changes to their sexual practices once they had begun taking PrEP. Rather, participants reported experiencing a sense of relief or reprieve from HIV-related stress. This unburdening of fear did not necessarily lead to condomless sex. Instead, men expressed feeling a sense of security and less free-floating fear of HIV. We contend that no longer living under the threat of HIV is a significant benefit that has not been adequately explored in HIV prevention research. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2017	Koff, Alan; Goldberg, Carole; Ogbuagu, Onyema	Condomless sex and HIV transmission among serodifferent couples: current evidence and recommendations.	Annals of Medicine	-	-	-	1365-2060 0785-3890	10.1080/07853890.2017.1320423	https://pubmed.ncbi.nlm.nih.gov/28409656/	Human immunodeficiency virus (HIV) infection remains a global pandemic. The primary driver of HIV incidence is sexual transmission between serodifferent individuals. Condoms, when used consistently and correctly, are effective at preventing sexually transmitted HIV infections and are considered an integral component of a comprehensive approach to HIV prevention. However, the demonstrated effectiveness of antiretroviral therapy (ART) to prevent HIV transmission, known as treatment as prevention and of pre-exposure prophylaxis, have raised an intriguing dilemma on the necessity and additive preventive benefit of condom use among individuals in serodifferent relationships utilizing these prevention strategies. Recent published evidence, although of limited follow-up duration, has shown no linked HIV transmissions with condomless sex among serodifferent couples where the infected partner was on ART and virologically suppressed. This paper will review the evidence surrounding HIV transmission risk among serodifferent couples with and without the use of condoms and will highlight factors that increase or attenuate this risk. It will also address the important benefits that condomless sex offers couples. This paper aims to provide a template for providers to have personalized discussions with their patients, particularly those with an HIV-positive sexual partner, around their individual risk of HIV transmission and the role of condom use. Differences in Cumulative Exposure and Adherence to Tenofovir in the VOICE, iPrEx OLE, and PrEP Demo Studies as Determined via Hair Concentrations	AIDS Research and Human Retroviruses	-	-	-	8892229	10.1089/aid.2016.0202	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026883112&doi=10.1089%2faid.2016.0202&partnerID=40&md5=4d3073659c83b29121b4d1297d9a6120	Pre-exposure prophylaxis (PrEP) with oral tenofovir disoproxil fumarate (TDF)/emtricitabine (FTC) prevented HIV acquisition among men and women in several trials and is broadly recommended. In the VOICE and FEM-PrEP trials, however, TDF/FTC-based PrEP did not prevent HIV acquisition among women in eastern and southern Africa. Tenofovir was detected in plasma, reflecting exposure and adherence in recent days, in fewer than one-third of participants. Drug concentrations in hair, which represent cumulative exposure and adherence over weeks to months, have never previously been examined among women on PrEP. We compared tenofovir hair concentrations among women assigned to oral TDF/FTC in the VOICE trial to those among men and transgender women enrolled in 2 open-label PrEP studies, the iPrEx open-label extension (OLE) study and the U.S. PrEP Demonstration Project (PrEP Demo). Tenofovir hair concentrations were detectable in 55% of person-visits in VOICE, 75% of person-visits in iPrEx OLE (p = .006), and 98% of person-visits in PrEP Demo (p < .001). Median tenofovir hair concentrations corresponded to an estimated 0.2, 2.9, and 6.0 TDF/FTC doses taken per week in the three studies, respectively. In VOICE, combining tenofovir concentration data from plasma and hair suggested inconsistent, low-level product use. Incorporation of both short- and long-term adherence measures may allow for an improved understanding of patterns of drug-taking among women during global PrEP roll-out. © 2017 Mary Ann Liebert, Inc.	adherence monitoring; hair concentrations; HIV and women; HIV prevention; plasma concentrations; pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2017	Krakower, Douglas S; Ware, Norma C; Maloney, Kevin M; Wilson, Ira B; Wong, John B; Mayer, Kenneth H	Differing Experiences with Pre-Exposure Prophylaxis in Boston Among Lesbian, Gay, Bisexual, and Transgender Specialists and Generalists in Primary Care: Implications for Scale-Up.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2017.0031	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5512323	The Centers for Disease Control and Prevention estimates that one in four sexually active men who have sex with men (MSM) could decrease their HIV risk by using HIV pre-exposure prophylaxis (PrEP). Because many MSM access healthcare from primary care providers (PCPs), these clinicians could play an important role in providing access to PrEP. Semistructured qualitative interviews were conducted with 31 PCPs in Boston, MA, to explore how they approach decisions about prescribing PrEP to MSM and their experiences with PrEP provision. Purposive sampling included 12 PCPs from an urban community health center specializing in the care of lesbian, gay, bisexual, and transgender persons ("LGBT specialists") and 19 PCPs from a general academic medical center ("generalists"). Analyses utilized an inductive approach to identify emergent themes. Both groups of PCPs approached prescribing decisions about PrEP as a process of informed decision-making with patients. Providers would defer to patients' preferences if they were unsure about the appropriateness of PrEP. LGBT specialists and generalists were at vastly different stages of adopting PrEP into practice. For LGBT specialists, PrEP was a disruptive innovation that rapidly became normative in practice. Generalists had limited experience with PrEP; however, they desired succinct decision-support tools to help them achieve proficiency, because they considered preventive medicine to be central to their professional role. As generalists vastly outnumber LGBT specialists in the United States, interventions to support PrEP provision by generalists could accelerate the scale-up of PrEP for MSM nationally, which could in turn decrease HIV incidence for this priority population. Article	2017	Kuhns, Lisa M; Hotton, Anna L; Schneider, John; Garofalo, Robert; Fujimoto, Kayo	Use of Pre-exposure Prophylaxis (PrEP) in Young Men Who Have Sex with Men is Associated with Race, Sexual Risk Behavior and Peer Network Size	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1739-0	https://www.proquest.com/scholarly-journals/use-pre-exposure-prophylaxis-prep-young-men-who/docview/1883470032/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) is efficacious to prevent HIV infection, however, uptake among young men who have sex with men (YMSM) is relatively low. The purpose of this study was to describe PrEP use and related factors in a representative sample of YMSM in two cities, Chicago and Houston. YMSM, ages 16-29, were recruited via respondent-driven sampling (RDS) from 2014 to 2016. Correlates of PrEP uptake were assessed in weighted multivariable logistic regression models. A total of 12.2% of participants (of 394) reported ever taking PrEP; Black YMSM had the lowest rates of uptake (4.7%) and Whites the highest (29.5%). In a multivariable regression model, having an HIV positive sex partner, reporting recent group sex, peer network size, and city (Chicago) were significantly and positively associated with use of PrEP, while Black race was negatively associated with it. Given evidence of racial/ethnic disparities in PrEP uptake in this study, further research is needed to identify potential mechanisms of action and points of intervention. Article	2017	Lahuerta M.; Zerbe A.; Baggaley R.; Falcao J.; Ahoua L.; Di Mattei P.; Morales F.; Ramiro I.; El-Sadr W.M.	Feasibility, acceptability, and adherence with short-term HIV preexposure prophylaxis in female sexual partners of migrant miners in Mozambique	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001518	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038561994&doi=10.1097%2fQAI.0000000000001518&partnerID=40&md5=efe7e48d5d9db4d757f7048b59c3971d	Background: Preexposure prophylaxis (PrEP) offers protection from HIV acquisition if taken as prescribed. We evaluated the feasibility, acceptability, and adherence with short-term PrEP among female sexual partners of migrant miners in Mozambique. Methods: HIV-negative female sexual partners of migrant miners were offered daily tenofovir/emtricitabine (TDF/FTC) for 6 weeks concurrent with miners' return home. Study visits occurred at baseline, week 4, 6, and 8. Dried blood spots (DBSs) were collected at week 4 and 6. Results: Seventy-four women (median age: 42 years) were enrolled, 95% reported having 1 sexual partner and 80% reported never or rarely using condoms. At baseline, 41% had never tested for HIV; 65% were unaware of partners' HIV status. Of all women, 72 (97%) initiated PrEP, 7 (9%) discontinued PrEP before week 6; only 1 due to adverse events. Missed doses in the last week were self-reported by 8% and 3% of women at week 4 and 6, respectively. Of 66 (89%) women with DBS at week 4, 79% had detectable tenofovir diphosphate (TFV-DP) and 44% had levels consistent with $4 pills/wk ($700 fmol/punch). Of 63 (88%) women with DBS at week 6, 76% had detectable TFV-DP and 42% had levels consistent with $4 pills/wk. Conclusions: In this first study assessing the use of short-term PrEP, a high percent of female partners of migrant workers initiated PrEP and had detectable DP levels during follow-up. Further efforts are needed to enhance adherence to ensure protection from HIV acquisition. Short-term PrEP offers promise for populations who are at high risk of HIV during specific periods of time. Medication adherence, condom use and sexually transmitted infections in Australian preexposure prophylaxis users	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001519	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026434131&doi=10.1097%2fQAD.0000000000001519&partnerID=40&md5=622ec3cd1ecd249dc62a87bf8e4997c5	Objective: HIV preexposure prophylaxis (PrEP) decreases risk of HIV acquisition; however, its efficacy is closely dependent on adherence. There is also concern that the preventive effect of PrEP may be offset by risk compensation, notably an increase in condomless anal sex. Design: Multisite, open-label demonstration study that recruited people at current or recent risk of HIV infection in Melbourne, Australia. Methods: Participants were recruited from three general practice clinics and one sexual health clinic in Melbourne and consented to take daily tenofovir/emtricitabine (TFV/FTC) for 30 months. Sexual practice data, HIV and sexually transmitted infection (STI) test results were collected at baseline and 3-monthly during follow-up. PrEP adherence was evaluated by self-report at clinical visits, online surveys, refill-based assessments and dried blood spot testing. We present a 12-month interim analysis. Results: A total of 114 people were recruited. We observed a significant decline in condom use which occurred concomitantly with a significant increase in STIs over the first 12 months of PrEP. Incidence (per 100 person-years) of any STI was 43.2 and 119.8 at months 0-3 and 3-12, respectively incidence rate ratio 2.77 (1.52, 5.56). Adherence to PrEP medication was high by all measures, including 6 month TFV/FTC levels in dried blood spot. Conclusion: We found a significant reduction in condom use and an increase in STIs over the first 12 months of follow-up. High medication adherence rates occurring with a decline in condom use and a rise in STIs, suggest that prevention, early detection and treatment of STIs is a chief research priority in the current era of HIV PrEP. Article	2017	Lalley-Chareczko L.; Clark D.; Zuppa A.F.; Moorthy G.; Conyngham C.; Mounzer K.; Koenig H.	A case study of chewed Truvada® for PrEP maintaining protective drug levels as measured by a novel urine tenofovir assay	Antiviral Therapy	-	-	-	-	13596535	10.3851/IMP3151	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021742651&doi=10.3851%2fIMP3151&partnerID=40&md5=526010e905a2bc6ab3b4f129a6b6dcb1	Emtricitabine/tenofovir disoproxil fumarate (FTC/TDF; Truvada) given as pre-exposure prophylaxis (PrEP) successfully blocks HIV when taken once daily prior to potential HIV exposure. A 22-year-old male reported difficulty swallowing FTC/TDF for PrEP and subsequently began chewing the FTC/TDF tablets. Monthly urine samples assessed using liquid chromatography-tandem mass spectrometry (LC-MS/MS) indicated tenofovir levels >1,000 ng/ml, indicative of protection from HIV acquisition, over a 48-week period. Data from observational studies of HIV-positive patients details the successful treatment of HIV using crushed FTC/TDF delivered via feeding and gastronomy tubes while small, randomized trials of healthy volunteers demonstrate bioequivalence between whole and crushed FTC/TDF. ©2017 International Medical Press. Editorial	2017	Landers, Stewart; Kapadia, Farzana	Preexposure Prophylaxis: Adapting HIV Prevention Models to Achieve Worldwide Access.	American Journal of Public Health	-	-	-	-	1541-0048	10.2105/AJPH.2017.304035	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5607704	The efficacy of Truvada as a means of preexposure prophylaxis (PrEP) for individuals at high risk for HIV infection is well established with the first comprehensive guidelines for administration of PrEP developed and published by the Centers for Disease Control and Prevention in 2014.1 The availability of PrEP as a biomedical mechanism for HIV prevention is considered a "game changer" in HIV prevention efforts, much as the widespread availability of highly active antiretroviral therapy (HAART—more commonly referred to as "ART") was considered for HIV treatment in 1996. However, many of the questions that followed this breakthrough in HIV treatment are now being put forth regarding PrEP. How much does it cost? Who should pay for it? Will there be disparities in access to PrEP in the United States and how will we overcome these disparities? How can we afford to pay for PrEP when many people around the world still do not have access to ART? Article	2017	Landovitz, Raphael J, MD, MSc; Beymer, Matthew, PhD, MPH; Kofron, Ryan, MS; Amico, Kathy Rivet, PhD; Psaros, Christina, PhD; Bushman, Lane, BChem; Anderson, Peter L, PharmD; Flynn, Risa, BA; Lee, David P, MSW, MPH; Bolan, Robert K, MD; Jordan, Wilbert C, MD, MPH; Tseng, Chi-Hong, PhD; Dierst-Davies, Rhodri, PhD, MPH; Rooney, Jim, MD; Wohl, Amy Rock, PhD, MPH	Plasma Tenofovir Levels to Support Adherence to TDF/FTC Preexposure Prophylaxis for HIV Prevention in MSM in Los Angeles, California: JAIDS	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	NA	https://www.proquest.com/scholarly-journals/plasma-tenofovir-levels-support-adherence-tdf-ftc/docview/1988488493/se-2?accountid=8113	Background: Tenofovir disoproxil fumarate/emtricitabine preexposure prophylaxis (PrEP) is effective against HIV acquisition when taken as prescribed. Strategies that identify and intervene with those challenged by adherence to daily medication are needed. Setting: PATH-PrEP was an open-label single-arm interventional cohort study conducted at 2 community-based clinical sites in Los Angeles, CA. Methods: We enrolled self-identified men who have sex with men and transgender women ≥18 years of age at an elevated risk of HIV acquisition. Participants received a postexposure prophylaxis (PEP)-based or PrEP-based HIV prevention package for at least 48 weeks. Plasma tenofovir levels from each PrEP visit assessed as below the limit of quantitation (<10 ng/mL) triggered increased adherence support. Results: Three hundred one participants enrolled. Forty-eight-week retention in the PrEP cohort was 75.1%. Biomarker evidence of PrEP adherence consistent with ≥4 doses per week at weeks 4, 12, 24, 36, and 48 was found in 83.1%, 83.4%, 75.7%, 71.6%, and 65.5% of participants, respectively; younger and African American participants were less likely to have protective drug levels. Most of those with suboptimal adherence had adherence improvement after brief intervention. One seroconversion occurred in a participant who discontinued PrEP. Nearly half (46.4%) of participants were diagnosed with at least 1 incident sexually transmitted infection during 48 weeks of study follow-up. Conclusions and Relevance: PrEP was acceptable and well tolerated in a diverse population of men who have sex with men in Los Angeles. A brief intervention triggered from biomarkers of poor adherence was associated with improved adherence. Drug level monitoring has the potential to allow targeting of additional adherence support to those struggling with daily tablet adherence. Article	2017	Lau, Andrew; Kong, Fabian; Fairley, Christopher K; Donovan, Basil; Chen, Marcus; Bradshaw, Catriona; Boyd, Mark; Amin, Janaki; Timms, Peter; Tabrizi, Sepehr; Regan, David G; Lewis, David A; McNulty, Anna; Hocking, Jane S	Treatment efficacy of azithromycin 1 g single dose versus doxycycline 100 mg twice daily for 7 days for the treatment of rectal chlamydia among men who have sex with men - a double-blind randomised controlled trial protocol.	BMC Infectious Diseases	-	-	-	-	1471-2334	10.1186/s12879-016-2125-7	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5217553	BACKGROUND: Rectal infection with Chlamydia trachomatis is one of the most common bacterial sexually transmissible infections among men who have sex with men (MSM) with diagnosis rates continuing to rise. Current treatment guidelines recommend either azithromycin 1 g single dose or doxycycline 100 mg twice daily for 7 days. However, there are increasing concerns about treatment failure with azithromycin. We are conducting the first randomised controlled trial (RCT) to compare treatment efficacy of azithromycin versus doxycycline for the treatment of rectal chlamydia in MSM. METHODS/DESIGN: The Rectal Treatment Study will recruit 700 MSM attending Australian sexual health clinics for the treatment of rectal chlamydia. Participants will be asked to provide rectal swabs and will be randomised to either azithromycin 1 g single dose or doxycycline 100 mg twice daily for 7 days. Participants will be asked to complete questionnaires about adverse drug reactions, sexual behaviour and drug adherence via short message service and online survey. The primary outcome is the treatment efficacy as determined by a negative chlamydia nucleic acid amplification test at 4 weeks post treatment. Secondary outcomes will utilise whole genome sequencing and mRNA assay to differentiate between treatment failure, reinfection or false positive results. DISCUSSION: Rectal chlamydia is an increasing public health concern as use of pre-exposure prophylaxis against HIV becomes commonplace. Optimal, evidence-based treatment is critical to halting ongoing transmission. This study will provide the first RCT evidence comparing azithromycin and doxycycline for the treatment of rectal chlamydia. The results of this trial will establish which treatment is more efficacious and inform international management guidelines. TRIAL REGISTRATION: Australian New Zealand Clinical Trials Registry ACTRN12614001125617. Theses and Dissertations	2017	Le, Anh Quan	Investigating biomedical HIV prevention approach for HIV negative patients : Oral PrEP (Pre-exposure Prophylaxis) from a nursing perspective	-	-	Yrkeshögskolan Arcada	Yrkeshögskolan Arcada	-	NA	NA	http://www.theseus.fi/handle/10024/137574	This research study aims to shed light on the biomedical approach to HIV prevention and in particular PrEP is investigated. Three research questions sought to answer the role of PrEP plays in HIV prevention, the challenges regarding PrEP that a nurse faces when encountering patients of high risk of HIV and how those problems can be solved. The study adopts the HIV prevention continuum model by Horn T et al. (2016). Only half of the model for HIV negative patients was used which was the primary HIV prevention process that focuses on HIV testing, risk and needs assessment; linkage to prevention services as well as retention, engagement and adherence. A literature review based on secondary data was carried out for investigating the research questions. By adopting inclusion and exclusion criteria for the keywords chosen for data collection, 10 articles were selected from 235 items across a variety of scientific databases. The keywords used for selection criteria are PrEP, HIV, HIV prevention, Oral pre-exposure Prophylaxis, Nursing, Healthcare Providers, and Transgender. All articles were filtered to be after 2012 since that was the year the FDA approved PrEP. After data collection, inductive approach of qualitative content analysis by Graneheim & Lundman (2004) was used for data analysis. The findings manifest that PrEP is effective in HIV prevention for those vulnerable to the infection which, to name a few, are MSM, Transgender, heterosexual women, IDUs, sex workers and those in discordant relationships. Moreover, there were challenges regarding PrEP faced by both the patients and the HCPs. The typically identified challenges were adherence, cost, mistrust, drug resistance, risk compensation, etc. The measures taken to counteract these obstacles that nurses should adopt as discussed, are thorough need & risks assessment, referring the patients to HIV prevention services like mental health services, STI clinics, specific community, etc. In addition, nurses are recommended to build trust with the patients, provide accurate information about PrEP, set reminders such as phone calls and text messages for pill taking and follow up, provide feedback and counseling as well as cooperating with social workers. One of the limitations of this study is that HIV prevention methods are predicted to change in the future which may supercede some concepts described in this paper. More research is recommended to look at the model by Horn T et al. (2016) as a whole and/or incorporate the concepts of behavioral interventions, biomedical interventions and structural interventions into the study. Theses and Dissertations	2017	Le, Anh Quan	Word-of-Mouth influence in prescription medication : Case: PrEP (Pre-Exposure Prophylaxis) – HIV prevention medication	-	-	Yrkeshögskolan Arcada	Yrkeshögskolan Arcada	-	NA	NA	http://www.theseus.fi/handle/10024/125040	This research aims to sheds lights on identifying the key characteristics of word-of-mouth (WOM) influence in the recommendation of PrEP and scrutinizes their impact of PrEP recommendation on PrEP users´ perceived influence. Through literature review, WOM marketing was found to have a potential influence on healthcare marketing which motivated this study. By adopting the theoretical framework from the study of Akira and Young (2016), identified WOM determinants are characteristics of message sender (expertise and trustworthiness), the message (richness of message content and strength of message delivery), homophily and involvement. All mentioned independent latent variables were treated as antecedents impacting dependent variable WOM influence. The data was collected by disseminating a survey on the Facebook group called ´PrEP facts: Rethinking HIV prevention and sex´ asking current PrEP users to recall the most recent accepted recommendation about PrEP. Following the quantitative research, the findings manifest that WOM influence in PrEP recommendation was positively impacted by expertise, strength & richness of message delivery and homophily. Accordingly, Gilead Sciences Inc., the drug producer, is recommended to increase the marketing of PrEP to healthcare professionals, adopt storytelling in their message delivery and embrace patient advocacy groups. Article	2017	Lee Y.-C.; Chang S.-Y.; Lin K.-Y.; Chang L.-H.; Liu W.-C.; Wu C.-H.; Sun H.-Y.; Hung C.-C.; Chang S.-C.	Awareness and willingness towards pre-exposure prophylaxis against HIV infection among individuals seeking voluntary counselling and testing for HIV in Taiwan: A cross-sectional questionnaire survey	BMJ Open	-	-	-	-	20446055	10.1136/bmjopen-2016-015142	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85031779667&doi=10.1136%2fbmjopen-2016-015142&partnerID=40&md5=02d487fbca86f3abee41fe4e23796382	Objectives We aimed to investigate the awareness and willingness towards pre-exposure prophylaxis (PrEP) among individuals seeking voluntary counselling and testing (VCT) for HIV in Taiwan, where PrEP is currently not reimbursed by the insurance. Methods Between April and October 2016, a questionnaire interview was conducted among VCT clients to inquire about the attitudes towards PrEP against HIV infection. Multivariate logistic regression analysis was performed to identify the associated factors with willingness to initiate PrEP. Results During the 6-month period, 1173 VCT clients (99.8%) completed the interviews, with 67.4% being homosexual or bisexual male. While 67.2% of the clients knew of postexposure prophylaxis, 40.2% heard of PrEP. Overall, 546 clients (46.5%) were willing to initiate PrEP and 89.5% of them would choose event-driven PrEP. In multivariate analysis, male gender (OR 1.796; 95% CI 1.165 to 2.768), full-Time job (OR 1.354; 95% CI 1.052 to 1.742), one-night stand (OR 1.374; 95% CI 1.043 to 1.810), having casual sex partners within 3 months (OR 1.329; 95% CI 1.031 to 1.714), condomless anal sex (OR 1.405; 95% CI 1.122 to 1.878) and ever having chemsex or attending a drug party in the past 1 year (OR 2.571; 95% CI 1.541 to 4.287), regular screening for HIV infection (OR 1.321; 95% CI 1.021 to 1.711) and knowledge of PrEP (OR 1.504; 95% CI, 1.159 to 1.953) were associated with willingness to initiate PrEP. Conclusions Understanding the willingness to initiate PrEP against HIV among the VCT clients in Taiwan, which was associated with male gender, risky sexual behaviours and awareness of PrEP, will help inform the implementation of PrEP programme. © Article author(s) (or their employer(s) unless otherwise stated in the text of the article) 2017. Theses and Dissertations	2017	Leenman, Theodore S	Reconceiving Risk: Relational Understandings of Pre-Exposure Prophylaxis and the Down-Low.	-	-	Harvard University	Harvard University	-	NA	NA	http://nrs.harvard.edu/urn-3:HUL.InstRepos:40046557	This research advances sociological theorizing of risk through examinations of a sexual technology and a sexual practice. The sexual technology is the preventative HIV medication, Truvada for PrEP. The sexual practice is the "down-low" - the behavior of men who secretly engage in male-male sex but do not identify as gay. Previous studies of sexual risk examine categories of "at risk" people and rational calculations of risk. My analysis situates risk fully within sexual relationships and the temporal, unfolding process of sex. This perspective illuminates meanings related to risk that emerge from interaction as well as the emotions and uncertainty involved in the experience of risk-taking. Content-analysis of online media articles about Truvada for PrEP (N=214) shows how PrEP is individualized and desexualized with reference to categories of people portrayed as "risky." Subsequent interview analyses with White and Black men who engage in sexual relations with men (N=60) reveal disjunctures between categorical representations of PrEP and understandings derived from sexual relations. Respondents' evaluations of risk are contingent on social comparisons to others and perceptions of intimacy in their relationships. Finally, drawing from a subset of interviews (N=36), this relational understanding of risk is applied to the case of the down-low. I argue that, due to their boundary work against an out-gay lifestyle, PrEP may not be viewed as relevant by this population. However, understanding the relational contexts of more intimate partnerships can help reframe PrEP as compatible with down-low sexual practices. Article	2017	Levy, Matthew E; Patrick, Rudy; Gamble, Jonjelyn; Rawls, Anthony; Opoku, Jenevieve; Magnus, Manya; Kharfen, Michael; Greenberg, Alan E; Kuo, Irene	Willingness of community-recruited men who have sex with men in Washington, DC to use long-acting injectable HIV pre-exposure prophylaxis.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0183521	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5565177	OBJECTIVES: Clinical trials are currently investigating the safety and efficacy of long-acting injectable (LAI) agents as HIV pre-exposure prophylaxis (PrEP). Using National HIV Behavioral Surveillance data, we assessed the self-reported willingness of men who have sex with men (MSM) to use LAI PrEP and their preference for LAI versus daily oral PrEP. METHODS: In 2014, venue-based sampling was used to recruit MSM aged ≥18 years in Washington, DC. Participants completed an interviewer-administered survey followed by voluntary HIV testing. This analysis included MSM who self-reported negative/unknown HIV status at study entry. Correlates of being "very likely" to use LAI PrEP and preferring it to daily oral PrEP were identified using multivariable logistic regression. RESULTS: Of 314 participants who self-reported negative/unknown HIV status, 50% were <30 years old, 41% were non-Hispanic Black, 37% were non-Hispanic White, and 14% were Hispanic. If LAI PrEP were offered for free or covered by health insurance, 62% were very likely, 25% were somewhat likely, and 12% were unlikely to use it. Regarding preferred PrEP modality, 67% chose LAI PrEP, 24% chose oral PrEP, and 9% chose neither. Correlates of being very likely versus somewhat likely/unlikely to use LAI PrEP included age <30 years (aOR 1.64; 95% CI 1.00-2.68), reporting ≥6 (vs. 1) sex partners in the last year (aOR 2.60; 95% CI 1.22-5.53), previous oral PrEP use (aOR 3.67; 95% CI 1.20-11.24), and being newly identified as HIV-infected during study testing (aOR 4.83; 95% CI 1.03-22.67). Black (vs. White) men (aOR 0.48; 95% CI 0.24-0.96) and men with an income of <$20,000 (vs. ≥$75,000; aOR 0.37; 95% CI 0.15-0.93) were less likely to prefer LAI to oral PrEP. CONCLUSIONS: If LAI PrEP were found to be efficacious, its addition to the HIV prevention toolkit could facilitate more complete PrEP coverage among MSM at risk for HIV. Book Section	2017	Liegler T.; Grant R.	HIV-1 drug resistance in pre-exposure prophylaxis trials	-	Handbook of Antimicrobial Resistance	-	-	1493906933	-	10.1007/978-1-4939-0694-9_24	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85032930518&doi=10.1007%2f978-1-4939-0694-9_24&partnerID=40&md5=b8ccd5c1186248b8cbb6524d1e22e1b5	When used with other proven strategies for prevention of HIV-1 acquisition, oral and topical preexposure prophylaxis (PrEP) has been shown to be effective in multiple randomized, placebo-controlled clinical trials throughout the world. Preexposure prophylaxis trials have included over 20,000 men and women at risk for HIV infection through sexual or intravenous exposure. A consistent finding is that drug exposure is essential for PrEP efficacy. In PrEP users with breakthrough infection, selection of drug-resistant virus is a possible outcome, presenting a unique sequence of events and outcomes compared with therapeutic use of antiretroviral drugs. Study findings have indicated that drug resistance selected by PrEP occurs rarely, except in cases where PrEP is initiated in very early infection, prior to seroconversion, and detectable only with nucleic acid tests. In this review, we discuss the factors associated with PrEP which may contribute to drug resistance and summarize the frequency and characteristics of HIV-1 drug resistance reported to date from global clinical trials. A theoretical framework of the causes and consequences of drug resistance in PrEP is considered as a basis of the real-life outcomes and challenges in implementing PrEP. © Springer Science+Business Media New York 2017. Article	2017	Liu, Albert Y.; Buchbinder, Susan P.	CROI 2017: HIV Epidemic Trends and Advances in Prevention.	Topics in Antiviral Medicine	-	-	-	-	2161-5853 2161-5861	NA	https://www.iasusa.org/wp-content/uploads/2017/05/25-2-35.pdf	At the 2017 Conference on Retroviruses and Opportunistic Infections (CROI), trends in the HIV epidemic were highlighted, with decreasing HIV incidence reported across several countries, although key groups remain underdiagnosed and undertreated. In the United States, men who have sex with men (MSM) continue to comprise the largest number of new and undiagnosed HIV infections, with rising incidence in MSM 25 to 34 years old and Latino MSM. Phylogenetics are being used to identify rapidly growing HIV transmission clusters, which can inform prevention efforts. HIV testing is a crucial first step for accessing HIV prevention and treatment, and several innovative strategies to increase HIV testing show promise. Sexually transmitted infections (STIs) have been on the rise but predate widespread use of HIV preexposure prophylaxis (PrEP); enhanced STI screening and treatment coupled with PrEP could substantially reduce STI incidence in the United States. Several studies indicate increasing PrEP awareness and use, although disparities exist in vulnerable populations. PrEP persistence remains a challenge, and practitioner adherence to prescribing guidelines is suboptimal. Novel PrEP delivery models are being developed to increase PrEP knowledge, access, and support. Article	2017	Liu, Zhi-Jun; Bai, Jing; Liu, Feng-Li; Zhang, Xiang-Yang; Wang, Jing-Zhang	Focus on the therapeutic efficacy of 3BNC117 against HIV-1: In vitro studies, in vivo studies, clinical trials and challenges.	International Immunopharmacology	-	-	-	-	1878-1705	10.1016/j.intimp.2017.08.016	https://dx.doi.org/10.1016/j.intimp.2017.08.016	3BNC117, which was discovered in 2011, is a broadly neutralizing antibody (bNAb) and specifically neutralizes the human immunodeficiency virus type-1 (HIV-1) by targeting the CD4-binding site. This is the first comprehensive review that focuses on the role of 3BNC117 in the prevention of HIV-1 and acquired immune deficiency syndrome (AIDS). Briefly, 3BNC117 neutralizes many HIV/SHIV strains in vitro, blocks HIV-1 acquisition in animal models via a pre-exposure prophylaxis, alleviates HIV-1-associated viremia via a post-exposure therapeutic effect, prevents the establishment of latent HIV-1 reservoirs, and induces both humoral and cellular anti-HIV immune responses in vivo. The outcomes of Phase I and Phase IIa clinical trials in 2015 and 2016 showed the safety, tolerability, and therapeutic efficacy of 3BNC117 in HIV-1-infected human individuals. Nevertheless, anti-3BNC117 antibodies and HIV-1 strains resistant to 3BNC117 pose clinical challenges to immunotherapy with 3BNC117, so potential strategies for optimizing the potency of 3BNC117 are suggested here. Predictably, HIV-1 prevention and AIDS treatment will benefit from combinational immunotherapies with 3BNC117 and other pharmaceuticals (bNAbs, antiretroviral medicines, viral inducers, etc.) in the near future. Article	2017	Livant E.; Heaps A.; Kelly C.; Maharaj R.; Samsunder N.; Nhlangulela L.; Karugaba P.; Panchia R.; Marrazzo J.; Chirenje Z.M.; Parikh U.M.	The fourth generation AlereTM HIV Combo rapid test improves detection of acute infection in MTN-003 (VOICE) samples	Journal of Clinical Virology	-	-	-	-	13866532	10.1016/j.jcv.2017.06.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85023193338&doi=10.1016%2fj.jcv.2017.06.006&partnerID=40&md5=18f2b367feeba08880afd2652e73d1ae	Background Early and accurate detection of HIV is crucial when using pre-exposure prophylaxis (PrEP) for HIV prevention to avoid PrEP initiation in acutely infected individuals and to minimize the risk of drug resistance in individuals with breakthrough infection. Objective To determine if fourth-generation antigen/antibody (Ag/Ab) rapid diagnostic tests (RDT) would have detected HIV infection earlier than the third-generation RDT used in MTN-003 (VOICE). Study design 5029 VOICE participants were evaluated with third-generation Alere Determine™ HIV-1/2, OraQuick ADVANCE® Rapid HIV-1/2, Uni-Gold™ Recombigen® HIV-1/2 and Bio-Rad GS HIV-1/2 + O EIA; and fourth-generation Alere Determine™ HIV-1/2 Ag/Ab Combo, Conformité Européene (CE)-Marked Alere™ HIV Combo and Bio-Rad HIV Combo Ag/Ab EIA. Multispot®, GS HIV-1 Western Blot (WB) and Geenius™ (Bio-Rad) were also evaluated. Results Of 57 antibody-negative pre-seroconversion plasma samples with HIV RNA >20 copies/mL identified, 16 (28%) were reactive by CE-Marked Alere™ HIV Combo (1 Ab; 9 Ag; 6 Ag/Ab reactive) and 4 (7%) by Alere Determine™ HIV-1/2 Ag/Ab Combo (2 Ab; 2 Ag; 0 Ag/Ab reactive) (p = 0.0005). Multispot® confirmed only 1 of 16 acute infections while WB and Geenius™ confirmed none. GS HIV Combo Ag/Ab EIA identified 27 of 57 (47%) pre-seroconversion RNA-positive samples. Conclusion In VOICE, 28% of infections missed by current third-generation RDT would have been identified with the use of CE-Marked Alere™ HIV Combo. Geenius™, Multispot® and WB were all insensitive (< 10%) in confirming infections detected by fourth-generation assays. An improved diagnostic algorithm that includes a fourth-generation RDT with HIV RNA testing will be essential for efficiently identifying seroconverters on PrEP. © 2017	4th generation rapid test; Acute infection; HIV confirmatory test; HIV diagnostics; HIV-1; Pre-exposure prophylaxis	English	Netherlands	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Lochlainn L.N.; O'Donnell K.; Hurley C.; Lyons F.; Igoe D.	Using data from a behavioural survey of men who have sex with men (MSM) to estimate the number likely to present for HIV pre-exposure prophylaxis (PrEP) in Ireland, 2017	Eurosurveillance	-	-	-	-	1025496X	10.2807/1560-7917.ES.2017.22.48.17-00768	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037354741&doi=10.2807%2f1560-7917.ES.2017.22.48.17-00768&partnerID=40&md5=7ce2fce41cc9748cb643e9f420412e51	In Ireland, men who have sex with men (MSM) have increased HIV risk. Pre-exposure prophylaxis (PrEP), combined with safe sex practices, can reduce HIV acquisition. We estimated MSM numbers likely to present for PrEP by applying French PrEP criteria to Irish MSM behavioural survey data. We adjusted for survey bias, calculated proportions accessing testing services and those likely to take PrEP. We estimated 1–3% of MSM in Ireland were likely to present for PrEP. © 2017, European Centre for Disease Prevention and Control (ECDC). All rights reserved. Article	2017	Logo, Martin K; Denawi, Hadi; Ferraro, Aimee	Prescribing HIV PrEP and Education Needs Among Care Providers	Journal of Social, Behavioral and Health Sciences	-	-	-	-	19483260	10.5590/JSBHS.2017.11.1.14	https://www.proquest.com/scholarly-journals/prescribing-hiv-prep-education-needs-among-care/docview/2839037213/se-2?accountid=8113	Preexposure prophylaxis (PrEP) is a biomedical intervention to prevent the spread of HIV. Underprescribing PrEP could increase the probability of HIV exposure among serodivergent couples/partners and people who do not practice safer sex. Previous research on PrEP did not assess the association between awareness of PrEP, years of experience of the providers, provider types, and the frequency of PrEP among physicians. The purpose of this study is to test the hypothesis that awareness of PrEP, years of experience, and provider types might be predictors of the frequency of PrEP among physicians. Precaution adoption process model and cross-sectional design were applied to survey 100 physicians. Kendall's b correlation test and Fisher's exact test showed that awareness was the primary barrier to prescribing PrEP at the providers' level. Higher awareness of PrEP and years of experience were associated with the frequency of PrEP prescription. However, there was an insignificant difference between provider types and the frequency of PrEP prescription. The findings support the notion that independent from their years of experience and specialty, the more physicians know about PrEP, the more they prescribe it. The results and recommendations contribute to positive social change by providing information to develop a comprehensive PrEP education curriculum for care providers. Our findings indicate that physicians need education and training to fully understand the potential for PrEP to reduce HIV transmission. Article	2017	Lykins W.R.; Luecke E.; Johengen D.; van der Straten A.; Desai T.A.	Long acting systemic HIV pre-exposure prophylaxis: an examination of the field	Drug Delivery and Translational Research	-	-	-	-	2190393X	10.1007/s13346-017-0391-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85032570805&doi=10.1007%2fs13346-017-0391-6&partnerID=40&md5=70437005f662658735df57e2270537a5	Oral pre-exposure prophylaxis for the prevention of HIV-1 transmission (HIV PrEP) has been widely successful as demonstrated by a number of clinical trials. However, studies have also demonstrated the need for patients to tightly adhere to oral dosing regimens in order to maintain protective plasma and tissue concentrations. This is especially true for women, who experience less forgiveness from dose skipping than men in clinical trials of HIV PrEP. There is increasing interest in long-acting (LA), user-independent forms of HIV PrEP that could overcome this adherence challenge. These technologies have taken multiple forms including LA injectables and implantables. Phase III efficacy trials are ongoing for a LA injectable candidate for HIV PrEP. This review will focus on the design considerations for both LA injectable and implantable platforms for HIV PrEP. Additionally, we have summarized the existing LA technologies currently in clinical and pre-clinical studies for HIV PrEP as well as other technologies that have been applied to HIV PrEP and contraceptives. Our discussion will focus on the potential application of these technologies in low resource areas, and their use in global women's health. © 2017, Controlled Release Society. Theses and Dissertations	2017	MacAulay, Margaret	Virtual friction: Networking sexuality and HIV prevention in the digital age	-	-	Simon Fraser University	Simon Fraser University	-	NA	NA	https://summit.sfu.ca/_flysystem/fedora/sfu_migrate/18076/etd10534_MMacAulay.pdf	From advances in HIV prevention science bringing us pre-exposure prophylaxis (PrEP) to the proliferation of hook-up apps like Grindr, the late 20th/early 21st centuries have introduced intense socio-technical transformations in gay men's intimate lives. In particular, the networked decentralization and privatization of sexuality has generated a corresponding set of discourses within gay men's communities and in the social world of HIV prevention. Community narratives either construct the Internet as a virtual community where acceptance, solidarity, friendship, romance, and sex become easily accessible in a largely hetero-normative world, or a virtual bathhouse accelerating the depoliticization and commodification of gay life (Kapp, 2011; Ward & Arsenault, 2012). In public health, accounts oscillate between exploring the Internet's potential to revitalize HIV prevention efforts (Chiasson et al., 2009; Rhodes et al., 2011; Rosser et al., 2010), and debating its possible role in facilitating HIV risk and transmission (Berry et al., 2008; Bull & McFarlane, 2000; Wohlfeiler & Potterat, 2005). Intersecting perspectives from communication, Internet studies, and public health, this dissertation traces the erotic and epidemiological contours of a "network society" (Castells, 1996) where the Internet plays an ambivalent role in social life. Based on archival research, personal experience, and 31 interviews with gay men, public health actors, and Internet entrepreneurs in San Francisco and Vancouver, this project uses the concept of virtual friction to think through the tensions, contradictions, and paradoxes that characterize the networking of sexuality and HIV prevention in the digital age. Broadly speaking, I ask whether and how the Internet has transformed sexuality and HIV prevention by examining the discourses, subjectivities, and practices that have emerged, as well as the subsequent set of opportunities and challenges they generate for the various social worlds involved (Strauss, 1978). I argue that virtual friction is not only an inevitable but necessary part of the process because it renders visible the limits of imagining social problems and solutions in purely technological terms. Friction challenges us to acknowledge the competing epistemologies, interests, and perspectives that underpin life in the digital age, taking us out of our comfort zones by asking how we know and believe what we do about science, technology and society. Article	2017	Machado, Daisy Maria; de Sant'Anna Carvalho, Alexandre Machado; Riera, Rachel	Adolescent pre-exposure prophylaxis for HIV prevention: current perspectives.	Adolescent Health, Medicine and Therapeutics	-	-	-	-	1179-318X	10.2147/AHMT.S112757	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5716324	Adolescents are a critical population that is disproportionately impacted by the HIV epidemic. More than 2 million adolescents between the age group of 10 and 19 years are living with HIV, and millions are at risk of infection. HIV risks are considerably higher among girls, especially in high-prevalence settings such as eastern and southern Africa. In addition to girls, there are other vulnerable adolescent subgroups, such as teenagers, who use intravenous (IV) drugs, gay and bisexual boys, transgender youth, male sex workers, and people who fall into more than one of these categories. Pre-exposure prophylaxis (PrEP) is a new intervention for people at high risk for acquiring HIV, with an estimated HIV incidence of >3%. Recent data from trials show evidence of the efficacy of PrEP as a powerful HIV prevention tool in high-risk populations, including men who have sex with men, HIV-1-serodiscordant heterosexual couples, and IV drug users. The reported efficacy in those trials of the daily use of oral tenofovir, alone or in combination with emtricitabine, to prevent HIV infection ranged from 44% to 75% and was heavily dependent on adherence. Despite the proven efficacy of PrEP in adult trials, concerns remain about its feasibility in real-life scenarios due to stigma, cost, and limited clinician experience with PrEP delivery. Recent studies are attempting to expand the inquiry into the efficacy of such HIV prophylaxis approaches in adolescent populations, but there are still many gaps in knowledge, and no country has yet approved it for use with adolescents. The aim of this review was to identify and summarize the evidence from studies on PrEP for adolescents. We have compiled and reviewed published studies focusing on safety, feasibility, adherence to therapeutics, self-perception, and legal issues related to PrEP in people aged between 10 and 24 years. Article	2017	Madrasi K.; Chaturvedula A.; Haberer J.E.; Sale M.; Fossler M.J.; Bangsberg D.; Baeten J.M.; Celum C.; Hendrix C.W.	Markov Mixed Effects Modeling Using Electronic Adherence Monitoring Records Identifies Influential Covariates to HIV Preexposure Prophylaxis	Journal of Clinical Pharmacology	-	-	-	-	912700	10.1002/jcph.843	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85008249178&doi=10.1002%2fjcph.843&partnerID=40&md5=d1b3cd07f135644b4261449587dda7a1	Adherence is a major factor in the effectiveness of preexposure prophylaxis (PrEP) for HIV prevention. Modeling patterns of adherence helps to identify influential covariates of different types of adherence as well as to enable clinical trial simulation so that appropriate interventions can be developed. We developed a Markov mixed-effects model to understand the covariates influencing adherence patterns to daily oral PrEP. Electronic adherence records (date and time of medication bottle cap opening) from the Partners PrEP ancillary adherence study with a total of 1147 subjects were used. This study included once-daily dosing regimens of placebo, oral tenofovir disoproxil fumarate (TDF), and TDF in combination with emtricitabine (FTC), administered to HIV-uninfected members of serodiscordant couples. One-coin and first- to third-order Markov models were fit to the data using NONMEM® 7.2. Model selection criteria included objective function value (OFV), Akaike information criterion (AIC), visual predictive checks, and posterior predictive checks. Covariates were included based on forward addition (α = 0.05) and backward elimination (α = 0.001). Markov models better described the data than 1-coin models. A third-order Markov model gave the lowest OFV and AIC, but the simpler first-order model was used for covariate model building because no additional benefit on prediction of target measures was observed for higher-order models. Female sex and older age had a positive impact on adherence, whereas Sundays, sexual abstinence, and sex with a partner other than the study partner had a negative impact on adherence. Our findings suggest adherence interventions should consider the role of these factors. © 2016, The American College of Clinical Pharmacology	adherence; HIV; Markov models; medication event-monitoring systems; preexposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
Article	2017	Malik, Tanushree; Chauhan, Gaurav; Rath, Goutam; Murthy, R S R; Goyal, Amit K	"Fusion and binding inhibition" key target for HIV-1 treatment and pre-exposure prophylaxis: targets, drug delivery and nanotechnology approaches.	Drug Delivery	-	-	-	-	1521-0464	10.1080/10717544.2016.1228717	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8241151	More than 35 million people are living with HIV worldwide with approximately 2.3 million new infections per year. Cascade of events (cell entry, virus replication, assembly and release of newly formed virions) is involved in the HIV-1 transmission process. Every single step offers a potential therapeutic strategy to halt this progression and HIV fusion into the human host cell is one such stage. Controlling the initial event of HIV-1 transmission is the best way to control its dissemination especially when prophylaxis is concerned. Action is required either on the HIV's or host's cell surface which is logically more rational when compared with other intracellular acting moieties. Aim of this manuscript is to detail the significance and current strategies to halt this initial step, thus blocking the entry of HIV-1 for further infection. Both HIV-1 and the possible host cell's receptors/co-receptors are under focus while specifying the targets available for inhibiting this fusion. Current and under investigation moieties are categorized based on their versatile mechanisms. Advanced drug delivery and nanotechnology approaches present a key tool to exploit the therapeutic potential in a boosted way. Current drug delivery and the impact of nanotechnology in potentiating this strategy are detailed. Article	2017	Maljaars, Lennart P.; Gill, Katherine; Smith, Philip J.; Gray, Glenda E.; Dietrich, Janan J.; Gomez, Gabriela B.; Bekker, Linda-Gail	Condom migration after introduction of pre-exposure prophylaxis among HIV-uninfected adolescents in South Africa: A cohort analysis	Southern African Journal of HIV Medicine	-	-	-	-	2078-6751	10.4102/sajhivmed.v18i1.712	http://www.scielo.org.za/scielo.php?script=sci_arttext&pid=S2078-67512017000100017&lang=pt	BACKGROUND: Approximately 3 million adolescents and young adults (AYA), between the ages of 15 years and 24 years, are living with HIV in sub-Saharan Africa. The use of pre-exposure prophylaxis (PrEP) may be a promising HIV prevention tool to bridge the high-risk years of AYA between sexual debut and adulthood OBJECTIVES: Concerns have been raised that the use of PrEP could lead to an increase in sexual risk behaviour and sexually transmitted infections in general and less condom use in particular among adolescents METHODS: This study assesses condom use among South African adolescents enrolled on a demonstration PrEP study, called Plusspills, being conducted in Cape Town and Soweto. A questionnaire on sexual risk behaviour was administered at baseline and after 4, 8 and 12 weeks. Three different questions on condom use were asked at each visit. Unless all answers indicated condom use at all times, a participant was scored 'at risk'. McNemar's tests and a Cochran's Q test were used to investigate changes in condom use over time RESULTS: We interviewed 148 adolescents (66% female) at baseline. Eighty-nine participants completed all visits. In this group, an increase in condom use was observed over the period of 12 weeks. Most participants who reported behavioural changes mentioned an increase in condom use CONCLUSION: There was no sign of sexual risk compensation in the 12 weeks of the study. Observed increase in condom use can be explained by an increased awareness of personal HIV risk or by social desirability or recall biases. In future research, additional data including other biomarkers of unprotected sex and longer follow-up time would be useful to help understand the relationship between PrEP use, sexual risk perception and consequent behaviours, especially in adolescents	NA	English	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Quantitative
Article	2017	Maloney K.M.; Krakower D.S.; Ziobro D.; Rosenberger J.G.; Novak D.; Mayer K.H.	Culturally competent sexual healthcare as a prerequisite for obtaining preexposure prophylaxis: Findings from a qualitative study	LGBT Health	-	-	-	-	23258292	10.1089/lgbt.2016.0068	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85027015243&doi=10.1089%2flgbt.2016.0068&partnerID=40&md5=96e6f3ead094915eb46d38672530d3fc	Purpose: Men who have sex with men (MSM) experience stigma in healthcare settings, which impedes disclosure of sexual behavior, potentially limiting uptake of preexposure prophylaxis (PrEP). The purpose of this study was to describe the context of this limitation and explore geographical variability. Methods: To understand how discomfort in healthcare settings affects PrEP utilization, we conducted two online focus groups with geographically diverse samples of MSM. Results: Respondents identified primary care providers as preferred sources for PrEP, but potential uptake was limited by barriers to establishing nonjudgmental relationships with these providers. Conclusion: Improved patient-provider communication about sexual behaviors might increase PrEP use among MSM. © Mary Ann Liebert, Inc. 2017.	barriers to care; focus group; HIV/AIDS; MSM (men who have sex with men); prevention; qualitative methods	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2017	Mandal, Subhra; Khandalavala, Karl; Pham, Rachel; Bruck, Patrick; Varghese, Marisa; Kochvar, Andrew; Monaco, Ashley; Prathipati, Pavan Kumar; Destache, Christopher; Shibata, Annemarie	Cellulose Acetate Phthalate and Antiretroviral Nanoparticle Fabrications for HIV Pre-Exposure Prophylaxis.	Polymers	-	-	-	-	2073-4360	10.3390/polym9090423	https://pubmed.ncbi.nlm.nih.gov/30450244/	To adequately reduce new HIV infections, development of highly effective pre-exposure prophylaxis (PrEP) against HIV infection in women is necessary. Cellulose acetate phthalate (CAP) is a pH sensitive polymer with HIV-1 entry inhibitory properties. Dolutegravir (DTG) is an integrase strand transfer inhibitor with potent antiretroviral activity. DTG delivered in combination with CAP may significantly improve current PrEP against HIV. In the present study the development of DTG-loaded CAP nanoparticles incorporated in thermosensitive (TMS) gel at vaginal pH 4.2 and seminal fluid pH 7.4 is presented as proof-of-concept for improved PrEP. Water-oil-in-water homogenization was used to fabricate DTG-loaded CAP nanoparticles (DTG-CAP-NPs). Size, polydispersity, and morphological analyses illustrate that DTG-CAP-NPs were smooth and spherical, ≤200 nm in size, and monodispersed with a polydispersity index PDI ≤ 0.2. The drug encapsulation (EE%) and release profile of DTG-CAP-NPs was determined by HPLC analysis. The EE% of DTG in DTG-CAP-NPs was evaluated to be ~70%. The thermal sensitivity of the TMS gel was optimized and the pH dependency was evaluated by rheological analysis. DTG release studies in TMS gel revealed that DTG-CAP-NPs were stable in TMS gel at pH 4.2 while DTG-CAP-NPs in TMS gel at pH 7.4 rapidly release DTG (≥80% release within 1 h). Cytotoxicity studies using vaginal cell lines revealed that DTG-CAP-NPs were relatively non-cytotoxic at concentration <1 μg/mL. Confocal microscopic studies illustrate that ≥98% cells retained DTG-CAP-NPs intracellularly over seven days. Antiretroviral drug loaded nanocellulose fabrications in TMS gel delivered intravaginally may enhance both microbicidal and antiretroviral drug efficacy and may present a novel option for female PrEP against HIV. Article	2017	Mao X.; Yu H.; Hu Q.; Zhang J.; Chu Z.; Wang Y.; Geng W.; Jiang Y.; Xu J.	Acceptability of pre-exposure HIV prophylaxis clinical trial among MSM in Shenyang city	Chinese Journal of Endemiology	-	-	-	-	10004955	10.3760/cma.j.issn.0254-6450.2017.08.017	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050793951&doi=10.3760%2fcma.j.issn.0254-6450.2017.08.017&partnerID=40&md5=0dd7392f1dc374c9966bb30a8ab61081	Objective: To investigate the acceptability and related factors of an "on-demand" pre-exposure prophylaxis (PrEP) to prevent HIV transmission among MSM in Shenyang. Methods: MSM recruited by non-probability sampling method and questionnaire survey conducted by investigators to collect information on social and behavioral characteristics, awareness of PrEP, Truvada and the acceptability of two different PrEP-based trials. Multivariate logistic regression was employed for statistical analysis. Results: Among the 292 respondents, 34.2% had heard of PrEP and 58.2% (170/292) reported were interested in participating a PrEP trial-"on-demand" use or 48.3% (141/292) interested on "daily" use (χ^2 = 5.785, P=0.02). Factors independently associated with those "on-demand" would include: having more than 2 male sexual partners during the past 6 month (aOR = 1.7, 95%C7: 1.1-2.7), concerning on the positive effect of PrEP (vs. side effects) (aOR = 6A, 95%CI: 2.2-18.9), having an HIV-infected sexual partners (aOR=5.1, 95% CI: 1.0-63.3) and self-reported high risk for HIV (aOR = 2.6, 95% CI: 1.2-6.0). The last two factors were only associated with the "on-demand" group. Conclusions: "On-demand" PrEP (as opposed to daily) seemed a more feasible prevention strategy on HIV and particularly in those having high risk behavior of HIV. For those who could not follow the daily medication or having HIV risk perception, "On-demand" basis PrEP trial should be recommended for them to follow. © 2017 Chinese Medical Association. Article	2017	Markowitz, Martin; Frank, Ian; Grant, Robert M; Mayer, Kenneth H; Elion, Richard; Goldstein, Deborah; Fisher, Chester; Sobieszczyk, Magdalena E; Gallant, Joel E; Van Tieu, Hong; Weinberg, Winkler; Margolis, David A; Hudson, Krischan J; Stancil, Britt S; Ford, Susan L; Patel, Parul; Gould, Elizabeth; Rinehart, Alex R; Smith, Kimberly Y; Spreen, William R	Safety and tolerability of long-acting cabotegravir injections in HIV-uninfected men (ECLAIR): a multicentre, double-blind, randomised, placebo-controlled, phase 2a trial.	The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(17)30068-1	https://dx.doi.org/10.1016/S2352-3018(17)30068-1	BACKGROUND: Cabotegravir (GSK1265744) is an HIV-1 integrase strand transfer inhibitor with potent antiviral activity and a long half-life when administered by injection that prevented simian-HIV infection upon repeat intrarectal challenge in male macaques. We aimed to assess the safety, tolerability, and pharmacokinetics of long-acting cabotegravir injections in healthy men not at high risk of HIV-1 infection. METHODS: We did this multicentre, double-blind, randomised, placebo-controlled, phase 2a trial at ten sites in the USA. Healthy men (aged 18-65 years) deemed not at high risk of acquiring HIV-1 at screening were randomly assigned (5:1), via computer-generated central randomisation schedules, to receive cabotegravir or placebo. Participants received oral cabotegravir 30 mg tablets or matching placebo once daily during a 4 week oral lead-in phase, followed by a 1 week washout period and, after safety assessment, three intramuscular injections of long-acting cabotegravir 800 mg or saline placebo at 12 week intervals. Study site staff and participants were masked to treatment assignment from enrolment through week 41 (time of the last injection). The primary endpoint was safety and tolerability from the first injection (week 5) to 12 weeks after the last injection. We did analysis in the safety population, defined as all individuals enrolled in the study who received at least one dose of the study drug. This study is registered with ClinicalTrials.gov identifier, NCT02076178. FINDINGS: Between March 27, 2014, and Feb 23, 2016, we randomly assigned 127 participants to receive cabotegravir (n=106) or placebo (n=21); 126 (99%) participants comprised the safety population. Most participants were men who have sex with men (MSM; n=106 83%) and white (n=71 56%). 87 (82%) participants in the cabotegravir group and 20 (95%) participants in the placebo group completed the injection phase. Adverse events (n=7 7%) and injection intolerability (n=4 4%) were the main reasons for withdrawal in the cabotegravir group. The frequency of grade 2 or higher adverse events was higher in participants in the long-acting cabotegravir group (n=75 80%) than in those in the placebo group (n=10 48%; p=0·0049), mostly due to injection-site pain (n=55 59%). No significant differences were noted in concomitant medications, laboratory abnormalities, electrocardiogram, and vital sign assessments. Geometric mean trough plasma concentrations were 0·302 μg/mL (95% CI 0·237-0·385), 0·331 μg/mL (0·253-0·435), and 0·387 μg/mL (0·296-0·505) for injections one, two, and three, respectively, indicating lower than predicted exposure. The geometric mean apparent terminal phase half-life estimated after the third injection was 40 days. Two (2%) MSM acquired HIV-1 infection, one in the placebo group during the injection phase and one in the cabotegravir group 24 weeks after the final injection when cabotegravir exposure was well below the protein-binding-adjusted 90% inhibitory concentration. INTERPRETATION: Despite high incidence of transient, mild-to-moderate injection-site reactions, long-acting cabotegravir was well tolerated with an acceptable safety profile. Pharmacokinetic data suggest that 800 mg administered every 12 weeks is a suboptimal regimen; alternative dosing strategies are being investigated. Our findings support further investigation of long-acting injectable cabotegravir as an alternative to orally administered pre-exposure prophylaxis regimens. FUNDING: ViiV Healthcare. Article	2017	Marks, Sarah J; Merchant, Roland C; Clark, Melissa A; Liu, Tao; Rosenberger, Joshua G; Bauermeister, Jose; Mayer, Kenneth H	Potential Healthcare Insurance and Provider Barriers to Pre-Exposure Prophylaxis Utilization Among Young Men Who Have Sex with Men.	AIDS Patient Care and STDs	-	-	-	-	1557-7449	10.1089/apc.2017.0171	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5665093	Young adult men-who-have-sex-with-men (YMSM) continue to have among the highest incidence of HIV infection in the United States. Pre-exposure prophylaxis (PrEP) is an effective and safe method of preventing HIV infection; however, despite US Food and Drug Administration approval, utilization remains low, in part, due to structural barriers, particularly access to healthcare. In this study, we used social media to recruit black, Hispanic, and white HIV-uninfected 18- to 24-year-old YMSM. Participants completed an online survey about their sexual behaviors, healthcare access, and previous use of PrEP. Of the 2297 YMSM surveyed, only 3.4% had used PrEP. PrEP use was associated with higher levels of education, living alone, older age, higher levels of sexual activity, and greater healthcare access, specifically having healthcare insurance and a clinic or primary care provider (PCP) from whom they received care. Among PrEP nonusers, 65% met at least one of the US Centers for Disease Control and Prevention recommended indications for PrEP use, and of these, 59% had healthcare insurance and received care in a clinic and/or had a PCP. Multi-variable multi-nomial logistic regression modeling identified disparities in access to healthcare by age, race/ethnicity, education, and region. Specifically, older YMSM, blacks and Hispanics, those with fewer years of formal education, and residents of the southern and the western United States were more likely to lack healthcare access. These results demonstrate both potential opportunities and barriers to the scale-up of PrEP among YMSM. Theses and Dissertations	2017	Marmelo, André Filipe de Palma	PrEP (profilaxia pré-exposição) no HIV: perspetivas atuais e futuras	-	-	RCAAP	-	NA	NA	http://hdl.handle.net/10400.1/10410	O vírus do HIV continua, após 30 anos desde o primeiro caso, a ser motivo de preocupação para a saúde pública mundial. Estima-se que, desde o começo da propagação da doença, tenham sido infetadas com o vírus cerca de 70 milhões de pessoas em todo o mundo, resultando na morte de 35 milhões de pessoas (OMS); em Portugal, só no ano de 2014, foram infetadas com o vírus cerca de 1476 pessoas, declarando-se 457 óbitos (DGS). Muito se fez entretanto, por governos e organizações não-governamentais, para travar o vírus. O método de prevenção mais difundido em todo o mundo – o preservativo – garante uma redução da probabilidade de seroconversão que varia entre os 90% e os 95% (Handbook of Nonprescription Drugs). No entanto isso tem-se provado insuficiente para travar a epidemia. O uso do preservativo, embora seguro, não é completamente fiável, e nem sempre utilizado durante o contato sexual, quer seja por razões religiosas, culturais, sociais, ou por simples descuido humano no momento da relação. Foram portanto necessárias novas medidas de combate à transmissão do vírus do HIV. Em Julho de 2012, a FDA, autoridade responsável pelo medicamento nos Estados Unidos da América, aprovou, pela primeira vez, a utilização de um fármaco antiviral na diminuição do risco de transmissão do HIV. Este fármaco (Truvadaâ – emtricitabina e tenofovir disoproxil) seria utilizado por pessoas não-seropositivas antes do contacto com o vírus, de forma a diminuir o risco de transmissão do mesmo. A esta medida designou-se o nome de Pre-Exposure Prophylaxis (PrEP). (FDA) Esta nova abordagem pode ser o passo determinante na erradicação de um vírus que tende a persistir, causando consequências catastróficas, não só a nível de óbitos e doentes infetados, como de recursos económicos e humanos empregues numa doença altamente perigosa e que foi perdendo, gradualmente, espaço de debate na sociedade contemporânea. Article	2017	Marrazzo, Jeanne M	HIV Prevention: Opportunities and Challenges.	Topics in Antiviral Medicine	-	-	-	2161-5853	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5677047	Preexposure prophylaxis (PrEP) with tenofovir disoproxil fumarate (TDF)-based regimens has been shown to be effective in preventing acquisition of HIV infection, with protective efficacy being dependent on adherence to treatment. Data from the PROUD (Preexposure Option for Reducing HIV in the UK) and IPERGAY (Action to Prevent Risk Exposure By and For Gay Men) studies, the later of which employed event-driven PrEP, showed a high rate of protective efficacy of PrEP with TDF and emtricitabine among men who have sex with men. Data from the ASPIRE (A Study to Prevent Infection With a Ring for Extended Use) study of a dapivirine vaginal ring showed a moderate rate of protective efficacy among women older than 21 years. Ongoing investigations are examining long-acting PrEP modalities and combination PrEP and contraception products. This article summarizes a presentation by Jeanne M. Marrazzo, MD, MPH, at the IAS-USA continuing education program, Improving the Management of HIV Disease, held in Washington, DC, in April 2016. Article	2017	Martin, Jonathan; Burke, Kerianne; Boettcher, Jessica; Bhalerao, Neil; Huhn, Gregory	Reluctance to Prescribe Pre-Exposure Prophylaxis (PrEP) Among Internal Medicine Residents (IMRs) Training at a U.S. Hospital with a Large HIV-infected Population	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1093/ofid/ofx163.1143	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5630762/	Abstract Background PrEP is effective in HIV prevention, though access to PrEP in the US has been concentrated in HIV/STI healthcare settings. We examined IMRs' willingness to prescribe PrEP in an urban hospital in Chicago associated with a large HIV outpatient center. Methods IMRs were anonymously surveyed regarding their knowledge and likelihood of prescribing PrEP stratified by patient risk behaviors and their own attitudes and perceptions. Bivariate analysis was performed, and p-values with α <0.05 for significance were calculated for comparisons by IMRs who had rotated on a dedicated HIV inpatient service, by level of training (PGY-1 vs. >PGY-2), and between planning on specializing in primary care (PC), infectious disease (ID) vs. other specialties. Results Most 86/120 (71%) of IMRs completed the survey and 30/86 (35%) had completed an inpatient HIV service rotation. The majority (88.4%) believed it is "very important" to universally screen patients for HIV, and most (72.1%) said they were "comfortable" or "very comfortable" taking a sexual history. Very few (2.3%) had ever prescribed PrEP, though only 3.5% reported requests for PrEP in their practice, and 44.2% would be "unlikely" or "somewhat unlikely" to prescribe PrEP to patients if requested. IMRs with HIV service experience correctly identified the number of pills in PrEP compared with IMRs with no experience (47.0% vs 18.9%, P = 0.01). IMRs planning on other specialties were more likely to rank knowledge of PrEP as "not familiar" when compared with IMRs entering PC and ID, (21.0% vs. 0%, P = 0.02). The most common barriers to prescribing PrEP were lack of familiarity, lack of program guidance, cost, and unclear risk to benefit ratios (75.6%, 41.9%, 29.1%, 26.7%, respectively). Conclusion While recognizing that HIV testing is important, IMRs surveyed displayed a lack of knowledge of PrEP, most likely due to limited exposure in their medical education/training. Rotations on an HIV service appeared to increase PrEP knowledge as did planned entry into PC or ID. In order to increase PrEP knowledge and usage, enhanced PrEP education, and importantly exposure to high-risk patients should be incorporated into the curriculum of evidence-based prevention interventions during IMR training. Article	2017	Martin, Michael; Vanichseni, Suphak; Suntharasamai, Pravan; Sangkum, Udomsak; Mock, Philip A; Chaipung, Benjamaporn; Worrajittanon, Dararat; Leethochawalit, Manoj; Chiamwongpaet, Sithisat; Kittimunkong, Somyot; Gvetadze, Roman J; McNicholl, Janet M; Paxton, Lynn A; Curlin, Marcel E; Holtz, Timothy H; Samandari, Taraz; Choopanya, Kachit	Factors associated with the uptake of and adherence to HIV pre-exposure prophylaxis in people who have injected drugs: an observational, open-label extension of the Bangkok Tenofovir Study.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(16)30207-7	https://dx.doi.org/10.1016/S2352-3018(16)30207-7	BACKGROUND: Results of the randomised, double-blind, placebo-controlled Bangkok Tenofovir Study (BTS) showed that taking tenofovir daily as pre-exposure prophylaxis (PrEP) can reduce the risk of HIV infection by 49% in people who inject drugs. In an extension to the trial, participants were offered 1 year of open-label tenofovir. We aimed to examine the demographic characteristics, drug use, and risk behaviours associated with participants' uptake of and adherence to PrEP. METHODS: In this observational, open-label extension of the BTS (NCT00119106), non-pregnant, non-breastfeeding, HIV-negative BTS participants, all of whom were current or previous injecting drug users at the time of enrolment in the BTS, were offered daily oral tenofovir (300 mg) for 1 year at 17 Bangkok Metropolitan Administration drug-treatment clinics. Participant demographics, drug use, and risk behaviours were assessed at baseline and every 3 months using an audio computer-assisted self-interview. HIV testing was done monthly and serum creatinine was assessed every 3 months. We used logistic regression to examine factors associated with the decision to take daily tenofovir as PrEP, the decision to return for at least one PrEP follow-up visit, and greater than 90% adherence to PrEP. FINDINGS: Between Aug 1, 2013, and Aug 31, 2014, 1348 (58%) of the 2306 surviving BTS participants returned to the clinics, 33 of whom were excluded because they had HIV (n=27) or grade 2-4 creatinine results (n=6). 798 (61%) of the 1315 eligible participants chose to start open-label PrEP and were followed up for a median of 335 days (IQR 0-364). 339 (42%) participants completed 12 months of follow-up; 220 (28%) did not return for any follow-up visits. Participants who were 30 years or older (odds ratio OR 1·8, 95% CI 1·4-2·2; p<0·0001), injected heroin (OR 1·5, 1·1-2·1; p=0·007), or had been in prison (OR 1·7, 1·3-2·1; p<0·0001) during the randomised trial were more likely to choose PrEP than were those without these characteristics. Participants who reported injecting heroin or being in prison during the 3 months before enrolment were more likely to return for at least one open-label follow-up visit than those who did not report injecting heroin (OR 3·0, 95 % CI 1·3-7·3; p=0·01) or being in prison (OR 2·3, 1·4-3·7; p=0·0007). Participants who injected midazolam or were in prison during open-label follow-up were more likely to be greater than 90% adherent than were those who did not inject midazolam (OR 2·2, 95% CI 1·2-4·3; p=0·02) or were not in prison (OR 4·7, 3·1-7·2; p<0·0001). One participant tested positive for HIV, yielding an HIV incidence of 2·1 (95% CI 0·05-11·7) per 1000 person-years. No serious adverse events related to tenofovir use were reported. INTERPRETATION: More than 60% of returning, eligible BTS participants started PrEP, which indicates that a substantial proportion of PWID who are knowledgeable about PrEP might be interested in taking it. Participants who had injected heroin or been in prison were more likely to choose to take PrEP, suggesting that participants based their decision to take PrEP, at least in part, on their perceived risk of incident HIV infection. Article	2017	Matthews L.T.; Burns B.F.; Bajunirwe F.; Kabakyenga J.; Bwana M.; Ng C.; Kastner J.; Kembabazi A.; Sanyu N.; Kusasira A.; Haberer J.E.; Bangsberg D.R.; Kaida A.	Beyond HIV-serodiscordance: Partnership communication dynamics that affect engagement in safer conception care	PLOS One	-	-	-	19326203	10.1371/journal.pone.0183131	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85028970928&doi=10.1371%2fjournal.pone.0183131&partnerID=40&md5=b3308028b22a7dc1cd33ebfa87268686	Introduction: We explored acceptability and feasibility of safer conception methods among HIV-affected couples in Uganda. Methods: We recruited HIV-positive men and women on antiretroviral therapy (ART) ('index') from the Uganda Antiretroviral Rural Treatment Outcomes cohort who reported an HIV-negative or unknown-serostatus partner ('partner'), HIV-serostatus disclosure to partner, and personal or partner desire for a child within two years. We conducted in-depth interviews with 40 individuals from 20 couples, using a narrative approach with tailored images to assess acceptability of five safer conception strategies: ART for the infected partner, pre-exposure prophylaxis (PrEP) for the uninfected partner, condomless sex timed to peak fertility, manual insemination, and male circumcision. Translated and transcribed data were analyzed using thematic analysis. Results: 11/20 index participants were women, median age of 32.5 years, median of 2 living children, and 80% had HIV-RNA <400 copies/mL. Awareness of HIV prevention strategies beyond condoms and abstinence was limited and precluded opportunity to explore or validly assess acceptability or feasibility of safer conception methods. Four key partnership communication challenges emerged as primary barriers to engagement in safer conception care, including: (1) HIV-serostatus disclosure: Although disclosure was an inclusion criterion, partners commonly reported not knowing the index partner's HIV status. Similarly, the partner's HIV-serostatus, as reported by the index, was frequently inaccurate. (2) Childbearing intention: Many couples had divergent childbearing intentions and made incorrect assumptions about their partner's desires. (3) HIV risk perception: Participants had disparate understandings of HIV transmission and disagreed on the acceptable level of HIV risk to meet reproductive goals. (4) Partnership commitment: Participants revealed significant discord in perceptions of partnership commitment. All four types of partnership miscommunication introduced constraints to autonomous reproductive decision-making, particularly for women. Such miscommunication was common, as only 2 of 20 partnerships in our sample were mutually-disclosed with agreement across all four communication themes. Conclusions: Enthusiasm for safer conception programming is growing. Our findings highlight the importance of addressing gendered partnership communication regarding HIV disclosure, reproductive goals, acceptable HIV risk, and commitment, alongside technical safer conception advice. Failing to consider partnership dynamics across these domains risks limiting reach, uptake, adherence to, and retention in safer conception programming. © 2017 Matthews et al. Article	2017	Maude, Rapeephan; Volpe, Gretchen; Stone, David	Knowledge, Attitude and Practice of Pre-exposure prophylaxis (PrEP) against HIV infection of medical providers at an academic center	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1093/ofid/ofx163.1106	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5631590/	Abstract Background Pre-exposure prophylaxis (PrEP) against HIV infection is available for people at risk of acquiring HIV infection and who are not positive for HIV infection. It is proven to be effective at preventing HIV infection in many studies in various populations. However, due to lack of knowledge or due to attitudes towards PrEP, this mode of prevention may be underutilized by people at risk and their providers. Our aim is to assess the baseline knowledge of, attitudes towards and practice of medical providers at Tufts Medical Center. Methods survey of 80 medical providers at Tufts Medical Center with a short questionnaire. Results The median age of the participants were 31 years old (IQR 28–34.5, range 22–71). 38.75% were male. Ethnicity were White (60%), Asian (20%), and others (20%). Fifty-five percent were Doctor of Medicine or Doctor of Osteopathic (MD/DO), 20% Physician assistant (PA), 8.75% Registered nurse (RN) and 7.5% were medical students. Other groups included Nurse practicioner (NP), medical assistant, research coordinator and PA student. Knowledge. Approximately two-third (67.5%) of study participants heard of PREP. In MD/DO group, 81.81% (36/44) heard about PREp. 46.26% responded correctly that PREP should be given daily. 68.75% answered correctly that Tenofovir disoproxil fumarate plus emtricitabine (TDF/FTC; Truvada) is the standard regimen. Attitude. 31.81% of the MD/DO group were not comfortable prescribing PREP. Top three barriers perceived for prescribing PREP were "Not enough knowledge" 72.5%; "Lack of experience" 56.25% and "Not covered by insurance" 17.5%. Practice. Of 61 participants who are eligible to prescribe medications (MD/DO, PA, NP), 15.27% prescribed PREP prior to the survey. Over 75% would refer patients to infectious diseases or other providers to prescribe PREP. Conclusion There are some knowledge and practice gap of PREP. Most are not comfortable prescribing PREP thus will refer patients to infectious diseases. It is essential to promote knowledge and attitude about PREP in medical providers who have an important role in advising at-risk patients about PrEP which will lead to a better practice. Article	2017	Mayer, Kenneth H; Maloney, Kevin M; Levine, Kenneth; King, Dana; Grasso, Chris; Krakower, Douglas S; Rosenberg, Eli S; Boswell, Stephen L	Sociodemographic and Clinical Factors Associated With Increasing Bacterial Sexually Transmitted Infection Diagnoses in Men Who Have Sex With Men Accessing Care at a Boston Community Health Center (2005-2015).	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1093/ofid/ofx214	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5695616	BACKGROUND: The reasons why bacterial sexually transmitted infections (BSTIs) are increasing in US men who have sex with men (MSM) have not been fully characterized. METHODS: An open cohort of MSM accessing medical care at a Boston community health center was used to assess secular trends in BSTI diagnoses. Frequency of infection and the estimated population size were used to calculate diagnosis rates. Poisson models were fit for multivariable analyses. RESULTS: Between 2005 and 2015, 19 232 men had at least 1 clinic visit. Most (72.4%) were white; 6.0% were black, and 6.1% were Latino. Almost half had documented self-report of identifying as gay (42.6%) or bisexual (3.2%). Most had private health insurance (61.7%); 5.4% had Medicare, 4.6% had Medicaid, and 8.4% reported no insurance. Between 2005 and 2015, BSTI diagnoses increased more than 8-fold. In 2015, of 1319 men who were diagnosed with at least 1 BSTI; 291 were diagnosed with syphilis, 554 with gonorrhea (51.4% rectal, 31.0% urogenital), and 679 with chlamydia (69.1% rectal, 34.3% urogenital). In 2015, 22.7% of BSTIs were diagnosed among HIV-infected patients (15.4% of the clinic population), and 32.8% of BSTIs were diagnosed among HIV-uninfected patients using pre-exposure prophylaxis (PrEP; 10.1% of all men in care). In multivariable analyses, age 18 to 24 years, being HIV-infected, using PrEP, being nonwhite, or reporting Medicaid or not reporting having private insurance or Medicare were independently associated with being diagnosed with a new BSTI. CONCLUSIONS: Over the past decade, BSTI diagnosis rates increased in HIV-infected and uninfected MSM, with disproportionate increases in PrEP users, racial and ethnic minority MSM, those aged 25 to 34 years, and those without stable health insurance, warranting focused education, screening, and accessible services for these key subpopulations.	chlamydia, HIV, gonorrhea, Men who have sex with men, syphilis	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Mayer, Kenneth H; Safren, Steven A; Elsesser, Steven A; Psaros, Christina; Tinsley, Jake P; Marzinke, Mark; Clarke, William; Hendrix, Craig; Wade Taylor, S; Haberer, Jessica; Mimiaga, Matthew J	Optimizing Pre-Exposure Antiretroviral Prophylaxis Adherence in Men Who Have Sex with Men: Results of a Pilot Randomized Controlled Trial of "Life-Steps for PrEP".	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-016-1606-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5380582	Antiretroviral pre-exposure prophylaxis (PrEP) has been demonstrated to decrease HIV acquisition in multiple efficacy trials, but medication adherence is critical, and was suboptimal in several studies. Fifty HIV-uninfected at risk men who have sex with men (MSM) were randomized to a cognitive behavioral intervention condition or a time and session-matched comparison counseling intervention. The experimental intervention entailed four nurse-delivered initial and two booster sessions based on Life-Steps, an ART treatment adherence intervention. The comparison condition provided information and supportive counseling. The primary analyses compared adherence (Wisepill and tenofovir plasma levels) at 3 and 6 months. Fifty-eight MSM were screened to enroll 50 participants. Median age was 38.2 years old, 86% were white; 64% had completed college. Wisepill adherence was high in both groups, and not statistically different. Plasma tenofovir levels were significantly higher in the intervention group at 6 months using mean substitution analysis (i.e., computing missing variables) (p = 0.037), however, in the completer analyses (i.e., using only those completing all study visits), there were no statistically significant differences between randomization conditions. Medication adherence was high across a cognitive-behavioral (Life-Steps) and time-matched counseling intervention for PrEP adherence, with some evidence suggesting superiority of Life-Steps in this pilot RCT. Further evaluation in a fully powered efficacy trial is warranted to assess the robustness of this intervention.	HIV; MSM; Medication adherence; Pre-exposure antiretroviral prophylaxis. Article	2017	McKenney J.; Chen A.; Hoover K.W.; Kelly J.; Dowdy D.; Sharifi P.; Sullivan P.S.; Rosenberg E.S.	Optimal costs of HIV pre-exposure prophylaxis for men who have sex with men	PLOS One	-	-	-	19326203	10.1371/journal.pone.0178170	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85019994878&doi=10.1371%2fjournal.pone.0178170&partnerID=40&md5=722c2019b93a7f881816c70d7c1437b1	Introduction: Men who have sex with men (MSM) are disproportionately affected by HIV due to their increased risk of infection. Oral pre-exposure prophylaxis (PrEP) is a highly effective HIV-prevention strategy for MSM. Despite evidence of its effectiveness, PrEP uptake in the United States has been slow, in part due to its cost. As jurisdictions and health organizations begin to think about PrEP scale-up, the high cost to society needs to be understood. Methods: We modified a previously-described decision-analysis model to estimate the cost per quality-adjusted life-year (QALY) gained, over a 1-year duration of PrEP intervention and lifetime time horizon. Using updated parameter estimates, we calculated: 1) the cost per QALY gained, stratified over 4 strata of PrEP cost (a function of both drug cost and provider costs); and 2) PrEP drug cost per year required to fall at or under 4 cost per QALY gained thresholds. Results: When PrEP drug costs were reduced by 60% (with no sexual disinhibition) to 80% (assuming 25% sexual disinhibition), PrEP was cost-effective (at <$100,000 per QALY averted) in all scenarios of base-case or better adherence, as long as the background HIV prevalence was greater than 10%. For PrEP to be cost saving at base-case adherence/efficacy levels and at a background prevalence of 20%, drug cost would need to be reduced to $8,021 per year with no disinhibition, and to $2,548 with disinhibition. Conclusion: Results from our analysis suggest that PrEP drug costs need to be reduced in order to be cost-effective across a range of background HIV prevalence. Moreover, our results provide guidance on the pricing of generic emtricitabine/tenofovir disoproxil fumarate, in order to provide those at high risk for HIV an affordable prevention option without financial burden on individuals or jurisdictions scaling-up coverage. Article	2017	Meng, Jianing; Agrahari, Vivek; Ezoulin, Miezan J.; Purohit, Sudhaunshu S.; Zhang, Tao; Molteni, Agostino; Dim, Daniel; Oyler, Nathan A.; Youan, Bi-Botti C.	Spray-Dried Thiolated Chitosan-Coated Sodium Alginate Multilayer Microparticles for Vaginal HIV Microbicide Delivery.	The AAPS Journal	-	-	-	1550-7416	10.1208/s12248-016-0007-y	https://pubmed.ncbi.nlm.nih.gov/28138910/	It is hypothesized that novel thiolated chitosan-coated multilayer microparticles (MPs) with enhanced drug loading are more mucoadhesive than uncoated MPs and safe in vivo for vaginal delivery of topical anti-HIV microbicide. Formulation optimization is achieved through a custom experimental design and the alginate (AG) MPs cores are prepared using the spray drying method. The optimal MPs are then coated with the thiolated chitosan (TCS) using a layer-by-layer method. The morphological analysis, in situ drug payload, in vitro drug release profile, and mucoadhesion potential of the MPs are carried out using scanning electron microscopy, solid-state (31)P NMR spectroscopy, UV spectroscopy, fluorescence imaging and periodic acid Schiff method, respectively. The cytotoxicity and preclinical safety of MPs are assessed on human vaginal (VK2/E6E7) and endocervical (End1/E6E7) epithelial cell lines and in female C57BL/6 mice, respectively. The results show that the MPs are successfully formulated with an average diameter ranging from 2 to 3 μm with a drug loading of 7-12% w/w. The drug release profile of these MPs primarily follows the Baker-Lonsdale and Korsmeyer-Peppas models. The MPs exhibit high mucoadhesion (20-50 folds) compared to native AGMPs. The multilayer MPs are noncytotoxic. Histological and immunochemical analysis of the mice genital tract shows neither signs of damage nor inflammatory cell infiltrate. These data highlight the potential use of TCS-coated AG-based multilayer MPs templates for the topical vaginal delivery of anti-HIV/AIDS microbicides. Article	2017	Méthy, Nicolas; Meyer, Laurence; Bajos, Nathalie; Velter, Annie	Generational analysis of trends in unprotected sex in France among men who have sex with men: The major role of context-driven evolving patterns.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0171493	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5295686	OBJECTIVE: Using a generational approach, this study analyses how unprotected anal intercourse has evolved since 1991 in France across different generations of men who have sex with men (MSM) whose sexual lives began at different periods in the history of the HIV epidemic. DESIGN: Data were collected from 18-59 year-old respondents to the French Gay Press surveys Enquêtes Presse Gay, conducted repeatedly between 1991 and 2011 (N = 32,196) using self-administered questionnaires distributed in gay magazines and over the internet. METHODS: Trends in unprotected anal intercourse (i.e. condomless anal sex) with casual partners of unknown or different HIV serostatus (hereafter "UAId" in this manuscript) were studied. Responses were analysed according to year and then reorganised for age-cohort analyses by generation, based on the year respondents turned 18. RESULTS: UAId rates fell from 1991 to 1997, and then rose from 13.4% in 1997 to 25.5% in 2011 among seronegative respondents, and from 24.8% to 63.3%, respectively, among seropositive respondents. Both in seropositive and seronegative respondents, UAId increased over time for all generations, indicative of a strong period effect. CONCLUSION: Analyses of data from several generations of MSM who started their sexual lives at different time points in the HIV epidemic, revealed very similar trends in UAId between generations, among both seropositive and seronegative respondents. This strong period effect suggests that sexual behaviours in MSM are influenced more by contextual than generational factors. The fact that prevention practices are simultaneously observed in different generations and that there are most likely underlying prevention norms among MSM, suggests that PrEP could become widely accepted by all generations of MSM exposed to the risk of HIV. Article	2017	Metz, Verena E; Sullivan, Maria A; Jones, Jermaine D; Evans, Elizabeth; Luba, Rachel; Vogelman, Jonathan; Comer, Sandra D	Racial Differences in HIV and HCV Risk Behaviors, Transmission, and Prevention Knowledge among Non-Treatment-Seeking Individuals with Opioid Use Disorder.	Journal of Psychoactive Drugs	-	-	-	2159-9777	10.1080/02791072.2016.1259518	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5950713	In light of New York's recently reinforced strategy to end the AIDS epidemic by expanding testing, treatment, and access to pre-exposure prophylaxis (PrEP), we assessed drug use and sexual risk behaviors, along with HIV/Hepatitis C virus (HCV) transmission and prevention knowledge among non-treatment-seeking adults with opioid use disorder (OUD) in New York City. Over the course of 18 months, volunteers screening for research studies in the Opioid Laboratory at the New York State Psychiatric Institute completed a locally developed self-assessment questionnaire. A total of 138 adults with OUD (24 female, 114 male) with a mean age of 46.5 years (SD = 9.5 yrs) were assessed. Significant differences among the four racial/ethnic subgroups (n = 65 African-Americans, n = 34 Hispanics, n = 31 Caucasians or Whites, n = 8 Multiracial) were found. Whites were the youngest (p = 0.001), most frequently injecting drugs (p < 0.001), and engaged more often in risky drug use and sexual behaviors, although their virus transmission knowledge was comparable to that of the other subgroups. Few participants had heard about PrEP. White opioid users showed the most risk behaviors among races/ethnicities, despite comparable prevention knowledge. Better HIV/HCV prevention interventions targeting individuals with opioid use disorders who are not currently in treatment would be desirable, given their large health burden.	opioid users; risk behaviors; HIV; Hepatitis C; prevention; ethnicities	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Milinkovic, Ana; Benn, Paul; Arenas-Pinto, Alejandro; Brima, Nataliya; Copas, Andrew; Clarke, Amanda; Fisher, Martin; Schembri, Gabriel; Hawkins, David; Williams, Andy; Gilson, Richard	Randomized controlled trial of the tolerability and completion of maraviroc compared with Kaletra® in combination with Truvada® for HIV post-exposure prophylaxis (MiPEP Trial).	Journal of Antimicrobial Chemotherapy	-	-	-	1460-2091	10.1093/jac/dkx062	https://dx.doi.org/10.1093/jac/dkx062	Objectives: Post-exposure prophylaxis (PEP) for HIV is often poorly tolerated and not completed. Alternative PEP regimens may improve adherence and completion, aiding HIV prevention. We conducted a randomized controlled trial of a maraviroc-based PEP regimen compared with a standard-of-care regimen using ritonavir-boosted lopinavir. Methods: Patients meeting criteria for PEP were randomized to tenofovir disoproxil/emtricitabine (200/245 mg) once daily plus ritonavir-boosted lopinavir (Kaletra ® 400/100 mg) or maraviroc 300 mg twice daily. The composite primary endpoint was completion of 28 days of the allocated PEP regimen without grade 3 or 4 clinical or laboratory adverse events (AEs) related to the PEP medication. Results: Two hundred and thirteen individuals were randomized (107 to maraviroc; 106 to Kaletra ® arm). Follow-up rates were high in both groups. There was no difference in the primary endpoint; 70 (71%) in the maraviroc and 64 (65%) in the Kaletra ® arm (P = 0.36) completed PEP without grade 3 or 4 AEs. Discontinuation of PEP was the same (18%) in both groups. There were no grade 3 or 4 clinical AEs in either arm, but more grade 1 or 2 clinical AEs in the Kaletra ® arm (91% versus 70%; P < 0.001). Antidiarrhoeal medication use was higher in the Kaletra ® arm (67% versus 25%; P < 0.001). There were no HIV seroconversions in the study period. Conclusions: The completion rate in the absence of grade 3 or 4 AEs was similar with both regimens. Maraviroc-based PEP was better tolerated, supporting its use as an option for non-occupational PEP. Article	2017	Millar, Brett M; Starks, Tyrel J; Grov, Christian; Parsons, Jeffrey T	Sexual Risk-Taking in HIV-Negative Gay and Bisexual Men Increases with Depression: Results from a U.S. National Study.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-016-1507-6	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5323369	The link between depression and sexual risk-taking has received mixed findings in the literature. The current study analyzed the links between depression and recent condomless anal sex (CAS) with casual partners among 1033 HIV-negative, non-PrEP-using, gay and bisexual men. When CAS was dichotomized as either none or some, depression was not associated with the odds of CAS (with receptive and insertive combined) or insertive CAS only, but was positively associated with the odds of receptive CAS. When CAS was tallied as a count variable of events, depression was positively associated with total CAS, receptive CAS, and insertive CAS. With the addition of a quadratic term for depression, a positive quadratic effect was only found for total CAS and receptive CAS, but not for insertive CAS. These findings highlight the utility of using count data for CAS events and treating CAS separately with regard to receptive and insertive positioning when considering the role of depression among gay and bisexual men. Article	2017	Mocumbi, Sibone; Gafos, Mitzy; Munguambe, Khatia; Goodall, Ruth; McCormack, Sheena	High HIV prevalence and incidence among women in Southern Mozambique: Evidence from the MDP microbicide feasibility study.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0173243	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5369694	BACKGROUND: The study aimed to assess the feasibility of conducting large scale HIV prevention clinical trials in Mozambique by measuring HIV prevalence and incidence among women of reproductive age. This paper describes the baseline socio-demographic characteristics of the Mozambique Microbicides Development Programme (MDP) feasibility cohort, baseline prevalence of HIV and other STIs, and HIV incidence. METHODS: The Mozambique MDP feasibility study was conducted from September 2007 to August 2009 in urban Mavalane and rural Manhiça, in Southern Mozambique. Sexually active, HIV negative women aged 18 years and above were recruited to attend the study clinic every 4 weeks for a total of 40 weeks. At baseline, we collected demographic and sexual behaviour data, samples to test for sexually transmitted infections (STI) and conducted HIV rapid testing. STI and HIV testing were repeated at clinical follow-up visits. We describe HIV prevalence of women at screening, the demographic, behavioural and clinical characteristics of women at enrolment, and HIV incidence during follow-up. RESULTS: We screened 793 women (369 at Mavalane and 424 at Manhiça) and enrolled 505 eligible women (254 at Mavalane and 251 at Manhiça). Overall HIV prevalence at screening was 17%; 10% at Mavalane and 22% at Manhiça. Women screened at Manhiça were twice as likely as women screened at Mavalane to be HIV positive and HIV positive status was associated with younger age (18-34), lower educational level, not using a reliable method of contraception and being Zionist compared to other Christian religions. At enrolment contraceptive use was low in both clinics at 19% in Mavalane and 21% in Manhiça, as was reported condom use at last sex act at 48% in Mavalane and 25% in Manhiça. At enrolment, 8% of women tested positive for Trichomonas vaginalis, 2% for Neisseria gonorrhoeae, 4% for Chlamydia trachomatis and 46% for bacterial vaginosis. In Manhiça, 8% of women had active syphilis at screening. HIV incidence was 4.3 per 100 person years at Mavalane and 9.2 per 100 person years at Manhiça. CONCLUSIONS: We demonstrated the ability to recruit a cohort of women at risk of HIV who were willing to participate in clinical research. The high HIV incidence necessitates additional action around HIV prevention for women and offers opportunities to evaluate the impact of available prevention options, such as treatment as prevention and oral PrEP. The high HIV incidence and STI prevalence also offers opportunities to evaluate the added benefit of potential prevention options such as new formulations of oral PrEP, vaginal microbicides (also called topical PrEP), vaccines, and multi-purpose technologies for HIV, STIs and contraception. Article	2017	Mofenson L.M.; Baggaley R.C.; Mameletzis I.	Tenofovir disoproxil fumarate safety for women and their infants during pregnancy and breastfeeding	AIDS	-	-	-	2699370	10.1097/QAD.0000000000001313	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84994726334&doi=10.1097%2fQAD.0000000000001313&partnerID=40&md5=a2db15a5c2349e4fa8bae2fc274ac30e	Objectives: Pregnant/lactating women in some sub-Saharan Africa settings are at substantial risk of HIV acquisition and could benefit from preexposure prophylaxis (PrEP) with tenofovir disoproxil fumarate (TDF), but safety data in pregnancy/lactation are limited. Design: Systematic data review through August 2016. Methods: We reviewed research reports/conference abstracts with maternal/child adverse outcome data in HIV-infected and HIV-uninfected pregnant/lactating women receiving TDF alone or in combination with other drugs compared with non-TDF regimens. Results: In total, 26 articles in HIV-infected and seven in HIV-uninfected women were identified. No statistically significant differences were observed between TDF and comparison non-TDF regimens in pregnancy incidence, stillbirth/pregnancy loss, preterm delivery less than 37 weeks, low birth weight <2500/<1500 g, small for gestational age, birth defects, or infant (>14 days) or maternal mortality. One study reported significantly higher very preterm delivery (<34 weeks) and neonatal mortality with TDF versus non-TDF antiretroviral therapy (ART), but no significant difference between TDF ART and zidovudine/single-dose nevirapine. Most studies report normal infant linear growth; one study showed slightly lower, and one higher 1-year length-forage z-score in TDF ART-exposed infants. No significant differences were reported in abnormal laboratory values or bone markers between TDF and non-TDF-exposed infants in four studies. Lower maternal bone mineral density was observed at 74 weeks postpartum in breastfeeding women on TDF ART compared with no ART in one study. Conclusion: Given available safety data, there does not appear to be a safety-related rationale for prohibiting PrEP during pregnancy/lactation or for discontinuing PrEP in HIV-uninfected women receiving PrEP who become pregnant and are at continuing risk of HIV acquisition. Efficacy, safety, and effect on sexual behaviour of on-demand pre-exposure prophylaxis for HIV in men who have sex with men: an observational cohort study	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(17)30089-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85025430174&doi=10.1016%2fS2352-3018%2817%2930089-9&partnerID=40&md5=bfd53a762e4c3a128d8641fafc7270e1	Background Data for on-demand pre-exposure prophylaxis (PrEP) are scarce. We implemented a cohort study to assess its efficacy, safety, and effect on sexual behaviour. Methods We invited men and transgender women who have sex with men, previously enrolled in the randomised placebo-controlled ANRS IPERGAY trial at seven sites (six in France and one in Canada), to participate in an open-label extension with on-demand tenofovir disoproxil fumarate (300 mg) and emtricitabine (200 mg) to be taken before and after sexual intercourse. We assessed the incidence of HIV and other sexually transmitted infections (STIs), PrEP adherence, safety, and sexual behaviour. Statistical analyses included comparisons of proportions and incidence between the randomised phase of the ANRS IPERGAY trial and the open-label phase, and all participants were included in safety analyses. ANRS IPERGAY is registered with ClinicalTrials.gov, number NCT01473472. Findings Between Nov 4, 2014, and Jan 27, 2015, we enrolled 361 participants. Median follow-up was 18·4 months (IQR 17·7–19·1). One participant who discontinued PrEP acquired HIV infection. HIV incidence was 0·19 per 100 person-years (95% CI 0·01–1·08), compared with 6·60 per 100 person-years (3·60–11·05) in the placebo group of the randomised study, indicating a relative reduction of 97% (95% CI 81–100) in the incidence of HIV with on-demand PrEP. Participants used a median of 18 pills of study drugs per month (IQR 11–25), and at the 6 month visit 240 (71%) of 336 participants had tenofovir detected in plasma. Drug-related gastrointestinal events were reported in 49 participants (14%) but were self-limited. Only four participants (1%) discontinued PrEP, three because of an increase in plasma creatinine. The proportion of participants reporting condomless sex at their last receptive anal intercourse significantly increased from 77% (136 of 176 participants) at baseline to 86% (66 of 77 participants) at 18 months' follow-up (p for trend=0·0004). The incidence of a first bacterial STI during this open-label phase did not change significantly compared with the randomised phase (59·0 vs 49·1 per 100 person-years, respectively; p=0·11). Interpretation On-demand oral PrEP is highly effective at preventing HIV infection among high-risk men who have sex with men and therefore represents an alternative to daily PrEP, expanding choices for HIV prevention. High rates of STIs resulting from low condom use did not undermine PrEP efficacy, but warrant frequent testing. The efficacy of pre-exposure prophylaxis (PrEP) makes it obligatory to include it in an integral program of prevention of HIV transmission, together with other measures, such as use of the condom, training, counseling, and appropriate treatment of infected individuals. In this document, the AIDS Study Group (GeSIDA) of the Spanish Society of Infectious Diseases and Clinical Microbiology (Sociedad Española de Enfermedades Infecciosas y Microbiología Clínica SEIMC) provides its views on this important subject. The available evidence on the usefulness of PrEP in the prevention of transmission of HIV is presented, and the components that should make up a PrEP program and whose development and implementation are feasible in Spain are set out (AU)	HIV infection; Infección por VIH; Pre-exposure prophylaxis; Prevención; Prevention; Profilaxis pre-exposición; Tenofovir	English	Spain	Western and Central Europe and North America	Spain	Western and Central Europe and North America	Spain	Western and Central Europe and North America	Review
Article	2017	Morgan, Ethan; Skaathun, Britt; Lancki, Nicola; Jimenez, Antonio D; Ramirez-Valles, Jesus; Bhatia, Ramona; Masiello-Schuette, Stephanie; Benbow, Nanette; Prachand, Nikhil; Schneider, John A	Trends in HIV Risk, Testing, and Treatment among MSM in Chicago 2004-2014: Implications for HIV Elimination Planning.	Journal of Urban Health	-	-	-	1468-2869	10.1007/s11524-017-0175-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5610127	Men who have sex with men (MSM) in the USA continue to have high rates of HIV infection. Increasingly, in addition to behavioral factors, biomedical interventions have been found to play important roles in HIV prevention. In this analysis, we used four waves of cross-sectional data (2004, 2008, 2011, and 2014) from the National HIV Behavioral Surveillance System (NHBS) to examine trends in key behaviors and biomedical interventions among MSM in Chicago (N = 3298). Logistic regression was used to determine changes in behaviors and use of biomedical interventions. Condomless sex increased significantly in waves 3 and 4, compared to wave 1: wave 3 (AOR = 2.07; 95% CI 1.53, 2.78) and wave 4 (AOR = 2.19; 95% CI 1.62, 2.96). Compared to those aged 18-24, older participants were significantly less likely to be routinely tested for HIV: 30-39 (AOR = 0.63; 95% CI 0.48, 0.83), 40-49 (AOR = 0.40; 95% CI 0.29, 0.55), and >50 (AOR = 0.28; 95% CI 0.18, 0.43). Awareness of both post-exposure prophylaxis (PEP)(âAOR = 3.13; 95% CI 1.22, 8.03) and pre-exposure prophylaxis (PrEP)(âAOR = 10.02; 95% CI 2.95, 34.01) increased significantly in wave 4, compared to wave 3. These results suggest a potential increase in HIV rates among men with main and casual partners and should be monitored closely as PrEP becomes more widespread among MSM of all races and ethnicities in Chicago. This study also suggests that further analyses of the barriers to PEP and PreP uptake among high-risk populations are necessary. Standardized messaging, sensitive to the barriers and motivators to HIV treatment and prevention, is needed for widespread scale-up of this approach. Methods: Within the Partners Demonstration Project, a prospective interventional project among 1013 serodiscordant couples in Kenya and Uganda, we offered ART to eligible HIV-positive partners and PrEP to HIV-negative partners before ART initiation and through the HIV-positive partner's first 6 months of ART use. We conducted individual and group discussions with counseling staff to elicit the health communication framework and key messages about ART and PrEP that were delivered to couples. Results: Counseling sessions for serodiscordant couples about PrEP and ART included discussions of HIV serodiscordance, PrEP and ART initiation and integrated use, and PrEP discontinuation. ART messages emphasized daily, lifelong use for treatment and prevention, adherence, viral suppression, resistance, side effects, and safety of ART during pregnancy. PrEP messages emphasized daily dosing, time-limited PrEP use until the HIV-positive partner sustained 6 months of high adherence to ART, adherence, safety during conception, side effects, and other risks for HIV. Conclusions: Counseling messages for HIV-serodiscordant couples are integral to the delivery of time-limited PrEP as a "bridge" to ART-driven viral suppression. Their incorporation into programmatic scale-up will maximize intervention impact on the global epidemic. Article	2017	Mravcík, Viktor; Pitonák, Michal; Hejzák, Robert; Janíková, Barbara; Procházka, Ivo	HIV epidemic among men who have sex with men in the Czech Republic, 2016: high time for targeted action.	Eurosurveillance	-	-	-	1560-7917	10.2807/1560-7917.ES.2017.22.48.17-00079	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5725790	Reported incidence of human immunodeficiency virus (HIV) infection in the Czech Republic increased steeply over the past decade from 90 new cases in 2005 to 266 in 2015. This increase is almost exclusively attributed to sexual transmissions between men who have sex with men (MSM). In 2015, there were 79% (n=210) newly diagnosed cases among MSM, 17% (n=45) were attributed to heterosexual transmission and 1% (n=3) to people who inject drugs. Interventions targeted at MSM have not yet been prioritised in the broadly focused national HIV prevention strategy which this is envisaged to change in the programme set out for 2018 to 2022. The national budget for HIV prevention has been reduced, however, and this remains. Availability of voluntary counselling and testing has decreased substantially in the past decade. Post- and pre-exposure prophylaxis for sexual intercourse among MSM are not part of the HIV prevention policy and the concept of treatment as prevention is not fully recognised. Provision of a combined prevention strategy with a focus on MSM, reflecting the above factors including stigmatisation, should contribute to reverse the development of a concentrated HIV epidemic among MSM in the Czech Republic. Article	2017	Mullins T.L.K.; Zimet G.; Lally M.; Xu J.; Thornton S.; Kahn J.A.	HIV Care Providers' Intentions to Prescribe and Actual Prescription of Pre-Exposure Prophylaxis to At-Risk Adolescents and Adults	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2017.0147	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038603065&doi=10.1089%2fapc.2017.0147&partnerID=40&md5=c7234a58679c81866a18391469a848b8	Pre-exposure prophylaxis (PrEP) is indicated for use in US adults, and little is known about clinician intentions to prescribe and actual prescription of PrEP to adolescents younger than 18. Fifty-six clinicians who care for HIV-infected and at-risk youth completed an anonymous online survey in 2014. Primary outcomes were (1) intentions to prescribe PrEP to adolescents and adults in four risk categories men who have sex with men (MSM), transgender women, heterosexuals with multiple partners of unknown HIV status, heterosexuals with HIV-infected partners; and (2) actual prescription of PrEP to adolescents and adults in these risk groups. Independent variables included clinician characteristics, experience prescribing nonoccupational postexposure prophylaxis, familiarity with and knowledge of PrEP and PrEP guidance, attitudes toward PrEP, and facilitating factors for prescribing PrEP and incorporation of PrEP guidance into practice. Variables associated with intention to prescribe ("very likely to prescribe" vs. other responses) and actual prescription of PrEP stratified by age and risk category were identified in logistic regression models. Mean age was 45.9 years (standard deviation 10.7); 64% were physicians. More clinicians reported high intention to prescribe PrEP to adult versus adolescent MSM (p = 0.02) and transgender women (p = 0.001). Variables associated with intention to prescribe and prescription of PrEP differed by age and risk category. In adolescents, those variables included positive beliefs, higher number of facilitating factors, and fewer barriers to PrEP prescription. Designing strategies based on these findings that address both facilitating factors and barriers to PrEP prescription may improve PrEP uptake by at-risk youth. © Copyright 2017, Mary Ann Liebert, Inc. Article	2017	Ngandu, Nobubelo K.; Carlson, Jonathan M.; Chopera, Denis R.; Ndabambi, Nonkululeko; Abdool Karim, Quarraisha; Abdool Karim, Salim; Williamson, Carolyn	Selection of HIV-1 Variants With Higher Transmission Potential by 1% Tenofovir Gel Microbicide.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000001458	https://pubmed.ncbi.nlm.nih.gov/28797020/	BACKGROUND: Women in the CAPRISA 004 trial assigned to use 1% tenofovir (TFV) microbicide gel, who became HIV-1 infected, had higher viral load set-point and slower antibody avidity maturation compared with placebo participants. We investigated whether TFV gel was selected for viruses with altered genetic characteristics. SETTING: The participants of the CAPRISA 004 trial (n = 28 TFV and 43 placebo) were from KwaZulu-Natal Province, South Africa and were infected with HIV-1 subtype C. After HIV-1 diagnosis, they were recruited into the CAPRISA 002 cohort. METHODS: We analyzed gag sequences from the earliest time point post infection (within 3 months of estimated time of infection). Transmission index was measured using a model which predicts the likelihood of an amino acid to be transmitted. Phylogenetic distance from a regional consensus sequence was calculated from a maximum likelihood phylogenetic tree. RESULTS: Transmission index and distance from the most common (consensus) sequence have been shown to be markers of transmission fitness. We found that viruses infecting TFV gel recipients were closer to the consensus sequence of regional strains (P = 0.003) and had higher transmission index (P = 0.01). The transmission index was weakly correlated with concomitant viral load (Spearman r = 0.22, P = 0.06). CONCLUSION: Decreased acquisition risk may have increased the barrier to infection therefore selecting for fitter, more consensus-like viruses. Such virus fitness effects will need to be considered for future pre-exposure prophylaxis and vaccine trials. Article	2017	Ngure, Kenneth; Kimemia, Grace; Dew, Kristin; Njuguna, Njambi; Mugo, Nelly; Celum, Connie; Baeten, Jared M.; Heffron, Renee	Delivering safer conception services to HIV serodiscordant couples in Kenya: perspectives from healthcare providers and HIV serodiscordant couples.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.20.2.21309	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5577704/	INTRODUCTION: For HIV serodiscordant couples in resource-limited settings, pregnancy is common despite the risk of sexual and/or perinatal HIV transmission. Some safer conception strategies to reduce HIV transmission during pregnancy attempts are available but often not used for reasons including knowledge, accessibility, preference and others. We sought to understand Kenyan health providers' and HIV serodiscordant couples' perspectives and experiences with safer conception. METHODS: Between August 2015 and March 2016, we conducted key informant interviews (KIIs) with health providers from public and private HIV care and fertility clinics and in-depth interviews (IDIs) and focus group discussions (FGDs) with HIV serodiscordant couples participating in an open-label study of integrated pre-exposure prophylaxis (PrEP) and antiretroviral therapy (ART) for HIV prevention (the Partners Demonstration Project). An inductive analytic approach identified a number of themes related to experiences with and perceptions of safer conception strategies. RESULTS: We conducted 20 KIIs with health providers, and 21 IDIs and 4 FGDs with HIV serodiscordant couples. HIV clinic providers frequently discussed timed condomless sex and antiretroviral medications while providers at private fertility care centres were more comfortable recommending medically assisted reproduction. Couples experienced with ART and PrEP reported that they were comfortable using these strategies to reduce HIV risk when attempting pregnancy. Timed condomless sex in conjunction with ART and PrEP was a preferred strategy, often owing to them being available for free in public and research clinics, as well as most widely known; however, couples often held inaccurate knowledge of how to identify days with peak fertility in the upcoming menstrual cycle. CONCLUSIONS: Antiretroviral-based HIV prevention is acceptable and accessible to meet the growing demand for safer conception services in Kenya, since medically assisted interventions are currently cost prohibitive. Cross-disciplinary training for health providers would expand confidence in all prevention options and foster the tailoring of counselling to couples' preferences. Article	2017	Ngure, Kenneth; Trinidad, Susan Brown; Beima-Sofie, Kristin; Baeten, Jared M; Mugo, Nelly R; Bukusi, Elizabeth A; Heffron, Renee; John-Stewart, Grace; Kelley, Maureen C	The role of male partners in women's participation in research during pregnancy: a case study from the partners demonstration project.	Reproductive Health	-	-	-	-	1742-4755	10.1186/s12978-017-0424-0	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5751399	The exclusion of pregnant women from health research remains a significant challenge globally. In settings where cultural traditions and gender norms support a more restricted decision-making role for women in general, little is known about the attitudes of male partners toward the inclusion of women in research during pregnancy. Understanding the expectations of both men and women in such cultural settings offers an opportunity to engage and address local ethical concerns to improve women's access to research during pregnancy and enhance intervention development. In this paper, we present a qualitative research ethics case study, drawn from the Partners Demonstration Project of pre-exposure prophylaxis (PrEP) in Kenya, regarding the role of male partners in decision-making to continue PrEP during pregnancy. PrEP is an effective HIV prevention tool; however, since pregnant women were excluded from early PrEP clinical trials, safety and efficacy data during pregnancy are limited. Given continued high rates of HIV infection for women, some pregnant women are now being provided with PrEP or are involved in PrEP research. Men and women in our study were equally concerned about the health risks of PrEP to the fetus and depended on healthcare provider guidance to understand these risks. Because the demonstration project enrolled couples, an implicit social expectation for many women's continuation of PrEP during pregnancy was consultation with male partners. Some women reported that consenting to participate was exclusively a woman's decision; however, many reported that they deferred to their male partner's opinion and support during the decision-making process. Most male partners believed women should not participate in research studies without their partner's permission, while a few men believed participation was ultimately a woman's decision. We suggest that relational autonomy can support a middle ground for informed consent that promotes women's autonomy while accommodating partner engagement. Article	2017	Nic Lochlainn, Laura; O'Donnell, Kate; Hurley, Caroline; Lyons, Fiona; Igoe, Derval	Using data from a behavioural survey of men who have sex with men (MSM) to estimate the number likely to present for HIV pre-exposure prophylaxis (PrEP) in Ireland, 2017.	Eurosurveillance	-	-	-	-	1560-7917	10.2807/1560-7917.ES.2017.22.48.17-00768	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5725788	In Ireland, men who have sex with men (MSM) have increased HIV risk. Pre-exposure prophylaxis (PrEP), combined with safe sex practices, can reduce HIV acquisition. We estimated MSM numbers likely to present for PrEP by applying French PrEP criteria to Irish MSM behavioural survey data. We adjusted for survey bias, calculated proportions accessing testing services and those likely to take PrEP. We estimated 1-3% of MSM in Ireland were likely to present for PrEP. Article	2017	Nikolopoulos G.K.; Christaki E.; Paraskevis D.; Bonovas S.	Pre-exposure prophylaxis for HIV: Evidence and perspectives	Current Pharmaceutical Design	-	-	-	-	13816128	10.2174/1381612823666170329145053	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85025127410&doi=10.2174%2f1381612823666170329145053&partnerID=40&md5=937a61b6f51f0e2cd0c4156c647a187c	HIV remains an important public health issue worldwide. However, new prevention approaches have recently been developed and are very promising. Antiretroviral treatment as prevention, or as a prophylaxis after exposure to HIV, has been shown to reduce the likelihood of HIV acquisition. Over the last years, animal studies and randomized clinical trials in humans showed that antiretrovirals can also be efficacious and safe if used once daily, or intermittently, as prophylaxis before an individual is exposed to HIV (Pre-exposure Prophylaxis-PrEP). Fears about development of resistant strains have not been justified insofar given the accumulated evidence from research studies. Demonstration projects are ongoing and first results indicate that interests in the uptake of PrEP are high and adherence is satisfactory. Models suggest that PrEP could be a cost-effective or cost-saving approach under certain provisions including delivery to people at high risk of HIV infection, using less expensive medications, delivery in high HIV prevalence settings, short-term use for periods of higher risk, and evaluation in a longer-term period. The current review summarizes evidence on efficacy, safety and effectiveness of PrEP, and discusses future challenges and perspectives. © 2017 Bentham Science Publishers. Article	2017	Nunn A.S.; Brinkley-Rubinstein L.; Oldenburg C.E.; Mayer K.H.; Mimiaga M.; Patel R.; Chan P.A.	Defining the HIV pre-exposure prophylaxis care continuum	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001385	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5333727/	Pre-exposure prophylaxis (PrEP) is an effective HIV prevention strategy. There is little scientific consensus about how to measure PrEP program implementation progress. We draw on several years of experience in implementing PrEP programs and propose a PrEP continuum of care that includes: (1) identifying individuals at highest risk for contracting HIV, (2) increasing HIV risk awareness among those individuals, (3) enhancing PrEP awareness, (4) facilitating PrEP access, (5) linking to PrEP care, (6) prescribing PrEP, (7) initiating PrEP, (8) adhering to PrEP, and (9) retaining individuals in PrEP care. We also propose four distinct categories of PrEP retention in care that include being: (1) indicated for PrEP and retained in PrEP care, (2) indicated for PrEP and not retained in PrEP care, (3) no longer indicated for PrEP, and (4) lost to follow-up for PrEP care. This continuum of PrEP care creates a framework that researchers and practitioners can use to measure PrEP awareness, uptake, adherence, and retention. Understanding each point along the proposed continuum of PrEP care is critical for developing effective PrEP interventions and for measuring public health progress in PrEP program implementation. © 2017 Wolters Kluwer Health, Inc. Article	2017	Nwokolo, Nneka; Whitlock, Gary; McOwan, Alan	Not just PrEP: other reasons for London's HIV decline.	The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(17)30044-9	https://dx.doi.org/10.1016/S2352-3018(17)30044-9	Introduction Multipurpose prevention technologies (MPTs) combining contraception with HIV prevention offer a promising solution to uptake and adherence challenges faced with oral pre-exposure prophylaxis (PrEP). The Dual Prevention Pill (DPP), which combines oral PrEP with an oral contraceptive pill (OCP), could address unmet need for family planning (FP) and HIV prevention. This study aimed to identify barriers and motivators for DPP uptake to inform the development of a DPP demand generation strategy and broader introduction efforts for MPTs. Materials and methods Qualitative, ethnographic research employing human-centered design techniques was conducted in Kenya, South Africa, and Zimbabwe. A research consortium conducted 45 immersions, 34 key informant interviews, and 12 friendship circles with potential end users, male romantic partners, healthcare providers (HCPs), and cultural commentators. Creative concepts were subsequently co-created and validated in workshops with end users, male partners, and HCPs. Results Four major themes emerged. Women struggled to balance personal motivations with societal expectations. Relationship goals strongly influenced sexual and reproductive health decisions, particularly related to financial security and social status. Negative experiences, such as untrustworthy partners, were significant triggers for OCP and PrEP use. Lastly, male partners were concerned about the DPP upending gender norms but held more positive individual attitudes. Five initial audience segments for the DPP were identified: women seeking enjoyment outside of their primary relationship; new mothers adhering to social norms; women wanting to maintain romantic relationships; women at risk of unintended pregnancy; and women with unfaithful partners. Segments informed the development of three communication themes, with the preferred route highlighting the DPP as a tool to prepare for life's unpredictability. Discussion To effectively generate demand for the DPP, several strategies should be considered. Connecting with women's diverse identities and goals and celebrating their individuality is crucial. Linking the DPP to relationship goals reframes it as a means to protect relationships rather than a risk. Leveraging negative triggers through targeted media campaigns empowers women to take control of their sexual health during challenging moments. A balance in channel placement is necessary to raise public awareness while using more discrete channels for potentially controversial messages with male partners and wider communities.	pre-exposure prophylaxis, oral contraception, HIV prevention, family planning, multi-purpose prevention technologies, end users, human-centered design, demand generation	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Qualitative
Article	2017	Nydegger, Liesl A; Ames, Susan L; Stacy, Alan W	Predictive utility and measurement properties of the Strength of Implementation Intentions Scale (SIIS) for condom use.	Social Science & Medicine	-	-	-	-	1873-5347	10.1016/j.socscimed.2017.05.035	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5524460	BACKGROUND: Implementation intentions are situation-linked action plans that increase health behaviors such as condom use. Few studies have measured the strength of implementation intentions, especially regarding condom use. Non-injection drug users are at high risk for HIV due to risky sexual practices. Substance use before sex may increase risky sexual behaviors, and implementation intentions are a promising, practical route for HIV prevention. PURPOSE: This prospective study assessed the measurement properties of the newly developed Strength of Implementation Intentions Scale (SIIS) for condom use and investigated whether the SIIS predicted condom use one-year later. The study evaluated whether behavioral intentions and alcohol or methamphetamine use before sex modified the relationship between the SIIS and condom use. METHODS: Participants were 590 non-injection drug users convicted of nonviolent drug offenses in court-mandated outpatient drug diversion programs. They completed self-directed computer assessments at baseline and at one-year follow-up. Measures included demographics, behavioral intentions to use condoms, the SIIS for condom use, alcohol and methamphetamine use before or during sex, and condom use. Psychometric properties, direct, and interaction effects of the SIIS were evaluated using structural equation modeling and general linear regressions. RESULTS: The SIIS, behavioral intentions, and condom use were positively correlated and there was discriminant validity between all three constructs. In addition, the SIIS predicted condom use one-year later in this high-risk population. No significant interactions were detected. CONCLUSIONS: The SIIS is predictive of condom use behavior, is psychometrically sound and distinct from behavioral intentions, and can be incorporated into HIV prevention interventions and used as a mediator variable. In addition, it can be used as an outcome measure where a follow-up is not feasible. The SIIS can also be tailored for additional HIV-related behaviors such as HIV-testing, adhering to antiretroviral medication, prescribing and adhering to pre-exposure prophylaxis, and other health behaviors. Article	2017	Okafor, Chukwuemeka N; Gorbach, Pamina M; Ragsdale, Amy; Quinn, Brendan	Correlates of Preexposure Prophylaxis (PrEP) Use among Men Who Have Sex with Men (MSM) in Los Angeles, California	Journal of Urban Health	-	-	-	-	1099-3460	https://doi.org/10.1007/s11524-017-0172-z	https://escholarship.org/uc/item/1dr4t5qj	We assessed socio-structural and behavioral correlates of preexposure prophylaxis (PrEP) for HIV infection among a sample of high-risk HIV-negative men who have sex with men (MSM) in Los Angeles, California. Participants from an ongoing 5-year prospective cohort study investigating the direct impacts of substance use on HIV transmission dynamics were enrolled between February 2015 and January 2017. All men completed a computer-assisted self-interview every 6 months that assessed recent (past 6 months) PrEP use and socio-structural and behavioral factors. Of the total 185 MSM (mean age = 29 years) included in the study, majority were African American (40%) or Hispanic (41%) and reported current health insurance coverage (80%). In multivariable analysis using log-binomial regression, having health insurance coverage adjusted prevalence ratio (aPR) 2.02; 95% confidence interval (CI) 1.01 to 4.01, p = 0.04 was associated with recent PrEP use. Unstable housing (aPR = 0.44, 95% CI 0.22 to 0.90, p = 0.02) was associated with lower PrEP use. Behavioral factors associated with recent PrEP use include sex with a HIV-positive partner (aPR = 3.63, 95% CI 1.45 to 9.10, p = 0.01), having six or more sex partners (aPR = 2.20, 95% CI 1.26 to 3.82, p = <0.01), and popper use (aPR = 2.76, 95% CI 1.58 to 4.84, p = <0.01). In this sample of predominantly racial/ethnic minority MSM, socio-structural and behavioral factors were important factors associated with recent PrEP use. These findings provide considerations for intervention development to promote PrEP use among key groups of MSM. Article	2017	Okoro, Olihe N; Whitson, Shanasha O	HIV risk and barriers to care for African-born immigrant women: a sociocultural outlook.	International Journal of Women's Health	-	-	-	-	1179-1411	10.2147/IJWH.S129355	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5476631	BACKGROUND: Data from the Minnesota Department of Health (MDH) HIV/AIDS Surveillance Report 2015 show that African-born (AB) women continue to be disproportionately affected by HIV. In 2015, these women accounted for more than half (54%) of all new cases of HIV reported among females in Minnesota and 34% of all new cases in the state. This study was a needs assessment for HIV pre-exposure prophylaxis (PrEP) in vulnerable subgroups within the AB population and adequacy of HIV care for AB persons. The primary objective of this study was to gain an insight into the strategies that will limit the spread of HIV infection and enhance HIV care among AB immigrants. METHODS: Community advocates, community-based organizations (CBOs), clinicians, and other HIV-related service providers were invited to participate in a focus group, structured interview or complete an assessment tool using the same questionnaire about HIV and PrEP among AB persons. A thematic analysis was then conducted on the open-ended questions addressing perceived barriers. RESULTS: Findings suggest the following gender-specific sociocultural factors that drive HIV transmission and constitute barriers to HIV treatment for AB women: domestic/intimate partner violence, gender-biased stigma, discriminatory cultural beliefs and normative values/expectations, unprotected sex with husbands who have sex with other men, gender discordance in health care (preference for female provider), and sexual/reproductive health illiteracy. RECOMMENDATION: Based on recommendations, a community-based sexual and reproductive health education is being initiated with a curriculum that will be 1) broad (inclusive but not limited to HIV), 2) culturally sensitive/responsive, and 3) at appropriate literacy level for all women, including those who have little or no formal education. Article	2017	Ong K.J.; Desai S.; Field N.; Desai M.; Nardone A.; van Hoek A.J.; Gill O.N.	Economic evaluation of HIV pre-exposure prophylaxis among men-who-have-sex-with-men in England in 2016	Eurosurveillance	-	-	-	-	1025496X	10.2807/1560-7917.ES.2017.22.42.17-00192	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85032006028&doi=10.2807%2f1560-7917.ES.2017.22.42.17-00192&partnerID=40&md5=b49eb10783d7e634bfeb80ddbd61aa5a	Clinical effectiveness of pre-exposure prophylaxis (PrEP) for preventing HIV acquisition in men who have sex with men (MSM) at high HIV risk is established. A static decision analytical model was constructed to inform policy prioritisation in England around cost-effectiveness and budgetary impact of a PrEP programme covering 5,000 MSM during an initial highrisk period. National genitourinary medicine clinic surveillance data informed key HIV risk assumptions. Pragmatic large-scale implementation scenarios were explored. At 86% effectiveness, PrEP given to 5,000 MSM at 3.3 per 100 person-years annual HIV incidence, assuming risk compensation (20% HIV incidence increase), averted 118 HIV infections over remaining lifetimes and was cost saving. Lower effectiveness (64%) gave an incremental cost-effectiveness ratio of + GBP 23,500 (EUR 32,000) per quality-adjusted life year (QALY) gained. Investment of GBP 26.9 million (EUR 36.6 million) in year-1 breaks even anywhere from year-23 (86% effectiveness) to year-33 (64% effectiveness). PrEP cost-effectiveness was highly sensitive to year-1 HIV incidence, PrEP adherence/ effectiveness, and antiretroviral drug costs. There is much uncertainty around HIV incidence in those given PrEP and adherence/effectiveness, especially under programme scale-up. Substantially reduced PrEP drug costs are needed to give the necessary assurance of cost-effectiveness, and for an affordable public health programme of sufficient size. © 2017, European Centre for Disease Prevention and Control (ECDC). Article	2017	Ortblad, Katrina; Kibuuka Musoke, Daniel; Ngabirano, Thomson; Nakitende, Aidah; Magoola, Jonathan; Kayiira, Prossy; Taasi, Geoffrey; Barresi, Leah G.; Haberer, Jessica E.; McConnell, Margaret A.; Oldenburg, Catherine E.; Bärnighausen, Till	Direct provision versus facility collection of HIV self-tests among female sex workers in Uganda: A cluster-randomized controlled health systems trial.	PLOS Medicine	-	-	-	-	1549-1676 1549-1277	10.1371/journal.pmed.1002458	https://pubmed.ncbi.nlm.nih.gov/29182634/#:~:text=Conclusions%3A%20In%20this%20study%2C%20HIV,for%20collection%20in%20healthcare%20facilities.	BACKGROUND: HIV self-testing allows HIV testing at any place and time and without health workers. HIV self-testing may thus be particularly useful for female sex workers (FSWs), who should test frequently but face stigma and financial and time barriers when accessing healthcare facilities. METHODS AND FINDINGS: We conducted a cluster-randomized controlled health systems trial among FSWs in Kampala, Uganda, to measure the effect of 2 HIV self-testing delivery models on HIV testing and linkage to care outcomes. FSW peer educator groups (1 peer educator and 8 participants) were randomized to either (1) direct provision of HIV self-tests, (2) provision of coupons for free collection of HIV self-tests in a healthcare facility, or (3) standard of care HIV testing. We randomized 960 participants in 120 peer educator groups from October 18, 2016, to November 16, 2016. Participants' median age was 28 years (IQR 24-32). Our prespecified primary outcomes were self-report of any HIV testing at 1 month and at 4 months; our prespecified secondary outcomes were self-report of HIV self-test use, seeking HIV-related medical care and ART initiation. In addition, we analyzed 2 secondary outcomes that were not prespecified: self-report of repeat HIV testing-to understand the intervention effects on frequent testing-and self-reported facility-based testing-to quantify substitution effects. Participants in the direct provision arm were significantly more likely to have tested for HIV than those in the standard of care arm, both at 1 month (risk ratio RR 1.33, 95% CI 1.17-1.51, p < 0.001) and at 4 months (RR 1.14, 95% CI 1.07-1.22, p < 0.001). Participants in the direct provision arm were also significantly more likely to have tested for HIV than those in the facility collection arm, both at 1 month (RR 1.18, 95% CI 1.07-1.31, p = 0.001) and at 4 months (RR 1.03, 95% CI 1.01-1.05, p = 0.02). At 1 month, fewer participants in the intervention arms had sought medical care for HIV than in the standard of care arm, but these differences were not significant and were reversed at 4 months. There were no statistically significant differences in ART initiation across study arms. At 4 months, participants in the direct provision arm were significantly more likely to have tested twice for HIV than those in the standard of care arm (RR 1.51, 95% CI 1.29-1.77, p < 0.001) and those in the facility collection arm (RR 1.22, 95% CI 1.08-1.37, p = 0.001). Participants in the HIV self-testing arms almost completely replaced facility-based testing with self-testing. Two adverse events related to HIV self-testing were reported: interpersonal violence and mental distress. Study limitations included self-reported outcomes and limited generalizability beyond FSWs in similar settings. CONCLUSIONS: In this study, HIV self-testing appeared to be safe and increased recent and repeat HIV testing among FSWs. We found that direct provision of HIV self-tests was significantly more effective in increasing HIV testing among FSWs than passively offering HIV self-tests for collection in healthcare facilities. HIV self-testing could play an important role in supporting HIV interventions that require frequent HIV testing, such as HIV treatment as prevention, behavior change for transmission reduction, and pre-exposure prophylaxis. Article	2017	Ouyang, Bingchen; Zhou, Fang; Zhen, Le; Peng, Ying; Sun, Jianguo; Chen, Qianying; Jin, Xiaoliang; Wang, Guangji; Zhang, Jingwei	Simultaneous determination of tenofovir alafenamide and its active metabolites tenofovir and tenofovir diphosphate in HBV-infected hepatocyte with a sensitive LC-MS/MS method.	Journal of Pharmaceutical and Biomedical Analysis	-	-	-	-	1873-264X 0731-7085	10.1016/j.jpba.2017.08.028	https://pubmed.ncbi.nlm.nih.gov/28881311/	Tenofovir (TFV), a first-line anti-viral agent, has been prepared as various forms of prodrugs for better bioavailability, lower systemic exposure and higher target cells loading of TFV to enhance efficacy and reduce toxicity. TFV undergoes intracellular phosphorylation to form TFV diphosphate (TFV-DP) in target cell to inhibit viral DNA replication. Hence, TFV-DP is the key active metabolite that exhibits anti-virus activity, its intracellular exposure and half-life determine the final activity. Therefore, simultaneous monitoring prodrug, TFV and TFV-DP in target cells will comprehensively evaluate TFV prodrugs, both considering the stability of ester prodrug, and the intracellular exposure of TFV-DP. Thus we intended to develop a convenient general analytical method, taking tenofovir alafenamide (TAF) as a representative of TFV prodrugs. A sensitive LC-MS/MS method was developed, and TAF, TFV and TFV-DP were separated on a XSelect HSS T3 column (4.6mm×150mm, 3.5μm, Waters) with gradient elution after protein precipitation. The method provided good linearity for all the compounds (2-500nM for TFV and TAF; 20-5000nM for TFV-DP) with the correlation coefficients (r) greater than 0.999. Intra- and inter-day accuracies (in terms of relative error, RE<10.4%) and precisions (in terms of coefficient of variation, CV<14.1%) satisfied the standard of validation. The matrix effect, recovery and stability were also within acceptable criteria. Finally, we investigated the intracellular pharmacokinetics of TAF and its active metabolites in HepG2.2.15 cells with this method. Article	2017	Owens, MP; Buffington, C; Frost, MP; Waldner, RJ	The South Dakota Model: Health Care Professions Student Disaster Preparedness and Deployment Training	Disaster Medicine and Public Health Preparedness	-	-	-	-	1935-7893	10.1017/dmp.2017.116	https://pubmed.ncbi.nlm.nih.gov/29070085/	Objective: The Association of American Medical Colleges recommended an increase in medical education for public health emergencies, bioterrorism, and weapons of mass destruction in 2003. The University of South Dakota Sanford School of Medicine (USD SSOM) implemented a 1-day training event to provide disaster preparedness training and deployment organization for health professions students called Disaster Training Day (DTD). Methods: Hospital staff and emergency medical services personnel provided the lecture portion of DTD using Core Disaster Life Support (CDLS; National Disaster Life Support Foundation) as the framework. Pre-test and post-test analyses were presented to the students. Small group activities covered leadership, anaphylaxis, mass fatality, points of dispensing deployment training, psychological first aid, triage, and personal protective equipment. Students were given the option to sign up for statewide deployment through the South Dakota Statewide Emergency Registry of Volunteers (SERV SD). DTD data and student satisfaction surveys from 2009 to 2016 were reviewed. Results: Since 2004, DTD has provided disaster preparedness training to 2246 students across 13 health professions. Significant improvement was shown on CDLS post-test performance with a t-score of -14.24 and a resulting P value of < 0.00001. Students showed high levels of satisfaction on a 5-level Likert scale with overall training, small group sessions, and perceived self-competency relating to disaster response. SERV SD registration increased in 2015, and 77.5% of the participants registered in 2016. Conclusion: DTD at the USD SSOM provides for an effective 1-day disaster training course for health professions students. Resources from around the state were coordinated to provide training, liability coverage, and deployment organization for hundreds of students representing multiple health professions. Article	2017	Özdener, Ayse Elif; Park, Tae Eun; Kalabalik, Julie; Gupta, Rachna	The future of pre-exposure prophylaxis (PrEP) for human immunodeficiency virus (HIV) infection.	Expert Review of Anti-Infective Therapy	-	-	-	-	1744-8336	10.1080/14787210.2017.1309292	https://dx.doi.org/10.1080/14787210.2017.1309292	INTRODUCTION: People at high risk for HIV acquisition should be offered pre-exposure prophylaxis (PrEP). Tenofovir disoproxil fumarate (TDF)/emtricitabine (FTC) is currently the only medication recommended for pre-exposure prophylaxis (PrEP) by the Centers for Disease Control and Prevention (CDC) in people at high risk for HIV acquisition. This article will review medications currently under investigation and the future landscape of PrEP therapy. Areas covered: This article will review clinical trials that have investigated nontraditional regimens of TDF/FTC, antiretroviral agents from different drug classes such as integrase strand transfer inhibitors (INSTI), nucleoside reverse transcriptase inhibitors (NRTI), and non-nucleoside reverse transcriptase inhibitors (NNRTI) as potential PrEP therapies. Expert commentary: Currently, there are several investigational drugs in the pipeline for PrEP against HIV infection. Increased utilization of PrEP therapy depends on provider identification of people at high risk for HIV transmission. Advances in PrEP development will expand options and access for people and reduce the risk of HIV acquisition. Article	2017	Page K.R.; Martinez O.; Nieves-Lugo K.; Zea M.C.; Grieb S.D.; Yamanis T.J.; Spear K.; Davis W.W.	Promoting pre-exposure prophylaxis to prevent hiv infections among sexual and gender minority hispanics/latinxs	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2017.29.5.389	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85032505226&doi=10.1521%2faeap.2017.29.5.389&partnerID=40&md5=b0dcba19a1f2d16352b0acc15cd3bcc9	Sexual and gender minority Hispanics/Latinxs (henceforth: Latinxs) continue to be disproportionately impacted by HIV/AIDS in the U.S. Pre-exposure prophylaxis (PrEP) is a biomedical prevention approach which holds significant promise for at risk and vulnerable populations. We discuss barriers and facilitators to uptake of PrEP among sexual and gender minority Latinxs living in the U.S. through an ecosocial lens that takes into account structural, community, and individual contexts. The impact of immigration status on PrEP uptake emerges as a major and recurrent theme that must be understood and addressed by HIV prevention programs aiming to promote an inclusive strategy for sexual and gender minority Latinxs living in the U.S. © 2017 The Guilford Press. Article	2017	Page, Kimberly; Bacon, Oliver	Commitment issues: PrEP adherence in injecting drug users.	The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(16)30208-9	https://dx.doi.org/10.1016/S2352-3018(16)30208-9	People who inject drugs (PWID) are a key population that is being left behind in the global scope of HIV prevention programmes; they comprised 51% of people with new HIV infections in eastern Europe and central Asia and 13% in Asia and the Pacific in 2014, according to the Joint UN Programme on HIV/AIDS (UNAIDS). Despite abundant evidence that HIV infection rates decline when PWID have access to harm reduction and other evidence-based interventions, only 80 of 192 reporting countries have opiate substitution therapy programmes, and 90 reported offering needle and syringe programmes. In 2014, WHO added pre-exposure prophylaxis (PrEP) to the recommended combination HIV prevention package for PWID, and in 2015, issued guidance for PrEP implementation, with strong language on the need for respect, inclusivity, and choice. Article	2017	Palich, Romain; Martin-Blondel, Guillaume; Cuzin, Lise; Le Talec, Jean-Yves; Boyer, Pierre; Massip, Patrice; Delobel, Pierre	Experiences of HIV postexposure prophylaxis (PEP) among highly exposed men who have sex with men (MSM).	Sexually Transmitted Diseases	-	-	-	-	1472-3263	10.1136/sextrans-2016-052901	https://dx.doi.org/10.1136/sextrans-2016-052901	OBJECTIVES: HIV postexposure prophylaxis (PEP) is indicated after sexual exposure with high risk of transmission. Men who have sex with men (MSM) are the main target of PEP. The aim of our study was to investigate the experience and shortcomings of PEP among people with a high risk of HIV exposure. DESIGN AND METHODS: Subjects with ongoing follow-up for HIV infection and PEP history were selected for the qualitative study. Semistructured interviews were conducted at the patients' homes. They were audio-recorded, transcribed and deidentified before data analysis, double coding and thematic analysis with an inductive approach. RESULTS: Twenty-three patients were eligible for the qualitative study. Thirteen interviews were carried out. All patients were 20-60-year-old MSM. The median time between PEP and HIV diagnosis was 3.3 years (interquartile range (IQR)25-75=0.9-4.9). Many participants reported negative PEP experiences: awkward access to the PEP clinic, uneasiness and shame in the hospital setting, unpleasant interaction and moral disapprobation from the medical staff, treatment intolerance and prevention messages that were 'inconsistent with real life' CONCLUSION: Our data highlight PEP management failures among its target population that may have compromised any subsequent attempts to seek out PEP. Practitioners should be more aware of MSM sexual contexts and practices. PEP consultations should provide the opportunity to discuss prevention strategies with highly exposed HIV-negative subjects, which may include pre-exposure prophylaxis.	hiv; homosexuality; postexposure prophylaxis (hiv); qualitative research; sexual behaviour	English	United States	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Qualitative

Awareness, discussion and non-prescribed use of HIV pre-exposure prophylaxis among persons living with HIV/AIDS in Italy: A Nationwide, cross-sectional study among patients on antiretrovirals and their treating HIV physicians	BMC Infectious Diseases	-	-	-	-	14712334	10.1186/s12879-017-2819-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85035141315&doi=10.1186%2fs12879-017-2819-5&partnerID=40&md5=2021a07c1149ce85088732a7c9e76de1	Background: Before Pre-Exposure Prophylaxis (PrEP) was officially recommended and made available, a few surveys among gay and bisexual men, and persons living with HIV/AIDS (PLWHA), identified an informal use of antiretrovirals (ARVs) for PrEP among HIV-negative individuals. Before PrEP availability in Italy, we aimed to assess whether PLWHA in Italy shared their ARVs with HIV-negative individuals, whether they knew people who were on PrEP, and describe the level of awareness and discussion on this preventive measure among them and people in their close circle. Methods: Two anonymous questionnaires investigating personal characteristics and PrEP awareness, knowledge, and experience were proposed to HIV specialists and their patients on ARVs in a one-week, cross-sectional survey (December 2013-January 2014). Among PLWHA, a Multivariable Logistic Regression analysis was conducted to identify factors associated with PrEP discussion with peers (close circle and/or HIV associations), and experience (use in close circle and/or personal ARV sharing). Results: Eighty-seven specialists in 31 representative Infectious Diseases departments administered the questionnaire to 1405 PLWHA. Among specialists, 98% reported awareness, 65% knew the dosage schedule, and 14% had previously suggested or prescribed PrEP. Among PLWHA, 45.6% were somewhat aware, discussed or had direct or indirect experience of PrEP: 38% "had heard" of PrEP, 24% were aware of studies in HIV-negative individuals demonstrating a risk reduction through the use of ARVs, 22% had discussed PrEP, 12% with peers; 9% reported PrEP use in close circle and 1% personal ARV sharing. Factors predictive of either PrEP discussion with peers or experience differed between men and women, but across all genders were mainly related to having access to information, with HIV association membership being the strongest predictor. Conclusions: At a time and place where there were neither official information nor proposals or interventions to guide public policies on PrEP in Italy, a significant number of PLWHA were aware of it, and approximately 10% reported PrEP use in their close circle, although they rarely shared their ARVs with uninfected people for this purpose. Official policies and PrEP availability, along with implementation programs, could avoid risks from uncontrolled PrEP procurement and self-administration practices. © 2017 The Author(s). Article	2017	Parsons, Jeffrey T; Rendina, H Jonathon; Lassiter, Jonathan M; Whitfield, Thomas H F; Starks, Tyrel J; Grov, Christian	Uptake of HIV Pre-Exposure Prophylaxis (PrEP) in a National Cohort of Gay and Bisexual Men in the United States.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000001251	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5315535	OBJECTIVES: The HIV care cascade provides milestones to track the progress of HIV-positive people from seroconversion through viral suppression. We propose a Motivational pre-exposure prophylaxis (PrEP) Cascade involving 5 stages based on the Transtheoretical Model of Change. METHODS: We analyzed data from 995 men in One Thousand Strong, a longitudinal study of a national panel of HIV-negative gay and bisexual men in the United States. RESULTS: Nearly all (89%) participants were sexually active in the past 3 months and 65% met Centers for Disease Control criteria for PrEP candidacy. Of those identified as appropriate candidates, 53% were Precontemplative (stage 1; unwilling to take or believing they were inappropriate candidates for PrEP) and 23% were in Contemplation (stage 2; willing and self-identified as appropriate candidates). Only 11% were in PrEParation (stage 3; seeing PrEP as accessible and planning to initiate PrEP) and 4% were in PrEP Action (stage 4; prescribed PrEP). Although few of those who were identified as appropriate candidates were on PrEP, nearly all PrEP users (98%) reported adhering to 4 or more doses per week and most (72%) were returning for recommended quarterly medical visits, resulting in 9% of PrEP candidates reaching Maintenance and Adherence (stage 5). CONCLUSIONS: The large majority of participants were appropriate candidates for PrEP, yet fewer than 1 in 10 were using and adherent to PrEP. These findings highlight the need for interventions tailored to address the unique barriers men face at each stage of the cascade, particularly at the earliest stages where the most dramatic losses were identified. Article	2017	Patel R.R.; Mena L.; Nunn A.; McBride T.; Harrison L.C.; Oldenburg C.E.; Liu J.; Mayer K.H.; Chan P.A.	Impact of insurance coverage on utilization of pre-exposure prophylaxis for HIV prevention	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0178737	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85020014423&doi=10.1371%2fjournal.pone.0178737&partnerID=40&md5=e1f3f94d206ff528dd59dc70fe9a1828	Pre-exposure prophylaxis (PrEP) can reduce U.S. HIV incidence. We assessed insurance coverage and its association with PrEP utilization. We reviewed patient data at three PrEP clinics (Jackson, Mississippi; St. Louis, Missouri; Providence, Rhode Island) from 2014± 2015. The outcome, PrEP utilization, was defined as patient PrEP use at three months. Multivariable logistic regression was performed to determine the association between insurance coverage and PrEP utilization. Of 201 patients (Jackson: 34%; St. Louis: 28%; Providence: 28%), 91% were male, 51% were White, median age was 29 years, and 21% were uninsured; 82% of patients reported taking PrEP at three months. Insurance coverage was significantly associated with PrEP utilization. After adjusting for Medicaid-expansion and individual socio-demographics, insured patients were four times as likely to use PrEP services compared to the uninsured (OR: 4.49, 95% CI: 1.68-12.01; p = 0.003). Disparities in insurance coverage are important considerations in implementation programs and may impede PrEP utilization. © 2017 Patel et al. Article	2017	Patrick R.; Forrest D.; Cardenas G.; Opoku J.; Magnus M.; Phillips G., II; Greenberg A.; Metsch L.; Kharfen M.; LaLota M.; Kuo I.	Awareness, Willingness, and Use of Pre-exposure Prophylaxis Among Men Who Have Sex With Men in Washington, DC and Miami-Dade County, FL: National HIV Behavioral Surveillance, 2011 and 2014	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001414	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85030999174&doi=10.1097%2fQAI.0000000000001414&partnerID=40&md5=29c4de63f1ad172e7cf8f04c8e19bed1	Introduction: Despite the effectiveness of oral pre-exposure prophylaxis (PrEP) for HIV prevention, knowledge, and uptake of this new prevention intervention over time has not been fully studied. Using NHBS data from 2 urban areas highly impacted by HIV, we examined awareness, use, and willingness to use daily oral PrEP and factors associated with willingness to take oral PrEP among men who have sex with men (MSM) over time. Methods: MSM from Washington, DC and Miami, FL were recruited in 2011 and 2014 using venue-based sampling. Participants completed behavioral surveys and HIV testing. Awareness, use, and willingness to use oral PrEP were examined. Demographic and behavioral correlates of being "very likely" to use PrEP in 2011 and 2014 were assessed. Results: PrEP awareness increased from 2011 to 2014 in both cities (DC: 39.1%-73.8% and Miami: 19.4%-41.2%), but use remained low in 2014 (DC: 7.7%; Miami: 1.4%). Being very likely to use PrEP decreased over time in DC (61%-48%), but increased in Miami (48%-60%). In DC, minority race was associated with increased odds of being very likely to use PrEP, whereas reduced odds of being very likely to use PrEP was observed for MSM with 1 or 2-5 partners versus having 6+ partners. In Miami, a higher proportion of white versus Hispanic MSM reported being very likely to use PrEP in 2011, but this observation was reversed in 2014. Conclusion: Geographic differences in awareness, use, and willingness to use PrEP indicate that innovative strategies are needed to educate MSM about this effective prevention strategy. Article	2017	Peitzmeier S.M.; Tomko C.; Wingo E.; Sawyer A.; Sherman S.G.; Glass N.; Beyrer C.; Decker M.R.	Acceptability of microbicidal vaginal rings and oral pre-exposure prophylaxis for HIV prevention among female sex workers in a high-prevalence US city	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2017.1300628	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85014671766&doi=10.1080%2f09540121.2017.1300628&partnerID=40&md5=06663522d90b9af9e3a25dca15ef60a2	Biomedical HIV prevention tools including oral pre-exposure prophylaxis (PrEP) and vaginal microbicidal rings hold unique value for high-risk women who may have limited capacity for condom negotiation, including the key populations of sex workers and drug users. Commercial sex is a PrEP indicator in CDC guidelines, yet little is known about female sex workers' (FSWs) knowledge of and attitudes toward PrEP or the recently developed monthly vaginal microbicide rings. We describe knowledge and attitudes toward PrEP and microbicide rings in a sample of 60 mostly drug-using FSWs in Baltimore, Maryland, a high HIV-prevalence US city. Just 33% had heard of PrEP, but 65% were interested in taking daily oral PrEP and 76% were interested in a microbicide vaginal ring; 87% were interested in at least one of the two methods. Results suggest method mix will be important as biomedical tools for HIV prophylaxis are implemented and scaled up in this population, as 12% were interested in PrEP but not vaginal rings, while 19% were interested in vaginal rings but not in PrEP. Self-efficacy for daily oral adherence was high (79%) and 78% were interested in using PrEP even if condoms were still necessary. Women who had experienced recent client-perpetrated violence were significantly more interested in PrEP (86% vs 53%, p = 0.009) and microbicidal rings (91% vs 65%, p = 0.028) than women who had not recently experienced violence. No differences were observed by demographics nor HIV risk behaviors, suggesting broad potential interest in daily PrEP and monthly-use vaginal microbicides in this high-risk population. © 2017 Informa UK Limited, trading as Taylor & Francis Group.	microbicides; people who inject drugs; pre-exposure prophylaxis; Sex workers; vaginal rings; violence	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Petroll A.E.; Walsh J.L.; Owczarzak J.L.; McAuliffe T.L.; Bogart L.M.; Kelly J.A.	PrEP Awareness, Familiarity, Comfort, and Prescribing Experience among US Primary Care Providers and HIV Specialists	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-016-1625-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84996671386&doi=10.1007%2fs10461-016-1625-1&partnerID=40&md5=bf42493cf9ed39ece9f610ebcfec6001	HIV pre-exposure prophylaxis (PrEP) was FDA approved in 2012, but uptake remains low. To characterize what would facilitate health care providers' increased PrEP prescribing, we conducted a 10-city, online survey of 525 primary care providers (PCPs) and HIV providers (HIVPs) to assess awareness, knowledge, and experience with prescribing PrEP; and, comfort with and barriers to PrEP-related activities. Fewer PCPs than HIVPs had heard of PrEP (76 vs 98%), felt familiar with prescribing PrEP (28 vs. 76%), or had prescribed it (17 vs. 64%). PCPs were less comfortable than HIVPs with PrEP-related activities such as discussing sexual activities (75 vs. 94%), testing for acute HIV (83 vs. 98%), or delivering a new HIV diagnosis (80 vs. 95%). PCPs most frequently identified limited knowledge about PrEP and concerns about insurance coverage as prescribing barriers. PCPs and HIVPs differ in needs that will facilitate their PrEP prescribing. Efforts to increase PrEP uptake will require interventions to increase the knowledge, comfort, and skills of providers to prescribe PrEP. © 2016, Springer Science+Business Media New York. Article	2017	Pierce A.B.; El-Hayek C.; Mccarthy D.; Armishaw J.; Watson K.; Wilkinson A.; Price B.; Wright E.J.; Hoy J.F.; Stoové M.A.	Comparing non-occupational post-exposure prophylaxis drug regimens for HIV: Insights from a linked HIV surveillance system	Sexual Health	-	-	-	-	14485028	10.1071/SH16132	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85017159783&doi=10.1071%2fSH16132&partnerID=40&md5=6cf1d22216ff6bcb84b65de4434745a	Background International non-occupational post-exposure prophylaxis (NPEP) guidelines recommend routine use of three drug NPEP regimens, despite absence of evidence for greater prevention efficacy compared with two drug regimens. This study examines the potential for excess HIV seroconversions among high-risk men who have sex with men (MSM) reporting receptive anal intercourse with a source of unknown HIV serostatus (RAIU) following a two-drug versus a three-drug NPEP regimen. Methods: Data for MSM in the Victorian NPEP service database between 10 August 2005 and 31 December 2012 were linked with all Victorian HIV notifications up to 31 December 2013. The primary outcome was NPEP failure following NPEP presentation among MSM reporting RAIU, stratified by the number of drugs prescribed. Results: Among 1482 MSM reporting 2002 episodes of RAIU and prescribed two- or three-drug NPEP, 70 seroconverted to HIV, but only 19 were considered possible NPEP failures. HIV diagnosis incidence among men reporting RAIU was 1.2/100 person years (PY) (95%CI≦1.0-1.6); 1.1/100 PY (95%CI≦0.8-1.4) among MSM prescribed two drugs and 2.2/100 PY (95%CI≦1.4-3.7) among MSM prescribed three drugs (P<0.01). Of the 19 possible NPEP failures, 13 (0.7%) were prescribed two drugs and six (2.7%) three drugs (P<0.001). Conclusions: This study suggests that two-drug NPEP regimens do not result in excess seroconversions compared with three-drug regimens when used following RAIU. Clinical services should carefully consider their use of three drug NPEP and whether resources might be better invested in other prevention strategies, particularly pre-exposure prophylaxis (PrEP). © CSIRO 2017. Article	2017	Pintye J.; Beima-Sofie K.M.; Kimemia G.; Ngure K.; Trinidad S.B.; Heffron R.A.; Baeten J.M.; Odoyo J.; Mugo N.; Bukusi E.A.; Kelley M.C.; John-Stewart G.C.	"I Did Not Want to Give Birth to a Child Who has HIV ": Experiences Using PrEP during Pregnancy among HIV-Uninfected Kenyan Women in HIV-Serodiscordant Couples	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001516	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85031664893&doi=10.1097%2fQAI.0000000000001516&partnerID=40&md5=a2e89ac4dc33328acb254332082df3d7	Objectives: The perceptions, motivations, and beliefs of HIV-uninfected women about pre-exposure prophylaxis (PrEP) use during pregnancy can influence its uptake and adherence. This study elicited the views of HIV-uninfected women with personal experience taking PrEP during pregnancy. Design: Qualitative interviews were conducted with HIV-uninfected women who had personal experience taking PrEP while pregnant. Methods: Semistructured interviews were conducted with 21 HIV-uninfected Kenyan women in HIV-serodiscordant couples enrolled in an open-label PrEP demonstration project who became pregnant while using PrEP and continued PrEP through their pregnancy. Interviews were audio-recorded and transcribed into English. A qualitative descriptive analysis was performed, using a constant comparison approach to identify key themes related to PrEP use in pregnancy. Results: Desire to remain HIV uninfected and have an HIV-free infant were strong motivators influencing continued use of PrEP during pregnancy. Supporting HIV-infected partners and childbearing within an HIV-serodiscordant relationship were also motivators. Women had challenges distinguishing normal pregnancy symptoms from PrEP side effects and were concerned that observed side effects could be signs of danger for the infant related to PrEP exposure. Health care providers were important conduits of knowledge about PrEP, and continuity of PrEP providers throughout pregnancy facilitated adherence. Conclusions: HIV-uninfected women in HIV-serodiscordant couples were motivated to use PrEP during pregnancy to remain HIV uninfected and to have an HIV-free child but had concerns about side effects. Health care providers will be important for PrEP messaging and adherence support in this unique population. Copyright © 2017 The Author(s). Published by Wolters Kluwer Health, Inc. Article	2017	Pintye J.; Drake A.L.; Kinuthia J.; Unger J.A.; Matemo D.; Heffron R.A.; Barnabas R.V.; Kohler P.; Scott McClelland R.; John-Stewart G.	A Risk Assessment Tool for Identifying Pregnant and Postpartum Women Who May Benefit From Preexposure Prophylaxis	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciw850	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85030778198&doi=10.1093%2fcid%2fciw850&partnerID=40&md5=dd70be8d18a1f2f0ac1fae660c727d4d	Background.: A human immunodeficiency virus (HIV) risk assessment tool for pregnant women could identify women who would most benefit from preexposure prophylaxis (PrEP) while minimizing unnecessary PrEP exposure. Methods.: Data from a prospective study of incident HIV among pregnant/postpartum women in Kenya were randomly divided into derivation (n = 654) and validation (n = 650) cohorts. A risk score was derived using multivariate Cox proportional hazards models and standard clinical prediction rules. Ability of the tool to predict maternal HIV acquisition was assessed using the area under the curve (AUC) and Brier score. Results.: The final risk score included the following predictors: having a male partner with unknown HIV status, number of lifetime sexual partners, syphilis, bacterial vaginosis (BV), and vaginal candidiasis. In the derivation cohort, AUC was 0.84 (95% confidence interval CI, .72-.95) and each point increment in score was associated with a 52% (hazard ratio HR, 1.52 95% CI, 1.32-1.76; P < .001) increase in HIV risk; the Brier score was 0.11. In the validation cohort, the score had similar AUC, Brier score, and estimated HRs. A simplified score that excluded BV and candidiasis yielded an AUC of 0.76 (95% CI, .67-.85); HIV incidence was higher among women with risk scores >6 than with scores ≤6 (7.3 vs 1.1 per 100 person-years, respectively; P < .001). Women with simplified scores >6 accounted for 16% of the population but 56% of HIV acquisitions. Conclusions.: A combination of indicators routinely assessed in antenatal clinics was predictive of HIV risk and could be used to prioritize pregnant women for PrEP. © 2016 The Author. Importance of risk perception Predictors of PrEP acceptance among Thai MSM and TG women at a community-based health service	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001536	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037696632&doi=10.1097%2FQAI.0000000000001536&partnerID=40&md5=2b4a4f3f4e7b42d5b7964d5c7e1cb1e7	Background: HIV prevalence among Thai men who have sex with men (MSM) and transgender women (TG) are 9.15% and 11.8%, respectively, compared with 1.1% in the general population. To better understand early adopters of pre-exposure prophylaxis (PrEP) in Thailand, we analyzed behavioral and sociodemographic characteristics of PrEP-eligible MSM and TG. Setting: Four Thai urban community clinics between October 2015 and February 2016. Methods: Sociodemographics, HIV risk characteristics, and PrEP knowledge and attitudes were analyzed in association with PrEP initiation among eligible Thai MSM and TG. Adjusted analysis explored factors associated with PrEP acceptance. We then analyzed HIV risk perception, which was strongly associated with PrEP initiation. Results: Of 295 participants, 35% accepted PrEP (40% of MSM, 24% of TG). Perceived HIV risk levels were associated with PrEP acceptance odds ratio (OR) 4.3, 95% confidence interval (95% CI): 1.9 to 12.2). OR: 3.6;95% CI: 2.1 to 19.8. OR: 14.7; 95% CI: 3.9 to 55.1; for minimal, moderate, and high perceived risks, respectively. HIV risk perception was associated with previous HIV testing (OR: 2.2; 95% CI: 1.4 to 3.5), inconsistent condom use (OR: 1.8; 95% CI: 1.1 to 2.9), amphetamine use in the past 6 months (OR: 3.1; 95% CI: 1.1 to 8.6); and uncertainty in the sexually transmitted infection history (OR: 2.3; 95% CI: 1.4 to 3.7). Approximately half of those who reported either inconsistent condom use (48%), multiple partners (59%), group sex (48%), or had baseline bacterial sexually transmitted infections (48%) perceived themselves as having no or mild HIV risk. Conclusions: HIV risk perception plays an important role in PrEP acceptance. Prevention does not consistently reflect actual risk. It is therefore critical to assess a client's risk perception and provide education about HIV risk factors that will improve the accuracy of perceived HIV risk. Essay	2017	Portman, Mags	Pre-exposure prophylaxis: making history.	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2016-053059	https://sti.bmj.com/content/93/1/7	August 2016 was a truly momentous month for HIV prevention in the UK. We saw the National AIDS Trust successfully challenge NHS England with regards to the withdrawal of pre-exposure prophylaxis "PrEP" from the Selective Licensing process. I There was huge media representation of the case, with PrEP making the main headline on BBC News at 10pm on 2nd August. We argued this outcome, but November 2016 saw the result uphold.2,3 The optimal outcome of "PrEP for all who need it", provided via the NHS has not been reached yet, but NHSE agreed funding to provide for PrEP for 10,000 people in an implementation trial.4 But will the trial be fully funded by NHSE and implemented by PHE; there are concerns that it could results in another "Prevention Postcode Lottery", as per the current HPV vaccination pilot. We need reassurance that a full-PrEP roll out will follow. The legal challenge by NAT was ... Article	2017	Poteat, Tonia; Malik, Mumtaz; Scheim, Ayden; Elliott, Ayana	HIV Prevention Among Transgender Populations: Knowledge Gaps and Evidence for Action.	Current HIV/AIDS Reports	-	-	-	1548-3576	10.1007/s11904-017-0360-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5809031/	PURPOSE OF REVIEW: The purpose of this review is to summarize the available evidence-based HIV prevention interventions tailored for transgender people. RECENT FINDINGS: A limited number of evidence-based HIV prevention interventions have been tested with transgender populations. Most existing interventions target behavior change among transgender women, with only one HIV prevention program evaluated for transgender men. Studies addressing biomedical interventions for transgender women are ongoing. Few interventions address social and structural barriers to HIV prevention, such as stigma, discrimination, and poverty. Evidence-based multi-level interventions that address the structural, biomedical, and behavioral risks for HIV among transgender populations, including transgender men, are needed to address disparities in HIV prevalence. Future research should address not only pre-exposure prophylaxis uptake and condom use but also structural barriers that limit access to these prevention strategies.	transgender, HIV prevention, stigma, structural determinants, behavioral interventions, biomedical interventions	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2017	Prathipati P.K.; Mandal S.; Pon G.; Vivekanandan R.; Destache C.J.	Pharmacokinetic and Tissue Distribution Profile of Long Acting Tenofovir Alafenamide and Elvitegravir Loaded Nanoparticles in Humanized Mice Model	Pharmaceutical Research	-	-	-	724874l	10.1007/s11095-017-2255-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029441250&doi=10.1007%2Fs11095-017-2255-7&partnerID=40&md5=b0cb3605548e0398a1128ad07f5cdeb1	Purpose: Non-adherence to the antiretroviral (ARV) regimen is a critical factor in determining efficacy of ARV drugs for pre-exposure prophylaxis (PrEP). A long-acting parenteral formulation may be an effective alternative to daily oral dosing. A pharmacokinetic and tissue distribution study of drug-loaded nanoparticle (NP) was performed in female humanized CD34+/NSG mice. Methods: Mice received 200 mg/kg each of tenofovir alafenamide (TAF) and elvitegravir (EVG) as free drugs (7 nM + 8 nM) or as drug loaded NP (7 nM + 8 nM) subcutaneously (SubQ) administration (n=6/group). Plasma and tissue were collected to determine tenofovir (TFV) and EVG concentrations using LC-MS/MS. Non-compartmental analysis was performed using WinNonlin. Results: SubQ administration of TAF + EVG NP formulation resulted in long residence time and exposure for both drugs. The AUC0-28h of TFV and EVG was 14.1 ± 2.0, 7.2 ± 1.8 μg * hr/mL from drugs in solution (free) and the AUC0-168(hr) for the same drugs was 23.1 ± 4.4, 39.7 ± 6.7 μg * hr/mL from NPs. The observed elimination half-life (t1/2) for TFV of free and NPs were 14.2 h, 5.1 days and for EVG 10.8 h, 3.3 days, respectively. TFV-DP in PBMC was sustained for 7 days from NP formulation. Conclusion: Tenofovir alafenamide and elvitegravir nanoparticle is a promising long-acting drug formulation for HIV prophylaxis. © 2017, Springer Science+Business Media, LLC.	cobicistat; nanoformulation; pharmacokinetics; tenofovir alafenamide; tissue distribution profile	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Purcell D.W.; Higa D.; Mizuno Y.; Lyles C.	Quantifying the Harms and Benefits from Serosorting Among HIV-Negative Gay and Bisexual Men: A Systematic Review and Meta-analysis	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1800-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85020110901&doi=10.1007%2Fs10461-017-1800-x&partnerID=40&md5=2420fa594e8c86ad56ac4fa5d4570bf5b	We conducted a systematic review and meta-analysis of the association between serosorting and HIV infection among HIV-negative men who have sex with men (MSM). Compared to no condomless anal sex (i.e., consistent condom use or no anal sex), serosorting was associated with increased HIV risk (RR = 1.64, 95% CI 1.37–1.96). Compared to condomless discordant anal sex, serosorting was associated with reduced HIV risk (RR = 0.46, 95% CI 0.33–0.65). Serosorting may be an important harm reduction strategy when condoms are not consistently used, but can be harmful if HIV-negative MSM who consistently use condoms shift to using serosorting as their primary prevention strategy. The protective effects of serosorting and ways in which MSM are operationalizing serosorting are becoming more complex as additional factors affecting risk are considered (e.g., durable viral load suppression, PrEP). Understanding the potential risk and benefit of serosorting continues to be important, particularly within the context of other prevention strategies. © 2017, Springer Science+Business Media New York (outside the USA). Article	2017	Puri A.; Sivaraman A.; Zhang W.; Cheh M.R.; Banga A.K.	Expanding the domain of drug delivery for HIV prevention: Exploration of the transdermal route	Critical Reviews in Therapeutic Drug Carrier Systems	-	-	-	7434863	10.1615/CritRevTherDrugCarrierSyst.2017020147	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85033847256&doi=10.1615%2FCritRevTherDrugCarrierSyst.2017020147&partnerID=40&md5=8c6dfc3ab7fa2ba814ccf88a84b4ba8a	Constant efforts for HIV prevention using antiretroviral drugs, pre- and postexposure prophylactic agents, and microbicides are being made by researchers. Drug-delivery systems such as oral tablets and orally dispersible vaginal gels are short acting, require daily application, and are associated with user adherence issues, whereas the orally independent systems such as injectables and biodegradable implants are long acting, lasting several months, during which time the termination of prophylaxis is impractical in case of adverse effects. An effective drug-delivery system to be used as an intermediate duration, if available, would be an attractive alternative option for users in terms of adherence. Transdermal delivery systems, overcoming most of the limitations of the other routes of administration and aiming to provide sustained delivery of drugs through skin, may be explored for HIV prevention. Future and physical enhancement techniques may be deployed synergistically to improve the transdermal delivery of HIV preventive agents. © 2017 Begell House, Inc. Article	2017	Rajan, Sudhinaraset, Jamuar, Fuller, Sarah, Johnson, Cheryl, Sanders, Eduard J. Sted, Omar, Sanz-Citron, Aster, Pilcher, Christopher D, Fraser, Christopher, Cohen, Myron S, Vitoria, Marco, Doherty, Meg, Tucker, Joseph D	Implementation of long-acting antiretroviral nanoformulation pharmacokinetics using experimental and computational methods	University of Liverpool	-	NA	10.17638/03087936	https://doi.org/10.17638/03087936https://livepoolnsh.sharepoint.com/sites/pure/Deposits/Forms/AllItems.aspx?RootFolder=%2Fsites%2Fpure%2FDeposits%2Fliverpool.ac.uk-50079361-1200949200_Jan2017.pdf	Antiretrovirals (ARVs) can find clinical application for both treatment and prevention of HIV infection. Pre-exposure prophylaxis (PrEP) strategies have been recently introduced to protect individuals who are at high risk of acquiring HIV infection. The majority of existing ARVs are oral formulations which necessitate lifelong daily dosing and suboptimal adherence to this dosing regimen could result in development of viral resistance against treatment. Long-acting injectable (LAI) nanoformulations administered either intramuscularly or subcutaneously could be a valuable pharmacological option. LAIs could potentially simplify dosing regimen, reducing the total amount of drug consumed thus reducing the oral cost of treatment/PrEP and most importantly addressing the problem of suboptimal adherence. The development of novel LAI therapies is complicated by several pharmacological factors including ARV pharmacokinetics and compatibility with existing formulation strategies. The overall aim of this thesis was to investigate physiologically relevant in vitro and in silico biopharmaceutical tools to enable the quantitative prediction of in vivo performance of LAI nanoformulations. The successful development of LAI formulations would be significantly expedited if the in vivo performance could be predicted from in vitro experiments. Physiologically based pharmacokinetic (PBPK) modelling represents the mathematical description of anatomical, physiological and molecular processes that define pharmacokinetics in humans. In the recent past, PBPK models have been developed for several disease areas to simulate pharmacokinetics in humans, which currently play an active role in the design of clinical trials and regulatory approvals. In Chapter 2, human adult PBPK models have been developed and validated against clinically available pharmacokinetic data of oral formulations for the adult ARVs. These validated models were then used to identify theoretical optimal dose and release rates of LAI formulations for weekly and monthly administration. Clinical studies in paediatric patients encounters ethical issues and possesses concerns during dose optimization. In Chapter 3 and 4, PBPK models have been developed and validated for children and adolescents for existing LAI formulations of cabotegravir and rilpivirine. Doses were optimized for monthly administration such that the plasma concentrations stay over the assumed target concentrations, for paediatric population according to different weight groups recommended by FDA guidelines. In Chapter 5, a minimal physiologically based pharmacokinetic (mPBPK) model was developed and validated against in vivo data of LAI nanosuspensions of CAB and RPV were developed. The in vitro release rates were correlated with clinical release rates to obtain a mathematical equation describing the in vitro–in vivo correlation (IVIVC) in Chapter 6. Novel computational and experimental methods to support the development and optimization of LAI formulations are required. These findings represent valuable applications of novel methods to simulate and characterise the pharmacology of LAI formulations. The reported findings could help simplify ARV dosing strategies by providing an initial dosing guideline for clinical trials in humans. This approach could improve therapy thus addressing the problem of suboptimal adherence and reduce cost of overall treatment. PBPK models and IVIVE could be an innovative strategy to evaluate drug pharmacokinetics in humans and optimise dose and release rates of novel formulations for LAI HIV therapy. Article	2017	Rambharose, Sanjeev; Kalhapure, Rahul S.; Govender, Thirumala	Nanoenvelged using a Sucpholess heterolipid as a novel approach to enhance transdermal permeation of tenofovir.	Colloids and Surfaces B: Biointerfaces	-	-	-	1873-4367-0927-7765	10.1016/j.colsurfb.2017.03.040	https://pubmed.ncbi.nlm.nih.gov/28343120/	Improvements in permeation enhancement strategies, such as nanoemulsions (NEs) and nanoemulpsh (NEGs), have led to a renewed interest in transdermal drug delivery (TDD). This study aimed to investigate the potential of LLA1H, a novel dendritic permeation enhancer, as an oily phase in the development of a NEG for the TDD of tenofovir (TNF). TNF loaded NEs (TNEs) were prepared and analysed for mean globule diameter (MGD), polydispersity index (PDI), zeta potential (ZP) and morphology. NEGs of the TNEs (TNEGs) were prepared and evaluated for ex vivo TNF transdermal permeation efficacy. The skin integrity before and after the experiments was assessed using histology and transepithelial electrical resistance (TEER). TNEs had a MGD of 120.06±3.35nm, a PDI of 0.192±0.038 and a ZP of -26.03±0.56 mV. Entrapment efficiency (EE) of TNF in the TNEs was >90%. There was no significant change in these properties after incorporating the TNEs into the hydrogel, as NEG. PEG and ZP of TNEGs were found to be 134.13±2.26nm, 0.182±0.026 and -28.9±2.20mV, respectively. Ex vivo permeation studies showed that the TNEG significantly enhanced the TNF permeation by 39.65-fold, with a cumulative amount of 1866.54±108.62μg/cm(2). Histological and TEER measurements showed no significant difference between effects on the skin by TNEGs, indicating that this novel TNEG nanosystem has the potential to	Administration, Cutaneous; Anti-HIV Agents*metabolism; Cells, Electric Impedance; Rats; Rats, Wistar; Histocytochemistry; Nanostructures*chemistry; Nanostructures*chemistry; *Drug Carriers; Permeability; Tenofovir*metabolism; Emulsions; Diffusion Chambers, Culture; Heterolipid; Linolenic acid; Nanomedicine; Nanoparticles; Polyethylene Glycols*chemistry; Skin Absorption*physiology; Skin/anatomy & histology/drug effects*metabolism; Stearic Acids*chemistry; Transdermal permeation enhancer	English	Netherlands	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Clinical
Article	2017	Reisner S.L.; Jadwin-Cakmak L.; White Hughto J.M.; Martinez M.; Salomon L.; Harper G.W.	Characterizing the HIV Prevention and Care Continua in a Sample of Transgender Youth in the U.S.	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1938-8	https://pubmed.ncbi.nlm.nih.gov/28730419/?dopt=Abstract	In the U.S., transgender and other gender minority (TGI) youth are an at-risk group underenrolled in HIV prevention and treatment. This study sought to characterize the HIV prevention and care continua in a diverse sample of 181 sexually-active TG ages 16–24 years (mean age = 20.7 years; 76.8% trans feminine; 69.1% youth of color) recruited July–December 2015 in Boston, MA. Among those living with HIV, of which 71.4% were on antiretroviral therapy (ART) and 55.0% were medication adherent, 65.6% were known to be virally suppressed. In multivariable models, medical gender affirmation was associated with lower odds of viral suppression. Medical gender affirmation and stigma in HIV care were each independently associated with elevated odds of having missed HIV care appointments. Among at-risk TG youth not living with HIV, only 8.2% had accessed pre-exposure prophylaxis (PrEP). Early biobehavioral prevention and treatment interventions are needed for TG youth. © 2017, Springer Science+Business Media, LLC. Article	2017	Rendina, H. Jonathon; Whitfield, Thomas H. F.; Grov, Christian; Starks, Tyrell J.; Parsons, Jeffrey T.	Distinguishing hypothetical willingness from behavioral intentions to initiate HIV pre-exposure prophylaxis (PrEP): Findings from a large cohort of gay and bisexual men in the U.S.	Social Science & Medicine	-	-	-	1873-5347-0277-9536	10.1016/j.socscimed.2016.10.030	https://pubmed.ncbi.nlm.nih.gov/27866750/	RATIONALE: Much of the data on the acceptability of HIV Pre-Exposure Prophylaxis (PrEP) is based on willingness to take PrEP (i.e., hypothetical receptivity) rather than actual intentions (i.e., planned behavioral action) to do so. OBJECTIVE: We sought to examine differences between hypothetical willingness and behavioral intentions to begin PrEP in a national sample of gay and bisexual men (GBM) across the U.S. METHODS: We utilized data collected in 2015 to examine differences between these Use×Beg (42.6% v = 375), Willing but not intending (41.4%, n = 365), and willing and Intending to take PrEP (15.9%, n = 140) in a multivariable, multinomial logistic regression. RESULTS: Men with less education had higher odds of Intending to take PrEP. Compared to Non-users, those who Intended PrEP, relative to those who believed PrEP was at least 90% efficacious had higher odds of Intending to take PrEP. Those who saw themselves as appropriate candidates for PrEP had higher odds of Intending to take PrEP than those who did not see themselves as candidates for PrEP. Those who had Intended to take PrEP had lower odds of condomless sex with serodiscordant partners and lower odds of condom non-use because of perceived sexual pressure by partners was associated with higher odds of Intending to take PrEP. The groups did not differ by risk behavior nor recent STI diagnoses. CONCLUSIONS: Overall, the distinction between willingness and intentions to take PrEP was meaningful and may help explain disparities between PrEP acceptability and uptake. While much of the literature has focused on hypothetical willingness to take PrEP, these results highlight the importance of simultaneously assessing willingness and intentions when examining correspondence with uptake and developing interventions to increase PrEP uptake. Article	2017	Rosser A.E.; Tocco J.U.; Mantell J.E.; Lalani Y.; Gichangi P.; Mavovanire T.B.; Chabeda S.V.; Sandfort T.G.M.	Perspectives on HIV pre-and postexposure prophylaxis (prep and pep) among female and male sex workers in mombasa, kenya: Implications for integrating biomedical prevention into sexual health services	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2017.29.2.141	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85018436748&doi=10.1521%2Faeap.2017.29.2.141&partnerID=40&md5=5c6c5b0da8bd0a3ae1abe1345a1822	Pre- and post-exposure prophylaxis (PrEP and PEP) can reduce the risk of HIV acquisition, yet often are inaccessible to sex workers and underutilized by most vulnerable populations, including sex workers in sub-Saharan Africa. We conducted in-depth interviews with 30 female and male sex workers in Mombasa, Kenya, to explore perceptions and acceptability of PrEP and PEP over time, although willingness to use both was high, participants felt PrEP would be unpersuasive and give added protection against infection, although some expressed concerns about side effects. Despite PEP's availability, few knew about it and even fewer had used it, but most who had would use it again. Sex workers valued confidentiality, privacy, trustworthiness, and convenient location in health services and wanted thorough HIV/STI assessments. These findings suggest the importance of situating PrEP and PEP within sex worker–friendly health services and conducting outreach to promote biomedical prevention methods for Kenyan sex workers. © 2017 The Guilford Press	NA	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2017	Reynders, Thijs; Hoornenborg, Ekke; Vuylsteke, Bea; Westers, Kristien; Lage, Marie	Pre-exposure prophylaxis (PrEP) for men who have sex with men in Europe: review of evidence for a much needed prevention tool	Sexually Transmitted Infections	-	-	-	13684973	10.1136/sextrans-2016-052699	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-prep-men-who-have-sex/docview/1920589851/se-2?accountid=9113	In many Western countries with good coverage of antiretroviral treatment (ART) programmes the annual number of HIV infections is still high and not (yet) declining among men who have sex with men (MSM). This might indicate that antiretroviral-treatment roll-out alone will not turn around the course of the epidemic and that new, additional tools are needed. Antiretrovirals used as prevention tools for people not yet infected with HIV, such as pre-exposure prophylaxis (PrEP) could be such important additional tools. PrEP is now top of European HIV prevention agenda. This review looks at the efficacy of antiretrovirals before, during and after (periods of) sexual exposure to HIV. In the review, we will focus on PrEP as a new prevention tool for MSM at high risk in Europe, including its evidence for effectiveness, challenges for implementation, ongoing European demonstration studies, as well as how PrEP relates to other existing prevention tools. In light of European Medicines Agency's recent recommendation for approval of PrEP we briefly review the potential implications. Article	2017	Ridder S.A.; Hosuk M.; Banerjee G.; Premraja A.; Tutshana B.O.; Pather A.; Siva S.; Jeyaseelan N.; Nair G.; Selepe P.; Kalwoga S.; Palanee-Phillips T.; Panchia R.; Mhlanga F.; Levy L.; Lissat E.; Patterson K.; Eltanir Y.; Bulos J.	HIV disease progression among women following seroconversion during a tenofovir-based HIV prevention trial	PLOS One	-	-	-	19526203	10.1371/journal.pone.0170594	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021644648&doi=10.1371%2Fjournal.pone.0170594&partnerID=40&md5=e916c47a51c4d8fd5f9957c5c0fbc8	Background Little is known regarding HIV disease outcomes among individuals who become infected with HIV while receiving antiretroviral medications for prevention. We compared HIV disease parameters among women who seroconverted while receiving tenofovir-containing oral or vaginal pre-exposure prophylaxis (PrEP) to placebo. Methods Participants with HIV seroconversion in a randomized placebo-controlled trial of oral tenofovir, oral tenofovir/emtricitabine, and vaginal tenofovir gel (MTN-003) were followed in a longitudinal cohort study (MTN-015). The effect of oral and vaginal tenofovir-containing PrEP on HIV disease parameters was assessed by comparing seroconverters who received tenofovir to those who received placebo. Results Among 2,120 participants enrolled in MTN-003, 224 seroconverted with HIV, and 214 were eligible for MTN-015. Results A total of 224 participants were included in the seroconverter cohort, 106 in the tenofovir arm, 93% from Africa and 94% male. C +mn. No differences in HIV RNA at steady state or the trajectory over 12 months were observed for each sex arm compared to placebo; tenofovir gel recipients had higher CD4+T cell counts (722 vs 596 cells/mm3; p = 0.02) at 96 days after estimated HIV seroconversion and higher average rates of change over 12 months compared to placebo (-141 vs +52 cells/mm3/per year; p = 0.08). With a median follow-up of 31 months, no significant differences were observed for time to CD4+T cell count 350 cells/mm3, or the composite endpoint of CD4+T cells 350 cells/mm3, initiation of antiretroviral therapy or death for each active arm compared to placebo. Additionally, there were no significant differences in the HIV RNA or CD4+ T cell counts at baseline, the change in count from baseline to 12 months, or any disease progression outcomes among participants with oral drug detected and no oral drug detected compared to placebo. Conclusions No clinically significant differences in HIV seroconversion outcomes were observed among women randomized to tenofovir-containing oral or vaginal PrEP regimens, however low overall adherence limits the generalizability of these findings. © This is an open access article, free of all copyright, and may be freely reproduced, distributed, transmitted, modified, built upon, or otherwise used by anyone for any lawful purpose. Article	2017	Schumacher, CM; Baechus, S; Chandran, A; Kingon, Y; Fields, E; Bandermose, K; Munro, R; Chaulk, P; Jennings, JM	IDENTIFYING HEALTH CARE SETTINGS FOR PREP DELIVERY TO MSM AT HIGH RISK FOR HIV ACQUISITION	Sexually Transmitted Infections	-	-	-	1368-4973	10.1136/sextrans-2017-053264.282	https://sti.bmj.com/content/93/Suppl_2/A110.1	Abstract Introduction Syphilis rates among MSM are increasing sharply in urban areas across the U.S. MSM with syphilis are at high risk for acquiring HIV, and may be an important subgroup to increase awareness and delivery of pre-exposure prophylaxis (PrEP). Key, however, is identifying access points to this population. Our objective was to determine health centers and sites settings where syphilis positive and HIV negative (vs. HIV positive) MSM were diagnosed to prioritize and tailor to settings for PrEP delivery. Setting: A mid-Atlantic U.S. city which has seen a 102% increase in early (primary, secondary and early latent) syphilis among MSM from 2009-2015. Methods We analyzed routinely collected public health surveillance data on MSM diagnosed with early syphilis reported to a city health department between 2009–2015. We compared diagnosing provider information by HIV status overall and in 2015 using Chi-squared tests. Results Of the 1,495 MSM diagnosed with early syphilis between 2009–2015, the majority was aged ≤ 25 years (75%), African American (80%) and HIV co-infected (47%). Overall, 52% were diagnosed in private health care settings, and 25% were diagnosed in publically funded sexually transmitted infection (STI) clinics. Early syphilis positive/HIV negative MSM were more likely than HIV positive MSM to receive a syphilis diagnosis at STI clinics (38% vs. 19% p=<0.0001) and Emergency Departments (ED) (10% vs. 4% p=0.0001), and less likely to be diagnosed at private practices (36% vs. 66%, p=<0.0001). Conclusion EDs/CCs and are important access points for MSM at high risk for HIV but rates may change over time. Efforts by the city health department to increase PrEP delivery at these sites are being initiated. Article	2017	Schwartz J.; Grimm J.	Online News Coverage of Preexposure Prophylaxis	Communication Research Reports	-	-	-	8824096	10.1080/08824096.2017.1285758	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85014529278&doi=10.1080%2F08824096.2017.1285758&partnerID=40&md5=5d67ba3e97dc2b06a29b5e02a1f5f286	Human immunodeficiency virus, or HIV continues to be a serious issue, especially for men who have sex with men (MSM). A new means of HIV prevention, called preexposure prophylaxis (PrEP), significantly reduces the chance of HIV infection. However, adoption of the drug has been slow. In this study, a content analysis of 234 online news articles about PrEP from popular U.S. news Web sites was conducted, focusing on how articles were framed in terms of benefits to PrEP, barriers to PrEP, the severity of HIV, and the susceptibility of MSM to HIV. Results showed that coverage contained conflicting information about PrEP and failed to cast HIV as a serious problem. © 2017 Eastern Communication Association. Article	2017	Schwartz S.R.; Bassett J.; Holmes C.B.; Yende N.; Phofa R.; Sanne I.; Van Rie A.	Client uptake of safer conception strategies: Implementation outcomes from the Sakh'umndeni safer conception clinic in South Africa	Journal of the International AIDS Society	-	-	-	-	17582652	10.7448/IAS.20.2.21291	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85016589558&doi=10.7448%2fIAS.20.2.21291&partnerID=40&md5=782260cd4058d553d9e3b585ace31053	Introduction: Implementation of safer conception services for HIV-affected couples within primary healthcare clinics in resource-limited settings remains limited. We review service utilization and safer conception strategy uptake during the first three years of Sakh'umndeni, which is a safer conception clinic in South Africa. Methods: Sakh'umndeni is located at Witkoppen Health and Welfare Centre, a high-volume primary healthcare clinic in northern Johannesburg. Men and women desiring to conceive in less than or equal to six months and in relationships in which one or both partners are living with HIV are eligible for safer conception services. Clients receive a baseline health assessment and counselling around periconception HIV risk reduction strategies and choose which strategies they plan to use. Clients are followed-up monthly. We describe client service utilization and uptake and continuation of safer conception methods. Factors associated with male partner attendance are assessed using robust Poisson regression. Results: Overall 440 individuals utilized the service including 157 couples in which both partners attended (55%) and 126 unaccompanied female partners. Over half of the couples (55%) represented were in serodiscordant/unknown status relationships. Higher economic status and HIV-negative status of the women increased male partner involvement, while HIV-negative status of the men decreased male involvement. Regarding safer conception strategies, uptake of antiretroviral therapy initiation (90%), vaginal self-insemination among partnerships with HIV-negative men (75%) and timed condomless intercourse strategies (48%) were variable, but generally high. Overall uptake of pre-exposure prophylaxis (PrEP) was 23% and was lower among HIV-negative men than women (7% vs. 44%, p < 0.001). Male medical circumcision (MMC) was used by 28% of HIV-negative men. Over 80% of clients took up at least one recommended safer conception strategy. Continuation of selected strategies over attempted conception attempts was >60%. Conclusions: Safer conception strategies are generally used by clients per recommendations. High uptake of strategies suggests that the proposed combination prevention methods are acceptable to clients and appropriate for scale-up; however, low uptake of PrEP and MMC among HIV-negative men needs improvement. Targeted community-based efforts to reach men unlinked to safer conception services are needed, alongside streamlined approaches for service scale-up within existing HIV and non-HIV service delivery platforms. © 2017 Schwartz SR et al; licensee International AIDS Society. Article	2017	Schwartz, Joseph; Grimm, Josh	PrEP on Twitter: Information, Barriers, and Stigma.	Health Communication	-	-	-	-	1532-7027	10.1080/10410236.2016.1140271	https://dx.doi.org/10.1080/10410236.2016.1140271	On May 14, 2014 the Centers for Disease Control and Prevention (CDC) endorsed the drug Truvada as an HIV preventative, called pre-exposure prophylaxis (PrEP). PrEP has been shown to dramatically reduce the risk of HIV infection, but its rate of adoption has been slow, and discourse surrounding it has been marked by stigma and uncertainty. The purpose of this study was to investigate how PrEP was discussed on Twitter. Our analysis focused on barriers to PrEP adoption and stigmatization of PrEP users. We analyzed a random sample of 1,093 top tweets about PrEP posted to Twitter a year before and a year after the CDC's endorsement. Our results showed that tweets likely reinforced uncertainty about barriers to PrEP adoption and that users employed Twitter's functionality to counter stigmatizing narratives about PrEP. We suggest that our findings illuminate both the limitations and strengths of Twitter as a mechanism for health promotion. Article	2017	Seidman, DL; Weber, S; Cohan, D	Offering pre-exposure prophylaxis for HIV prevention to pregnant and postpartum women: a clinical approach	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.20.2.21295	https://pubmed.ncbi.nlm.nih.gov/28361503/	Introduction: HIV prevention during pregnancy and lactation is critical for both maternal and child health. Pregnancy provides a critical opportunity for clinicians to elicit women's vulnerabilities to HIV and offer HIV testing, treatment and referral and/or comprehensive HIV prevention options for the current pregnancy, the postpartum period and safer conception options for future pregnancies. In this commentary, we review the safety of oral pre-exposure prophylaxis with tenofovir/emtricitabine in pregnant and lactating women and suggest opportunities to identify pregnant and postpartum women at substantial risk of HIV. We then describe a clinical approach to caring for women who both choose and decline pre-exposure prophylaxis during pregnancy and postpartum, highlighting areas for future research. Discussion: Evidence suggests that pre-exposure prophylaxis with tenofovir/emtricitabine is safe in pregnancy and lactation. Identifying women vulnerable to HIV and eligible for pre-exposure prophylaxis is challenging in light of the myriad of individual, community, and structural forces impacting HIV acquisition. Validated risk calculators exist for specific populations but have not been used to screen and offer HIV prevention methods. Partner testing and engagement of men living with HIV are additional means of reaching at-risk women. However, women's vulnerabilities to HIV change over time. Combining screening for HIV vulnerability with HIV and/or STI testing at standard intervals during pregnancy is a practical way to prompt providers to incorporate HIV screening and prevention counselling. We suggest using shared decision-making to offer women pre-exposure prophylaxis as one of multiple HIV prevention strategies during pregnancy and postpartum, facilitating open conversations about HIV vulnerabilities, preferences about HIV prevention strategies, and choosing a method that best meets the needs of each woman. Conclusion: Growing evidence suggests that pre-exposure prophylaxis with tenofovir/emtricitabine during pregnancy and lactation is safe and effective. Shared decision-making provides one approach to identify at-risk women and offers pre-exposure prophylaxis but requires implementation research in diverse clinical settings. Including pregnant and breastfeeding women in future HIV prevention research is critical for the creation of evidence-driven public health policies and clinical guidelines. Article	2017	Shacklett, Barbara L; Derdeyn, Cynthia A; Folayan, Morenike Oluwatoyin; Landovitz, Raphael J; Anthony, Colin; Behrens, Anna-Janina; Hope, Thomas J; Landais, Elise; Leal, Lorna; Marrazzo, Jeanne M; Morris, Lynn; Mugo, Nelly; Ngure, Kenneth; Noseda, Veronica; Ranasinghe, Srinika; Tully, Damien C; Voronin, Yegor; Warren, Mitchell; Wibmer, Constantinos Kurt; Xie, Irene Y; Scarlatti, Gabriella; Thyagarajan, Bargavi	HIVR4P 2016, Partnering for Prevention: Conference Summary and Highlights.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405	10.1089/AID.2017.0125	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5564036	HIV Research for Prevention: AIDS Vaccine, Microbicide, and ARV-based Prevention Science (HIVR4P) was built on a growing consensus that effective HIV prevention requires a combination of approaches and that understanding, analyzing, and debating the cross-cutting issues that impact prevention research are all essential to combat the global HIV/AIDS epidemic. To that end, the biennial HIVR4P conference is dedicated to all biomedical HIV prevention research approaches, including HIV vaccines, microbicides, pre-exposure prophylaxis, and treatment as prevention. The HIVR4P 2016 conference was held in Chicago, Illinois (USA), on October 17-21, and included more than 700 scientific presentations and 21 satellite sessions covering the latest and most promising advances across the HIV prevention research field. The theme "Partnering for Prevention" represented the conference's commitment to breaking down silos between research disciplines as well as between researchers, program developers, care providers, advocates, communities, and funders. Delegates spanning 42 countries attended the conference. One-third of those in attendance were early career investigators, which reflects a firm commitment to emerging researchers and ultimately to the goal of developing a sustainable scientific enterprise well into the future. This article presents a concise summary of highlights from the conference. For a more detailed account, one may find full abstracts, daily summaries, and webcasts on the conference website at hivr4p.org. Article	2017	Shadianloo, S	HUMAN IMMUNODEFICIENCY VIRUS (HIV) PREVENTION AND USE OF PRE-EXPOSURE PROPHYLAXIS (PREP) IN ADOLESCENTS	Journal of the American Academy of Child and Adolescent Psychiatry	-	-	-	-	0890-8567	10.1542/pir.2020-002048	https://pubmed.ncbi.nlm.nih.gov/34970687/	Human immunodeficiency virus (HIV) prevention holds the promise of decreasing the burden of HIV infections worldwide. Access to HIV prevention services, including preexposure prophylaxis (PrEP), is a key strategy in reducing HIV transmission, but it continues to be underused. PrEP, a once-daily medication for HIV prevention, is approved for adolescents. A pediatrician's role is critical in identifying and increasing access for adolescents and young adults to PrEP services and reducing HIV acquisition in youth.	28-36	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2017	Shaver J.; Sullivan P.; Siegler A.; de Voux A.; Phaswana-Mafuya N.; Bekker L.-G.; Baral S.D.; Wirtz A.L.; Beyrer C.; Brown B.; Stephenson R.	Comparing Provider and Client Preferences for HIV Prevention Services in South Africa among Men Who Have Sex with Men	Journal of the International Association of Physicians in AIDS Care	-	-	-	-	23259574	10.1177/2325957417736611	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038416575&doi=10.1177%2f2325957417736611&partnerID=40&md5=09a9380b801726c9fbf3b6181aead23c	Combination prevention efforts are now recommended toward reducing HIV incidence among men who have sex with men (MSM). Understanding the perceptions of both MSM and service providers is critical to informing the development of prevention packages and ultimately improving intervention effectiveness. This study assessed the preferences of MSM and health service providers in the administration of HIV-prevention efforts. Qualitative data were gathered from a series of separate MSM and health care provider focus groups in 2 South African cities. Participants discussed HIV-prevention services and MSM client experiences within South Africa and identified the 3 most important client characteristics and 3 most important HIV-prevention services for MSM clients. Priorities indicated by both MSM and health care providers were confidentiality of visit, friendly staff, and condoms, while discrepancies existed between MSM and providers regarding provider consistency and the provision of pre-exposure prophylaxis/post-exposure prophylaxis (PrEP/PEP) and lubricant as prevention methods. Effective interventions must address these discrepancies through the design of intervention and provider training to optimally accommodate MSM. © 2017, © The Author(s) 2017. Article	2017	Shieh, Eugenie C; Weld, Ethel D; Fuchs, Edward J; Hiruy, Hiwot; Buckheit, Karen W; Buckheit, Robert W; Breakey, Jennifer; Hendrix, Craig W	Lubricant Provides Poor Rectal Mucosal HIV Coverage.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405	10.1089/AID.2016.0318	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5564025	Given the rising HIV incidence in men who have sex with men (MSM) despite repeatedly proven effectiveness of oral HIV pre-exposure prophylaxis, behaviorally congruent periodic dosing strategies, such as dosing microbicides as lubricants, are now in demand. Rectal microbicide gel studies largely administer gels using vaginal applicators, which have not been well received and do not mimic lubricant use. We compared rectal gel manually dosed as lubricant with applicator dosing in five healthy, HIV-negative MSM who received 10 or 3.5 ml of 99mTc-DTPA-radiolabeled hydroxyethyl cellulose universal placebo gel intrarectally. After washout, participants received 10 ml of radiolabeled Wet® Original® lubricant to apply to the anus with fingers and/or a phallus in a manner typical of sexual lubricant use with a partner, followed by simulated receptive anal intercourse. Single-photon emission computed tomography was performed 4 h after each gel administration. Manual dosing was associated with more variable rectosigmoid distribution, 4.4-15.3 cm from the anorectal junction, compared with more uniform distribution, 5.9-7.4 and 5.3-7.6 cm after 10 and 3.5 ml applicator dosing, respectively. A significantly smaller fraction of the initial 10 ml dose was retained within the colon after manual dosing, 3.4%, compared with 94.9% and 88.4% after 10 and 3.5 ml applicator dosing, respectively (both p < .001). Manual dosing of a sexual lubricant delivered a small, variable fraction of the dose with variable rectosigmoid distribution compared with applicator dosing. These results raise concern that dosing a rectal microbicide gel as a sexual lubricant may not provide adequate or predictable mucosal coverage for HIV protection.	gastrointestinal distribution; human immunodeficiency virus; microbicide; pharmacokinetics; pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Shrestha R.; Altice F.; Karki P.; Copenhaver M.	Developing an integrated, brief biobehavioral HIV prevention intervention for high-risk drug users in treatment: The process and outcome of formative research	Frontiers in Immunology	-	-	-	-	16643224	10.3389/fimmu.2017.00561	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85019982768&doi=10.3389%2ffimmu.2017.00561&partnerID=40&md5=82a543fd5598c32f9a71a01df5b71db1	To date, HIV prevention efforts have largely relied on singular strategies (e.g., behavioral or biomedical approaches alone) with modest HIV risk-reduction outcomes for people who use drugs (PWUD), many of whom experience a wide range of neurocognitive impairments (NCI). We report on the process and outcome of our formative research aimed at developing an integrated biobehavioral approach that incorporates innovative strategies to address the HIV prevention and cognitive needs of high-risk PWUD in drug treatment. Our formative work involved first adapting an evidence-based behavioral intervention-guided by the Assessment-Decision-Administration-Production-Topical experts-Integration-Training-Testing model-and then combining the behavioral intervention with an evidence-based biomedical intervention for implementation among the target population. This process involved eliciting data through structured focus groups (FGs) with key stakeholders-members of the target population (n = 20) and treatment providers (n = 10). Analysis of FG data followed a thematic analysis approach utilizing several qualitative data analysis techniques, including inductive analysis and cross-case analysis. Based on all information, we integrated the adapted community-friendly health recovery program-a brief evidence-based HIV prevention behavioral intervention-with the evidence-based biomedical component i.e., preexposure prophylaxis (PrEP), an approach that incorporates innovative strategies to accommodate individuals with NCI. This combination approach-now called the biobehavioral community-friendly health recovery program-is designed to address HIV-related risk behaviors and PrEP uptake and adherence as experienced by many PWUD in treatment. This study provides a complete example of the process of selecting, adapting, and integrating the evidence-based interventions-taking into account both empirical evidence and input from target population members and target organization stakeholders. The resultant brief evidence-based biobehavioral approach could significantly advance primary prevention science by cost-effectively optimizing PrEP adherence and HIV risk reduction within common drug treatment settings. © 2017 Shrestha, Altice, Karki and Copenhaver. Article	2017	Shrestha R.; Karki P.; Altice F.L.; Huedo-Medina T.B.; Meyer J.P.; Madden L.; Copenhaver M.	Correlates of willingness to initiate pre-exposure prophylaxis and anticipation of practicing safer drug- and sex-related behaviors among high-risk drug users on methadone treatment	Drug and Alcohol Dependence	-	-	-	-	3768716	10.1016/j.drugalcdep.2016.12.023	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85013176700&doi=10.1016%2fj.drugalcdep.2016.12.023&partnerID=40&md5=797e4117fe3f0caabeca1fc6260e3fc6	Background Although people who use drugs (PWUD) are key populations recommended to receive pre-exposure prophylaxis (PrEP) to prevent HIV, few data are available to guide PrEP delivery in this underserved group. We therefore examined the willingness to initiate PrEP and the anticipation of HIV risk reduction while on PrEP among high-risk PWUD. Methods In a cross-sectional study of 400 HIV-negative, opioid dependent persons enrolled in a methadone program and reporting recent risk behaviors, we examined independent correlates of being willing to initiate PrEP. Results While only 72 (18%) were aware of PrEP, after being given a description of it, 251 (62.7%) were willing to initiate PrEP. This outcome was associated with having neurocognitive impairment (aOR = 3.184, p = 0.004) and higher perceived HIV risk (aOR = 8.044, p < 0.001). Among those willing to initiate PrEP, only 12.5% and 28.2%, respectively, indicated that they would always use condoms and not share injection equipment while on PrEP. Consistent condom use was associated with higher income (aOR = 8.315, p = 0.016), always using condoms with casual partners (aOR = 6.597, p = 0.001), and inversely associated with ongoing drug injection (aOR = 0.323, p = 0.027). Consistent safe injection, however, was inversely associated with age (aOR = 0.948, p = 0.035), ongoing drug injection (aOR = 0.342, p < 0.001), and perceived HIV risk (aOR = 0.191, p = 0.019). Conclusions While willingness to initiate PrEP was high and correlated with being at elevated risk for HIV, anticipated higher risk behaviors in this group even while on PrEP suggests that the next generation of HIV prevention approaches may need to combine biomedical and behavioral components to sustain HIV risk reduction over time. © 2017 Elsevier B.V. Article	2017	Shrestha R.; Karki P.; Huedo-Medina T.B.; Copenhaver M.	Intent to Use Preexposure Prophylaxis (PrEP), HIV Risk Behaviors, and Self-Report Neurocognitive Symptoms by High-Risk Drug Users: A Mediation Analysis	Journal of the Association of Nurses in AIDS Care	-	-	-	-	10553290	10.1016/j.jana.2017.04.005	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85018976433&doi=10.1016%2fj.jana.2017.04.005&partnerID=40&md5=a11d6440743ae84e1a9c68ca2e23b5be	Neurocognitive impairment (NCI) and HIV risk are significant correlates of intent to use preexposure prophylaxis (PrEP). The extent to which similar outcomes could occur when these factors operate together, particularly for people who use drugs (PWUD), remains an important unanswered question. We therefore sought evidence that HIV risk behavior mediated the relationship between NCI and intent to use PrEP in high-risk PWUD in treatment. HIV-uninfected, methadone-maintained people who reported HIV-risk behaviors were enrolled (n = 400). Variables of interest (NCI, HIV risk behaviors, intent to use PrEP) were assessed using audio computer-assisted self-interview. We found preliminary evidence of indirect effect of HIV risk behaviors, such that NCI had an increased impact on intent to use PrEP via HIV risk behaviors. As a result of having this information, clinicians and researchers will be better equipped for evidence-informed targeting and dissemination efforts to optimize PrEP uptake by this underserved population. © 2017 Association of Nurses in AIDS Care	HIV prevention; HIV risk behaviors; methadone maintenance treatment; neurocognitive impairment; people who use drugs; preexposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Shrestha, Roman; Altice, Frederick L.; Huedo-Medina, Tania B.; Karki, Pramila; Copenhaver, Michael	Willingness to Use Pre-Exposure Prophylaxis (PrEP): An Empirical Test of the Information-Motivation-Behavioral Skills (IMB) Model among High-Risk Drug Users in Treatment.	AIDS and Behavior	-	-	-	-	1573-3254 1090-7165	10.1007/s10461-016-1650-0	https://pubmed.ncbi.nlm.nih.gov/27990587/	Evidence from recent pre-exposure prophylaxis (PrEP) trials has demonstrated its safety and efficacy in significantly reducing the risk of HIV acquisition for those who are at considerable risk of acquiring HIV infection. With a rapid increase in the amount of research on the efficacy of PrEP for HIV prevention, complementary research on the willingness to use PrEP has grown, especially among MSM, but limited research has been focused among people who use drugs (PWUD). As part of the formative process, we utilized the information-motivation-behavioral skills (IMB) model of health behavior change to characterize and guide intervention development for promoting willingness to use PrEP among high-risk PWUD. The analysis included 400 HIV-negative high-risk PWUD enrolled in a community-based methadone maintenance treatment who reported drug- and/or sex-related HIV risk behaviors in the past 6-months. Analyses revealed support for the IMB model as PrEP-related behavioral skills were found to mediate the influence of PrEP-related information and motivation on willingness to use PrEP. The results provide evidence as to the utility of the IMB model to increase willingness to use PrEP among high-risk PWUD. It therefore makes an important contribution to our understanding of the applicability of theoretically-grounded models of willingness to use PrEP among high-risk PWUD, who are one of the key risk populations who could benefit from the use of PrEP. Article	2017	Siegler, Aaron J; Wirtz, Susan; Weber, Shannon; Sullivan, Patrick S	Developing a Web-Based Geolocated Directory of HIV Pre-Exposure Prophylaxis-Providing Clinics: The PrEP Locator Protocol and Operating Procedures.	JMIR Public Health and Surveillance	-	-	-	-	2369-2960	10.2196/publichealth.7902	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5607436	BACKGROUND: Human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) is highly effective in preventing HIV transmission, yet patients interested in learning more about PrEP or in getting a PrEP prescription may not be able to find local medical providers willing to prescribe PrEP. OBJECTIVE: We sought to create a national database of PrEP-providing clinics to allow for patients to have access to a unified, vetted source of PrEP providers in an easily accessible database. METHODS: To develop the protocol and operating procedures for the PrEP Locator, we conducted a series of 7 key informant interviews with experts who had organized PrEP or other HIV service directories. We convened an external advisory committee and a collaborators board to gain expert and community-situated perspectives. RESULTS: At its public release in September 2016, the database included 1,272 PrEP-providing clinics, including clinics in all 50 states and in Puerto Rico. Web searches, referrals, and outreach to state health departments identified 58 unique lists of PrEP-providing clinics, with 33 from state health departments, 6 from government localities, 2 from professional medical organizations, and 19 from nongovernmental organizations. Out of the 2,420 clinics identified from the lists and Web searches, we removed 798 as duplicate entries, and we determined that 350 were ineligible for listing. The most common reasons for ineligibility were not having the appropriate medical licensure to prescribe PrEP (67/350) or not prescribing PrEP, based on self-report (192/350). Key informant interviews shaped important protocol decisions, such as listing clinics instead of individual clinicians as the primary data element and streamlining data collection to facilitate scalability. We developed a Web interface to provide public access to the data, with geolocated data display, search filter functionality, a webform for public suggestions of new clinics, and a publicly available directory Web tool that can be embedded in websites. In the 6 months following release, preplocator.org and hosting websites had received over 35,000 unique views and 300 clinic additions, and 5 websites had initiated hosting of the widget. CONCLUSIONS: Directories exist for many preventive and treatment services. As new medical applications become available, there will be a corresponding need to develop new directories for service provision. Geolocated directories can assist patients in accessing care and have the potential to increase demand for and access to newer, more efficacious medical interventions. Early choices in the development of service directories have long-lasting impact, because once data collection begins, it can be challenging to reverse course. The PrEP Locator protocol may inform early decisions in the development of future service directories. Additionally, the case study on developing the PrEP Locator demonstrates the importance of formative work in identifying service-specific factors that can guide decisions on directory development. Article	2017	Silapaswan, Andrew; Krakower, Douglas; Mayer, Kenneth H	Pre-Exposure Prophylaxis: A Narrative Review of Provider Behavior and Interventions to Increase PrEP Implementation in Primary Care	Journal of General Internal Medicine	-	-	-	-	8848734	10.1007/s11606-016-3899-4	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-narrative-review/docview/2001388001/se-2?accountid=8113	Since FDA approval of HIV pre-exposure prophylaxis (PrEP) for HIV prevention, attention has been focused on PrEP implementation. The CDC estimates that 1.2 million U.S. adults might benefit from PrEP, but only a minority are using PrEP, so there is a significant unmet need to increase access for those at risk for HIV. Given the large numbers of individuals who have indications for PrEP, there are not enough practicing specialists to meet the growing need for providers trained in providing PrEP. Moreover, since PrEP is a preventive intervention for otherwise healthy individuals, primary care providers (PCPs) should be primary prescribers of PrEP. There are important clinical considerations that providers should take into account when planning to prescribe PrEP, which are highlighted in the clinical case discussed. A growing body of research also suggests that some providers may be cautious about prescribing PrEP because of concerns regarding its "real-world" effectiveness, anticipated unintended consequences associated with its use, and ambiguity as to who should prescribe it. This review summarizes findings from studies that have assessed prescriber behavior regarding provision of PrEP, and offers recommendations on how to optimize PrEP implementation in primary care settings. Development and dissemination of educational interventions for PCPs and potential PrEP users are needed, including improved methods to assist clinicians in identifying appropriate PrEP candidates, and programs to promote medication adherence and access to social and behavioral health services. PCPs are well-positioned to prescribe PrEP and coordinate health-related services to improve the sexual health of their patients, but tailored educational programs are needed. Article	2017	Simpson L.; Gumel A.B.	Mathematical assessment of the role of pre-exposure prophylaxis on HIV transmission dynamics	Applied Mathematics and Computation	-	-	-	-	963003	10.1016/j.amc.2016.07.043	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84983786170&doi=10.1016%2fj.amc.2016.07.043&partnerID=40&md5=3613beaeab4730c1f47b7e143dc99651	A new deterministic model for HIV/AIDS that incorporates pre-exposure prophylaxis (PrEP) is designed and used to assess the population-level impact of the use of PrEP on the transmission dynamics of the disease within an MSM population. Conditions for the effective control (or elimination) and persistence of HIV/AIDS in the MSM population are determined by rigorously analyzing this model. Uncertainty and sensitivity analysis is carried out, using data relevant to HIV transmission dynamics in the MSM community in the U.S. State of Minnesota, to determine the effect of the uncertainties in the parameter values on the outcome (response) variable (the associated reproduction number) and to identify the parameters that have the most effect on the disease transmission dynamics. Numerical simulations show that, with the current rate of administration of antiretroviral treatment (to HIV-infected individuals), HIV burden decreases with increasing PrEP coverage. Furthermore, for this setting, this study suggests that HIV can be effectively controlled in the MSM population if, in addition to the current rate of administration of anti-retroviral therapy in the community, at least 61–77% (with mean of about 70%) of the susceptible members of the MSM community are on PrEP (adjusted by PrEP efficacy). © 2016 Elsevier Inc. Article	2017	Sin How Lim; Gitau Mburu; Bourne, Adam; Pang, Joselyn; Wickersham, Jeffrey A; Clayton Koh Thuan Wei; Yee, Ilias Adam; Wang, Bangyuan; Cassolato, Matteo; Iskandar Azwa	Willingness to use pre-exposure prophylaxis for HIV prevention among men who have sex with men in Malaysia: Findings from an online survey	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0182838	https://www.proquest.com/scholarly-journals/willingness-use-pre-exposure-prophylaxis-hiv/docview/1938527010/se-2?accountid=8113	Objective We examined willingness to use pre-exposure prophylaxis (PrEP) for HIV prevention among men who have sex with men (MSM) in Malaysia. Methods An online survey of 990 MSM was conducted between March and April 2016. Eligibility criteria included being biological male, Malaysian citizen, 18 years of age or above, identifying as MSM, and being HIV negative or unknown status. Participants' demographics, sexual and drug use behaviors, attitudes towards PrEP, and preferences regarding future access to PrEP were collected. Bivariate analysis and logistic regression were performed to determine factors associated with willingness to use PrEP. Results Fewer than half of participants (44%) knew about PrEP before completing the survey. Overall, 39% of the sample were willing to take PrEP. Multivariate logistic regression indicated that Malay men (AOR: 1.73, 95% CI:1.12, 2.70), having 2 or more male anal sex partners in the past 6 months (AOR: 1.98, 95% CI: 1.29, 3.05), previous knowledge of PrEP (AOR: 1.40, 95%CI: 1.06, 1.86), lack of confidence in practising safer sex (AOR: 1.36, 95% CI: 1.02, 1.81), and having ever paid for sex with a male partner (AOR: 1.39, 95% CI: 1.01, 1.91) were independently associated with greater willingness to use PrEP, while men who identified as heterosexual were less willing to use PrEP (AOR, 0.36, 95% CI: 0.13, 0.97). Majority of participants preferred to access PrEP at affordable cost below 100 Malaysian Ringgit (USD25) per month from community based organisations followed by private or government hospitals. Conclusions Overall, MSM in Malaysia reported a relatively low level of willingness to use PrEP, although willingness was higher among those previously aware of PrEP. There is a need to provide PrEP at affordable cost, increase demand and awareness of PrEP, and to provide access to this preventative medication via diverse, integrated and tailored sexual health services. Article	2017	Sithole B.	HIV prevention needs for men who have sex with men in Swaziland	African Journal of AIDS Research	-	-	-	-	16085906	10.2989/16085906.2017.1379420	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85033775846&doi=10.2989%2f16085906.2017.1379420&partnerID=40&md5=63d9ab3b8a16d331f2c9079cec2116f9	Men who have sex with men (MSM) have a high HIV burden and also often face multiple other challenges accessing HIV services, including legal and social issues. Although Swaziland recently started responding with interventions for MSM, significant gaps still exist both in information and programming. This study aimed to explore the HIV prevention needs of MSM in Swaziland, including factors elevating their risks and vulnerabilities to HIV infection; to find out what HIV prevention strategies exist; and to determine how best to meet the prevention needs of MSM. A total of 50 men who reported anal sex with other men in the past 12 months were recruited through simple respondent driven sampling. They completed either a structured quantitative survey (n = 35) or participated in a semi-structured qualitative interview (n = 15). Both quantitative and qualitative findings indicated perceived and experienced stigma among MSM. This predominantly manifested as internalised stigma, which may lead to alcohol abuse and sexual risky behaviours. At least 83% (29/35) of the quantitative sample had been labelled with derogatory terms because of their sexual orientation, while 66% (23/35) had experienced being avoided. There was limited knowledge of risk practices: When asked, 54% (19/35) of quantitative respondents reported that vaginal and anal sex carry an equal risk of HIV infection. Participants also had little knowledge on new HIV prevention methods such as pre-exposure prophylaxis (PrEP) and rectal microbicides. MSM needs included safe spaces in form of drop-in centres and non-hostile HIV services. Although Swaziland recently started interventions for key populations, including MSM, there is still a general lack on information to inform managers and implementers on the HIV prevention needs of MSM in Swaziland. Such information is crucial for designers of official and HIV programmes. Research is needed to increase knowledge on the HIV prevention needs for key populations, including MSM. © 2017 The Author(s).	fear; key populations; risks; stigma; vulnerabilities	English	South Africa	Eastern and Southern Africa	Swaziland	Eastern and Southern Africa	Swaziland	Western and Central Europe and North America	Mixed methods
Article	2017	Sivay, MV; Li, M; Piwowar-Manning, E; Zhang, Y; Hudelson, SE; Marzinke, MA; Amico, RK; Redd, A; Hendrix, CW; Anderson, PL; Bokoch, K; Bekker, LG; van Griensven, F; Mannheimer, S; Hughes, JP; Grant, R; Eshleman, SH	Characterization of HIV Seroconverters in a TDF/FTC PrEP Study: HPTN 067/ADAPT	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	28328548	10.1097/QAI.0000000000001374	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01413337/full	BACKGROUND: HIV Prevention Trials Network (HPTN) 067/ADAPT evaluated tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) pre-exposure prophylaxis (PrEP) in women (South Africa) and men who have sex with men (Thailand, US). Participants received once-weekly directly observed therapy (DOT) of TDF/FTC, and were then randomized to daily, time-driven, or event-driven PrEP. This report describes characterization of 12 HIV seroconversion events in this trial. METHODS: HIV rapid testing was performed at study sites. Retrospective testing included fourth generation assays, HIV RNA testing, Western blot, an HIV-1/2 discriminatory assay, resistance testing, and antiretroviral drug testing. RESULTS: Six of the 12 seroconverters received TDF/FTC in the DOT phase, but were not randomized (3 were acutely infected at enrollment; 2 were infected during the DOT phase; 1 was not randomized because of pregnancy). One of the 6 randomized participants had acute infection at randomization but was not diagnosed for 3-4 months because HIV rapid tests were nonreactive; continued daily PrEP use was associated with false-negative antibody tests and low HIV RNA levels. The 5 participants infected after randomization included 4 with low adherence to the PrEP regimen, and one who reported a 7-day period without dosing before infection. Three participants had TDF/FTC resistance (M184I, K65R), including 2 who received only 4 once-weekly TDF/FTC doses; most TDF/FTC mutations were detected by next generation sequencing only. CONCLUSIONS: In HPTN 067/ADAPT, participants who acquired HIV infection had infrequent PrEP dosing or low/suboptimal adherence. Sensitive assays improved detection of HIV infection and drug resistance. Drug resistance was observed with limited PrEP exposure. Article	2017	Slogrove, Amy L.; Clayden, Polly; Abrams, Elaine J.	Toward a universal antiretroviral regimen: special considerations of pregnancy and breast feeding.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318 1746-630X	10.1097/COH.0000000000000386	https://pubmed.ncbi.nlm.nih.gov/28426519/	PURPOSE OF REVIEW: As optimized antiretroviral therapy (ART) regimens are prepared for introduction in low-income and middle-income countries (LMIC), we consider the current evidence related to dosing, efficacy and safety during pregnancy and breastfeeding of next-generation first-line and second-line ART regimens proposed for imminent introduction in the global marketplace. RECENT FINDINGS: Pregnancy pharmacokinetic considerations include potentially insufficient efavirenz exposure if dosed at 400mg/day, the need for twice daily darunavir dosing and the paucity of data related to tenofovir alafenamide and dolutegravir dosing, safety and efficacy. Increasingly evidence suggests an association with adverse birth outcomes, particularly in women conceiving on ART, and with varying risk by drug and drug combination. Clinical trials and studies are in progress or planned that aim to determine dosing, safety and efficacy of several new antiretrovirals (ARVs). SUMMARY: Having a universal, highly potent and safe ART regimen for all individuals living with HIV in LMIC including pregnant women is clearly the most beneficial strategy to keep mothers alive and healthy and to prevent transmission of HIV to their children. It will have to be determined whether the use of this next generation of optimized ARVs will also optimize health outcomes of pregnant women and their children. Article	2017	Smith D.K.; Van Handel M.; Huggins R.	Estimated coverage to address financial barriers to HIV preexposure prophylaxis among persons with indications for its use, United States, 2015	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001532	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037560917&doi=10.1097%2fQAI.0000000000001532&partnerID=40&md5=6019bcb0f7ed731517b2c83f6ce7660d	Background: An estimated 1.2 million American adults engage in sexual and drug use behaviors that place them at significant risk of acquiring HIV infection. Engagement in health care for the provision of daily oral antiretroviral medication as preexposure prophylaxis (PrEP), when clinically indicated, could substantially reduce the number of new HIV infections in these persons. However, resources to cover the financial cost of PrEP care are anticipated barriers for many of the populations with high numbers of new HIV infections. Methods: Using nationally representative data, we estimated the current national met and unmet need for financial assistance with covering the cost of PrEP medication, clinical visits, and laboratory tests among adults with indications for its use, overall and by transmission risk population. Results: This study found that of the 1.2 million adults estimated to have indications for PrEP use, <1% (~7300) are in need of financial assistance for both PrEP medication and clinical care, at an estimated annual cost of $89 million. An additional 7% (~86,300) are in need of financial assistance only for PrEP clinical care at an estimated annual cost of $119 million. Conclusions: This information on PrEP care costs, insurance coverage, and unmet financial need among persons in key HIV transmission risk subpopulations can inform policy makers at all levels as they consider how to address remaining financial barriers to the use of PrEP and accommodate any changes in eligibility for various insurance and financial assistance programs that may occur in coming years. Article	2017	Smith J.M.; Moss J.A.; Srinivasan P.; Butkyavichene I.; Gunawardana M.; Fanter R.; Miller C.S.; Sanchez D.; Yang F.; Ellis S.; Zhang J.; Marzinke M.A.; Hendrix C.W.; Kapoor A.; Baum M.M.	Novel multipurpose pod-intravaginal ring for the prevention of HIV, HSV, and unintended pregnancy: Pharmacokinetic evaluation in a macaque model	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0185946	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85030787161&doi=10.1371%2fjournal.pone.0185946&partnerID=40&md5=dc5d81c9d5731c4b217705684c0fb812	Globally, women bear an uneven burden for sexual HIV acquisition. Results from two clinical trials evaluating intravaginal rings (IVRs) delivering the antiretroviral agent dapivirine have shown that protection from HIV infection can be achieved with this modality, but high adherence is essential. Multipurpose prevention technologies (MPTs) can potentially increase product adherence by offering protection against multiple vaginally transmitted infections and unintended pregnancy. Here we describe a coitally independent, long-acting pod-IVR MPT that could potentially prevent HIV and HSV infection as well as unintended pregnancy. The pharmacokinetics of MPT pod-IVRs delivering tenofovir alafenamide hemifumarate (TAF2) to prevent HIV, acyclovir (ACV) to prevent HSV, and etonogestrel (ENG) in combination with ethinyl estradiol (EE), FDA-approved hormonal contraceptives, were evaluated in pigtailed macaques (N = 6) over 35 days. Pod IVRs were exchanged at 14 days with the only modification being lower ENG release rates in the second IVR. Plasma progesterone was monitored weekly to determine the effect of ENG/EE on menstrual cycle. The mean in vivo release rates (mg d-1) for the two formulations over 30 days ranged as follows: TAF2 0.35–0.40; ACV 0.56–0.70; EE 0.03–0.08; ENG (high releasing) 0.63; and ENG (low releasing) 0.05. Mean peak progesterone levels were 4.4 ± 1.8 ng mL-1 prior to IVR insertion and 0.075 ± 0.064 ng mL-1 for 5 weeks after insertion, suggesting that systemic EE/ENG levels were sufficient to suppress menstruation. The TAF2 and ACV release rates and resulting vaginal tissue drug concentrations (medians: TFV, 2.4 ng mg-1; ACV, 0.2 ng mg-1) may be sufficient to protect against HIV and HSV infection, respectively. This proof of principle study demonstrates that MPT-pod IVRs could serve as a potent biomedical prevention tool to protect women's sexual and reproductive health and may increase adherence to HIV PrEP even among younger high-risk populations. © 2017, Public Library of Science. Article	2017	Smith, David R M; Mideo, Nicole	Modelling the evolution of HIV-1 virulence in response to imperfect therapy and prophylaxis.	Evolutionary Applications	-	-	-	-	1752-4571	10.1111/eva.12458	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5322411	Average HIV-1 virulence appears to have evolved in different directions in different host populations since antiretroviral therapy first became available, and models predict that HIV drugs can select for either higher or lower virulence, depending on how treatment is administered. However, HIV virulence evolution in response to "leaky" therapy (treatment that imperfectly suppresses viral replication) and the use of preventive drugs (pre-exposure prophylaxis) has not been explored. Using adaptive dynamics, we show that higher virulence can evolve when antiretroviral therapy is imperfectly effective and that this evolution erodes some of the long-term clinical and epidemiological benefits of HIV treatment. The introduction of pre-exposure prophylaxis greatly reduces infection prevalence, but can further amplify virulence evolution when it, too, is leaky. Increasing the uptake rate of these imperfect interventions increases selection for higher virulence and can lead to counterintuitive increases in infection prevalence in some scenarios. Although populations almost always fare better with access to interventions than without, untreated individuals could experience particularly poor clinical outcomes when virulence evolves. These findings predict that antiretroviral drugs may have underappreciated evolutionary consequences, but that maximizing drug efficacy can prevent this evolutionary response. We suggest that HIV virulence evolution should be closely monitored as access to interventions continues to improve.	adaptive dynamics, antiretroviral therapy, pre-exposure prophylaxis, set-point viral load, virulence evolution	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Clinical
Article	2017	Smith, Don E; Gardiner, Jill; Oliver, Rebekah; Fagan, Damien	Overlapping HIV prevention strategies; Case report of pre-exposure and postexposure prophylaxes used for a single risk event between two men	Sexually Transmitted Infections	-	-	-	-	13684973	10.1136/sextrans-2014-051989	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84929603256&doi=10.1136%2fsextrans-2014-051989&partnerID=40&md5=c20bf25934b93f59064264657acd9270	A range of prevention strategies have been considered in an attempt to reduce HIV transmission. The use of continuous antiretrovirals (ARVs) in high-risk HIV-negative individuals (pre-exposure prophylaxis or PrEP) and the short-term use of ARVs following a high-risk exposure (postexposure prophylaxis or PEP) are among these strategies. We report a case of the contemporaneous use of PEP and PrEP in a sexual liaison between two men. In an attempt to reduce the number of new cases of HIV infection, a range of prevention strategies have been advocated. Prior to the availability of ARV therapy, the key prevention measure was condom promotion and modifying sexual behaviour such as partner number reduction within high-risk groups. This was followed by: the introduction of PEP, treating all HIV cases with ARVs to reduce the probability of transmission (treatment as prevention) and in the past few years the use of PrEP. Case-control, observational and randomised clinical trial data exist to support these strategies. We describe what we believe is the first reported use of PrEP and PEP in a sexual liaison between two men in Sydney. © Published by the BMJ Publishing Group Limited. Article	2017	Spinks, Crystal B.; Zidan, Ahmed S.; Khan, Mansoor A.; Habib, Muhammad J.; Faustino, Patrick J.	Pharmaceutical characterization of novel tenofovir liposomal formulations for enhanced oral drug delivery: in vitro pharmaceutics and Caco-2 permeability investigations.	Clinical Pharmacology: Advances and Applications	-	-	-	-	1179-1438	10.2147/CPAA.S119875	https://pubmed.ncbi.nlm.nih.gov/28260952/	Tenofovir, currently marketed as the prodrug tenofovir disoproxil fumarate, is used clinically to treat patients with HIV/AIDS. The oral bioavailability of tenofovir is relatively low, limiting its clinical effectiveness. Encapsulation of tenofovir within modified long-circulating liposomes would deliver this hydrophilic anti-HIV drug to the reticuloendothelial system for better therapeutic efficacy. The objectives of the current study were to prepare and pharmaceutically characterize model liposomal tenofovir formulations in an attempt to improve their bioavailability. The entrapment process was performed using film hydration method, and the formulations were characterized in terms of encapsulation efficiency and Caco-2 permeability. An efficient reverse-phase high-performance liquid chromatography method was developed and validated for tenofovir quantitation in both in vitro liposomal formulations and Caco-2 permeability samples. Separation was achieved isocratically on a Waters Symmetry C8 column using 10 mM Na(2)PO(4)/acetonitrile pH 7.4 (95:5 v/v). The flow rate was 1 mL/min with a 12 min elution time. Injection volume was 10 µL with ultraviolet detection at 270 nm. The method was validated according to United States Pharmacopeial Convention category I requirements. The obtained result showed that tenofovir encapsulation within the prepared liposomes was dependent on the employed amount of the positive charge-imparting agent. The obtained results indicated that calibration curves were linear with r(2) > 0.9995 over the analytical range of 1-10 µg/mL. Inter- and intraday accuracy and precision values ranged from 95% to 101% and 0.3% to 2.6%, respectively. The method was determined to be specific and robust. Regarding the potential of the prepared vectors to potentiate tenofovir permeability through the Caco-2 model, a 10-fold increase in tenofovir apparent permeability was observed compared to its oral solution. In conclusion, this novel and validated method was successfully applied to characterize both in vitro encapsulation efficiency and Caco-2 permeability transport for the pharmaceutical assessment of novel tenofovir formulations.	tenofovir; chromatography; liposomes; entrapment; permeation; targeting	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Stahlman, Shauna; Lyons, Carrie; Sullivan, Patrick S; Mayer, Kenneth H; Hosein, Sean; Beyrer, Chris; Baral, Stefan D	HIV incidence among gay men and other men who have sex with men in 2020: where is the epidemic heading?	Sexual Health	-	-	-	-	1448-5028	10.1071/SH16070	https://dx.doi.org/10.1071/SH16070	The goal to effectively prevent new HIV infections among gay, bisexual, and other men who have sex with men (MSM) is more challenging now than ever before. Despite declines in the late 1990s and early 2000s, HIV incidence among MSM is now increasing in many low- and high-income settings including the US, with young, adolescent, and racial/ethnic minority MSM being among those at highest risk. Potentiating HIV risks across all settings are individual-, network-, and structural-level factors such as stigma and lack of access to pre-exposure prophylaxis (PrEP) and antiretroviral treatment as prevention. To make a sustained impact on the epidemic, a concerted effort must integrate all evidence-based interventions that will most proximally decrease HIV acquisition and transmission risks, together with structural interventions that will support improved coverage and retention in care. Universal HIV treatment, increased access to HIV testing, and daily oral PrEP have emerged as integral to the prevention of HIV transmission, and such efforts should be immediately expanded for MSM and other populations disproportionately affected by HIV. Respect for human rights and efforts to combat stigma and improve access to prevention services are needed to change the trajectory of the HIV pandemic among MSM. Article	2017	Stalter, Randy M; Tharaldson, Jenae; Owen, Derek H; Okumu, Eunice; Moench, Thomas; Mack, Natasha; Tolley, Elizabeth E; MacQueen, Kathleen M	Attitudes and perceptions towards novel objective measures of ARV-based vaginal ring use: Results from a global stakeholder survey.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0180963	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5510854	Results of recent microbicide and pre-exposure prophylaxis clinical trials have shown adherence to be a significant challenge with new HIV prevention technologies. As the vaginal ring containing dapivirine moves into two open label follow-on studies (HOPE/MTN-025 and DREAM) and other antiretroviral-based and multi-purpose prevention technology ring products advance through the development pipeline, there is a need for more accurate and reliable measures of adherence to microbicide ring products. We previously conducted a comprehensive landscape analysis to identify new technologies that could be applied to adherence measurement of vaginal rings containing antiretrovirals. To explore attitudes and perceptions towards the approaches that we identified, we conducted a survey of stakeholders with experience and expertise in microbicide and HIV prevention clinical trials. From May to July 2015 an electronic survey was distributed via email to 894 stakeholders; a total of 206 eligible individuals responded to at least one question and were included in the data analysis. Survey respondents were presented with various objective measures and asked about their perceived acceptability to trial participants, feasibility of implementation by study staff, usefulness for measuring adherence and ethical concerns. Methods that require no additional input from the participant and require no modifications to the existing ring product (i.e., measurement of residual drug or excipient, or a vaginal analyte that enters the ring) were viewed as being more acceptable to trial participants and more feasible to implement in the field. Respondents saw value in using objective measures to provide real-time feedback on adherence. However, approaches that involve unannounced home visits for sample collection or spot checks of ring use, which could provide significant value to adherence feedback efforts, were met with skepticism. Additional research on the acceptability of these methods to potential trial participants and trial staff is recommended. Article	2017	Stanley, Kristi; Lora, Meredith; Merjavy, Stephen; Chang, Jennifer; Arora, Sanjay; Menchine, Michael; Jacobson, Kathleen R	HIV Prevention and Treatment: The Evolving Role of the Emergency Department.	Annals of Emergency Medicine	-	-	-	-	1097-6760	10.1016/j.annemergmed.2017.01.018	https://dx.doi.org/10.1016/j.annemergmed.2017.01.018	Historically, the role of the emergency physician in HIV care has been constrained to treating sick patients with opportunistic infections and postexposure prophylaxis for occupational exposures. However, advances in HIV care have led to medications that have substantially fewer issues with toxicity and resistance, opening up an exciting new opportunity for emergency physicians to participate in treating the HIV virus itself. With this new role, it is crucial that emergency physicians be familiar with the advances in testing and medications for HIV prevention and treatment. To our knowledge, to date there has not yet been an article addressing this expansion of practice. We have compiled a summary of what the emergency physician needs to know, including misconceptions associated with antiretroviral therapy, medication complexity, toxicity, resistance, and usability. Additionally, we review potential indications for prescribing these drugs in the emergency department, including the role of the emergency physician in postexposure prophylaxis, preexposure prophylaxis, and treatment of acute HIV, as well as how emergency physicians can engage with chronic HIV infection. Article	2017	Storholm E.D.; Volk J.E.; Marcus J.L.; Silverberg M.J.; Satre D.D.	Risk Perception, Sexual Behaviors, and PrEP Adherence Among Substance-Using Men Who Have Sex with Men: a Qualitative Study	Prevention Science	-	-	-	13894986	10.1007/s11121-017-0799-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85020079892&doi=10.1007%2fs11121-017-0799-8&partnerID=40&md5=60de047470728493f5ced1972ad9a05e	The antiretroviral drug combination emtricitabine and tenofovir disoproxil fumarate (TDF/FTC) taken as pre-exposure prophylaxis (PrEP) is effective in preventing HIV infection, yet it also requires adherence and potentially decreases condom use. This study sought to examine these issues among a key population at risk of HIV infection, substance-using men who have sex with men (MSM). We conducted semi-structured interviews with an ethnically diverse sample of 30 young (aged 20–35) MSM prescribed PrEP within a large integrated healthcare system in San Francisco, who had reported recent drug use or hazardous drinking and one or more missed doses of PrEP. We explored participants' risk perception and sexual risk behavior, drug and alcohol use, and PrEP adherence in the context of substance use. Interviews were transcribed and coded using a directed content analysis approach to identify key categories and commonalities, and differences across participants. Salient subcategories included positive psychological effects of being on PrEP (e.g., decreased anxiety, feelings of empowerment), social effects (e.g., reduced HIV stigma), and reduction in overall perceptions of HIV risk. While overall reported use of condoms went down and many reported a brief period of increased condomless sex following PrEP initiation, others continued condom use with most of their sexual partners. Contextual factors influencing their decision to engage in condomless sex included how well they knew the partner and whether the partner was on PrEP or HIV antiretroviral treatment. Factors associated with poor adherence included disruptions in daily routine and use of alcohol and methamphetamine. PrEP-prescribing clinicians should support their patients in making informed decisions about condom use and identifying strategies to maximize adherence in the context of substance use. © 2017, RAND Corporation. Article	2017	Strauss B.B.; Greene G.J.; Phillips G., II; Bhatia R.; Madkins K.; Parsons J.T.; Mustanski B.	Exploring Patterns of Awareness and Use of HIV Pre-Exposure Prophylaxis Among Young Men Who Have Sex with Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1480-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84978032345&doi=10.1007%2fs10461-016-1480-0&partnerID=40&md5=cafeb1e80922ddee18112f7fc963cab4	Pre-exposure prophylaxis (PrEP) has shown promise as a safe and effective HIV prevention strategy, but there is limited research on awareness and use among young men who have sex with men (YMSM). Using baseline data from the "Keep It Up! 2.0" randomized control trial, we examined differences in PrEP awareness and use among racially diverse YMSM (N = 759; mean age = 24.2 years). Participants were recruited from study sites in Atlanta, Chicago, and New York City, as well as through national advertising on social media applications. While 67.5 % of participants reported awareness of PrEP, 8.7 % indicated using the medication. Awareness, but not use, varied by demographic variables. PrEP-users had twice as many condomless anal sex partners (ERR = 2.05) and more condomless anal sex acts (ERR = 1.60) than non-users. Future research should aim to improve PrEP awareness and uptake among YMSM and address condom use. © 2016, Springer Science+Business Media New York. Article	2017	Sullivan K.A.; Lyerly A.D.	Ethical considerations in developing an evidence base for pre-exposure prophylaxis in pregnant women	Reproductive Health	-	-	-	17424755	10.1186/s12978-017-0425-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041173416&doi=10.1186%2fs12978-017-0425-z&partnerID=40&md5=883c91e2654aa180a8a8849fbf4bde76	Though many women in need of access to HIV preventive regimes are pregnant, there is a dearth of data to guide these care decisions. While oral pre-exposure prophylaxis (PrEP) has been shown to prevent HIV infection in numerous high-risk populations, pregnant women have been excluded from all major prospective trials. We propose for ethical examination a theoretical trial - a prospective, observational study of PrEP for pregnant women at risk for HIV in sub-Saharan Africa - highlighting an ethical tradeoff that characterizes issues faced for advancing research in pregnancy. On the one hand, an "opportunistic" study design has certain ethical advantages: as formally construed, the research activity usually begins after decisions to use PrEP during pregnancy are made in the clinical setting. This minimizes research risks and avoids ethical problems that a randomized controlled trial (RCT) comparing PrEP to placebo would entail, particularly withholding care proven beneficial in other populations. On the other hand, observational studies yield less precise information than RCTs. This raises a broader question about the pace of research with pregnant women, as it typically takes many years after a drug's approval for use in the general population to determine safety of the medication in pregnancy. Such delays can have the effect of making it impossible to ethically conduct an RCT with pregnant women, reducing the likelihood that the research community is able to obtain robust, pregnancy-specific evidence. While an observational cohort is potentially the most ethically and scientifically justified research design to study PrEP in pregnancy, earlier involvement of pregnant women in studies of newer preventives may lead to evidence that is more timely and robust. © 2017 The Author(s). Article	2017	Sullivan P.S.; Driggers R.; Stekler J.D.; Siegler A.; Goldenberg T.; McDougal S.J.; Caucutt J.; Jones J.; Stephenson R.	Usability and acceptability of a mobile comprehensive hiv prevention app for men who have sex with men: A pilot study	JMIR mHealth and uHealth	-	-	-	22915222	10.2196/mhealth.7199	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026817719&doi=10.2196%2fmhealth.7199&partnerID=40&md5=e80589168c7c3777266a94817531b290	Background: Men who have sex with men (MSM) are the group most impacted by the human immunodeficiency virus (HIV) epidemic and the only subgroup in the United States among which new HIV diagnoses are not decreasing. To achieve the US National HIV/AIDS (acquired immunodeficiency syndrome) Strategy goals of reducing new diagnoses by 25%, high (eg, 30-50%) coverage of multiple HIV prevention interventions is needed in both urban and rural areas. Mobile phone "apps"are an important channel through which prevention services could be provided at scale and at low marginal cost. Objective: The aim of this study was to evaluate the usability and acceptability of a theory-based Android mobile phone app for HIV prevention. Methods: The app included self-assessment tools; prevention recommendations; commodity (condoms, HIV self-tests) ordering; reminders to MSM for basic HIV prevention services, HIV testing, condom use, screening for preexposure prophylaxis (PrEP) and nonoccupational postexposure prophylaxis (nPEP); and prevention and treatment provider locators. The study recruited HIV-negative, Android-using MSM in Atlanta and Seattle who were asked to use the app for 4 months and complete a post-use survey. We measured the use of the app and its features, ordering of commodities, self-report of establishing an HIV testing plan, being HIV tested in the community, and starting PrEP or using nPEP. Usability was assessed using the system usability scale (SUS). Results: A total of 121 MSM were enrolled (59.5%, 72/121 from Atlanta; 40.5%, 49/121 from Seattle). Median age was 28. Nearly half (48.8%, 59/121) were nonwhite, and most (85.9%, 104/121) were gay-identified. Most had tested for HIV in the past (85.1%, 103/121), and 52 (43.0%, 52/121) had a plan to test for HIV regularly. Men used the app for an average of 17.7 minutes over the first 4 months. Over the 4-month period, over half ordered condoms (63.6%, 77/121) and HIV test kits (52.8%, 64/121) on the app. Eight of 86 (9%) PrEP-eligible MSM started PrEP during the 4-month period; of those, 6 of the 8 reported that the app influenced their decision to start PrEP. The mean SUS was 73 (above average). Conclusions: A theory-based mobile phone app was acceptable to MSM and was rated as having above-average usability. Most men used the commodity-ordering features of the app during the 4-month evaluation period, and nearly 1 in 10 PrEP-eligible men started PrEP, with most attributing their decision to start PrEP in part to the app. A broader, randomized controlled study of the impact of the app on uptake of prevention behaviors for MSM is warranted. © 2020 Patrick S Sullivan, Robert Driggers, Joanne D Stekler, Aaron J Siegler, Tamar Goldenberg, Sarah J McDougal, Jason Caucutt, Jeb Jones, Rob Stephenson. Pre-exposure prophylaxis (PrEP) and nonoccupational postexposure prophylaxis (nPEP) are two important strategies for preventing HIV that should be considered standard of care and implemented as components of a comprehensive response to the epidemic. Pre-exposure prophylaxis is the use of certain antiretroviral medications by HIV-uninfected persons who are at high, ongoing risk of HIV acquisition, beginning before and continuing after potential HIV exposures. Postexposure prophylaxis (PEP) involves 28 days of antiretroviral medications immediately after a specific HIV exposure, and is nonoccupational when used after sexual and injection drug use exposures, rather than accidental exposures that occur in work contexts. The large financial cost of HIV infection and the young age of those newly diagnosed underscore the economic and social importance of preventing new infections. We hope that this guideline will contribute to reducing HIV incidence in Canada by improving the quality of care, increasing access to care, reducing inappropriate variation in practice and promoting the rigorous evaluation of biomedical prevention strategies nationwide. Article	2017	Tang Q.; Lu H.-Z.	Discussion on epidemic status and control strategies of HIV/AIDS	Fudan University Journal of Medical Sciences	-	-	-	16728467	10.3969/j.issn.1672-8467.2017.06.010	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85040659323&doi=10.3969%2fj.issn.1672-8467.2017.06.010&partnerID=40&md5=6c66454328c4654b37e05b5ffc02f3ea	Antiretroviral therapy (ART) is a chronic suppressive treatment that provides lifelong treatment effectively for patients with HIV, improving the quality of life for patients. Although the overall trend of new infections is declining, the number of new HIV infections per year and the number of deaths related AIDS is still very large, remaining one of the world's biggest public health challenges. In the field of epidemiology, HIV/AIDS distributed in poor areas with limited medical means such as Africa, and men who have sex with men (MSM), sex workers and people who inject drugs (PWID) become the main susceptible population; In the field of prevention, prevention of mother-to-child transmission (PMTCT) services, treatment as prevention (TasP) and pre-exposure prophylaxis (PrEP) have achieved initial success, but the coverage is still limited; In the field of treatment, the extent of HIV resistance in multiple countries increases to more than 10%, and the cure of HIV/AIDS research and vaccine development are currently in animal or cellular experiments. Over the past decade, China has established several measures to prevent the HIV epidemic further, and improve the quality of life of people living with HIV/AIDS patients. At the same time, China is also facing the following challenges: the targeted prevention program, susceptible groups increased (such as MSM, PWID and youth), long-term care of patients with HIV/AIDS, the coverage of PMTCT services, eliminate discrimination process, etc. Therefore, the purpose of this article is to review the epidemic status and control strategies of HIV/AIDS in China and the whole world in recent years. © 2017, Editorial Department of Fudan University Journal of Medical Sciences. "Life-Steps" for PrEP Adherence: Demonstration of a CBT-Based Intervention to Increase Adherence to Preexposure Prophylaxis (PrEP) Medication Among Sexual-Minority Men at High Risk for HIV Acquisition	Cognitive and Behavioral Practice	-	-	-	10777229	10.1016/j.cbpra.2016.02.004	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84963955068&doi=10.1016%2fj.cbpra.2016.02.004&partnerID=40&md5=99b3f9de34a496d79ce61882c5aa8ca8	One dramatic advance in human immunodeficiency virus (HIV) prevention efforts has been the prescription of medications typically used for HIV treatment as prophylaxis against acquiring HIV. As a preventative agent, this practice is referred to as "preexposure prophylaxis" (PrEP). The U.S. Federal Drug Administration approved daily PrEP for adults at risk for HIV who do not consistently use condoms during sex with HIV-infected or unknown-status partners. In this paper, we describe a cognitive-behavioral therapy (CBT) PrEP adherence intervention developed for use in high-risk sexual-minority men in the United States, adapted from "Life-Steps," an evidence-based CBT intervention to promote adherence to HIV treatment. Modules include creating a PrEP dosing schedule, adhering to daily PrEP, problem solving barriers to adherence, and sexual risk-reduction techniques. Supplemented with practical video vignettes, this novel intervention may help to enhance the clinical practice of health care providers in outpatient settings to increase PrEP adherence in sexual-minority men. © 2016	CBT; HIV; medication adherence; MSM; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Tetteh R.A.; Yankey B.A.; Nartey E.T.; Lartey M.; Leufkens H.G.M.; Dodoo A.N.O.	Pre-Exposure Prophylaxis for HIV Prevention: Safety Concerns	Drug Safety	-	-	-	1145916	10.1007/s40264-017-0505-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85010723232&doi=10.1007%2fs40264-017-0505-6&partnerID=40&md5=472a3944c74aecc9cb71f5c2d606d536	Available evidence supports the efficacy of pre-exposure prophylaxis (PrEP) in decreasing the incidence of human immunodeficiency virus (HIV) infection among high-risk individuals, especially when used in combination with other behavioural preventive methods. Safety concerns about PrEP present challenges in the implementation and use of PrEP. The aim of this review is to discuss safety concerns observed in completed clinical trials on the use of PrEP. We performed a literature search on PrEP in PubMed, global advocacy for HIV prevention (Aids Vaccine Advocacy Coalition) database, clinical trials registry "http://www.clinicaltrials.gov" and scholar.google, using combination search terms 'pre-exposure prophylaxis', 'safety concerns in the use of pre-exposure prophylaxis', 'truvada use as PrEP', 'guidelines for PrEP use', 'HIV pre-exposure prophylaxis' and 'tenofovir' to identify clinical trials and literature on PrEP. We present findings associated with safety issues on the use of PrEP based on a review of 11 clinical trials on PrEP with results on safety and efficacy as at April 2016. We also reviewed findings from routine real-life practice reports. The pharmacological intervention for PrEP was tenofovir disoproxil fumarate/emtricitabine in a combined form as Truvada® or tenofovir as a single entity. Both products are efficacious for PrEP and seem to have a good safety profile. Regular monitoring is recommended to prevent long-term toxic effects. The main adverse effects observed with PrEP are gastrointestinal related; basically mild to moderate nausea, vomiting and diarrhea. Other adverse drug effects worth monitoring are liver enzymes, renal function and bone mineral density. PrEP as an intervention to reduce HIV transmission appears to have a safe benefit-risk profile in clinical trials. It is recommended for widespread use but adherence monitoring and real-world safety surveillance are critical in the post-marketing phase to ensure that the benefits observed in clinical trials are maintained in real-world use. © 2017, The Author(s).	anti human immunodeficiency virus agent; creatinineanti human immunodeficiency virus agent; emtricitabine plus tenofovir disoproxil; tenofovir	English	United Kingdom	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Review
Article	2017	Thangaratinam, Shakila; Allotey, John; Marlin, Nadine; Dodds, Julie; Cheong-See, Fiona; von Dadelszen, Peter; Ganzevoort, Wessel; Akkermans, Joost; Kerry, Sally; Mol, Ben W; Moons, Karl G M; Riley, Richard D; Khan, Khalid S	Prediction of complications in early-onset pre-eclampsia (PREP): development and external multinational validation of prognostic models	BMC Medicine	-	-	-	1741-7015	10.1186/s12916-017-0827-3	https://abdn.elsevierpure.com/en/publications/prediction-of-complications-in-early-onset-pre-eclampsia-prep-dev	Unexpected clinical deterioration before 34 weeks gestation is an undesired course in early-onset pre-eclampsia. To safely prolong preterm gestation, accurate and timely prediction of complications is required. Women with confirmed early onset pre-eclampsia were recruited from 53 maternity units in the UK to a large prospective cohort study (PREP-946) for development of prognostic models for the overall risk of experiencing a complication using logistic regression (PREP-L), and for predicting the time to adverse maternal outcome using a survival model (PREP-S). External validation of the models were carried out in a multinational cohort (PIERS-634) and another cohort from the Netherlands (PETRA-216). Main outcome measures were C-statistics to summarise discrimination of the models and calibration plots and calibration slopes. A total of 169 mothers (18%) in the PREP dataset had adverse outcomes by 48 hours, and 633 (67%) by discharge. The C-statistics of the models for predicting complications by 48 hours and by discharge were 0.84 (95% CI, 0.81-0.87; PREP-S) and 0.82 (0.80-0.84; PREP-L), respectively. The PREP-S model included maternal age, gestation, medical history, systolic blood pressure, deep tendon reflexes, urine protein creatinine ratio, platelets, serum alanine amino transaminase, urea, creatinine, oxygen saturation and treatment with antihypertensives or magnesium sulfate. The PREP-L model included the above except deep tendon reflexes, serum alanine amino transaminase and creatinine. On validation in the external PIERS dataset, the reduced PREP-S model showed reasonable calibration (slope 0.80) and discrimination (C-statistic 0.75) for predicting adverse outcome by 48 hours. Reduced PREP-L model showed excellent calibration (slope: 0.93 PIERS, 0.90 PETRA) and discrimination (0.81 PIERS, 0.75 PETRA) for predicting risk by discharge in the two external datasets. PREP models can be used to obtain predictions of adverse maternal outcome risk, including early preterm delivery, by 48 hours (PREP-S) and by discharge (PREP-L), in women with early onset pre-eclampsia in the context of current care. They have a potential role in triaging high-risk mothers who may need transfer to tertiary units for intensive maternal and neonatal care. ISRCTN40384046 , retrospectively registered. Article	2017	Thomson, KA; Haberer, JE; Marzinke, MA; Mujugira, A; Hendrix, CW; Celum, C; Ndase, P; Ronald, A; Bangsberg, DR; Baeten, JM	medication Sharing Is Rare Among African HIV-1 Serodiscordant Couples Enrolled in an Efficacy Trial of Oral Pre-exposure Prophylaxis (PrEP) for HIV-1 Prevention	Journal of Acquired Immune Deficiency Syndromes	-	-	-	NA	10.1097/QAI.0000000000001356	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01375150/full	Sharing of pre-exposure prophylaxis (PrEP) medications is a concern for PrEP implementation. For HIV-1 serodiscordant couples, sharing may undermine the HIV-1 prevention benefit and also cause antiretroviral resistance if taken by HIV-1 infected partners. Within a PrEP efficacy trial among HIV-1 serodiscordant couples, we assessed the occurrence of PrEP sharing by self-report and plasma tenofovir concentrations in HIV-1 infected partners. PrEP sharing was self-reported at <0.01% of visits, and 0%-1.6% of randomly selected and 0% of purposively selected specimens from HIV-1 infected participants had detectable tenofovir concentrations (median: 66.5 ng/mL, range: 1.3-292 ng/mL). PrEP sharing within HIV-1 serodiscordant couples was extremely rare.	*Human immunodeficiency virus 1; *nonhuman; *pre exposure prophylaxis; Anti-HIV Agents; Black People; Clinical trial; Controlled clinical trial; Controlled study; Family Characteristics; Female; HIV Infections *prevention & control; HIV Seronegativity *drug effects; HIV Seropositivity *transmission; HIV-1 *drug effects; Human; Human tissue; Humans; Kenya epidemiology; Licence; Male; Medication Adherence *statistics & numerical data; Plasma; Prescription Drug Misuse *statistics & numerical data; Prevention; Pre-Exposure Prophylaxis; Randomized controlled trial; Risk-Taking; Self report; Tenofovir; Uganda epidemiology	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Theses and Dissertations	2017	TIWARI, CHANCHALA	Factors Associated with Pre-Exposure Prophylaxis (PrEP) Adherence Self-Efficacy among High-risk Drug Users in Treatment	-	-	University of Connecticut	-	NA	NA	https://opencommons.uconn.edu/gs_theses/1149 https://opencommons.uconn.edu/context/gs_theses/article/2255/viewcontent/Chanchala__Final_chapters.pdf	Recent studies on Pre-exposure prophylaxis treatment (PrEP) has received significant recognition as a promising preventive strategy among high-risk individuals. Although a significant amount of research has been conducted on willingness of PrEP use, and NCI as predictors of HIV risk behavior, no study to date, has explored the impact of various motivation factors along with the use of internet & technology devices and psychological aspects on PrEP adherence self-efficacy. So, the objectives of thesis analyses were to examine whether various motivation factors, psychological factors, and communication technology predicts PrEP adherence self-efficacy. Method: The study was conducted among 400 HIV-negative high-risk PWUD enrolled in a community based methadone maintenance treatment program. Participants completed an audio-computer-assisted self-interview (ACASI) which measured motivation, Neurocognitive impairment (NCI), depression, use of internet and technology devices and adherence self-efficacy. We conducted linear regression analyses of different factors on PrEP adherence self-efficacy. Result: The analysis showed the social motivation (β=0.32, p =0.0) and attitudes about PrEP use (β=0.139, p=.004) predicted PrEP adherence self-efficacy. However, intention motivation for PrEP (β= -0.241, p>0.05) showed a reciprocal relationship with adherence self-efficacy. Finding highlights that use of internet (β=0.09, p=0.017) has a positive impact on adherence self-efficacy along with the use of technology devices (β=0213, pConclusion: The, results suggest the significant association with motivation and use of technology benefits strengthens our knowledge about important factors affecting PrEP use among high risk individuals that may be valuable to incorporate into future interventions. Article	2017	Uyei, Jennifer; Fiellin, David A; Buchelli, Marianne; Rodriguez-Santana, Ramon; Braithwaite, R Scott	Effects of naloxone distribution alone or in combination with addiction treatment with or without pre-exposure prophylaxis for HIV prevention in people who inject drugs: a cost-effectiveness modelling study.	The Lancet Public Health	-	-	-	2468-2667	10.1016/S2468-2667(17)30006-3	https://dx.doi.org/10.1016/S2468-2667(17)30006-3	BACKGROUND: In the USA, an epidemic of opioid overdose deaths is occurring, many of which are from heroin. Combining naloxone distribution with linkage to addiction treatment or pre-exposure prophylaxis (PrEP) for HIV prevention through syringe service programmes has the potential to save lives and be cost-effective. We estimated the outcomes and cost-effectiveness of five alternative strategies: no additional intervention, naloxone distribution, naloxone distribution plus linkage to addiction treatment, naloxone distribution plus PrEP, and naloxone distribution plus linkage to addiction treatment and PrEP. METHODS: We developed a decision analytical Markov model to simulate opioid overdose, HIV incidence, overdose-related deaths, and HIV-related deaths in people who inject drugs in Connecticut, USA. Model input parameters were derived from published sources. We compared each strategy with no intervention, as well as simultaneously considering all strategies. Sensitivity analysis was done for all variables. Linkage to addiction treatment was referral to an opioid treatment programme for methadone. Endpoints were survival, life expectancy, quality-adjusted life-years (QALYs), number and percentage of overdose deaths averted, number of HIV-related deaths averted, total costs (in 2015 US$) associated with each strategy, and incremental cost per QALY gained. FINDINGS: In the base-case analysis, compared with no additional intervention, the naloxone distribution strategy yielded an incremental cost-effectiveness ratio (ICER) of $323 per QALY, and naloxone distribution plus linkage to addiction treatment was cost saving compared with no additional intervention (greater effectiveness and less expensive). The most efficient strategies (ie, those conferring the greatest health benefit for a particular budget) were naloxone distribution combined with linkage to addiction treatment (cost saving), and naloxone distribution combined with PrEP and linkage to addiction treatment (ICER $95â337 per QALY) at a willingness-to-pay threshold of $100â000. In probabilistic sensitivity analysis, the combination of naloxone distribution, PrEP, and linkage to addiction treatment was the optimal strategy in 37% of iterations and the combination of naloxone distribution and linkage to addiction treatment was the optimal strategy in 34% of iterations. INTERPRETATION: Naloxone distribution through syringe service programmes is cost-effective compared with syringe distribution alone, but when combined with linkage to addiction treatment is cost saving compared with no additional services. A strategy that combines naloxone distribution, PrEP, and linkage to addiction treatment results in greater health benefits in people who inject drugs and is also cost-effective. Article	2017	Vaccher S.J.; Gianacas C.; Templeton D.J.; Poynten I.M.; Haire B.G.; Ooi C.; Foster R.; McNulty A.; Grulich A.E.; Zablotska I.B.	Baseline preferences for daily, event-driven, or periodic hiv pre-exposure prophylaxis among gay and bisexual men in the prelude demonstration project	Frontiers in Public Health	-	-	-	22962565	10.3389/fpubh.2017.00341	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058038492&doi=10.3389%2ffpubh.2017.00341&partnerID=40&md5=fac92ae751877fc2a157528c1954a54d	introduction: The effectiveness of daily pre-exposure prophylaxis (PrEP) is well established. However, there has been increasing interest in non-daily dosing schedules among gay and bisexual men (GBM). This paper explores preferences for PrEP dosing schedules among GBM at baseline in the PRELUDE demonstration project. Materials and methods: Individuals at high-risk of HIV were enrolled in a free PrEP demonstration project in New South Wales, Australia, between November 2014 and April 2016. At baseline, they completed an online survey containing detailed behavioural, demographic, and attitudinal questions, including their ideal way to take PrEP: daily (one pill taken every day), event-driven (pills taken only around specific risk events), or periodic (daily dosing during periods of increased risk). results: Overall, 315 GBM (98% of study sample) provided a preferred PrEP dosing schedule at baseline. One-third of GBM expressed a preference for non-daily PrEP dosing: 20% for event-driven PrEP, and 14% for periodic PrEP. Individuals with a trade/ vocational qualification were more likely to prefer periodic to daily PrEP adjusted odds ratio (aOR) = 4.58, 95% confidence intervals (95% CI): (1.68, 12.49), compared to individuals whose highest level of education was high school. Having an HIV-positive main regular partner was associated with strong preference for daily, compared to event-driven PrEP aOR = 0.20, 95% CI: (0.04, 0.87). Participants who rated themselves better at taking medications were more likely to prefer daily over periodic PrEP aOR = 0.39, 95% CI: (0.20, 0.76). Discussion: Individuals' preferences for PrEP schedules are associated with demographic and behavioural factors that may impact on their ability to access health services and information about PrEP and patterns of HIV risk. At the time of data collection, there were limited data available about the efficacy of non-daily PrEP schedules, and clinicians only recommended daily PrEP to study participants. Further research investigating how behaviours and PrEP preferences change correspondingly over time is needed. © 2017 Vaccher, Gianacas, Templeton, Poynten, Haire, Ooi, Foster, McNulty, Grulich, Zablotska. Article	2017	Vaccher, Stefanie J; Grulich, Andrew E; Haire, Bridget G; Conway, Damian P; Poynten, Isobel M; Ooi, Catriona; Foster, Rosalind; Templeton, David J; Zablotska, Iryna B; on behalf of the PRELUDE Study Team	Validation of participant eligibility for pre-exposure prophylaxis: Baseline data from the PRELUDE demonstration project	PLOS One	-	-	-	NA	10.1371/journal.pone.0185398	https://www.proquest.com/scholarly-journals/validation-participant-eligibility-pre-exposure/docview/1943095510/se-2?accountid=8113	Background In Australia, pre-exposure prophylaxis (PrEP) is targeted to individuals at high risk for HIV infection. We describe the HIV risk profile and characteristics of PRELUDE participants, and evaluate the population validity of the sample in representing high-risk gay and bisexual men (GBM) eligible for PrEP. Methods PRELUDE is an on-going, open-label, single-arm observational study. Participants were identified in clinics and screened for eligibility using a paper-based risk assessment tool which followed the New South Wales (NSW) PrEP guidelines. Selection was validated using an independent online behavioural survey, completed by study participants upon enrolment. Demographic information was analysed using descriptive statistics, and kappa tests were used to determine agreement between reporting of high-risk practices in the risk assessment and behavioural survey. Results During 2014–15, 471 individuals were targeted for enrolment; 341 were assessed for PrEP eligibility and 313 were enrolled. Of these, 303 (97%) identified as GBM. Overall, 85% of GBM met at least one high-risk criterion; 68% reported receptive intercourse with an HIV-positive or unknown status casual male partner, and 37% reported methamphetamine use in the three months preceding enrolment. The remaining 15% were enrolled based on medium-risk behaviours, or at the clinicians' discretion. We found an 82% total agreement between self-reported high-risk behaviour and clinicians' categorisation of GBM as being at high risk for HIV based on PrEP eligibility criteria. Conclusions Behavioural eligibility criteria used by clinicians successfully identified individuals at high risk for HIV infection. This targeted approach ensures that the greatest public health and HIV prevention benefits can be derived in a setting without universal access to PrEP. Existe aún un diagnóstico tardío para 65%2 , de personas que llegan a los servicios hospitalarios de Cochabamba en etapa de sida, muchas de estas personas continúan falleciendo. Según información del Ministerio de Salud, el VIH/Sida tiene una prevalencia en la población general de 0,16% y 0,80% en gestantes; en trabajadoras sexuales 0,57%3 (3). No obstante, esta cifra asciende en la población GLBT–HSH (Gey, Lesbiana, Bisexual, Transexual-Hombres que tienen Sexo con Hombres) a 11,6% y en la población Trans a 19,70% (proyecciones EPPSpectrum)"	NA	Spanish	Bolivia	Latin America and the Caribbean	Bolivia	Latin America and the Caribbean	NA	NA	Other
Theses and Dissertations	2017	Valencia, Celina I., Valencia, Celina I.	Modeling social factors of HIV risk in Mexico	-	-	University of Arizona	-	NA	NA	http://hdl.handle.net/10150/625554	Human Immunodeficiency Virus (HIV) and Acquired Immunodeficiency Syndrome (AIDS) is an urgent public health issue in Mexico. Mexico has witnessed a 122% increase in reported prevalence of HIV since 2001 (Holtz et al., 2014). Country estimates suggest there are between 140,000-230,000 individuals living with HIV in Mexico (CENSIDA, 2014). While approximately 50% of individuals living with HIV in Mexico are unaware that they are living with the virus (CENSIDA, 2014). Despite a federal universal HIV program implemented in 2011, HIV in Mexico has not reached a chronic infectious disease status as seen in other regions of the globe (Deeks, 2013). The mortality rate among individuals with HIV/AIDS in Mexico is 4.2 per 100,000 (CENSIDA, 2014). There is a paucity of findings regarding social and epidemiological data focused on populations outside traditional at risk populations of HIV in Mexico (Martin-Onraët et al., 2016). Analyzing aggregate country level data for Mexico provides necessary insights to better understanding previously unconsidered social factors that are informing sexual and reproductive health trends influencing HIV health patterns. Methods: Secondary analyses were performed on Mexico's Encuesta Nacional de Salud y Nutrición 2012 (ENSANUT). Mexico's ENSANUT is a probabilistic aggregate national dataset with a multistage stratified cluster sampling design (Janssen et al., 2013). ENSANUT is Mexico's equivalent to the National Health and Nutrition Examination Survey (NHANES) in the United States. Data is collected via self-report interviews conducted at the participant's home. A structured questionnaire was administered to individuals 20 years of age and older (≥ 20) where sexual and reproductive data was collected from participants. The ENSANUT adult study sub-sample (n=46,227) is comprised of 42.75% men and 57.25% women. A general linear model (GLM), principal component analysis (PCA), chi-squares (χ^2), and logistic regressions were applied to the study adult subsample to disentangle social factors associated with sexually transmitted infections (STIs) in the population. Quantitative analyses were conducted on SAS 9.4. Findings: Men were more likely to have a STI diagnosis (OR=3.60; 95% CI 3.00, 4.32, p=<0.001). Previous HIV testing was found to be protective for STI diagnosis across both genders (OR=0.82, 95% CI 0.72, 0.94, p=<0.001). Co-infections of HIV/gonorrhea and HIV/syphilis (n=20) were the highest in the study population. The latent variable model indicates mental health and access to health care resources are critical for positive sexual and reproductive health outcomes in Mexico. Mental health was found to be non-protective for STI risk among the study population (OR=1.59, 95% CI 1.41, 1.81, p=<0.0001). Policy recommendations: 1. Increased access and utilization of HIV resources and mental health services would benefit the study population. Further qualitative research is needed to better understand the barriers to health care access and utilization in these two domains; 2. Increase in preventative programs and health initiatives that encourage established strategies for positive sexual and reproductive health outcomes. These strategies include: universal human papillomavirus (HPV) vaccines, wide availability of Pre-Exposure Prophylaxis (PrEP), and routine HIV/STI screenings; 3. Alternative data collection strategies for ENSANUT which are culturally appropriate for sexual and reproductive health constructs. Essay	2017	van de Laar, Thijs Jw; Richel, Olivier	Emerging viral STIs among HIV-positive men who have sex with men: the era of hepatitis C virus and human papillomavirus.	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2016-052677	https://dx.doi.org/10.1136/sextrans-2016-052677	The number of infectious disease outbreaks and the number of unique pathogens responsible have significantly increased since the 1980s. HIV-positive men who have sex with men (MSM) are a vulnerable population with regards to the introduction, spread and clinical consequences of (newly introduced) STIs. After the introduction of combination antiretroviral treatment (cART), the incidence of sexually acquired hepatitis C virus (HCV) infection and human papillomavirus (HPV)-induced anal cancers have significantly increased among HIV-positive MSM. The introduction and expansion of HCV is the result of increased sexual risk behaviour and sexually acquired mucosal trauma within large interconnected networks of HIV-positive MSM in particular. With the availability of cART, postexposure and pre-exposure prophylaxis (PEP and PrEP) and direct-acting antivirals (DAAs) for HCV, less concern for HIV and HCV might require a new approach to develop effective behavioural intervention strategies among MSM. The marked rise in HPV-induced anal cancers can be ascribed to the long-term immunologic defects in an ageing population affected by HIV. More evidence with regards to effective treatment options for anal dysplastic lesions and the usefulness of anal malignancy screening programmes is urgently needed. Most anal cancers in the future generation of HIV-positive MSM could be prevented with the inclusion of boys in addition to girls in current HPV vaccination programmes. Article	2017	Van Der Straten A.; Shapley-Quinn M.K.; Reddy K.; Cheng H.; Etima J.; Woeber K.; Musara P.; Palanee-Phillips T.; Baeten J.M.; Montgomery E.T.	Favoring "peace of Mind": A Qualitative Study of African Women's HIV Prevention Product Formulation Preferences from the MTN-020/ASPIRE Trial	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2017.0075	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85023748811&doi=10.1089%2fapc.2017.0075&partnerID=40&md5=f8106d253303db8e19756421a0e06656	Several formulations of HIV pre-exposure prophylaxis (PrEP) have shown varying levels of effectiveness in women. Little information is known about preference across formulations, especially among product experienced women. Seventy-one women (48% married; median age 26; range 18-45) who were participating in a vaginal ring trial for HIV prevention in Malawi, South Africa, Uganda, and Zimbabwe underwent an in-depth interview at their last study visit, during which they were presented with pictures and descriptions of nine possible product formulations (male and female condoms, oral tablets, injectables, implants, and a vaginal gel, ring, insert, and film). Each formulation was discussed, highlighting salient attribute(s) and contextual factors that may have informed stated preferences. Participants expressed most interest for long-acting PrEP formulations (rings, 94%; implants, 39%; injections, 34%), which were generally favored over short-acting ones. Participants appreciated the continuous protection offered, discreet usage, and the advantage of "peace of mind" imparted by simplified use and infrequent dosing, alleviating worries around forgetting doses. Preferred attributes of short-acting formulations included reversibility, user control, ease of administration, and low toxicity. Participants were least interested in the oral tablets (due to the daily dosing, difficulty swallowing pills, and HIV-related stigma), and the vaginal gel and film (due to vaginal insertion, coital dosing, effect on sex. and unfamiliarity with the method). Dislike for vaginally administered products was more pronounced among young women. Multiple factors played into potential users' considerations for preferred formulations, emphasizing how a suite of options for prevention might best respond to women's needs and wants. © Copyright 2017, Mary Ann Liebert, Inc. 2017. Essay	2017	van der Wal, Ran, MSc, LLM; Loutfi, David, MSc	Pre-exposure prophylaxis for HIV prevention in East and Southern Africa	Canadian Journal of Public Health	-	-	-	00084263	10.17269/CJPH.108.6254	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-hiv-prevention-east/docview/1991565219/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) has proven to be highly effective in preventing HIV in uninfected persons when properly adhered to. East and Southern African countries that suffer from high HIV prevalence and incidence are increasingly adopting PrEP as an HIV prevention strategy for their high-risk populations, including for young women. Structural factors such as poverty, lack of education, and gender-based violence may compromise their PrEP uptake and adherence, however. Choice-disabled young women are most at risk of HIV infection and least able to apply HIV prevention choices. For successful rollout of this biomedical solution, we need structural interventions that address these underlying drivers of the HIV epidemic.Resumé alternativo:Lorsqu'elle est bien suivie, la prophylaxie pré-exposition (PPrE) s'avere hautement efficace pour prévenir le VIH chez les personnes non infectées. Les pays d'Afrique de l'Est et d'Afrique australe aux prises avec des taux élevés de prévalence et d'incidence du VIH adoptent de plus en plus la PPrE comme stratégie de prévention du VIH dans les populations à risque élevé, en particulier les jeunes femmes. Les facteurs comme la pauvreté, le manque d'instruction et la violence sexiste peuvent toutefois compromettre l'utilisation et l'observance de la PPrE dans ces populations. Les jeunes femmes défavorisées sur le plan des choix sont les plus vulnérables aux infections à VIH et les moins capables de mettre en pratique les choix de prévention du VIH. Pour un déploiement réussi de cette solution biomédicale, nous avons besoin d'interventions structurelles qui tiennent compte des vecteurs sous-jacents de l'épidémie de VIH. Article	2017	van Griensven, Frits; Guadamuz, Thomas E.; de Lind van Wijngaarden, Jan Willem; Phanuphak, Nittaya; Solomon, Sunil Suhas; Lo, Ying-Ru	Challenges and emerging opportunities for the HIV prevention, treatment and care cascade in men who have sex with men in Asia Pacific.	Sexually Transmitted Infections	-	-	-	1472-3263 1368-4973	10.1136/sextrans-2016-052669	https://pubmed.ncbi.nlm.nih.gov/28729520/	In Asia Pacific, most countries have expanded HIV treatment guidelines to include all those with HIV infection and adopted antiretroviral treatment for prevention (TFP) as a blanket strategy for HIV control. Although the overall epidemic development associated with this focus is positive, the HIV epidemic in men who have sex with men (MSM) is continuing unperturbed without any signs of decline or reversal. This raises doubt about whether TFP as a blanket HIV prevention policy is the right approach. This paper reviews currently available biomedical HIV prevention strategies, national HIV prevention policies and guidelines from selected countries and published data on the HIV cascade in MSM. No evidence for efficacy of TFP in protecting MSM from HIV infection was found. The rationale for this approach is based on assumptions about biological plausibility and external validity of latency-based efficacy found in heterosexual couples. This is different from the route and timing of HIV transmission in MSM. New HIV infections in MSM principally occur in chains of acutely HIV-infected highly sexually active young men, in whom acquisition and transmission are correlated in space and time. By the time TFP renders its effects, most new HIV infections in MSM will have already occurred. On a global level, less than 6% of all reports regarding the HIV care cascade from 1990 to 2016 included MSM, and only 2.3% concerned MSM in low/middle-income countries. Only one report originated from Asia Pacific. Generally, HIV cascade data in MSM show a sobering picture of TFP in engaging and retaining MSM along the continuum. Widening the cascade with a preventive extension, including pre-exposure prophylaxis, the first proven efficacious and only biomedical HIV prevention strategy in MSM, will be instrumental in achieving HIV epidemic control in this group.	*Homosexuality, Male; Humans; Male; Young Adult; Risk-Taking; Risk Factors; HIV; Health Knowledge, Attitudes, Practice; antiretroviral therapy; Poverty; HIV Infections/*drug therapy/epidemiology/*prevention & control; pre-exposure prophylaxis; Pre-Exposure Prophylaxis; prevention and control; Asia/epidemiology; sexual behavior; acquired Immunodeficiency syndrome; Acquired Immunodeficiency Syndrome/*drug therapy/epidemiology/*prevention & control/*therapy	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2017	Van Rompay, Koen K A	Tackling HIV and AIDS: contributions by non-human primate models.	Lab Animal (NY)	-	-	-	1548-4475	10.1038/laban.1279	https://dx.doi.org/10.1038/laban.1279	During the past three decades, non-human primate (NHP) models have gained an increasing importance in HIV basic and translational research. In contrast to natural host models, infection of macaques with virulent simian or simian-human immunodeficiency viruses (SIV, SHIV) results in a disease that closely resembles HIV infection and AIDS. Although there is no perfect animal model, and each of the available models has its benefits and limitations, carefully designed NHP studies with selection of experimental variables have unraveled important questions of basic pathogenesis and have provided the tools to explore and screen intervention strategies. For example, NHP studies have advanced our understanding of the crucial events during early infection, and have provided proof-of-concept of antiretroviral drug treatment and prevention strategies such as pre-exposure prophylaxis (PrEP) regimes that are increasingly used worldwide, and upon overcoming further barriers of implementation, have the potential to make the next generation AIDS-free. Remaining goals include the pursuit of an effective HIV vaccine, and HIV cure strategies that would allow HIV-infected people to ultimately stop taking antiretroviral drugs. Through a reiterative process with feed-back from results of human studies, NHP models can be further validated and strengthened to advance our scientific knowledge and guide clinical trials. Depression and ART Initiation Among HIV Serodiscordant Couples in Kenya and Uganda	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1829-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021051284&doi=10.1007%2fs10461-017-1829-z&partnerID=40&md5=d81393a1d01fd4e5ffdc772f9e56f76d	Depression is a known barrier for antiretroviral therapy (ART) adherence, but less is understood about its effects on ART initiation. We followed 1013 HIV-infected individuals participating in the Partners Demonstration Project, an open-label study of integrated pre-exposure prophylaxis (PrEP) and ART delivery for HIV serodiscordant couples in Kenya and Uganda. Associations between depression, measured annually with the Hopkins Symptoms Checklist-Depression (HSCL-D), and ART initiation were assessed with Cox proportional hazards regression. At enrollment, 162 participants (16.0%) reported symptoms consistent with probable depression, defined by a HSCL-D mean score >1.75, and this proportion decreased during study follow-up (6.7 and 3.6% at 12- and 24-months, respectively; p value < 0.001). Greater depressive symptom severity was associated with a greater likelihood of ART initiation overall (adjusted hazard ratio aHR 1.32, 95% CI 1.01–1.73) and among participants with CD4 count ≤ 350 cells/µl (aHR 1.30, 95% CI 1.01–1.67). Depression decreased 6 months after ART initiation (adjusted odds ratio aOR 0.34, 95% CI 0.23–0.51). Among East African HIV-infected persons in HIV serodiscordant couples, depression was not a barrier to ART initiation. ART initiation was associated with improved depressive symptoms in this setting. © 2017, Springer Science+Business Media, LLC. Article	2017	Velloza, Jennifer; Heffron, Renee	The Vaginal Microbiome and its Potential to Impact Efficacy of HIV Pre-exposure Prophylaxis for Women.	Current HIV/AIDS Reports	-	-	-	1548-3576	10.1007/s11904-017-0362-z	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5693614	PURPOSE OF REVIEW: This review describes existing evidence addressing the potential modulation of pre-exposure prophylaxis (PrEP) products, specifically 1% tenofovir (TFV) gel and oral tenofovir-based PrEP, by vaginal dysbiosis and discusses future considerations for delivering novel, long-acting PrEP products to women at high risk for vaginal dysbiosis and HIV. RECENT FINDINGS: We describe results from analyses investigating the modification of PrEP efficacy by vaginal dysbiosis and studies of biological mechanisms that could render PrEP ineffective in the presence of specific microbiota. A secondary analysis from the CAPRISA-004 cohort demonstrated that there is no effect of the 1% TFV gel in the presence of non-Lactobacillus dominant microbiota. Another recent analysis comparing oral tenofovir-based PrEP efficacy among women with and without bacterial vaginosis in the Partners PrEP Study found that oral PrEP efficacy is not modified by bacterial vaginosis. Gardnerella vaginalis, commonly present in women with vaginal dysbiosis, can rapidly metabolize TFV particularly when it is locally applied and thereby prevent TFV integration into cells. Given that vaginal dysbiosis appears to modulate efficacy for 1% TFV gel but not for oral tenofovir-based PrEP, vaginal dysbiosis is potentially less consequential to HIV protection from TFV in the context of systemic drug delivery and high product adherence. Vaginal dysbiosis may undermine the efficacy of 1% TFV gel to protect women from HIV but not the efficacy of oral PrEP. Ongoing development of novel ring, injectable, and film-based PrEP products should investigate whether vaginal dysbiosis can reduce efficacy of these products, even in the presence of high adherence. Essay	2017	Viciana, Pompeyo	Rilpivirine: The Key for Long-term Success.	AIDS Reviews	-	-	-	1698-6997	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-29066858	During the past 30 years of antiretroviral therapy, continuous improvements in drug discovery have provided increasingly potent and safer antivirals that have transformed HIV infection in a chronic illness, rarely fatal. Non-nucleoside reverse-transcriptase inhibitors (NNRTIs) are frequently used as part of any antiretroviral combination therapy. Side effects and low resistance barrier of fi rst-generation NNRTIs (e.g., nevirapine and efavirenz) have been overcome with rilpivirine (RPV), and the last NNRTI approved for the treatment of HIV infection. The good efficacy, safety profi le, and convenient dosing of RPV account for the unique durability of RPV-based regimens. The advent of new oral fi xed-dose coformulations of RPV (e.g., along with dolutegravir or with tenofovir alafenamide TAF/emtricitabine FTC) as well as the development of long-acting injectable RPV nanoformulations will further expand its therapeutic landscape, including RPV use in dual maintenance therapy in HIV-infected patients or as pre-exposure prophylaxis in high-risk uninfected individuals. Article	2017	Vieira, Vinicius A; Avelino-Silva, Vivian I; Cerqueira, Natalia B; Costa, Dayane A; Costa, Priscilla R; Vasconcelos, Ricardo P; Madruga, Valdez R; Moreira, Ronaldo I; Hoagland, Brenda; Veloso, Valdilea G; Grinsztejn, Beatriz; Kallás, Esper G	Asymptomatic anorectal Chlamydia trachomatis and Neisseria gonorrhoeae infections are associated with systemic CD8+ T-cell activation.	AIDS	-	-	-	1473-5571	10.1097/QAD.0000000000001580	https://dx.doi.org/10.1097/QAD.0000000000001580	BACKGROUND: Oral preexposure prophylaxis (PrEP) has been established as a pivotal strategy in HIV prevention. However, bacterial sexually transmitted infections (STIs), such as Chlamydia trachomatis and Neisseria gonorrhoeae, are also highly prevalent. Although the presence of STI-related mucosal lesions is a known risk factor for HIV acquisition, the potential increase in risk associated with asymptomatic STIs is not completely understood. Recent data demonstrated higher T-cell activation is a risk factor for sexually acquired HIV-1 infection. We examined the effect of asymptomatic C. trachomatis and N. gonorrhoeae anorectal infection on systemic immune activation, potentially increasing the risk of HIV acquisition. METHODS: We analyzed samples from participants of PrEP Brasil, a demonstration study of daily oral emtricitabine/tenofovir disoproxil fumarate HIV PrEP among healthy MSM, for T-cell activation by flow cytometry. We included 34 asymptomatic participants with anorectal swab for C. trachomatis and/or N. gonorrhoeae infection, whereas negative for other STIs, and 35 controls. RESULTS: We found a higher frequency of human leukocyte antigen DRCD38 CD8 T cells (1.5 vs. 0.9%, Pâ‰¤0.005) and with memory phenotype in the group with asymptomatic C. trachomatis and/or N. gonorrhoeae infection. Exhaustion and senescence markers were also significant higher in this group. No difference was observed in the soluble CD14 levels. CONCLUSION: Our findings suggest asymptomatic anorectal C. trachomatis and/or N. gonorrhoeae increase systemic immune activation, potentially increasing the risk of HIV acquisition. Regular screening and treatment of asymptomatic STIs should be explored as adjuvant tools for HIV prevention. Theses and Dissertations	2017	Vinicius Adriano Vieira	Avaliação da ativação de linfócitos T em indivíduos com infecção anorretal assintomática por Chlamydia trachomatis e/ou Neisseria gonorrhoeae em uma população de homens que fazem sexo com homens	-	-	Universidade de São Paulo	-	NA	NA	http://www.teses.usp.br/teses/disponiveis/5/5146/tde-31012018-083320/	Oral antiretroviral pre-exposure prophylaxis (PrEP) has been established as a pivotal strategy in the prevention against HIV epidemic. However, the incidence of HIV-1 infections has been rising among the youth, as well as other sexually transmitted infections (STIs), acting as an important risk factor for HIV-1 acquisition. Infection by Chlamydia trachomatis (CT) and Neisseria gonorrhoeae (NG) are among the most diagnosed. Although the presence of mucosal lesions is a known risk factor for HIV-1 acquisition, the potential increase in risk associated with asymptomatic STIs is not completely understood. Recent data defined higher T cell activation as a single risk factor for sexually acquired HIV-1 infection. We examined the effect of asymptomatic CT and/or NG anorectal infection on immune activation. Peripheral blood mononuclear cells from participants of PrEP Brasil, a study of daily oral PrEP among healthy men who have sex with men, were analyzed for T cell activation by…	Ativação celular ; Ativação linfocitária ; Chamydia trachomatis ; HIV ; Homossexualidade masculina ; Imunidade celular ; Linfócitos T ; Neisseria gonorrhoeae ; Profilaxia préexposição ; Cellular activation ; Chlamydia trachomatis ; HIV ; Immunity cellular ; Lymphocyte activation, Homosexuality male ; Neisseria gonorrhoeae ; Pre-exposure prophylaxis ; T-lymphocyte	Portuguese	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	-	-	Clinical
Article	2017	Wagner, Cornelia M J; Carlberg-Racich, Suzanne; Linsk, Nathan L; Sherer, Renslow; Alabduljabbar, Salma A; Hasnain, Memoona; Rivero, Ricardo	Impacts of Longitudinal Mentorship to Strengthen the HIV Workforce: Qualitative Evidence of Changes in Clinicians' Knowledge, Attitudes, and Practice.	Journal of the Association of Nurses in AIDS Care	-	-	-	1552-6917	10.1016/j.jana.2017.06.013	https://dx.doi.org/10.1016/j.jana.2017.06.013	The Clinician Scholars Program at the Midwest AIDS Training and Education Center strengthens the workforce by increasing knowledge and skills related to HIV prevention and care. The 1-year individualized training program for minority-serving clinicians includes intensive mentoring and networking. Qualitative exit interviews (N = 50) conducted over 4 years demonstrate the effectiveness of the training, including changes at the individual and systems levels. Findings show that almost all graduates reported improvements in knowledge, two-thirds reported changes in empathic capacity and cultural competence, and nearly three-quarters reported changes in clinical practice. Scholars indicated improvements in knowledge and practice of HIV prevention, including pre-exposure prophylaxis and managing medications and comorbidities. A third of the Scholars reported improvements in their clinical practices related to linking and retaining patients in HIV care, which demonstrated positive movement along the HIV care continuum, a key focus area of the National HIV AIDS Strategy. Article	2017	Wahl, Angela; Ho, Phong T; Denton, Paul W; Garrett, Katy L; Hudgens, Michael G; Swartz, Glenn; O'Neill, Cynthia; Veronese, Fulvia; Kashuba, Angela D; Garcia, J Victor	Predicting HIV Pre-exposure Prophylaxis Efficacy for Women using a Preclinical Pharmacokinetic-Pharmacodynamic In Vivo Model.	Scientific Reports	-	-	-	2045-2322	10.1038/srep41098	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5286499	The efficacy of HIV pre-exposure prophylaxis (PrEP) relies on adherence and may also depend on the route of HIV acquisition. Clinical studies of systemic tenofovir disoproxil fumarate (TDF) PrEP revealed reduced efficacy in women compared to men with similar degrees of adherence. To select the most effective PrEP strategies, preclinical studies are critically needed to establish correlations between drug concentrations (pharmacokinetics PK) and protective efficacy (pharmacodynamics PD). We utilized an in vivo preclinical model to perform a PK-PD analysis of systemic TDF PrEP for vaginal HIV acquisition. TDF PrEP prevented vaginal HIV acquisition in a dose-dependent manner. PK-PD modeling of tenofovir (TFV) in plasma, female reproductive tract tissue, cervicovaginal lavage fluid and its intracellular metabolite (TFV diphosphate) revealed that TDF PrEP efficacy was best described by plasma TFV levels. When administered at 50 mg/kg, TDF achieved plasma TFV concentrations (370 ng/ml) that closely mimicked those observed in humans and demonstrated the same risk reduction (70%) previously attained in women with high adherence. This PK-PD model mimics the human condition and can be applied to other PrEP approaches and routes of HIV acquisition, accelerating clinical implementation of the most efficacious PrEP strategies. Article	2017	Waitt, Catriona; Diliiy Penchala, Sujan; Olagunju, Adeniyi; Amara, Alieu; Else, Laura; Lamorde, Mohammed; Khoo, Saye	Development, validation and clinical application of a method for the simultaneous quantification of lamivudine, emtricitabine and tenofovir in dried blood and dried breast milk spots using LC-MS/MS.	Journal of Chromatography B, Analytical Technologies in the Biomedical and Life Sciences	-	-	-	1873-376X 1570-0232	10.1016/j.jchromb.2017.06.012	https://pubmed.ncbi.nlm.nih.gov/28651173/	OBJECTIVES: To present the validation and clinical application of a LC-MS/MS method for the quantification of lamivudine (3TC), emtricitabine (FTC) and tenofovir (TFV) in dried blood spots (DBS) and dried breast milk spots (DBMS). METHODS: DBS and DBMS were prepared from 50 and 30μL of drug-spiked whole blood and human breast milk, respectively. Following extraction with acetonitrile and water, chromatographic separation utilised a Synergi polar column with a gradient mobile phase program consisting of 0.1% formic acid in water and 0.1% formic acid in acetonitrile. Detection and quantification was performed using a TSQ Quantum Ultra triple quadrupole mass spectrometer. The analytical method was used to evaluate NRTI drug levels in HIV-positive nursing mothers-infant pairs. RESULTS: The assay was validated over the concentration range of 16.6-5000ng/mL for 3TC, FTC and TFV in DBS and DBMS except for TFV in DBMS where linearity was established from 4.2-1250ng/mL. Intra and inter-day precision (%CV) ranged from 3.5-8.7 and accuracy was within 15% for all analytes in both matrices. The mean recovery in DBS was >61% and in DBMS >43% for all three analytes. Matrix effect was insignificant. Median AUC(0-8) values in maternal DBS and DBMS, respectively, were 4683 (4165-6057) and 6050 (5217-6417)ngh/mL for 3TC, 3312 (2259-4312) and 4853 (4124-6691)ngh/mL for FTC and 1559 (930-1915) and 56 (45-80)ngh/mL for TFV. 3TC and FTC were quantifiable (>16.6ng/mL) in DBS from 2/6 and 1/6 infants respectively whereas TFV was undetectable in all infants. CONCLUSIONS: DBS and DBMS sampling for bioanalysis of 3TC, FTC and TFV is straightforward, robust, accurate and precise, and ideal for use in low-resource settings. Article	2017	Walsh, Jennifer L; Petroll, Andrew E	Factors Related to Pre-exposure Prophylaxis Prescription by U.S. Primary Care Physicians.	American Journal of Preventive Medicine	-	-	-	1873-2607	10.1016/j.amepre.2017.01.025	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5438776	INTRODUCTION: Although pre-exposure prophylaxis (PrEP) greatly reduces risk of HIV infection in HIV-negative individuals, use is not widespread enough to impact HIV incidence. Involvement of primary care physicians (PCPs) in PrEP prescription is essential, but previous research has shown low rates of prescription among PCPs. To identify targets for interventions, the information-motivation-behavioral skills model for PrEP discussion and prescription was tested in a ten-city sample of PCPs. METHODS: PCPs from ZIP codes with high HIV incidence in ten U.S. cities (N=280, 52% male, 56% white) completed a survey online between July 2014 and May 2015. Information items assessed knowledge, motivation items evaluated attitudes, and behavioral skills items measured comfort with behaviors involved in prescribing PrEP. Providers indicated whether they had discussed PrEP with or prescribed PrEP to patients. Data were analyzed in 2015 and 2016. RESULTS: One third of PCPs had discussed and 17% had prescribed PrEP. A structural equation model with good fit supported the information-motivation-behavioral skills model. Information and motivation predicted behavioral skills (b=0.35, 95% CI=0.13, 0.57; and b=0.31, 95% CI=0.14, 0.47, respectively). Behavioral skills predicted prescription (b=0.27, 95% CI=0.12, 0.42). Furthermore, behavioral skills mediated effects of information and motivation on prescription (b=0.10, 95% CI=0.03, 0.19; and b=0.08, 95% CI=0.03, 0.16, respectively). CONCLUSIONS: The information-motivation-behavioral skills model can be applied to PCPs' PrEP discussion and prescription. Its constructs represent potential targets for PCP-directed interventions to increase PrEP use in high-risk populations. Article	2017	Walters, Suzan M; Reilly, Kathleen H; Neaigus, Alan; Braunstein, Sarah	Awareness of pre-exposure prophylaxis (PrEP) among women who inject drugs in NYC: the importance of networks and syringe exchange programs for HIV prevention	Harm Reduction Journal	-	-	-	1477-7517	10.1186/s12954-017-0166-x	https://pubmed.ncbi.nlm.nih.gov/28662716/	Women who inject drugs (WWID) are at heightened risk for HIV due to biological, behavioral, and structural factors. Pre-exposure prophylaxis (PrEP) could aid in HIV prevention for WWID. However, little is known about WWID awareness of PrEP, which is a necessary step that must occur before PrEP uptake. We report factors associated with greater awareness among WWID to identify efficient means of awareness dissemination. Data from the 2015 National HIV Behavioral Surveillance (NHBS) system cycle on injection drug use collected in New York City (NYC) were used. Bivariable analyses, using chi-squared statistics, were conducted to examine correlates of awareness of PrEP with socio-demographic, behavioral, and health care variables. Multivariable logistic regression was used to estimate adjusted associations and determine differences in awareness of PrEP. The analysis consisted of 118 WWID. Awareness of PrEP was relatively low (31%), and risk factors were high. In the last 12 months, almost two thirds (65%) reported condomless sex, approximately one third (31%) reported transactional sex, and one third (32%) reported sharing injection equipment. In multivariable logistic regression, increased PrEP awareness was associated with reported transactional sex (AOR 3.32, 95% CI 1.22-9.00) and having a conversation about HIV prevention at a syringe exchange program (SEP) (AOR 7.61, 95% CI 2.65-21.84). We did not find race, education, household income, age, binge drinking, or sexual identity to be significantly associated with PrEP awareness. Large proportions of WWID were unaware of PrEP. These findings suggest that social networks (specifically sex work and SEP networks) are an efficient means for disseminating messaging about prevention materials such as PrEP. We recommend that SEP access increase, SEP processes be adopted in other health care settings, and WWID networks be utilized to increase PrEP awareness. Article	2017	Walters, Suzan M; Rivera, Alexis V; Starbuck, Lila; Reilly, Kathleen H; Boldon, Nyasha; Anderson, Bridget J; Braunstein, Sarah	Differences in Awareness of Pre-exposure Prophylaxis and Post-exposure Prophylaxis Among Groups At-Risk for HIV in New York State: New York City and Long Island, NY, 2011-2013.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001415	https://dx.doi.org/10.1097/QAI.0000000000001415	BACKGROUND: Pre-exposure prophylaxis (PrEP) to reduce the risk of HIV was approved in 2012 and post-exposure prophylaxis (PEP) in 2005. We report the differences in awareness of PrEP/PEP and factors associated with awareness by examining 3 risk groups (men who have sex with men (MSM), people who inject drugs, and high-risk heterosexuals). METHODS: National HIV Behavioral Surveillance system data collected in New York City (NYC) and Long Island, NY in 2011-2013 were used. Logistic regressions by region were developed to estimate adjusted associations Adjusted Odds Ratios (AOR) and determine differences in awareness of PrEP/PEP. RESULTS: Awareness of PrEP/PEP was low for all groups. In multivariate analysis controlling for sociodemographic factors, noninjection drug use, HIV status, and exposure to HIV prevention, males who inject drugs in NYC had significantly decreased odds of PrEP/PEP awareness AOR: 0.45; confidence interval (CI): 0.25 to 0.81 compared with MSM. MSM aged 18-29 years had increased awareness of PrEP (AOR: 2.94; 95% CI 1.11 to 7.80). On Long Island, females who inject drugs (AOR: 0.18; 95% CI: 0.05 to 0.62), males who inject drugs (AOR: 0.14; 95% CI: 0.05 to 0.39), female heterosexuals (AOR: 0.25; 95% CI: 0.11 to 0.59), and male heterosexuals (AOR: 0.32; 95% CI: 0.14 to 0.73) had significantly decreased odds of PrEP/PEP awareness. Black MSM had increased awareness of PrEP (AOR: 4.08 CI:1.21 to 13.73). CONCLUSIONS: Large proportions of groups at-risk for HIV were unaware of PrEP/PEP. When comparing risk groups to MSM, we found MSM to have greater awareness in both regions. On Long Island, people who inject drugs and heterosexuals were far less likely to have PrEP/PEP awareness than in NYC. On Long Island, Black MSM had increased PrEP awareness and in NYC MSM aged 18-29 had increased PrEP awareness. These findings suggest that awareness may be spreading through networks and highlight the importance of targeted educational and prevention efforts by group and region. Article	2017	Wang Z.; Lau J.T.F.; Yang X.; Cai Y.; Gross D.L.; Ma T.; Liu Y.	Acceptability of Daily Use of Free Oral Pre-exposure Prophylaxis (PrEP) Among Transgender Women Sex Workers in Shenyang, China	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1869-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026918909&doi=10.1007%2fs10461-017-1869-4&partnerID=40&md5=8a3472c00cb9afd1fc6521d827a74223	This study investigated the acceptability of daily use of free oral pre-exposure prophylaxis (PrEP) and associated factors among transgender women sex workers in Shenyang, China, following a briefing on PrEP. A total of 183 HIV negative or sero-status unknown participants completed the cross-sectional survey. The prevalence of acceptability of daily use of free oral PrEP was 61.2%. Adjusting for education level and monthly income, variables on negative attitudes toward PrEP (i.e., having concerns about the side-effects of PrEP) Adjusted odds ratios (AOR): 0.26, perceived subjective norms (i.e., perceiving support from male partners to take PrEP) (AOR: 2.08), and perceived behavioral control (e.g., perceiving complete control over using PrEP) (AOR: 2.10–16.72) were significantly associated with acceptability of daily use of free oral PrEP. In addition, experiencing violence during sex work, perceived risk of contracting HIV from clients and probable anxiety were also significant. Future PrEP promotion campaigns should consider these factors. © 2017, Springer Science+Business Media, LLC. Article	2017	Weiser J.; Garg S.; Beer L.; Skarbinski J.	Prescribing of Human Immunodeficiency Virus (HIV) pre-exposure prophylaxis by HIV medical providers in the United States, 2013-2014	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/oid/ofx003	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85014248620&doi=10.1093%2fofid%2fofx003&partnerID=40&md5=9e911a31aada6bc8e2700c82f148a155	Background. Clinical trials have demonstrated the effectiveness of human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) for reducing HIV acquisition. Understanding how HIV care providers are prescribing PrEP is necessary to ensure success of this prevention strategy. Methods. During 2013-2014, we surveyed US HIV care providers who also provided care to HIV-negative patients. We estimated percentages who had prescribed PrEP and assessed associations between provider characteristics and PrEP prescribing. Results. An estimated 26% (95% confidence interval CI, 20-31) had ever prescribed PrEP. Of these, 74% (95% CI, 61-87) prescribed for men who have sex with men (MSM), 30% (95% CI, 21-39) for women who have sex with men, 23% (95% CI, 9-37) for men who have sex with women, 23% (95% CI, 15-30) for uninfected partners in HIV-discordant couples trying to conceive, and 1% (95% CI, 0-2) for persons who inject drugs. The following provider characteristics were significantly associated with having prescribed PrEP: male vs female (32% vs 16%; adjusted prevalence ratio aPR, 1.5; 95% CI, 1.0-2.2), lesbian/gay/bisexual vs heterosexual orientation (50% vs 21%; aPR, 2.0; 95% CI, 1.3-2.9), and HIV caseload (> 200, 51-200, and ≤50 patients, 39%, 29%, and 14%, respectively; > 200 vs ≤50 patients, aPR 2.4, 95% CI 1.1-5.2, and 51-200 vs ≤50 patients, aPR 2.2, 95% CI 1.2-4.0). Conclusions. In 2013-2014, one quarter of HIV care providers reported having prescribed PrEP, most commonly for MSM and rarely for persons who inject drugs. Lesbian/gay/bisexual providers and male providers were more likely than others to have prescribed PrEP. Additional efforts may enable more providers to prescribe PrEP to underserved clients needing the service. Article	2017	Weld, Ethel D; Hiruy, Hiwot; Guthrie, Kate Morrow; Fava, Joseph L; Vargas, Sara E; Buckheit, Karen; Buckheit, Robert; Spiegel, Hans; Breakey, Jennifer; Fuchs, Edward J; Hendrix, Craig W	A Comparative Pre-Phase I Study of the Impact of Gel Vehicle Volume on Distal Colon Distribution, User Experience, and Acceptability.	AIDS Research and Human Retroviruses	-	-	-	1931-8405	10.1089/AID.2016.0167	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5439405	For persons at risk of HIV infection who practice receptive anal intercourse (RAI), topical rectal microbicides represent a promising option for coitally dependent protection. The study compared colorectal distribution and user sensory experiences of two different volumes of rectal gel for suitability as rectal microbicide. Eight HIV-negative men with a history of recent RAI were enrolled into a two-period, sequence-randomized dosing study comparing 3.5 and 10 ml of radiolabeled (1 mCi 99mTc-DTPA) universal placebo, hydroxyethyl cellulose gel. Each participant received two doses in the research unit, one of each volume, separated by a washout period of at least 2 weeks. Each research unit dose was followed by a self-administered take-home dose in the context of preparing for RAI. Safety and gastrointestinal distribution were assessed after the research unit doses, safety, perceptibility, and acceptability were assessed after take-home doses. There were no adverse effects of Grade 2 or higher and all resolved spontaneously. Both volumes were well tolerated and received high acceptability scores. Perceptibility scores showed meaningful effect size differences ranging from Cohen's d = 0.5 to d = 1.2. The 3.5 and 10 ml gel volumes distributed similarly (p > .2) within the rectosigmoid, ranging from 0.69 to 18.84 cm and 1.21 to 19.01 cm from the anorectal junction, respectively. Both volumes covered the typical gastrointestinal distribution of ejaculate following simulated intercourse based on other studies. Either of these gel volumes could reasonably be pursued for the next phase of development of rectal microbicides.	microbicide, pre-exposure prophylaxis, human immunodeficiency virus, gastrointestinal distribution, pharmacokinetics, acceptability	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2017	Wenzel S.L.; Henwood B.; Harris T.; Winetrobe H.; Rhoades H.	Provider perceptions on HIV risk and prevention services within permanent supportive housing	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1330533	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85019539002&doi=10.1080%2f09540121.2017.1330533&partnerID=40&md5=0dfad3bd9c7e15e2a08c3c71880f0c5c	Permanent supportive housing (PSH) is an evidence-based solution to homelessness for persons experiencing chronic or long-term homelessness and one or more physical or behavioral health problems. Health services through PSH typically focus on physical and behavioral health. With the exception of programs specifically designed for persons living with HIV/AIDS, little attention has focused on services through PSH to prevent transmission of HIV or other sexually transmitted infections (STIs), yet sexual risk behavior continues after homeless persons move into PSH. The purpose of this study was to investigate how PSH providers approach HIV prevention and the challenges they perceive surrounding HIV prevention in PSH. Results serve as a critical first step toward addressing the acceptability and feasibility of providing HIV/STI prevention services to PSH residents. As part of a longitudinal mixed methods study examining HIV risk and prevention behavior among homeless unaccompanied adults moving into PSH in Los Angeles, we conducted eleven focus groups with a total of 60 frontline staff across 10 PSH agencies. Thirty-three percent of focus group participants were African American, 32% were Hispanic, and 55% were women. Results suggest that provider awareness and knowledge of PrEP is very limited, and provision of formal HIV prevention programing for residents is perceived as challenging. Informal, ad hoc conversations with residents about sexual risk and HIV prevention do occur when providers have rapport with clients and perceive risk. There are significant gaps in HIV prevention services through PSH but also opportunities to enhance providers' efforts to promote the health of residents through prevention. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2017	Wenzel, Suzanne L; Rhoades, Harmony; Harris, Taylor; Winetrobe, Hailey; Rice, Eric; Henwood, Ben	Risk behavior and access to HIV/AIDS prevention services in a community sample of homeless persons entering permanent supportive housing.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2016.1234690	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6232079	Homeless persons suffer disproportionately high rates of HIV infection, and moving into permanent supportive housing (PSH) can provide a stable base from which to access needed prevention services. However, little is known about HIV risk or prevention behavior during this critical time of transition. The current study investigated STI and HIV risk and prevention behavior and recent use of prevention and treatment services (i.e., education, testing, medication) among homeless persons preparing to move into PSH. Data come from interviews with 421 homeless adults before they moved into PSH. Thirty-seven percent of the respondents were sexually active; of those, 75.7% reported unprotected sex. Nearly two-thirds (64%) reported past year HIV testing and 40% reported testing for another STI. Fewer than one-third (31%) of respondents reported receiving posttest counseling at their last HIV test. HIV seropositivity was self-reported by 10%. Among those persons who were HIV-positive, 57.1% reported less than 100% antiretroviral (ARV) adherence. Among HIV-negative respondents, less than 1% had been prescribed preexposure prophylaxis (PrEP). Less than half (46.4%) of the sample reported any HIV prevention education in the past year. This population of homeless adults about to move into PSH report high rates of HIV risk behavior, but low rates of HIV prevention education and very little PrEP utilization. Further, low rates of ARV adherence among HIV-positive respondents indicate significant risk for HIV transmission and acquisition. Entering PSH is a period of transition for homeless persons when integrated care is critically important to ensure positive health outcomes, but these data suggest that PrEP and other HIV prevention services are poorly accessed among this population. As such, multipronged services that integrate PrEP and other HIV prevention services are needed to prevent transmission and acquisition of HIV in this high-risk, vulnerable population and ensure the health and wellbeing of PSH residents. Article	2017	Whitfield, THF; Rendina, HJ; Grov, C; Parsons, JT	SEXUAL SATISFACTION, ANXIETY, AND ESTEEM WHILE PRESCRIBED PRE-EXPOSURE PROPHYLAXIS (PREP) AMONG GAY AND BISEXUAL MEN.	Annals of Behavioral Medicine	-	-	-	0883-6612	NA	https://pubmed.ncbi.nlm.nih.gov/30777781/	Gay and bisexual men (GBM) with heightened fears of human immunodeficiency virus (HIV) acquisition have reported high levels of sexual anxiety and low sexual self-esteem. Similarly, sexual satisfaction has been reported to be lower among some GBM who rely solely on condom use as HIV prevention. We sought to explore whether pre-exposure prophylaxis (PrEP) had an impact on the sexual satisfaction, anxiety, and esteem of GBM. As part of a longitudinal cohort study of 1,071 GBM, participants reported at three time points on PrEP use and completed the Multidimensional Sexual Self-Concept Questionnaire (MSSCQ). A total of 137 GBM began taking PrEP in the 24 months following baseline. Comparing their responses during times before initiating PrEP and after, within adjusted multilevel models, there was a significant decrease in sexual anxiety (B = -0.27, p = 0.03) but no significant changes in sexual esteem or satisfaction. Our findings indicate important psychological improvements resulting from PrEP initiation. Further research should explore the potential for other psychological benefits of PrEP use among GBM. Article	2017	Whitlock, G; McCormack, C; Fearnley, J; McOwan, A	High HIV incidence in men who have sex with men attending for postexposure prophylaxis: a service evaluation.	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2016-052623	https://dx.doi.org/10.1136/sextrans-2016-052623	BACKGROUND/AIMS: There are limited outcome data for men who have sex with men (MSM) who have received HIV postexposure prophylaxis (PEP). The objective of this service evaluation was to determine HIV incidence and repeat PEP use among MSM PEP recipients in London, UK. METHODS: Retrospective electronic case-note review of all MSM who were prescribed PEP between January and April 2013 at a central London sexual health service. RESULTS: 530 MSM received PEP between 1 January and 30 June 2013. Of these, 449 had more than 30âdays subsequent follow-up at our service. Median age was 31âyears. PEP indication was unprotected anal intercourse, 98% (receptive 88% and insertive 10%) and other, 2%. Up to 1 November 2015, total follow-up was 756 person-years. 183 users received repeat PEP. The total number of repeat PEP courses was 442. 57 MSM newly acquired HIV: the HIV incidence was 7.6 per 100 person-years. CONCLUSIONS: PEP was associated with a high risk of subsequent HIV seroconversion in this cohort; this group may be appropriate candidates for pre-exposure prophylaxis. Article	2017	Williams, Brian G; Gupta, Somya; Wollmers, Matthew; Granich, Reuben	Progress and prospects for the control of HIV and tuberculosis in South Africa: a dynamical modelling study.	The Lancet Public Health	-	-	-	2468-2667	10.1016/S2468-2667(17)30066-X	https://dx.doi.org/10.1016/S2468-2667(17)30066-X	BACKGROUND: In September, 2016, South Africa adopted a policy of providing antiretroviral treatment to everyone infected with HIV irrespective of their CD4 cell count. Studies of universal treatment and expanded prevention of HIV differ widely in their projections of effects and the associated costs, so we did this analysis to attempt to find a consensus. METHODS: We used data on HIV from the Joint UN Programme on HIV and AIDS (UNAIDS) from 1988 to 2013 and from data from WHO on tuberculosis from 1980 to 2013 to fit a dynamical model to time trends in HIV prevalence, antiretroviral therapy (ART) coverage, and tuberculosis notification rates in South Africa. We then used the model to estimate current trends and project future patterns in HIV prevalence and incidence, AIDS-related mortality, and tuberculosis notification rates, and we used data from the South African National AIDS Council to assess current and future costs under different combinations of treatment and prevention approaches. We considered two treatment strategies: the Constant Effort strategy, in which people infected with HIV continue to start treatment at the rate in 2016, and the Expanded Treatment and Prevention (ETP) strategy, in which testing rates are increased, treatment is started immediately after HIV is detected, and prevention programmes are expanded. FINDINGS: Our estimates show that HIV incidence among adults aged 15 years or older fell from 2·3% per year in 1996 to 0·65% per year in 2016, AIDS-related mortality decreased from 1·4% per year in 2006 to 0·37% per year in 2016, and both continue to fall at a relative rate of 17% per year. Our model shows that maintenance of Constant Effort will have a substantial effect on HIV but will not end AIDS, whereas ETP could end AIDS by 2030, with incidence of HIV and AIDs-related mortality rates both at less than one event per 1000 adults per year. Under ETP the annual cost of health care and prevention will increase from US$2·3 billion in 2016 to $2·9 billion in 2018, then decrease to $1·7 billion in 2030 and $0·9 billion in 2050. Over the next 35 years, the expansion of treatment will avert an additional 3·8 million new infections, save 1·1 million lives, and save $3·2 billion compared with continuing Constant Effort up to 2050. Expansion of prevention, including provision of pre-exposure prophylaxis, condom distribution, and male circumcision, could avert a further 150â000 new infections, save 5000 lives, and cost an additional $5·7 billion compared with Constant Effort. INTERPRETATION: Our results suggest that South Africa is on track to reduce HIV incidence and AIDS-related mortality substantially by 2030, saving both lives and money. Success will depend on high rates of HIV testing, ART delivery and adherence, good patient monitoring and support, and data to monitor progress. FUNDING: None. Article	2017	Willie, Tiara; Kershaw, Trace; Campbell, Jacquelyn C; Alexander, Kamila A	Intimate Partner Violence and PrEP Acceptability Among Low-Income, Young Black Women: Exploring the Mediating Role of Reproductive Coercion	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1767-9	https://www.proquest.com/scholarly-journals/intimate-partner-violence-prep-acceptability/docview/1924200878/se-2?accountid=8113	A few studies suggest that women who experience intimate partner violence (IPV) are willing to use pre-exposure prophylaxis (PrEP), but no research has examined mediators of this relationship. The current study used path analysis to examine a phenomenon closely associated with IPV: reproductive coercion, or explicit male behaviors to promote pregnancy of a female partner without her knowledge or against her will. Birth control sabotage and pregnancy coercion--two subtypes of reproductive coercion behaviors--were examined as mediators of the relationship between IPV and PrEP acceptability among a cohort of 147 Black women 18-25 years of age recruited from community-based organizations in an urban city. IPV experiences were indirectly related to PrEP acceptability through birth control sabotage (indirect effect = 0.08; p < 0.05), but not to pregnancy coercion. Findings illustrate the importance of identifying and addressing reproductive coercion when assessing whether PrEP is clinically appropriate and a viable option to prevent HIV among women who experience IPV. Article	2017	Wood, Sarah M; Lee, Susan; Barg, Frances K; Castillo, Marne; Dowshen, Nadia	Young Transgender Women's Attitudes Toward HIV Pre-exposure Prophylaxis.	Journal of Adolescent Health	-	-	-	1879-1972	10.1016/j.jadohealth.2016.12.004	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5401785	PURPOSE: Our primary aim was to explore themes regarding attitudes toward HIV pre-exposure prophylaxis (PrEP) among young transgender women (YTW), in order to develop a theoretical model of PrEP uptake in this population disproportionally affected by HIV. METHODS: Qualitative study nested within a mixed-method study characterizing barriers and facilitators to health services for YTW. Participants completed an in-depth interview exploring awareness of and attitudes toward PrEP. Key themes were identified using a grounded theory approach. RESULTS: Participants (n = 25) had a mean age of 21.2 years (standard deviation 2.2, range 17-24) and were predominately multiracial (36%) and of HIV-negative or unknown status (68%). Most participants (64%) reported prior knowledge of PrEP, and 28% reported current use or intent to use PrEP. Three major content themes that emerged were variability of PrEP awareness, barriers and facilitators to PrEP uptake, and emotional benefits of PrEP. Among participants without prior PrEP knowledge, participants reported frustration that PrEP information has not been widely disseminated to YTW, particularly by health care providers. Attitudes toward PrEP were overwhelmingly positive; however, concerns were raised regarding barriers including cost, stigma, and adherence challenges. Both HIV-positive and negative participants discussed emotional and relationship benefits of PrEP, which were felt to extend beyond HIV prevention alone. CONCLUSIONS: A high proportion of YTW in this study had prior knowledge of PrEP, and attitudes toward PrEP were positive among participants. Our findings suggest several domains to be further explored in PrEP implementation research, including methods of facilitating PrEP dissemination and emotional motivation for PrEP uptake. Article	2017	Wu, Hsiu; Mendoza, Maria C B; Huang, Ya-Lin A; Hayes, Tameka; Smith, Dawn K; Hoover, Karen W	Uptake of HIV Preexposure Prophylaxis Among Commercially Insured Persons-United States, 2010-2014.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/ciw701	https://dx.doi.org/10.1093/cid/ciw701	BACKGROUND: Daily, oral use of tenofovir disoproxil fumarate and emtricitabine (TDF-FTC) for preexposure prophylaxis (PrEP) is an effective strategy to prevent acquisition of human immunodeficiency virus (HIV) infection. It is important to monitor PrEP uptake at the national level to increase our understanding of trends in its utilization, but national HIV surveillance data do not include PrEP uptake. Our objective was to develop feasible methods to estimate PrEP uptake and to estimate uptake each year among commercially insured persons during 2010-2014. METHODS: We conducted a retrospective analysis of the 2010-2014 MarketScan database, a national sample of persons with commercial health insurance in the United States. We developed an algorithm to identify persons aged ≥16 years who were prescribed TDF-FTC for PrEP each year. We generated nationally representative estimates of prevalence of persons prescribed PrEP. RESULTS: We found a significantly increasing trend in the proportion of persons prescribed TDF-FTC for PrEP during the study period, with 417 users in 2010 and 9375 in 2014 (P < .001); 97% of PrEP users were male and 98% lived in metropolitan areas in 2014. During the study period, the numbers of women prescribed PrEP were low. CONCLUSIONS: Our analytic method provides the only feasible means to monitor PrEP uptake in the United States. Although a marked increasing trend in uptake was observed for men, the number of women who used PrEP remained very low during the study period. Interventions are needed to increase PrEP use by women at substantial risk of acquiring HIV infection. Article	2017	Xie, P. Y.; Wang, X.; Liu, P. L.; Tan, X. D.; Zhou, W.	Willingness and influencing factors of using pre-exposure prophylaxis among 301 men have sex with men in Wuhan city, 2015.	Zhonghua Yu Fang Yi Xue Za Zhi (Chinese Journal of Preventive Medicine)	-	-	-	0253-9624	10.3760/cma.j.issn.0253-9624.2017.11.009	https://pubmed.ncbi.nlm.nih.gov/29136745/	Objective: To understand willingness and influencing factors of using pre-exposure prophylaxis (Pr-EP) among men who have sex with men (MSM). Methods: Snow ball sampling was employed to recruit MSM in the social spaces (like bars and bathrooms) with focused activities by MSM and internet (QQ and Wechat) in Wuhan between August and November, 2015. 304 MSM were considered eligible when they were self-identified MSM and has had sex with men in the previous 12 months, over the age of 18 and have full civil liability. On-site and online questionnaire surveys were conducted by self-designed questionnaires to collect information including demographic characteristics, sexual risks and practices, awareness of PrEP, and willingness to use PrEP. A total of 301 qualified questionnaires were obtained. Multivariate logistic regression models were constructed to identify factors associated with willingness to use Pr-EP. Results: The mean age of surveyed MSM were (27.51±8.31) years, between18-61. 149 on-site survey, online were152; 131 MSM have regular homosexual partners, 170 MSM have not regular homosexual partners. Only 17.28% (52/301) had heard of Pr-EP before this survey, 18.32% (24/130) had heard of Pr-EP among those who had regular homosexual partners and those who had not accounted for 16.47% (28/170). 74.42% (224/301) had willingness to use Pr-EP after they knew Pr-EP was safe and effective through the survey. The proportion among those who had regular homosexual partners was 74.05%(74), and the proportion among those who had not was 74.71% (127); Among those who had regular homosexual partners, results suggested that those who were married/cohabiting were more likely to report a willingness to use PrEP compared to unmarried/divorced or widowed (OR=5.60), compared with homosexual, heterosexuality was associated with decreased odds of willingness to use Pr-EP (OR= 0.22), compared with HIV status of sexual partner was negative or uncertain, positive infection status was associated with increased odds of willingness to use (OR=7.52). Compared with MSM who have not regular homosexual partners, those who were married/cohabiting were more likely to report a willingness to use PrEP compared to unmarried/divorced or widowed (OR=9.09), compared with those who think they have risk of infection, those who do not think they have risk of infection was associated with decreased odds of willingness to use Pr-EP (OR= 0.30), compared with those with a high frequency to seek sexual partners, those not often to seek was associated with decreased odds of willingness to use Pr-EP (OR= 0.27). All above P values were<0.05. Conclusion: The awareness rate of Pr-EP among MSM in Wuhan is low in 2015, but the willingness to use Pr-EP could get a considerable increase after introduction. It is considered that promotion of Pr-EP is feasible in China, and there are different influencing factors for the willingness between two MSM subgroups (having regular homosexual partners and having no regular homosexual partners).	*Homosexuality, Male; Adult; Humans; Male; Young Adult; HIV Infections/*prevention & control; Sexual Behavior; China; HIV; Sexual Partners; Surveys and Questionnaires; Logistic Models; *Pre-Exposure Prophylaxis; Sexual and Gender Minorities; Men who have sex with men; Internet; Cities; Cross-sectional studies; Protective agents; Using willingness	Chinese	China	Asia and the Pacific	China	Asia and the Pacific	NA	NA	Quantitative
Article	2017	Xu, J. Y.; Mou, Y. C.; Ma, Y. L.; Zhang, J. Y.	Compliancy of pre-exposure prophylaxis for HIV infection in men who have sex with men in Chengdu.	Zhonghua Liu Xing Bing Xue Za Zhi (Chinese Journal of Epidemiology)	-	-	-	0254-6450	10.3760/cma.j.issn.0254-6450.2017.05.017	https://pubmed.ncbi.nlm.nih.gov/28651403/	Objective: To evaluate the compliancy of HIV pre-exposure prophylaxis (PrEP) in men who have sex with men (MSM) in Chengdu, Sichuan province, and explore the influencing factors. Methods: From 1 July 2013 to 30 September 2015, a random, open, multi-center and parallel control intervention study was conducted in 328 MSM enrolled by non-probability sampling in Chengdu. The MSM were divided into 3 groups randomly, i.e. daily group, intermittent group (before and after exposure) and control group. Clinical follow-up and questionnaire survey were carried out every 3 months. Their PrEP compliances were evaluated respectively and multivariate logistic regression analysis was conducted to identify the related factors. Results: A total of 141 MSM were surveyed, in whom 59(41.8%) had good PrEP compliancy. The PrEP compliancy rate was 69.0% in daily group, higher than that in intermittent group (14.3%), the difference had significance (χ(2)=45.29,P<0.001). Multivariate logistic analysis indicated that type of PrEP was the influencing factors of PrEP compliancy. Compared with daily group, the intermittent group had worse PrEP compliancy (OR=0.07, 95%CI: 0.03-0.16). Conclusion: The PrEP compliance of the MSM in this study was poor, the compliancy would be influenced by the type of PrEP. Article	2017	Yah, Clarence S	Nurturing the Continuum of HIV Testing, Treatment and Prevention Matrix Cascade in Reducing HIV Transmission.	Ethiopian Journal of Health Sciences	-	-	-	2413-7170	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5811941	BACKGROUND: Despite the shift in antiretroviral therapy (ARVs) eligibility cascade from CD4 ≤ 200 to CD4 ≤ 350 to CD4 ≤ 500 mm3, HIV related morbidity and mortality continue to escalate annually, as do HIV infections. The new paradigm of treatment for all HIV positives individual irrespective of CD4 count may significantly reduce HIV and related illnesses. The author assumes that all HIV infected partners should be eligible for HIV treatment and care, irrespective of CD4 count. A second assumption is that high risk HIV negative partners have free access to continuum of HIV pre-exposure prophylaxis (PrEP), post exposure prophylaxis (PEP) and other prevention packages. METHODS: A literature review search was used to extract evidence-based ARVs-HIV treatment and prevention interventions among HIV positives and high risk partners respectively. Only articles published in English and indexed in journal nuclei were used for the study. The information was used to nurture understanding of HIV treatment and prevention approaches as well as HIV incidence multiplier effect among HIV serodiscordant partners. The imputed HIV incident reference was assumed at 1.2 per 100 person-years (2). This was based on the imputation that retention in care, adherence and other predetermined factors are functions of an effective health care delivery system. RESULT: The model showed a reduced HIV transmission from 1.2 per 100 person-years to 1.032 per 100 person-years in 6 months. The average threshold period of HIV suppressed partners on ARVs to an undetectable level. The combined multiplier protective-effect probability of transmitting HIV from HIV positive partners on ARVs-suppressed viremic load to HIV negative partners on PrEP/PEP-prevention was detected at 86. CONCLUSION: The model showed a significant reduction in HIV incidence. Placing serodiscordant sexual partners in HIV treatment and prevention plays a significant role in reducing and controlling HIV infection. Therefore, the policy of enrolling all HIV positives irrespective of CD4 count on ARVs and high risk partners on prevention if adopted and sustained may underpin reduction and control of HIV genotype and HIV related morbidity, mortality and opportunistic infections. Article	2017	Yi, Siyan; Ngin, Chanrith; Tuot, Sovannary; Chhoun, Pheak; Chhim, Srean; Pal, Khuondyla; Mun, Phalkun; Mburu, Gitau	HIV prevalence, risky behaviors, and discrimination experiences among transgender women in Cambodia: descriptive findings from a national integrated biological and behavioral survey.	BMC International Health and Human Rights	-	-	-	-	1472-698X	10.1186/s12914-017-0122-6	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5441093	BACKGROUND: Transgender people are disproportionately affected by HIV. Despite their high vulnerability to HIV, lack of adequate epidemiological and surveillance data related to this population in many countries prevents provision of appropriate services. This paper summarizes descriptive findings from a national integrated biological and behavioral survey and discusses policy implications of the findings on HIV prevention among transgender women in Cambodia. METHODS: This cross-sectional study was conducted between December 2015 and February 2016. Participants were recruited from 20 sites in the capital city and 12 provinces of Cambodia using Respondent Driven Sampling (RDS) method. Behavioral data were collected through structured questionnaire interviews, and rapid finger-prick HIV testing was performed. Descriptive data analyses were conducted using STATA. RESULTS: This study included 1,375 transgender women with a mean age of 25.9 years (SD = 7.1). The overall prevalence of HIV was 5.9%. The prevalence of HIV was significantly higher among urban participants compared to their rural counterparts (6.5 vs. 2.6%, p = 0.02). Almost one in five (19.6%) had never been tested for HIV prior to the study. Overall, 45.0% reported ever using gender affirming hormones. More than one-third (39.1%) reported not using condoms in their last sex, 29.8% had engaged in sex in exchange for money/gifts, and 14.0% reported that they had experienced at least one symptom of sexually transmitted infections (STI) in the past year. About one in ten (10.1%) reported having used some form of amphetamine-type stimulant drugs, while 6.5% reported having sex during or after using illicit drugs. A significant number of participants experienced sexual abuse (39.2%), losing a job (24.3%), or physical abuse (23.6%) because of their transgender identity. In addition, 82.9 and 88.9% would be willing to use the HIV self-test and pre-exposure prophylaxis (PrEP), respectively, if they become available. CONCLUSIONS: The high prevalence of HIV, STI, and related risk behaviors among transgender women in Cambodia is of great concern, suggesting an urgent need to further expand tailored prevention interventions for this key population focusing on individual, social, and structural drivers of HIV. HIV self-test and PrEP should be explored as a priority. Article	2017	Yi, Siyan; Tuot, Sovannary; Mwai, Grace W; Ngin, Chanrith; Chhim, Kolab; Pal, Khoundyla; Igbinedion, Ewemade; Holland, Paula; Choub, Sok Chamreun; Gitau Mburu	Awareness and willingness to use HIV pre-exposure prophylaxis among men who have sex with men in low- and middle-income countries: a systematic review and meta-analysis	Journal of the International AIDS Society	-	-	-	-	NA	10.7448/IAS.20.1.21580	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5515024/pdf/zias-20-1340539.pdf	Introduction: To facilitate provision of pre-exposure prophylaxis (PrEP) in low- and middle-income countries (LMIC), a better understanding of potential demand and user preferences is required. This review assessed awareness and willingness to use oral PrEP among men who have sex with men (MSM) in LMIC.Methods: Electronic literature search of Cochrane library, Embase, PubMed, PsychINFO, CINHAL, Web of Science, and Google Scholar was conducted between July and September 2016. Reference lists of relevant studies were searched, and nine authors contacted for additional data. Non-peer reviewed publications were excluded. Studies were screened for inclusion, and relevant data abstracted, assessed for bias, and synthesized.Results: In total, 2186 records were identified, of which 23 studies involving 14,040 MSM from LMIC were included. The proportion of MSM who were aware of PrEP was low at 29.7% (95% CI: 16.9–44.3). However, the proportion willing to use PrEP was higher, at 64.4% (95% CI: 53.3–74.8). Proportions of MSM aware of PrEP was <50% in 11 studies and 50–70% in 3 studies, while willingness to use PrEP was <50% in 6 studies, 50–70% in 9 studies, and over 80% in 5 studies. Several factors affected willingness to use PrEP. At the individual domain, poor knowledge of PrEP, doubts about its effectiveness, fear of side effects, low perception of HIV risk, and the need to adhere or take medicines frequently reduced willingness to use PrEP, while PrEP education and motivation to maintain good health were facilitators of potential use. Demographic factors (education, age, and migration) influenced both awareness and willingness to use PrEP, but their effects were not consistent across studies. At the social domain, anticipated stigma from peers, partners, and family members related to sexual orientation, PrEP, or HIV status were barriers to potential use of PrEP, while partner, peer, and family support were facilitators of potential use. At the structural domain, concerns regarding attitudes of healthcare providers, quality assurance, data protection, and cost were determinants of potential use.Conclusions: This review found that despite low levels of awareness of PrEP, MSM in LMIC are willing to use it if they are supported appropriately to deal with a range of individual, social, and structural barriers. Article	2017	Young, Lindsay E; Jonas, Adam B; Michaels, Stuart; Jackson, Joel D; Pierce, Mario L; Schneider, John A	Social-structural properties and HIV prevention among young men who have sex with men in the ballroom house and independent gay family communities	Social Science & Medicine	-	-	-	-	2779536	10.1016/j.socscimed.2016.12.009	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85006128038&doi=10.1016%2fj.socscimed.2016.12.009&partnerID=40&md5=3ab6f30c84dd01da15a7cceb5db40978	The endogenous social support systems of young Black men who have sex with men (YBMSM), like surrogate families and social networks, are considered crucial assets for HIV prevention in this population. Yet, the extent to which these social systems foster sexual health protections or risks remains unclear. We examine the networked patterns of membership in ballroom houses and independent gay families, both Black gay subcultures in the United States, and how these memberships are related to HIV protective and risk traits of members. Drawing from a population-based sample of 618 YBMSM living in Chicago between June 2013 and July 2014, we observe a suite of protective and risk traits and perform bivariate analyses to assess each of their associations with being a member of a house or family. We then present an analysis of the homophilous and heterophilous mixing on these traits that structures the patterns of house and family affiliations among members. The bivariate analyses show that members of the house and family communities were more likely than non-members to report protective traits like being aware of PrEP, having health coverage, having a primary care doctor, and discouraging sex drug use among peers. However, members were also more likely to engage in the use of sex drugs. With respect to how these traits inform specific house/family affiliations, results show that members who had a recent HIV test, who were PrEP aware, or who engaged in exchange sex were more likely to belong to the same house or family, while HIV positive individuals were less likely to cluster within houses or families. These findings provide insights regarding the strengths and vulnerabilities of the house and gay family communities that can inform more culturally specific interventions that build on the existing human and social capital in this milieu. © 2016 Elsevier Ltd	African American MSM; Ballroom house; Gay families; HIV prevention; Protective behaviors; Risk behaviors; Social networks; Social support; United States	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2017	Zablotska I.B.	Likely impact of pre-exposure prophylaxis on HIV epidemics among men who have sex with men	Sexual Health	-	-	-	-	14485028	10.1071/SH16153	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85012237730&doi=10.1071%2fSH16153&partnerID=40&md5=a6855ff64859b768cbb56f0ca8c7ce3d	Rapid developments in the field of HIV pre-exposure prophylaxis (PrEP) with antiretrovirals offer a promise to bring HIV transmission among gay and other men who have sex with men (MSM) to zero by 2030. This review evaluates studies, which modelled the impact of PrEP on HIV diagnoses, and discusses the progress towards PrEP implementation. Studies in English, conducted after 2010 among MSM in countries of the Organization for Economic Cooperation and Development (OECD) were reviewed. Six modelling studies were included, three of which had been conducted outside the US. None of the published models showed that PrEP alone can reduce HIV diagnoses to zero and eliminate HIV transmission by 2030. However, PrEP in combination with other biomedical interventions can reduce HIV diagnoses on the population level by ~95%. Other upcoming biomedical prevention strategies may strengthen combination prevention. Access to PrEP remains limited, even in the OECD countries. Modelling studies can assist governments with decision-making about PrEP implementation and add urgency to the implementation of PrEP. More work is needed on modelling of the impact of PrEP on HIV diagnoses trends outside the US where PrEP implementation is in its early stages. © CSIRO 2017.	combination prevention; effect; HIV/AIDS; implementation; mathematical model; pre-exposure prophylaxis (PrEP); review. Article	2017	Zablotska, Iryna B; Catherine C. O'Connor	Preexposure Prophylaxis of HIV Infection: the Role of Clinical Practices in Ending the HIV Epidemic	Current HIV/AIDS Reports	-	-	-	-	15483568	10.1007/s11904-017-0367-7	https://www.proquest.com/scholarly-journals/preexposure-prophylaxis-hiv-infection-role/docview/1965812437/se-2?accountid=8113	Purpose of ReviewThe aim of this study is to summarise the recent evidence from high-income settings about providers' ability to deliver on the UNAIDS goal of at least three million people at substantial risk of HIV infection with PrEP by 2020, including awareness and knowledge about PrEP, willingness to prescribe PrEP, current levels of prescribing and service delivery models and issues.Recent FindingsAwareness about PrEP among health providers is growing, but at different pace depending on provider type. HIV and sexual health specialists are more likely to have knowledge about PrEP than generalists, and to be willing to prescribe it, mainly because of their closer contact with people at high risk for HIV and better risk assessment skills. There is still no consensus as to who should be responsible for providing PrEP, but clearly all hands on deck will be useful in delivering on the international target of three million people at substantial risk for HIV on PrEP by 2020. Only about 5% of the target has been reached so far. Local guidance and large-scale education and information programs for clinicians will be necessary to upskill health providers. High cost of PrEP is still a major barrier for its broad implementation, even in countries were PrEP roll-out has started. Health services are facing major structural challenges due to implementation of PrEP services to a substantial volume of patients.SummaryThe early implementation experiences demonstrated that PrEP can be successfully delivered across a variety of settings, and a broad range of strategies and models of care can streamline PrEP delivery. Education of the providers and PrEP cost solutions will be essential for rapid roll-out of PrEP. Evaluation of a multidrug assay for monitoring adherence to a regimen for HIV preexposure prophylaxis in a clinical study, HIV prevention trials network 073	Antimicrobial Agents and Chemotherapy	-	-	-	-	664804	10.1128/AAC.02743-16	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021682242&doi=10.1128%2fAAC.02743-16&partnerID=40&md5=af026d38ae2b900fec2a3ce98a03ce71	Daily oral tenofovir disoproxil fumarate (TDF)-emtricitabine (FTC) is a safe and effective intervention for HIV preexposure prophylaxis (PrEP). We evaluated the performance of a qualitative assay that detects 20 antiretroviral (ARV) drugs (multidrug assay) in assessing recent PrEP exposure (detection limit, 2 to 20 ng/ml). Samples were obtained from 216 Black men who have sex with men (208 HIV-uninfected men and 8 seroconverters) who were enrolled in a study in the United States evaluating the acceptability of TDF-FTC PrEP (165 of the uninfected men and 5 of the seroconverters accepted PrEP). Samples from 163 of the 165 HIV-uninfected men who accepted PrEP and samples from all 8 seroconverters were also tested for tenofovir (TFV) and FTC using a quantitative assay (detection limit for both drugs, 0.31 ng/ml). HIV drug resistance was assessed in seroconverter samples. The multidrug assay detected TFV and/or FTC in 3 (1.4%) of the 208 uninfected men at enrollment, 84 (40.4%) of the 208 uninfected men at the last study visit, and 1 (12.5%) of the 8 seroconverters. No other ARV drugs were detected. The quantitative assay confirmed all positive results from the multidrug assay and detected TFV and/or FTC in 9 additional samples (TFV range, 0.65 to 16.5 ng/ml; FTC range, 0.33 to 14.6 ng/ml). Resistance mutations were detected in 4 of the 8 seroconverter samples. The multidrug assay had 100% sensitivity and specificity for detecting TFV and FTC at drug concentrations consistent with daily PrEP use. The quantitative assay detected TFV and FTC at lower levels, which also might have provided protection against HIV infection. Copyright © 2017 American Society for Microbiology. All Rights Reserved. Theses and Dissertations	2017	Zhang, Xinyu	Exploring Effect of Individual Risk Behavior Volatility on Model Inference of HIV Transmission Dynamics and HIV Phylogenetic Tree	-	-	University of Michigan	University of Michigan	-	NA	NA	http://hdl.handle.net/2027.42/140946	Men who have sex with men (MSM) are heavily affected by HIV infections. However, controlling HIV transmission among MSM population remains a challenging task due to the complexity of the transmission dynamics of HIV. Mathematical models can facilitate understanding such dynamics. They also provide a basis for estimating important epidemiological parameters that can guide public health decision. This thesis advances methods to achieve both of these objectives and makes a substantive advance in the first area. In this dissertation, we relaxed the constancy of individual risk behavior assumption, by allowing individual risk behavior to fluctuate among different levels over time, namely individual risk behavior volatility. We found that increasing risk volatility considerably increases fraction of transmission from acute HIV infection and prevalence at endemic equilibrium. In addition, we found that increasing risk volatility considerably reduces the minimum required individual effectiveness to eliminate HIV infections of Universal Test and Treat or universally applied pre-exposure prophylaxis (PrEP). Furthermore, our results suggest that increasing risk volatility reduces the extent that a case's risk level at HIV acquisition determines this case's capacity to cause onward transmission later during infection. Consequently, assuming no risk volatility may cause one to overestimate the benefit of prioritizing PrEP efforts to susceptible individuals experiencing high risk as a strategy to eliminate HIV infections. Finally, we explored the possibility of using HIV phylogeny to indicate when risk volatility affects HIV transmission dynamics. Our results suggest that risk volatility has unique and strong impact on phylogeny imbalance and clustering pattern. This implies that risk volatility is potentially identifiable from HIV sequence data. Research in this thesis contributions to the field of study that uses mathematical models to estimate epidemiological parameters of HIV transmission from two perspectives. Firstly, research in this thesis reveals the importance of evaluating individual risk behavior volatility to enhance robustness of model inference of epidemiological parameters and quantities. Secondly, research in this thesis suggests HIV sequence data is potentially valuable to improve the identifiability of risk volatility parameter. Therefore, research in this thesis takes significant steps forward to improve mathematical model inference of HIV transmission parameters. Article	2017	Zimmermann, H; Eekman, S; Achterbergh, R; Prins, M; van der Loeff, MS; de Vries, H; Hoornenborg, E; Davidovich, U; HIV Transmission Elimination Amste	Pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) in the Netherlands: motives to choose for, switch to or stop with daily or event-driven PrEP	Journal of the International AIDS Society	-	-	-	-	1758-2652	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6791997/	In settings where both daily and event-driven pre-exposure prophylaxis (PrEP) are offered to men who have sex with men (MSM), a clear understanding of the motives to choose between the different dosing-regimens can facilitate more effective PrEP implementation. We therefore studied the motives for choosing for, switching between, and stopping daily or event-driven PrEP. Methods We used data (August 2015-June 2017) from the prospective, longitudinal, open-label Amsterdam PrEP demonstration study, in which daily (dPrEP) and event-driven PrEP (edPrEP) were offered to 374 HIV-negative MSM and two transgender persons. Participants self-selected the preferred PrEP-regimen at baseline and could switch regimens at three-monthly follow-up visits. We measured motives for choosing PrEP-regimen at baseline and for switching and stopping PrEP at follow-up visits. Open- and closed-end items were combined and qualitatively analysed.	counseling, HIV, prevention, men who have sex with men, PrEP, sexual behaviour	English	United States	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Quantitative
Article	2018	Aaron E.; Blum C.; Seidman D.; Hoyt M.J.; Simone J.; Sullivan M.; Smith D.K.	Optimizing Delivery of HIV Preexposure Prophylaxis for Women in the United States	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2017.0201	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85040636233&doi=10.1089%2fapc.2017.0201&partnerID=40&md5=5ebc44fefd5afe9f76e48bc1e2afc5c5	Preexposure prophylaxis (PrEP) is a highly effective HIV prevention method; however, it is underutilized among women who are at risk for acquisition of HIV. Women comprise one in five HIV diagnoses in the United States, and significant racial disparities in new HIV diagnoses persist. The rate of new HIV diagnoses among black and African American women in 2015 was 16 times greater than that of white women. These disparities highlight the importance of HIV prevention strategies for women, including the use of PrEP. PrEP is the first highly effective HIV prevention method available to women that is entirely within their control. However, because so few women who may benefit from PrEP are aware of it, few women's healthcare providers offer PrEP to their patients, PrEP has not yet achieved its potential to reduce HIV infections in women. This article describes individual and systemic barriers for women related to the uptake of PrEP services; explains how providers can identify women at risk for HIV; reviews how to provide PrEP to women; and outlines client-centered models for HIV prevention services. Better access to culturally acceptable and affordable medical and social services may offer support to women for consistent and ongoing use of PrEP. This discussion may be used to inform HIV prevention activities for women and guide interventions to decrease racial/ethnic disparities in rates of HIV infection among US women. © 2018 Erika Aaron, et al. Article	2018	Abaasa, Andrew; Hendrix, Craig; Gandhi, Monica; Anderson, Peter; Kamali, Anatoli; Kibengo, Freddie; Sanders, Eduard J; Mutua, Gaudensia; Bumpus, Namandjé N; Priddy, Frances	Utility of Different Adherence Measures for PrEP: Patterns and Incremental Value	Publ Med	-	-	-	-	1090-7165	https://doi.org/10.1007/s10461-017-1951-y	https://escholarship.org/uc/item/11s4b5wt	Measuring PrEP adherence remains challenging. In 2009-2010, the International AIDS Vaccine Initiative randomized phase II trial participants to daily tenofovir disoproxil fumarate/emtricitabine or placebo in Uganda and Kenya. Adherence was measured by electronic monitoring (EM), self-report (SR), and drug concentrations in plasma and hair. Each adherence measure was categorised as low, moderate, or high and also considered continuously; the incremental value of combining measures was determined. Forty-five participants were followed over 4 months. Discrimination for EM adherence by area under receiver operating curves (AROC) was poor for SR (0.53) and best for hair (AROC 0.85). When combining hair with plasma or hair with self-report, discrimination was improved (AROC > 0.9). Self-reported adherence was of low utility by itself. Hair level was the single best PK measure to predict EM-assessed adherence; the other measurements had lower discrimination values. Combining short-term (plasma) and long-term (hair) metrics could be useful to assess patterns of drug-taking in the context of PrEP. Article	2018	Adams, Leah M; Balderson, Benjamin H; Brown, Kathy; Bush, Staci E; Packett Bruce J II	Who Starts the Conversation and Who Receives Preexposure Prophylaxis (PrEP)? A Brief Online Survey of Medical Providers' PrEP Practices	Health Education and Behavior	-	-	-	-	10901981	10.1177/1090198117752789	https://www.proquest.com/scholarly-journals/who-starts-conversation-receives-preexposure/docview/2104868898/se-2?accountid=8113	Uptake of preexposure prophylaxis (PrEP) has been slow, but is increasing. Although PrEP is indicated for many patients, it has been concentrated among men who have sex with men (MSM). Awareness of PrEP is limited among non-MSM individuals, and among some MSM. As such, individuals at risk for HIV who are unaware of PrEP must rely on their medical providers to initiate conversations about PrEP. Members of a national professional organization of HIV specialists with prescribing privileges, including physicians, nurse practitioners, and physician assistants, participated in an online survey (n = 342) to characterize their PrEP prescribing behaviors and the demographic membership of their PrEP caseload. Results indicated that when discussing PrEP with their patients, providers who more frequently initiated these conversations had a higher percentage of non-MSM patients in their PrEP caseload (e.g., women, people who inject drugs, transgender patients). Encouraging providers to initiate discussions about PrEP with their patients and helping them locate support to offset the cost may help increase uptake, particularly among at-risk patients who are underrepresented in PrEP adoption. Theses and Dissertations	2018	Adamson, Blythe	Mathematical Models to Evaluate the Clinical and Economic Impact of Biomedical HIV Prevention Strategies in the United States	-	-	University of Washington	University of Washington	-	NA	NA	http://hdl.handle.net/1773/42086	As the marginal clinical impact returns on innovations to treat and prevent HIV diminish, strategic investments are required for timely and efficient HIV eradication. The overall goal of this dissertation research is to evaluate the potential cost-effectiveness of several pharmacotherapy-related interventions included in the National HIV/AIDS Strategy for the United States in order to inform decision-making and policy design. Rising HIV program costs along with poor results in patient access and service utilization make determining the value of new HIV interventions very important for the vulnerable populations bearing the disease burden. Today, pre-exposure prophylaxis (PrEP) drugs are a short-term solution. Quite soon, programs offering financial incentives for viral suppression are expected to expand. Over the long term, many view the development of a safe and effective HIV vaccine as the only hope to completely eradicate AIDS. I develop a series of mathematical models to examine the clinical and economic impact of financial incentives, PrEP, and HIV vaccines using local and national surveillance data drawing on the results of large clinical trials. Importantly, I examine the potential interaction and competition between PrEP and HIV vaccines which needs to be understood to achieve optimal benefit from the combined use of the two in the coming decades. Lastly, I make policy and R&D investment recommendations aimed to support efficient progress towards the national strategic goals.	cost-effectiveness; financial incentives; HIV prevention; mathematical modeling; pharmacoeconomics; vaccines; Pharmaceutical sciences; Economics; Applied mathematics; Pharmaceutics	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Quantitative
Theses and Dissertations	2018	Adana, Misturah Yetunde.	Testicular morphological and biochemical perturbations in experimental animals under antiretroviral therapy and the role of Naringenin, a bioactive flavonoid.	-	-	University of KwaZulu-Natal	University of KwaZulu-Natal	-	NA	NA	https://researchspace.ukzn.ac.za/handle/10413/17922	Declining male fertility is one of the neglected concerns of people living with HIV/AIDS in spite of a dual outlook of a social and a health dilemma. This issue of infertility is particularly relevant as majority of affected individuals are in their reproductive years. This thesis examines the impacts of the Fixed Dose Combination (FDC) of Highly Active Antiretroviral Therapy (HAART) Tenofovir/ Emtricitabine and Efavirenz (TDF/FTC/EFV) on the male reproductive capacity. It also explores the protective potentials of a bioactive flavonoid, Naringenin in testicular perturbations. The study was motivated by two major research questions namely: (1) what are the impacts of the recently approved first line antiretroviral therapy for adults FDC, TDF/FTC/EFV on the testes? (2) What is the role of Naringenin in alleviating testicular perturbations induced by HAART? Previous studies point to the negative impacts of the older generation of FDC of HAART on the semen quality and histomorphometry of the testes following a long-term use. The study addresses both the long-term and short-term use of antiretroviral drugs as observed in pre-exposure prophylaxis (PrEP) and post exposure prophylaxis (PEP). The research assesses the impacts of the drugs on the reproductive capability as well. Findings from this study support the argument that the negative effects of the drugs were consequent upon both the short-term and long-term use. To illustrate this hypothesis, the study was conducted in two distinct phases. The first phase which lasted a total of 28 days considered the duration of PEP or PrEP. The second phase which lasted a total of ten weeks captured all the stages of spermatogenesis in rats. In this phase male Sprague Dawley rats were exposed to fertile females after the treatments. The study thus advances an understanding of the mechanism of HAART-induced testicular injury. A therapeutic dose of TDF/FTC/EFV adjusted for animal weight was administered on a total of 48 animals randomly divided into 6 equal groups each with a different treatment as follows; Group A: Control (Distilled water); Group B: HAART (TDF/FTC/EFV), Group C: Naringenin, 40 mg/kg; Group D: Naringenin, 80 mg/kg; Group E: HAART + Naringenin, 40 mg/kg; Group F: HAART+ Naringenin, 80 mg/kg. At the end of each phase, harvested testes were subjected to histomorphometry and ultrastructural analysis. The caudal epididymis was assessed for semen parameters and sperm mitochondrial DNA (mtDNA) fragmentation. Biochemical parameters such as serum levels of reproductive hormones (Luteinizing hormone and Testosterone) and intratesticular antioxidant enzyme activities were assayed. Contrary to prior beliefs, this research reveals that the immediate effects following short-term use of HAART are far more deleterious. This finding is consequent upon the significant drop in the sperm count (p<0.001) and sperms with normal morphology (p<0.001) compared to (p<0.01) in the long-term. Histomorphometric analysis also revealed a significantly shrunken seminiferous tubule following a…	Male fertility.; Mixed doze combination.; Antiretroviral Therapy (HAART).; Tenofovir.; Emtricitabine and Efavirenz. Article	2018	Agopian, A; Levy, M; Opoku, J; Rawls, A; Magnus, M; Kharfen, M; Greenberg, A; Kuo, I	Factors Associated With PrEP Discontinuation Among Men Who Have Sex With Men in Washington, DC	AIDS Research and Human Retroviruses	-	-	-	-	0889-2229	10.1097/QAI.0000000000001965	https://journals.lww.com/jaids/fulltext/2019/04150/factors_associated_with_sex_related_pre_exposure.9.aspx	Background: HPTN 067 assessed the feasibility of daily and non-daily dosing of open-label emtricitabine/tenofovir disoproxil fumarate (FTC/TDF)-based pre-exposure prophylaxis (PrEP). Methods: Factors associated with sex-related PrEP adherence were assessed among men who have sex with men (MSM) randomized to one of 3 PrEP dosing arms in HPTN 067 in New York City. Sex-related PrEP adherence was defined per protocol as at least 1 PrEP tablet taken within 4 days pre-sex and at least 1 additional PrEP tablet taken within 24 hours post-sex, assessed via electronic drug monitoring and weekly interviews. Demographic data and behavioral measures were evaluated for association with sex-related PrEP adherence. Logistic regression for clustered data was used to estimate the unadjusted and adjusted odds ratios. Results: Of 176 randomized MSM participants, 59% were Black, 10% White, 25% Hispanic, and 6% other; median age was 31 years. In the multivariable analyses, higher sex-related PrEP adherence was significantly associated with daily dosing arm, older age, employment, and higher PrEP adherence behavioral skills. Lower sex-related PrEP adherence was significantly associated with identifying as Black or Hispanic (compared with White), opiate use, and reporting "I forgot" as an adherence barrier. Conclusions: This analysis identified populations of MSM who might benefit from additional support to optimize PrEP adherence, including those who are younger, unemployed, or opiate users. MSM with lower PrEP behavioral skills may benefit from targeted interventions. Further study is needed to assess racial and ethnic disparities in PrEP adherence, which may reflect broader social and economic inequalities not captured in this study. Article	2018	Ajayi A.I.; Ismail K.O.; Adeniyi O.V.; Akpan W.	Awareness and use of pre-exposure and postexposure prophylaxes among Nigerian university students: Findings from a cross-sectional survey	Medicine (United States)	-	-	-	-	257974	10.1097/MD.0000000000012226	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054076782&doi=10.1097%2fMD.0000000000012226&partnerID=40&md5=2b79af86a240b764c9382749ffc9413	Despite the recent advances in biomedical preventive strategies, young adults—especially adolescent girls— continue to be disproportionately at risk of acquiring HIV. To avert this trend, it is critical that access to HIV preventive strategies, such as preexposure prophylaxis (PrEP) and postexposure prophylaxis be expanded, especially in sub-Saharan Africa, where young adults are known to engage in risky sexual practices. This study examined awareness levels and use of pre-exposure prophylaxis (PrEP) and postexposure prophylaxis (PEP) among Nigerian university students. A cross-sectional survey was conducted among 800 students selected using stratified random sampling at 2 Nigerian universities. Descriptive and inferential statistics were used for data analysis on 784 complete responses. The levels of awareness of PrEP and PEP were 18.9% and 25.4%, respectively. Ever tested for human immunodeficiency virus HIV (AOR: 1.58; 95% CI: 1.04–2.42) and knowledge of partner's HIV status (AOR: 1.87; 95% CI: 1.25–2.79) were the significant determinants of awareness to PrEP. In contrast, only ever tested for HIV (AOR: 1.50; 95% CI: 1.02–2.19), knowledge of partner's HIV status (AOR: 1.55; 95% CI: 1.07–2.24), ever used condoms (AOR: 1.65; 95% CI: 1.04–2.62), and nude exchanges (AOR: 1.62; 95% CI: 1.13–2.31) were independent determinants of awareness of PEP. Only a few students had seen (5.6%) or used (1.5%) any prophylaxes. The study findings indicate a low level of awareness and use of PrEP and PEP. To ensure no one is left behind in the goal of elimination of new HIV infections, intervention to expand access to these preventive strategies is needed in the study settings. Article	2018	Ammassari, Adriana; Stöhr, Wolfgang; Antinori, Andrea; Molina, Jean-Michel; Schwimmer, Christine; Domingo, Pere; Thalme, Anders; Di Pietro, Massimo; Wallet, Cedrick; Pozniak, Anton; Richert, Laura; Raffi, François	Patient Self-Reported Adherence to Ritonavir-Boosted Darunavir Combined With Either Raltegravir or Tenofovir Disoproxil Fumarate/Emtricitabine in the NEAT001/ANRS143 Trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000001834	https://pubmed.ncbi.nlm.nih.gov/30365452/	BACKGROUND: The NEAT001/ANRS143 trial demonstrated noninferiority of ritonavir-boosted darunavir combined with either raltegravir (RAL + DRV/r) or tenofovir disoproxil fumarate/emtricitabine (TDF/FTC + DRV/r) in HIV-positive, antiretroviral-naive adults. In post hoc analyses, however, RAL + DRV/r showed inferiority in patients with baseline CD4 <200/mm and HIV-1 RNA ≥100,000 copies per milliliter. This preplanned ancillary study was conducted to assess whether differences in adherence might explain efficacy results. SETTING: Phase III, open-label, randomized, multicenter study in 15 European countries (ClinicalTrials.gov, NCT01066962). METHODS: Seven hundred seventy-four participants self-reported adherence (modified AIDS Clinical Trials Group questionnaire) over 96 weeks 383 RAL + DRV/r (twice daily; 5 pills/day), 391 TDF/FTC + DRV/r (once daily; 4 pills/day). Primary endpoint was ≥95% versus <95% adherence to prescribed doses recorded (1) over the last 4 days or (2) on the visual analogue scale over the last 30 days. RESULTS: Characteristics, except age, were similar between arms; 9% had CD4 <200 cells/mm and HIV-1 RNA ≥100,000 copies per milliliter. Adherence ≥95% in the last 4 days (P = 0.029) or at the visual analogue scale (P = 0.0072) was higher with TDF/FTC + DRV/r than with RAL + DRV/r. Adherence ≥95% over the last 4 days was associated with lower probability of virological failure (P = 0.015). Adherence in patients with baseline CD4 <200 cells/mm and HIV-1 RNA ≥100,000 copies per milliliter was similar to the rest of the population, and not significantly associated with efficacy measures, with no significant differences between arms. CONCLUSION: Adherence was high and slightly better in the TDF/FTC + DRV/r than in the RAL + DRV/r arm. No convincing evidence was found that higher failure rate in the RAL + DRV/r arm in the subgroup with worse baseline viroimmunological status is caused by adherence differences. Article	2018	Anderson, Peter L; Liu, Albert Y; Castillo-Mancilla, Jose R; Gardner, Edward M; Seifert, Sharon M; McHugh, Cricket; Wagner, Theresa; Campbell, Kayla; Morrow, Mary; Ibrahim, Mustafa; Buchbinder, Susan; Bushman, Lane R; Kiser, Jennifer J; MaWhinney, Samantha	Intracellular Tenofovir-Diphosphate and Emtricitabine-Triphosphate in Dried Blood Spots following Directly Observed Therapy.	Antimicrobial Agents and Chemotherapy	-	-	-	-	1098-6596	10.1128/AAC.01710-17	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5740314	Studies of daily emtricitabine-tenofovir disoproxil fumarate (FTC-TDF) for HIV preexposure prophylaxis (PrEP) in men who have sex with men (MSM) modeled intracellular tenofovir-diphosphate (TFV-DP) in dried blood spots (DBS) to assess adherence and corresponding PrEP outcomes. We conducted a prospective, randomized, crossover pharmacokinetic study of TFV-DP in DBS during 33%, 67%, or 100% of daily dosing under directly observed therapy (DOT). Participants were assigned to two 12-week dosing regimens, separated by a 12-week washout. Forty-eight adults (25 women) from Denver and San Francisco were enrolled. TFV-DP exhibited a median half-life of 17 days, reaching steady state in 8 weeks. TFV-DP was dose proportional with mean (SD) steady-state concentrations of 530 (159), 997 (267), and 1,605 (405) fmol/punch for the 33%, 67%, and 100% arms, respectively. Prior work in MSM demonstrated clinically meaningful TFV-DP thresholds of 350, 700, and 1,250 fmol/punch, which were estimated 25th percentiles for 2, 4, and 7 doses/week. In the present study, corresponding TFV-DP was within 3% of the prior estimates, and subgroups by site, race, and sex were within 14% of prior estimates, although males had 17.6% (95% confidence intervals CIs, 6.5, 27.4%) lower TFV-DP than females. The thresholds of 350, 700, and 1,250 fmol/punch were achieved by 75% of men taking ≥1.2, 3.2, and 6 doses/week and 75% of women taking ≥0.6, 2.0, and 5.3 doses/week, indicating that lower dosing reached these thresholds for both sexes. In conclusion, TFV-DP arising from DOT was similar to previous estimates and is useful for interpreting PrEP adherence and study outcomes. (This study has been registered at ClinicalTrials.gov under identifier NCT02022657.). Article	2018	Arnold T.; Sims-Gomillia C.E.; Portz K.; Bologna E.; Williams B.	Preliminary investigation evaluating college students' willingness and need to take pre-exposure prophylaxis (PrEP) for HIV	HIV and AIDS Review	-	-	-	-	17301270	10.5114/hivar.2018.76370	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049197135&doi=10.5114%2fhivar.2018.76370&partnerID=40&md5=8cb084cce6a1b3e611eafd4c66d0ea43	Pre-exposure prophylaxis (PrEP) is a highly effective pharmacological approach to HIV prevention. This study sought to evaluate the need and willingness of African American college students to utilize PrEP. We evaluated students' perceived HIV risk, beliefs about medication, sexual risk behaviors, and need for PrEP. The sample consisted of 147 participants (Mage = 21.6 years, SDage = 4.8), and 57.7% were female. Most of the sample had been sexually active in the past. Participants were willing to initiate PrEP if they knew it would lower their chance of contracting HIV (88.2%), knew their partner was HIV positive (85.4%), or thought they were at high-risk for HIV infection (87.9%). Additionally, there was a strong positive relationship between willingness to initiate PrEP and beliefs about medicine (r = 0.217, p < 0.05). These findings have relevant implications that will aid in the promotion of PrEP uptake and initiation among at-risk college students. © 2018 Termedia Publishing House Ltd. All rights reserved. Theses and Dissertations	2018	Arscott, Joyell S.	Factors Affecting the Likely Use of Pre-Exposure Prophylaxis for Young African American Men Who Have Sex with Men	-	-	Duke University	Duke University	-	NA	NA	https://dukespace.lib.duke.edu/items/b1b8ff24-8026-46bd-95f9-35f826a2c50	African-American young men who have sex with men (YMSM) are seven and three times more likely than their White and Hispanic counterparts, respectively, to be infected with HIV. Once-daily oral co-formulated tenofovir disoproxil fumarate and emtricitabine FTC/TDF, for HIV pre-exposure prophylaxis, known as PrEP has been demonstrated to be an effective method of reducing rates of new HIV infections within this population. Despite this breakthrough in HIV prevention, African American YMSM use PrEP at a much lower and disproportionate rate in comparison to white MSM. Therefore, the aim of this dissertation was to develop a deeper understanding of the HIV prevention needs of African American YMSM as it relates to PrEP. This study was conducted using a descriptive qualitative approach, which was guided by a naturalistic design to explore and understand African American YMSM's cognitive and emotional processes as it relates to PrEP, and how these responses influence their likely future use of PrEP as an HIV prevention method. The findings revealed important individual-, social-, cultural-, and structural-level factors that affect African American YMSM's likely future use of PrEP. These findings revealed opportunities for future research and interventions to address the disparate rates of future PrEP use for African American YMSM. Article	2018	Atujuna M.; Newman P.A.; Wallace M.; Eluhu M.; Rubincam C.; Brown B.; Bekker L.-G.	Contexts of vulnerability and the acceptability of new biomedical HIV prevention technologies among key populations in South Africa: A qualitative study	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0191251	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041953558&doi=10.1371%2fjournal.pone.0191251&partnerID=40&md5=07ab3026ca3287ac39cacbab368e0c02	Background New biomedical prevention technologies (NPTs) may contribute to substantially reducing incident HIV infections globally. We explored acceptability and preferences for NPTs among key and other vulnerable populations in two South African townships. Methods We conducted six focus groups and 12 in-depth interviews with adolescents, and adult heterosexual men, women, and men who have sex with men (MSM) (n = 48), and eight in-depth interviews with key informant healthcare workers. The interview guide described preexposure prophylaxis (PrEP), vaginal rings, rectal microbicides and HIV vaccines, and explored acceptability and product preferences. Focus groups and in-depth interviews (45–80 minutes) were conducted in Xhosa, audiotaped, and transcribed and translated into English. Data were coded and reviewed using framework analysis with NVivo software. Results Overall, initial enthusiasm and willingness to use NPTs evolved into concerns about how particular NPTs might affect or require alterations in one's everyday lifestyle and practices. Different product preferences and motivations emerged by population based on similarity to existing practices and contexts of vulnerability. Adult women and female adolescents preferred a vaginal ring and HIV vaccine, motivated by longer duration of protection to mitigate feared repercussions from male partners, including threats to their marriage and safety, and a context of ubiquitous rape. Male adolescents preferred an HIV vaccine, seen as protection in serodiscordant relationships and convenient in obviating the HIV stigma and cost involved in buying condoms. Adult men preferred PrEP, given familiarity with oral medications and mistrust of injections, seen as enabling serodiscordant couples to have a child. MSM preferred a rectal microbicide given familiarity with gel-based lubricants, with concerns about duration of protection in the context of unplanned consensual sex and rape. Conclusions Biomedical interventions to prevent HIV transmission, rather than obviating social-structural factors that produce vulnerability, may be limited by these same factors. Implementation of NPTs should engage local communities to understand real-world constraints and strategise to deliver effective, multi-level combination prevention. © 2018 Atujuna et al. Article	2018	Ayala G.; Santos G.-M.; Arreola S.; Garner A.; Makofane K.; Howell S.	Blue-Ribbon Boys: factors associated with PrEP use, ART use and undetectable viral load among gay app users across six regions of the world	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/JIA2.25130	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071461131&doi=10.1002%2fJIA2.25130&partnerID=40&md5=fca77d8fb541ac1496f56708eebdcff2	Introduction: Gay social networking apps have grown in popularity among men who have sex with men offering opportunities for rapid and confidential collection of vital data as well as social connection. The goal of our study was to explore factors associated with utilization of pre-exposure prophylaxis (PrEP) and antiretroviral treatment (ART), and self-reported undetectable viral load (UVL) using data collected by the gay social networking app Hornet. Methods: In 2016, the Global Forum on MSM & HIV (MSMGF) partnered with Hornet, to support an educational initiative called Blue-Ribbon Boys. One aspect of the initiative prompts Hornet users to answer a short series of yes-no questions about their sexual health. Using survey responses, we evaluated factors associated with PrEP and ART use as well as self-reported UVL by fitting separate multivariable generalized estimating equation models. Results: In total, 16,008 unique Hornet users started the survey, of which 12,126 (76%) provided sufficient data for analyses. Of the 10,774 HIV-negative men, 13% reported PrEP use in the past year. PrEP use was associated with a recent sexually transmitted infection (STI) test or treatment (aOR = 2.19, CI = 1.49 to 3.21); and taking steps to protect oneself from HIV (aOR = 1.41, CI = 1.13 to 1.76). Among HIV-positive Hornet users (n = 1243), ART use was associated with older age (each year increase aOR = 1.02, CI = 1.01 to 1.04), a recent STI test or treatment (aOR = 4.54, CI = 2.65 to 7.78); and awareness of unlikely HIV transmission with UVL (aOR = 1.53, CI = 1.03 to 2.26). UVL was associated with older age (each year increase aOR = 1.03, CI = 1.01 to 1.04), a recent STI test or treatment (aOR = 4.84, CI = 2.74 to 8.55), and awareness of unlikely HIV transmission with UVL (aOR = 1.98, CI = 1.37 to 2.85). Conclusions: Study findings underscore the importance of STI testing and treatment as well as information about HIV trans-missibility for encouraging PrEP and ART use. Our findings also reveal age disparities, which can undermine incidence reduction among gay men. Gay social networking apps can be effectively used for rapid data collection and sexual health promotion with men who have sex with men. STI testing and treatment programmes offer important opportunities for encouraging PrEP and ART use. Information about HIV transmissibility with consistent ART use should be incorporated into prevention messag-ing tailored to various age groups. © 2018 The Authors. Article	2018	Bagchi A.D.; Holzemer W.	Support for PrEP Among New Jersey Health Care Workers	Journal of the Association of Nurses in AIDS Care	-	-	-	-	10553290	10.1016/j.jana.2018.06.003	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049441239&doi=10.1016%2fj.jana.2018.06.003&partnerID=40&md5=b47d4d310461083741a9e2c404c46fc3	We used an online survey of health care workers in New Jersey to assess awareness, perceptions, and support of preexposure prophylaxis (PrEP). We sampled respondents from diverse health care worker occupations, in HIV and non-HIV care settings. Of 174 participants, awareness of PrEP was high at 91% (n = 122), as was support for its use by members of at-risk groups (74%). Occupation was the only independent variable with significant variation in support of PrEP, with 41% of disease intervention specialists/health educators supporting PrEP completely, compared with 93% of nurses. Concerns that poor adherence could lead to resistant strains of HIV and that use could lead to "irresponsible sexual activity" were the most commonly endorsed barriers to PrEP support. The study suggests that, despite high levels of PrEP awareness, targeted education activities are needed to support New Jersey's efforts to expand PrEP availability and use. © 2018 Association of Nurses in AIDS Care	awareness; health care workers; HIV; PrEP; support	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Baisley K.; Chimbindi N.; Mthiyane N.; Floyd S.; McGrath N.; Pillay D.; Seeley J.; Zuma T.; Dreyer J.; Gareta D.; Smit T.; Mutevedzi T.; Fenty J.; Herbst K.; Birdthistle I.; Shahmanesh M.	High HIV incidence and low uptake of HIV prevention services: The context of risk for young male adults prior to DREAMS in rural KwaZulu-Natal, South Africa	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0208689	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059213783&doi=10.1371%2fjournal.pone.0208689&partnerID=40&md5=facc6298c32b80f23c07909f9e28ddd9	Background Young men are less likely than young women to engage with HIV prevention and care, and their HIV-related mortality is higher. We describe HIV incidence and uptake of HIV services in men 20–29 years(y) in rural KwaZulu-Natal, South Africa, before the roll-out of DREAMS. Methods We used data from a population-based demographic and HIV surveillance cohort. HIV incidence was estimated from anonymised testing in an annual serosurvey. Service uptake was assessed in 2011 and 2015, through two self-reported outcomes: 1) HIV testing in the past 12 months(m); 2) voluntary medical male circumcision(VMMC). Logistic regression was used to estimate odds ratios(OR) and 95% confidence intervals(CI) for factors associated with each outcome. Results HIV incidence in 2011–2015 was 2.6/100 person-years (95%CI = 2.0–3.4) and 4.2 (95%CI = 3.1–5.6) among men 20-24y and 25-29y, respectively, with no significant change from 2006–2010. N = 1311 and N = 1221 young men participated in the 2011 and 2015 surveys, respectively. In both years, <50% reported testing for HIV in the past 12m. In 2011, only 5% reported VMMC, but coverage in 2015 increased to 40% and 20% in men 20-24y and 25-29y, respectively. HIV testing was positively associated with higher education and mobility. Testing uptake was higher in men reporting >1 partner in the past 12m, or condom use at last sex, but lower in those reporting a casual partner (adjusted (a)OR = 0.53, 95%CI = 0.37–0.75). VMMC uptake was associated with survey year and higher education. Men aged 25-29y and those who were employed (aOR = 0.66; 95%CI = 0.49–0.89) were less likely to report VMMC. Conclusions HIV incidence in men 20-29y was very high, and pre-exposure prophylaxis (PrEP) should be considered in this population. Uptake of services was low. VMMC coverage increased dramatically from 2011 to 2015, especially among younger men, suggesting a demand for this service. Interventions designed with and for young men are urgently needed. © 2018 Baisley et al. Theses and Dissertations	2018	Baker, Zoe Gabriele; Gorbach, Pamina M.	The Impact of Partnership Factors on Adherence to HIV Pre-Exposure Prophylaxis and Antiretroviral Therapy	-	-	University of California	-	-	NA	https://www.proquest.com/dissertations-theses/impact-partnership-factors-on-adherence-hiv-pre/docview/2051919388/se-2?accountid=8113	Adherence to medications for HIV prevention and treatment is essential to reducing HIV transmission risk and improving health outcomes. Adherence to these medications remain insufficient in several key populations, however. Understanding how partnership types and dynamics may encourage or hinder HIV medication adherence is necessary to improving adherence rates among important sub-groups, including young men who have sex with men (YMSM), serodiscordant couples, and adolescent girls. My first paper identified the partnership and housing factors associated with adherence to oral PrEP among YMSM. PrEP adherence was relatively low in the study, declining from 46% at baseline to 39% at study conclusion. PrEP adherence was significantly associated with increasing age (OR=1.35; 95% CI: 1.14, 1.60), and race (African-Americans vs. other OR=0.37, 95% CI: 0.21, 0.66). Relationship type, length, and depth, number of partners, and partner's HIV status were not significantly associated with adherence. PrEP adherence was associated with housing insecurity, including ever being kicked out of the home (AOR=0.43; 95% CI: 0.18, 1.04), and the Housing Insecurity Index (AOR=0.64; 95% CI: 0.44, 0.93). PrEP adherence was also associated with privacy, including number of people living in the residence (AOR=0.82; 95% CI: 0.71, 0.95), sleeping in a private bedroom (AOR=2.10, 95% CI: 1.01, 4.40), and the Lack of Privacy Index (AOR=0.82; 95% CI: 0.71, 0.95). YMSM did not modify their PrEP-taking depending on relationship risk. Housing insecurity and lack of privacy may hinder PrEP adherence among YMSM. My second paper determined whether HIV viral suppression was associated with partnership status and partnership support among HIV-positive individuals and serodiscordant couples in Brazil. Viral suppression did not significantly differ between HIV-positive partnered (79% virally suppressed) and unpartnered (76% virally suppressed) individuals. Among individuals in partnerships, viral load suppression was significantly associated with having partners who attended monthly visits (AOR=2.99; 95% CI: 1.00, 8.93); among women in partnerships, viral load suppression was significantly associated with having a partner who actively reminded them to take ART (AOR=2.67; 95% CI: 1.04, 6.88). Practical measures of social support, including attending monthly visits and reminding a partner to take ART, may improve viral suppression among HIV-positive individuals in serodiscordant partnerships. My third paper assessed the product, relationship, and sex factors that affect acceptability of a vaginal ring (VR) for HIV prevention among adolescent girls aged 15 to 17 years. Product factors were most frequently mentioned as barriers to VR acceptability. Many participants reported concerns about the large size of the VR upon first impression, and some reported pain with VR insertion. Several participants reported concerns regarding cleanliness of the VR, particularly during menstruation. Relationship factors rarely appeared to act as barriers to VR acceptability; the majority of participants disclosed VR use to their sexual partners, and reactions from sexual partners regarding the VR were common. Emotional and/or physical discomfort surrounding VR use during sex was mentioned occasionally as a potentially barrier to VR acceptability. Relationship factors appear to be important in several populations for adherence to HIV-related medications. YMSM in high-risk sexual relationships may not modify PrEP-taking, leaving them at risk for HIV acquisition. Among serodiscordant couples, practical measures of partnership support may improve ART adherence and promote viral suppression. While adolescent girls most often reported that product-related factors inhibited VR acceptability, lack of partnership disclosure, negative partner reactions, and discomfort during sex may hinder VR acceptability among some girls. Article	2018	Baker, Zoë; Javanbakht, Marjan; Mierzwa, Stan; Pavel, Craig; Lally, Michelle; Zimet, Gregory	Predictors of Over-Reporting HIV Pre-exposure Prophylaxis (PrEP) Adherence Among Young Men Who Have Sex With Men (YMSM) in Self-Reported Versus Biomarker Data	AIDS and Behavior	-	-	-	1090-7165	https://doi.org/10.1007/s10461-017-1958-4	https://escholarship.org/uc/item/2pr6g4wr	Young men who have sex with men (YMSM) face a disproportionately high burden of HIV. Oral pre-exposure prophylaxis (PrEP) is effective in preventing HIV acquisition, but adherence to PrEP among YMSM may be inadequate. Medication adherence may be assessed via biomarkers, which are expensive and invasive, or via self-report through Audio Computer Assisted Self-Interview (ACASI), which may result in over-reporting of adherence. In this paper we assess the potential of a new method of self-report, the Interactive Questionnaire System (iQS), in validly estimating true adherence rates. PrEP adherence among 167 YMSM aged 15-23 was measured via dried blood spot (DBS), ACASI, and iQS twice over a 24-week study period. Both ACASI- and iQS-reported data revealed that over 40% of individuals self-reporting adequate PrEP adherence had DBS-estimated drug levels indicating inadequate adherence. Adjusted logistic repeated measures random intercept regression analyses indicated that younger YMSM had higher odds of over-reporting adherence than older YMSM-each 1 year increase in age was associated with 0.79 times the odds of over-reporting adherence (95% CI 0.63, 0.98; p value = 0.031), and being African American was associated with 3.22 times greater odds of over-reporting than non-African Americans (95% CI 1.51, 6.90; p-value = 0.0003). These results suggest that ACASI and iQS methods of self-report significantly overestimate true PrEP adherence rates among YMSM, and that the odds of over-reporting adherence may be affected by both age and race. Article	2018	Barrett S.E.; Teller R.S.; Forster S.P.; Li L.; Mackey M.A.; Skomski D.; Yang Z.; Fillgrove K.L.; Doto G.J.; Wood S.L.; Lebron J.; Grobler J.A.; Sanchez R.I.; Liu Z.; Lu B.; Niu T.; Sun L.; Gindy M.E.	Extended-duration MK-8591-eluting implant as a candidate for HIV treatment and prevention	Antimicrobial Agents and Chemotherapy	-	-	-	664804	10.1128/AAC.01058-18	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053908337&doi=10.1128%2fAAC.01058-18&partnerID=40&md5=13e2f5d87654806fbd3455a5bb173d6a	Regimen adherence remains a major hurdle to the success of daily oral drug regimens for the treatment and prevention of human immunodeficiency virus (HIV) infection. Long-acting drug formulations requiring less-frequent dosing offer an opportunity to improve adherence and allow for more forgiving options with regard to missed doses. The administration of long-acting formulations in a clinical setting enables health care providers to directly track adherence. MK-8591 (4=-ethynyl-2- fluoro-2=-deoxyadenosine EFdA) is an investigational nucleoside reverse transcriptase translocation inhibitor (NRTTI) drug candidate under investigation as part of a regimen for HIV treatment, with potential utility as a single agent for preexposure prophylaxis (PrEP). The active triphosphate of MK-8591 (MK-8591-TP) exhibits protracted intracellular persistence and, together with the potency of MK-8591, supports its consideration for extended-duration dosing. Toward this end, drug-eluting implant devices were designed to provide prolonged MK-8591 release in vitro and in vivo. Implants, administered subcutaneously, were studied in rodents and nonhuman primates to establish MK-8591 pharmacokinetics and intracellular levels of MK-8591- TP. These data were evaluated against pharmacokinetic and pharmacodynamic models, as well as data generated in phase 1a (Ph1a) and Ph1b clinical studies with once-weekly oral administration of MK-8591. After a single administration in animals, MK-8591 implants achieved clinically relevant drug exposures and sustained drug release, with plasma levels maintained for greater than 6 months that correspond to efficacious MK-8591-TP levels, resulting in a 1.6-log reduction in viral load. Additional studies of MK-8591 implants for HIV treatment and prevention are warranted. © 2018 American Society for Microbiology. Article	2018	Bauermeister J.A.; Golinkoff J.M.; Horvath K.J.; Hightow-Weidman L.B.; Sullivan P.S.; Stephenson R.	A multilevel tailored web app–based intervention for linking young men who have sex with men to quality care (Get Connected): Protocol for a randomized controlled trial	JMIR Research Protocols	-	-	-	19290748	10.2196/10444	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060133163&doi=10.2196%2f10444&partnerID=40&md5=16abc12a8b54415c4b047bc989d86319	Background: HIV epidemic among young men who have sex with men (YMSM) is characterized by strong racial disparities and concerns about the availability and access to culturally appropriate HIV prevention and care service delivery. Get Connected, a Web-based intervention that employs individual- and system-level tailoring technology to reduce barriers to HIV prevention care (eg, HIV or sexually transmitted infection STI testing, pre-exposure prophylaxis PrEP), was developed for YMSM (age 15-24 years). This protocol details the design and procedures of a 2-phase project that includes mystery shopping and a randomized controlled trial (RCT) to test the efficacy of Get Connected among YMSM in Philadelphia, Atlanta, and Houston. Objective: The objective of mystery shopping is to examine the quality of HIV test counseling and PrEP-related referrals for YMSM within local HIV or STI testing sites. The objective of the RCT is to test the efficacy of Get Connected for increasing HIV-negative or HIV-unknown YMSM's successful uptake of HIV prevention services (eg, routine HIV or STI testing), PrEP awareness, and likelihood to start PrEP (PrEP willingness), compared with those in the control condition, over a 12-month period. Methods: For Phase 1, we will create a master list of HIV and STI testing sites in each city. We will enroll and train 10-15 mystery shoppers per city; each testing site will be separately visited and assessed by 2 mystery shoppers. After each site visit, the mystery shoppers will complete a site evaluation to record their perceptions of various measures including lesbian, gay, bisexual, transgender, queer affirming, youth friendly, privacy and confidentiality, provider-patient interactions, and clinic environment. For Phase 2, we will enroll 480 YMSM for 12 months across the 3 iTech cities into a 2-arm prospective RCT. Participants randomized to the control condition are directed to the AIDSVu.org testing site locator. Participants randomized to the intervention condition will be granted access to a Web app with content tailored to their specific demographic characteristics (eg, age, race or ethnicity, location, and relationship status), HIV and STI risk behaviors (eg, HIV and STI testing history, substance use, communication with partners regarding status) and sociocultural context (eg, homelessness, incarceration). Study assessments will occur at enrollment and at 1, 3, 6, 9, and 12 months postenrollment. Results: Get Connected research activities began in September 2016 and are ongoing. To date, institutional review board (IRB) submission is complete and IRB authorization agreements are pending at several other universities. Conclusions: The deployment of Get Connected through a mobile-optimized Web app seeks to optimize the intervention's acceptability, accessibility, availability, and long-term affordability among YMSM. © José A. Article	2018	Baxi, SM; Vittinghoff, E; Bacchetti, P; Huang, Y; Chillag, K; Wiegand, R; Anderson, PL; Grant, R; Greenblatt, RM; Buchbinder, S; Gandhi, M; Liu, AY	Comparing pharmacologic measures of tenofovir exposure in a US pre-exposure prophylaxis randomized trial	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0190118	https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0190118	It is critical to assess adherence to pre-exposure prophylaxis (PrEP) in clinical trials. The relationship between pharmacokinetic measures of PrEP adherence and other adherence measures used in PrEP trials requires further characterization. Plasma, peripheral blood mononuclear cells (PBMCs), and hair samples were collected from 88 HIV-uninfected men who have sex with men in a placebo-controlled randomized PrEP trial; announced pill counts, medication electronic monitoring (MEMS), and self-report using visual analog scale (VAS) were also collected. Tenofovir (TFV or TFV-DP) in plasma, hair, and PBMCs were quantified. Proportions with drug detection, Spearman correlation coefficients, and univariate and multivariable regression models were used. Drug detection in plasma, PBMC, and hair samples was highly concordant with treatment arm assignment. TFV or TFV-DP levels were detected in most active-arm participants: 44/47 (94%) in plasma, 46/47 (98%) in hair, and 44/47 (94%) in PBMCs and in only 1/41 placebo arm participant. Correlation coefficients were r = 0.59 for plasma and PBMC, r = 0.34 for PBMC and hair and r = 0.36 for plasma and hair. MEMS and announced pill-counts were moderately correlated (r = 0.52) but less so with pharmacologic measures (range of r = 0.12 to 0.38). Self-reported adherence by visual analog scale demonstrated essentially no correlation with drug levels (r = 0.06 for hair, PBMC or plasma) and was a poor indicator of exposure to study product. Indices of drug exposure are important indicators in assessing adherence to PrEP; accounting for variability between measures may improve interpretation and use of adherence measures in future PrEP studies. Article	2018	Bayley, J; Nadarzynski, T; Portman, M; Owen, G; Pasvol, T; Nutland, W	Acceptability of native mobile phone applications (apps) in sexual health: is an app acceptable in men who have sex with men for those taking or considering taking PrEP	HIV Medicine	-	-	-	1464-2662	10.1007/s10461-013-0671-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3946790/	Young men who have sex with men (YMSM) are increasingly using mobile smartphone applications (“apps”), such as Grindr, to meet sex partners. A probability sample of 195 Grindrusing YMSM in Southern California were administered an anonymous online survey to assess patterns of and motivations for Grindr use in order to inform development and tailoring of smartphone-based HIV prevention for YMSM. The number one reason for using Grindr (29%) was to meet “hook ups.” Among those participants who used both Grindr and online dating sites, a statistically significantly greater percentage used online dating sites for “hook ups” (42%) compared to Grindr (30%). Seventy percent of YMSM expressed a willingness to participate in a smartphone app-based HIV prevention program. Development and testing of smartphone apps for HIV prevention delivery has the potential to engage YMSM in HIV prevention programming, which can be tailored based on use patterns and motivations for use. Article	2018	Bayley, J; Nadarzynski, T; Portman, M; Owen, G; Pasvol, T; Nutland, W	The trends in PrEP awareness, acceptability and uptake amongst MSM in London between 2016 and 2018	HIV Medicine	-	-	-	1464-2662	10.17269/s41997-018-0064-3	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6153704/	Objectives Pre-exposure prophylaxis (PrEP) with daily oral tenofovir/emtricitabine dramatically reduces HIV risk in men who have sex with men (MSM). However, uptake is slow worldwide. Methods We administered anonymous cross-sectional questionnaires to MSM presenting for anonymous HIV testing at a Toronto sexual health clinic at four successive time points during the period 2013–2016. We assessed trends in PrEP awareness, acceptability, and use over time using the Cochran-Armitage Trend Test, and identified barriers to using PrEP by constructing “PrEP cascades” using 2016 data. We assumed that to use PrEP, MSM must (a) be at risk for HIV, (b) be at objectively high risk (HIRI-MSM score ≥ 10), (c) perceive themselves to be at medium-to-high risk, (d) be aware of PrEP, (e) be willing to use PrEP, (f) have a family doctor, (g) be comfortable discussing sexual health with that doctor, and (h) have drug coverage/be willing to pay out of pocket. Results MSM participants were mostly white (54–59.5%), with median age 31 years (IQR = 26–38). PrEP awareness and use increased significantly over time (both p < 0.0001), reaching 91.3% and 5.0%, respectively, in the most recent wave. Willingness to use PrEP rose to 56.5%, but this increase did not reach statistical significance (p = 0.06). The full cascade, ABCDEFGH, suggested few could readily use PrEP under current conditions (11/400 = 2.8%). The largest barriers, in descending order, were low self-perceived HIV risk, unwillingness to use PrEP, and access to PrEP providers. Conclusion To maximize its potential public health benefits, PrEP scale-up strategies must address self-perceived HIV risk and increase access to PrEP providers. Article	2018	Bazzi A.R.; Biancarelli D.L.; Childs E.; Drainoni M.-L.; Edeza A.; Salhaney P.; Mimiaga M.J.; Biello K.B.	Limited Knowledge and Mixed Interest in Pre-Exposure Prophylaxis for HIV Prevention among People Who Inject Drugs	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0126	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058039994&doi=10.1089%2fapc.2018.0126&partnerID=40&md5=c42ba2c82e5565a56a2f1d488997ac92	People who inject drugs (PWID) experience sexual and injection-related HIV risks, but uptake of pre-exposure prophylaxis (PrEP) for HIV prevention among PWID has been low. Improving PrEP uptake in this population will require understanding of PrEP knowledge and interest. In 2017, we conducted in-depth, semistructured interviews with HIV-uninfected PWID and key informants (PrEP and harm reduction providers) in the US Northeast. Thematic analysis of coded data explored PrEP knowledge and the factors that influence PrEP interest. Among PWID (n = 33), median age was 36 years, 55% were male, 67% were white, and 24% identified as Hispanic/Latino. Accurate PrEP knowledge among PWID was low, which key informants (n = 12) attributed to PrEP marketing focused on other risk populations, as well as healthcare providers' lack of time and unwillingness to discuss PrEP with PWID. There was a discrepancy between self-reported HIV risk behaviors, which were common, and HIV risk perceptions, which varied and strongly influenced PrEP interest. Most PWID and key informants thought that PrEP would be most beneficial for those who shared syringes, used discarded syringes, engaged in transactional sex, or were homeless. Improving uptake of PrEP for HIV prevention among high-risk PWID will require education to increase PrEP knowledge and addressing factors that negatively influence PrEP interest such as perceptions regarding low HIV risk and the process for obtaining PrEP. This may require specialized PrEP marketing and outreach efforts and improved capacity of healthcare providers to effectively assess HIV risk (and perceptions) and communicate the benefits of PrEP to at-risk PWID. © 2018, Mary Ann Liebert, Inc., publishers.	harm reduction; HIV infections; needle sharing; pre-exposure prophylaxis; risk taking; sexual behavior	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Mixed methods
Article	2018	Bazzi A.R.; Yotebieng K.A.; Agot K.; Rota G.; Syvertsen J.L.	Perspectives on biomedical HIV prevention options among women who inject drugs in Kenya	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1363369	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026878825&doi=10.1080%2f09540121.2017.1363369&partnerID=40&md5=12cdbfe137fd0cd22881bcbaadc2700	Due to heightened vulnerability to HIV from frequent engagement in sex work and overlapping drug-using and sexual networks, women who inject drugs should be a high priority population for pre-exposure prophylaxis (PrEP) and other biomedical HIV prevention tools. Kenya is one of the first African countries to approve oral PrEP for HIV prevention among "key populations," including people who inject drugs and sex workers. The objective of this study was to explore preferences and perceived challenges to PrEP adoption among women who inject drugs in Kisumu, Kenya. We conducted qualitative interviews with nine HIV-uninfected women who inject drugs to assess their perceptions of biomedical HIV interventions, including oral PrEP, microbicide gels, and intravaginal rings. Despite their high risk and multiple biomedical studies in the region, only two women had ever heard of any of these methods. All women were interested in trying at least one biomedical prevention method, primarily to protect themselves from partners who were believed to have multiple other sexual partners. Although women shared concerns about side effects and product efficacy, they did not perceive drug use as a significant deterrent to adopting or adhering to biomedical prevention methods. Beginning immediately and continuing throughout Kenya's planned PrEP rollout, efforts are urgently needed to include the perspectives of high risk women who use drugs in biomedical HIV prevention research and programing. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Bekker, LG; Roux, S; Sebastien, E; Yola, N; Amico, KR; Hughes, JP; Marzinke, MA; Hendrix, CW; Anderson, PL; Elharrar, V; Stirratt, M; Rooney, JF; Piwowar-Manning, E; Eshleman, SH; McKinstry, L; Li, M; Dye, BJ; Grant, RM	Daily and non-daily pre-exposure prophylaxis in African women (HPTN 067/ADAPT Cape Town Trial): a randomised, open-label, phase 2 trial	The Lancet HIV	-	-	-	-	10.1016/S2352-3018(17)30156-X	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01423110/full	Background: The relative feasibility and acceptability of daily versus non-daily dosing of oral HIV pre-exposure prophylaxis (PrEP) among women are unknown. We aimed to investigate the feasibility of non-daily PrEP regimens in adult women. Methods: We did a randomised, open-label, phase 2 clinical trial (HPTN 067/ADAPT) of oral PrEP with emtricitabine plus tenofovir disoproxil fumarate at a research centre in Cape Town, South Africa. Participants were adult women (age ≥18 years) who received directly observed dosing once a week for 5 weeks followed by random assignment (1:1:1) at week 6 to one of three unblinded PrEP regimens for self-administered dosing over 24 weeks: daily; time-driven (twice a week plus a post-sex dose); or event-driven (one tablet both before and after sex). Primary outcomes were PrEP coverage (at least one dose within the 4 days before sex and one dose within 24 h after sex), pills needed or used to achieve regimen-specific adherence and coverage, and symptoms and side-effects. All analyses were by intention to treat. This trial is registered with ClinicalTrials.gov, number NCT01327651; the trial is completed and this report presents the final analysis. Findings: Between Sept 12, 2011, and Oct 3, 2012, 191 women were enrolled to the trial. 178 (93%) completed directly observed dosing and were randomly assigned one of the three PrEP regimens for the self-administered phase: 59 were allocated the daily regimen, 59 the time-driven regimen, and 60 the event-driven regimen. Median age of women was 26 years (IQR 21–37; range 18–52). In women allocated the daily regimen, 1459 (75%) of 1952 sex events were covered by PrEP, compared with 599 (56%) of 1074 sex events among those assigned the time-driven regimen (odds ratio OR 2·35, 95% CI 1·43–3·83; p=0·0007) and 798 (52%) of 1542 sex events among those allotted the event-driven regimen (2·76, 1·68–4·53; p<0·0001). Fewer pills were needed for complete adherence in women allocated non-daily regimens (vs daily regimen, relative mean 2·53 95% CI 2·39–2·69 for the time-driven regimen and 4·16 3·59–4·82 for the event-driven regimen; p<0·0001). Side-effects were uncommon. Eight HIV seroconversions occurred overall, with four documented during the self-administered phase (two with the time-driven regimen and two with the event-driven regimen). Adherence to the assigned regimen was 75% (7283 of 9652 doses taken) for women allocated the daily regimen compared with 65% for those assigned the time-driven regimen (2367 of 3616 doses taken; p=0·0028) and 53% for those allotted the event-driven regimen (1161 of 2203 doses taken; p<0·0001). When sex was reported in the previous week, PrEP drugs were detected (above the lower limits of quantification) more frequently in women assigned the daily regimen (73 68% of 107 samples) than in those allocated the time-driven regimen (42 58% of 72 samples) and the event-driven regimen (41 41% of 99 samples). Interpretation: Daily PrEP dosing resulted in higher coverage of sex events, increased adherence to the regimen, and augmented drug concentrations than did either time-driven or event-driven dosing. These findings support recommendations for daily use of PrEP with oral emtricitabine plus tenofovir disoproxil fumarate in women. Article	2018	Benítez-Gutiérrez, Laura; Soriano, Vicente; Requena, Silvia; Arias, Ana; Barreiro, Pablo; de Mendoza, Carmen	Treatment and prevention of HIV infection with long-acting antiretrovirals.	Expert Review of Clinical Pharmacology	-	-	-	1751-2441	10.1080/17512433.2018.1453805	https://dx.doi.org/10.1080/17512433.2018.1453805	INTRODUCTION: Current antiretroviral therapy allows to achieve and sustain maximal suppression of HIV replication in most treated patients. As result, the life expectancy of HIV-infected persons has improved dramatically and is nowadays similar to that of the HIV-negative population. However, oral antiretrovirals have to be taken daily and indefinitely to avoid resumption of HIV replication and selection of drug resistance. Unfortunately, drug adherence is often suboptimal and tends to decline over time. Areas covered: New drugs, formulations and delivery systems are being developed for extended-release of antiretrovirals. At this time, intramuscular cabotegravir and rilpivirine, dapivirine vaginal rings and tenofovir alafenamide subdermal implants are the products in more advanced stages of clinical development. Their pharmacokinetics/dynamics and safety/efficacy are reviewed. Expert commentary: In the absence of eradicative therapy for individuals with HIV infection and protective vaccines for persons at risk, long-term antiretroviral therapy is the best approach for preventing disease progression in patients and halting transmissions, either as result of 'treatment as prevention' for HIV carriers or 'pre-exposure prophylaxis' for uninfected individuals at risk. In all these scenarios, the advent of long-acting antiretrovirals will expand options for overcoming the challenge of suboptimal drug adherence and reduce the burden of HIV infection. Article	2018	Bergo, Pedro Henrique Fernandes; Bianchini, Talissa; Alves, Catherine Giusti; Ribeiro Júnior, Acir; Beck, Eduarda Kipper; Rigatto, Maria Helena Pitombeira	Profilaxia pré-exposição no controle do HIV: uma revisão de efetividade e potenciais complicações	Acta Médica (Porto Alegre)	-	-	-	0103-5037	NA	https://fi-admin.bvsalud.org/document/view/wxe9j	INTRODUÇÃO. A infecção por HIV permanece sendo um problema de saúde mundial. Dessa forma, a Profilaxia Pré-Exposição (PrEP) surgiu como um método complementar de prevenção. Este trabalho tem como objetivo avaliar a eficácia da PrEP contra a infecção por HIV, o contexto de resistência viral e incidência de infecções sexualmente transmissíveis. MÉTODOS. Revisão narrativa, com busca de artigos na plataforma PubMed, utilizando os descritores HIV AND PrEP, filtrando para artigos do tipo ensaio clínico ou coorte prospectiva, realizados em humanos, publicados há, no máximo, 10 anos e em língua inglesa. RESULTADOS. A eficácia da PrEP contra infecção por HIV foi avaliada por 8 estudos. Elevados níveis de proteção contra o HIV foram demonstrados, com taxas de efetividade variando entre 73% e 85% considerando aderência adequada ao tratamento profilático. A resistência viral foi reportada em 7 estudos que avaliaram pacientes infectados por HIV durante o uso da PrEP, 6 deles identificaram casos de resistência viral, variando conforme os níveis de aderência obtidos e o perfil de uso dos pacientes. Um estudo feito em Montreal, Canadá, verificou maior incidência de infecções sexualmente transmissíveis em indivíduos usuários de PrEP, com um aumento generalizado de 72%. CONCLUSÃO. A PrEP é uma medida eficaz na proteção contra o HIV, sendo uma importante ferramenta de saúde pública no controle da doença. Apesar de sua efetividade, a PrEP não é isenta de limitações, repercutindo em riscos elevados de infecções sexualmente transmissíveis associadas e resistência viral. O papel do profissional de saúde é fundamental na indicação adequada e acompanhamento de pessoas que podem se beneficiar do uso da PrEP. Article	2018	Beymer M.R.; DeVost M.A.; Weiss R.E.; Dierst-Davies R.; Shover C.L.; Landovitz R.J.; Beniasians C.; Talan A.J.; Flynn R.P.; Krysiak R.; McLaughlin K.; Bolan R.K.	Does HIV pre-exposure prophylaxis use lead to a higher incidence of sexually transmitted infections? A case-crossover study of men who have sex with men in Los Angeles, California	Sexually Transmitted Infections	-	-	-	13684973	10.1136/sextrans-2017-053377	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049099284&doi=10.1136%2fsextrans-2017-053377&partnerID=40&md5=7bd7242d317af5d328a937534a8359af	Background Pre-exposure prophylaxis (PrEP) is an effective method for reducing HIV incidence among at-risk populations. However, concerns exist over the potential for an increase in STIs following PrEP initiation. The objective of this study is to compare the STI incidence before and after PrEP initiation within subjects among a cohort of men who have sex with men in Los Angeles, California. Methods: The present study used data from patients who initiated PrEP services at the Los Angeles LGBT Center between October 2015 and October 2016 (n=275). A generalised linear mixed model was used with a case-crossover design to determine if there was a significant difference in STIs within subjects 365 days before (before-PrEP period) and 365 days after PrEP initiation (after-PrEP period). Results: In a generalised linear mixed model, there were no significant differences in urethral gonorrhoea (P=0.95), rectal gonorrhoea (P=0.33), pharyngeal gonorrhoea (P=0.65) or urethral chlamydia (P=0.71) between periods. There were modest increases in rectal chlamydia (rate ratio (RR) 1.83; 95% CI 1.13 to 2.98; P=0.01) and syphilis diagnoses (RR 2.97; 95% CI 1.23 to 7.18; P=0.02). Conclusions: There were significant increases in rectal chlamydia and syphilis diagnoses when comparing the periods directly before and after PrEP initiation. However, only 28% of individuals had an increase in STIs between periods. Although risk compensation appears to be present for a segment of PrEP users, the majority of individuals either maintain or decrease their sexual risk following PrEP initiation. © 2018 Article author(s).	chlamydia infection; gay men; prophylaxis; sexual health; syphilis	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2018	Beymer M.R.; Gildner J.L.; Holloway I.W.; Landovitz R.J.	Acceptability of injectable and on-demand pre-exposure prophylaxis among an online sample of young men who have sex with men in California	LGBT Health	-	-	-	23258292	10.1089/lgbt.2017.0244	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053136649&doi=10.1089%2flgbt.2017.0244&partnerID=40&md5=576f3d6381a109950ac2bab583059443	Purpose: Pre-exposure prophylaxis (PrEP) is an effective strategy to prevent HIV. However, low uptake of daily oral PrEP since Food and Drug Administration approval and low medication adherence among users have stimulated the investigation of other modalities for delivery, such as injectable PrEP and on-demand PrEP. The objective of this study was to determine the demographic and behavioral predictors of willingness to try alternative PrEP delivery mechanisms among young men who have sex with men (YMSM) who stated that they were unwilling to try daily oral PrEP. Methods: YMSM in California were recruited through geosocial networking applications; we analyzed a subsample who stated that they were either ambivalent about trying or unwilling to try daily oral PrEP (n = 265). We used chi-square and Fisher's exact tests to determine characteristics associated with willingness to try injectable PrEP, willingness to try on-demand PrEP, and willingness to try either alternative form. Results: For individuals who stated that they would not be willing to try daily oral PrEP, ∼85% were willing to try on-demand and/or injectable PrEP. Individuals who reported some college or more reported greater willingness to try injectable PrEP (adjusted odds ratio aOR: 2.92; 95% confidence interval CI: 1.32-6.46), on-demand PrEP (aOR: 2.28; 95% CI: 1.06-4.90), or either method (aOR: 5.54; 95% CI: 1.78-17.22). Conclusion: Future research should determine how to enhance uptake of emerging forms of PrEP among the individuals most at risk for HIV. © Mary Ann Liebert, Inc., publishers 2018.	gay/bisexual men; HIV pre-exposure prophylaxis; HIV prevention; men who have sex with men	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Quantitative
Article	2018	Bezerra, Vladimir Porfirio	PRÁTICAS E SENTIDOS DA SEXUALIDADE DE ALGUNS USUÁRIOS DA PROFILAXIA PRÉ-EXPOSIÇÃO (PrEP) AO HIV	CSOnline	-	-	-	1981-2140	10.34019/1981-2140.2017.17428	https://periodicos.ufjf.br/index.php/csonline/article/view/17428	Este artigo objetiva refletir sobre determinados aspectos da subjetividade de alguns participantes do projeto PrEP Brasil, pesquisa conduzida a partir de 2014 por três centros participantes: a Fiocruz, por meio do Laboratório de Pesquisas Clínicas (LaPClin), o Centro de Referência e Treinamento de AIDS da Secretaria Estadual de Saúde de São Paulo (CRT- AIDS/SP) e a Universidade de São Paulo (USP). O projeto PrEP Brasil envolveu a administração do medicamento antirretroviral Truvada, droga – comercializada nos EUA desde 2012 – que é majoritariamente utilizada por homens que fazem sexo com homens (HSH), e que promete diminuir o risco de infecção pelo vírus HIV em até 96%. Perscrutando alguns dos depoimentos extraídos de um fórum de discussão online sobre a PrEP e entrevistas na mídia, foi possível compreender como a equação "corpo, risco e prazer" se estrutura no cotidiano de alguns usuários desta nova tecnologia para prevenção contra o HIV. Article	2018	Bhatia R.; Modali L.; Lowther M.; Glick N.; Bell M.; Rowan S.; Keglovitz K.; Schneider J.	Outcomes of Preexposure Prophylaxis Referrals from Public STI Clinics and Implications for the Preexposure Prophylaxis Continuum	Sexually Transmitted Diseases	-	-	-	1485717	10.1097/OLQ.0000000000000690	https://pubmed.ncbi.nlm.nih.gov/28876282/	Background: Human immunodeficiency virus preexposure prophylaxis (PrEP) uptake remains low in high-risk populations. Sexually transmitted infection (STI) clinics reach PrEP-eligible persons and may be ideal settings to model PrEP implementation. Methods: Consenting PrEP-eligible patients identified at Chicago Department of Public Health STI Clinics were actively referred to PrEP partner sites between June 1, 2015, and May 31, 2016. Outcomes included successful contact by a partner site, linkage to a partner site, and receipt of a PrEP prescription. Bivariable and time to event analyses were conducted to determine significant associations of outcomes. Results: One hundred thirty-seven patients were referred; 126 (92%) were men who have sex with men, and mean age was 29 years. Ninety-eight (72%) were contacted by a PrEP partner, 43 (31%) were linked, and 40 (29%) received a prescription. Individuals aged 25 years and older were more likely to link (odds ratio, 3.10; 95% confidence interval, 1.30-7.41) and receive a PrEP prescription (odds ratio, 2.70; 95% confidence interval, 1.12-6.45) compared with individuals 24 years and younger. The average time between each step was greater for those 24 years and younger compared with those aged 25 years and older for all steps. Time to event analyses revealed that those aged 25 years and older were significantly more likely to receive a prescription compared to those aged 24 years and younger (hazard ratio, 3.62; 95% risk limits, 1.47-8.92). Conclusions: Preexposure prophylaxis active referrals from STI clinics to partner sites are feasible, though drop out was prominent in the initial steps of the continuum. Youth were less likely to link or receive prescriptions, indicating the need for tailored interventions for this vulnerable population. © Copyright 2017 American Sexually Transmitted Diseases Association. Article	2018	Biello K.B.; Bazzi A.R.; Mimiaga M.J.; Biancarelli D.L.; Edeza A.; Salhaney P.; Childs E.; Drainoni M.L.	Perspectives on HIV pre-exposure prophylaxis (PrEP) utilization and related intervention needs among people who inject drugs	Harm Reduction Journal	-	-	-	14777517	10.1186/s12954-018-0263-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056328926&doi=10.1186%2fs12954-018-0263-5&partnerID=40&md5=7052487c3e048cea92c570c2ceafd6c1	Background: Antiretroviral pre-exposure prophylaxis (PrEP) is clinically efficacious and recommended for HIV prevention among people who inject drugs (PWID), but uptake remains low and intervention needs are understudied. To inform the development of PrEP interventions for PWID, we conducted a qualitative study in the Northeastern USA, a region where recent clusters of new HIV infections have been attributed to injection drug use. Methods: We conducted qualitative interviews with 33 HIV-uninfected PWID (hereafter, "participants") and 12 clinical and social service providers (professional "key informants") in Boston, MA, and Providence, RI, in 2017. Trained interviewers used semi-structured interviews to explore PrEP acceptability and perceived barriers to use. Thematic analysis of coded data identified multilevel barriers to PrEP use among PWID and related intervention strategies. Results: Among PWID participants (n = 33, 55% male), interest in PrEP was high, but both participants and professional key informants (n = 12) described barriers to PrEP utilization that occurred at one or more socioecological levels. Individual-level barriers included low PrEP knowledge and limited HIV risk perception, concerns about PrEP side effects, and competing health priorities and needs due to drug use and dependence. Interpersonal-level barriers included negative experiences with healthcare providers and HIV-related stigma within social networks. Clinical barriers included poor infrastructure and capacity for PrEP delivery to PWID, and structural barriers related to homelessness, criminal justice system involvement, and lack of money or identification to get prescriptions. Participants and key informants provided some suggestions for strategies to address these multilevel barriers and better facilitate PrEP delivery to PWID. Conclusions: In addition to some of the facilitators of PrEP use identified by participants and key informants, we drew on our key findings and behavioral change theory to propose additional intervention targets. In particular, to help address the multilevel barriers to PrEP uptake and adherence, we discuss ways that interventions could target information, self-regulation and self-efficacy, social support, and environmental change. PrEP is clinically efficacious and has been recommended for PWID; thus, development and testing of strategies to improve PrEP delivery to this high-risk and socially marginalized population are needed. © 2018 The Author(s). Article	2018	Biello K.B.; Hosek S.; Drucker M.T.; Belzer M.; Mimiaga M.J.; Marrow E.; Coffey-Esquivel J.; Brothers J.; Mayer K.H.	Preferences for Injectable PrEP Among Young U.S. Cisgender Men and Transgender Women and Men Who Have Sex with Men	Archives of Sexual Behavior	-	-	-	40002	10.1007/s10508-017-1049-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029595346&doi=10.1007%2fs10508-017-1049-7&partnerID=40&md5=a8a0e52e879976cce3be77ff67aeb6cf	Young men who have sex with men account for approximately 20% of incident HIV infections in the U.S. Antiretroviral pre-exposure prophylaxis (PrEP) administered as a daily pill has been shown to decrease HIV acquisition in at-risk individuals. New modalities for PrEP are being developed and tested, including injectable PrEP; however, acceptability of these emerging modalities has not yet been examined in youth. We conducted six focus groups with 36 young men and transgender men and women who have sex with men in Boston, Chicago, and Los Angeles in 2016 to assess interest in and preference for different PrEP modalities. Youth were purposively recruited based on diversity of age, race/ethnicity, and prior PrEP experience. Data were coded using content coding based on key domains of the interview guide, in particular around the central themes of interest in and barriers and facilitators to injectable PrEP use. Participants were knowledgeable about oral PrEP but suggested barriers to broader uptake, including stigma, marginalization, and access to information. While participants were split on preference for injectable versus oral PrEP, they agreed quarterly injections may be more manageable and better for those who have adherence difficulties and for those who engage in sex more frequently. Concerns specific to injectable PrEP included: severity/duration of side effects, pain, level of protection prior to next injection, distrust of medical system and injections, and cost. Understanding barriers to and preferences for diverse prevention modalities will allow for more HIV prevention options, improved products, and better interventions, thus allowing individuals to make informed HIV prevention choices. © 2017, Springer Science+Business Media, LLC. Article	2018	Biello K.B.; Mimiaga M.J.; Santostefano C.M.; Novak D.S.; Mayer K.H.	MSM at Highest Risk for HIV Acquisition Express Greatest Interest and Preference for Injectable Antiretroviral PrEP Compared to Daily, Oral Medication	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1972-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85033397151&doi=10.1007%2fs10461-017-1972-6&partnerID=40&md5=c1c038c950606fa1b59e74a4329db8c2	Men who have sex with men (MSM) account for nearly 70% of new HIV diagnoses, with young black MSM at the highest risk for infection in the United States. Pre-exposure prophylaxis (PrEP) can decrease HIV acquisition in at-risk individuals by over 90%. However, efficacy requires a daily pill, posing adherence challenges. Experimental modalities, including injectable PrEP given once every 2 months, may improve adherence among those most in need. To assess interest in and preference for injectable PrEP, an online survey was mounted on two popular MSM sexual networking apps. Differences by age, race, and other characteristics were examined using multinomial logistic regressions. Of 4638 respondents, 73% expressed interest in injectable PrEP and 47% indicated they would prefer an injection (compared to 17% who prefer a daily pill and 36% who were unsure). Within this sample, interest in and preference for injectable PrEP was highest among MSM at highest risk for HIV infection (i.e., younger age groups, racial/ethnic minorities, those with riskier sexual behavior). As a result, if proven effective in clinical trials, injectable PrEP has the potential to reduce social disparities in HIV transmission among MSM. © 2017, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Bil, Janneke P; Hoornenborg, Elske; Prins, Maria; Hogewoning, Arjan; Dias Goncalves Lima, Fernando; de Vries, Henry J C; Davidovich, Udi	The Acceptability of Pre-Exposure Prophylaxis: Beliefs of Health-Care Professionals Working in Sexually Transmitted Infections Clinics and HIV Treatment Centers	Frontiers in Public Health	-	-	-	22962565	10.3389/fpubh.2018.00005	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057906055&doi=10.3389%2ffpubh.2018.00005&partnerID=40&md5=8c23e414c01bb1459a532c12bbef19ae	Background: Pre-exposure prophylaxis (PrEP) is highly effective for preventing HIV infections, but is not yet implemented in the Netherlands. As the attitudes of health-care professionals toward PrEP can influence future PrEP implementation, we studied PrEP knowledge and beliefs and their association with PrEP acceptability among professionals in clinics for sexually transmitted infection (STI professionals) and HIV treatment centers (HIV specialists). In addition, we examined preferred regimens, attitudes toward providing PrEP to key populations and to reimbursement of PrEP costs. Methods: An online questionnaire was distributed among 24 public health STI clinics and 27 HIV treatment centers nationwide in the Netherlands between January and August 2015. The acceptability of PrEP was measured on a 7-point Likert scale ranging from 1 = low to 7 = high acceptability. Univariable and multivariable linear regression analyses were used to explore associations between demographic characteristics, PrEP knowledge, beliefs about PrEP, and PrEP acceptability. Results: In total, 209 people (143 STI professionals and 66 HIV specialists) completed the questionnaire. The mean acceptability of PrEP implementation was 4.28 (SD 1.68) among STI professionals and 4.42 (SD 1.67) among HIV specialists. The mean score on self-perceived knowledge related to PrEP efficacy was 3.90 (SD 1.57) among STI professionals and 5.68 (SD 1.08) among HIV specialists (p-value of <0.001). Beliefs associated with lower PrEP acceptability among both groups were the fear that PrEP use will lead to a decrease in condom use and an increase in STI, the high costs of PrEP and ethical issues regarding prescribing antiretroviral medication to healthy individuals. No preference for a daily or an event-driven regimen was detected. Most participants deemed the following groups to be eligible for PrEP: men who have sex with men (MSM) who regularly get post-exposure prophylaxis, MSM who never used condoms with casual partners and MSM with an HIV-positive partner with a detectable viral load. Over half of the participants indicated that PrEP users should partly (54.1%) or fully (35.4%) pay the costs of PrEP. Conclusion: In 2015, PrEP acceptability was only moderate among Dutch STI professionals and HIV specialists, which is far from an optimal setting. Addressing barriers to PrEP acceptability in educational programs for various types of health-care professionals is needed to successfully implement PrEP in the Netherlands. © Copyright © 2018 Bil, Hoornenborg, Prins, Hogewoning, Dias Goncalves Lima, de Vries and Davidovich.	health personnel; HIV; implementation; pre-exposure prophylaxis; prevention	English	Switzerland	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Quantitative
Article	2018	Birdthistle, Isolde; Schaffnit, Susan B.; Kwaro, Daniel; Shahmanesh, Maryam; Ziraba, Abdhalah; Kabiru, Caroline W.; Phillips-Howard, Penelope; Chimbindi, Natsayi; Ondeng'e, Kenneth; Gourlay, Annabelle; Cowan, Frances M.; Hargreaves, James R.; Hensen, Bernadette; Chiyaka, Tarisai; Glynn, Judith R.; Floyd, Sian	Evaluating the impact of the DREAMS partnership to reduce HIV incidence among adolescent girls and young women in four settings: a study protocol.	BMC Public Health	-	-	-	1471-2458	10.1186/s12889-018-5789-7	https://bmcpublichealth.biomedcentral.com/articles/10.1186/s12889-018-5789-7	BACKGROUND: HIV risk remains unacceptably high among adolescent girls and young women (AGYW) in southern and eastern Africa, reflecting structural and social inequities that drive new infections. In 2015, PEPFAR (the United States President's Emergency Plan for AIDS Relief) with private-sector partners launched the DREAMS Partnership, an ambitious package of interventions in 10 sub-Saharan African countries. DREAMS aims to reduce HIV incidence by 40% among AGYW over two years by addressing multiple causes of AGYW vulnerability. This protocol outlines an impact evaluation of DREAMS in four settings. METHODS: To achieve an impact evaluation that is credible and timely, we describe a mix of methods that build on longitudinal data available in existing surveillance sites prior to DREAMS roll-out. In three long-running surveillance sites (in rural and urban Kenya and rural South Africa), the evaluation will measure: (1) population-level changes over time in HIV incidence and socio-economic, behavioural and health outcomes among AGYW and young men (before, during, after DREAMS); and (2) causal pathways linking uptake of DREAMS interventions to 'mediators' of change such as empowerment, through to behavioural and health outcomes, using nested cohort studies with samples of ~ 1000-1500 AGYW selected randomly from the general population and followed for two years. In Zimbabwe, where DREAMS includes an offer of pre-exposure HIV prophylaxis (PrEP), cohorts of young women who sell sex will be followed for two years to measure the impact of 'DREAMS+PrEP' on HIV incidence among young women at highest risk of HIV. In all four settings, process evaluation and qualitative studies will monitor the delivery and context of DREAMS implementation. The primary evaluation outcome is HIV incidence, and secondary outcomes include indicators of sexual behavior change, and social and biological protection. DISCUSSION: DREAMS is, to date, the most ambitious effort to scale-up combinations or 'packages' of multi-sectoral interventions for HIV prevention. Evidence of its effectiveness in reducing HIV incidence among AGYW, and demonstrating which aspects of the lives of AGYW were changed, will offer valuable lessons for replication. Article	2018	Biskupiak A.; Smith S.; Kushalnagar P.	Pre-exposure prophylaxis knowledge and perceived effectiveness to prevent HIV among deaf gay, bisexual, and queer men	LGBT Health	-	-	-	23258292	10.1089/lgbt.2018.0102	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058561936&doi=10.1089%2flgbt.2018.0102&partnerID=40&md5=f7336e05885de1712368ca8b07d29eb8	Purpose: There have been recent advances to the adoption of pre-exposure prophylaxis (PrEP) as an effective human immunodeficiency virus (HIV) preventive treatment among men who have sex with men, but PrEP services and resources are often not accessible to those who are deaf and use American Sign Language (ASL). This article investigates PrEP knowledge among deaf gay, bisexual, and queer (GBQ) men and the contribution of social support to their perceptions regarding the effectiveness of PrEP at preventing HIV. Methods: An online health survey in ASL and English included questions about sexual orientation, HIV testing, PrEP knowledge and perceived effectiveness at preventing HIV, coming out to healthcare providers, and social support. We gathered data from 121 deaf GBQ men recruited from diverse cities in the United States, with 87% self-identifying as gay. Logistic regression analyses were used to examine the relationships between self-reported level of social support and perceived effectiveness of PrEP at preventing HIV after controlling for sociodemographic and health-related variables. Results: There was a significant relationship between meeting new lesbian, gay, bisexual, transgender, and queer (LGBTQ) friends online and PrEP knowledge (χ^2 = 14.93; p < 0.001). After controlling for sociodemographic and health-related variables, those who discussed LGBT-related issues online and/or on a social networking site regularly were threefold more likely to perceive PrEP as being effective at preventing HIV than those who did not engage in online discussions (odds ratio = 3.12; 95% confidence interval: 1.12-8.75). Conclusion: For deaf GBQ men, PrEP knowledge might be attained through meeting and making new LGBTQ friends online. Active engagement in online discussions about LGBT-related issues might enhance perceptions regarding the effectiveness of PrEP to prevent HIV. © Mary Ann Liebert, Inc., publishers 2018.	deaf; gay; GBQ; health disparities; HIV; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Quantitative
Article	2018	Blaylock LTC, Jason M; Hakre, Shilpa; Decker, Catherine F; Bryan Wilson CPT; Bianchi, Elizabeth; Nelson Michael COL; Charmagne Beckett CAPT; Jason Okulicz Lt Col; Scott, Paul T	HIV PrEP in the Military: Experience at a Tertiary Care Military Medical Center	Military Medicine	-	-	-	00264075	10.1093/milmed/usx143	https://www.proquest.com/scholarly-journals/hiv-prep-military-experience-at-tertiary-care/docview/2430091894/se-2?accountid=8113	Objectives We evaluated human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) administration at the Walter Reed National Military Medical Center (WRNMMC), which serves a geographic area at high risk of HIV infection. Methods Medical records were reviewed for all patients initiating PrEP at WRNMMC from November 1, 2013, to March 30, 2016. Demographic, laboratory, clinical, and risk exposure characteristics and outcomes were described. Results One hundred fifty-nine patients received PrEP; 133 (84%) patients were active duty, 95 (60%) patients were over 28 yr old. The majority were non-Hispanic Whites (n = 87, 55%). The median men who have sex with men (MSM) risk index score was 18.0 (IQR 12.0–22.0); 20 patients scored less than 10. One hundred and thirty-one (82%) patients remained on PrEP through the evaluation period. Patients mainly discontinued PrEP for service-related or toxicity reasons. Incident STIs occurred in 31 (19%) patients. No cases of HIV seroconversion were observed. Conclusions In this first description of PrEP utilization in a U.S. military health care system, a significant number of patients were non-Hispanic Whites, well-educated, were older, or were otherwise at low risk for HIV acquisition. Further effort is needed to enhance PrEP use among the higher risk young African-American MSM population, and further studies are needed to determine the cost-effectiveness of PrEP in individuals who are not categorized as high risk. Article	2018	Bleyleck, Jason M; Hales, Shilpa; Okolicz, Jason F; Gargas, Eric; Wilson, Kerry; Ley, Jenny; Roska, Ellen A; Michael, Nelson L; Beckett, Charmagne G; Cersovsky, Steven B; Peel, Sheila A; Scott, Paul T	HIV Preexposure Prophylaxis in the U.S. Military Services - 2014-2016.	MMWR Recommendations and Reports	-	-	-	1545-861X	10.15585/mmwr.mm6726a1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6633196/	Human immunodeficiency virus (HIV) infection is a substantial health concern for the U.S. Department of Defense (DoD) and for service members stationed throughout the world. Each year, approximately 150 new HIV infections are diagnosed in members of the U.S. military services, with most infections acquired within the United States (1). The DoD populations most affected by HIV mirror those in the U.S. civilian population; the highest rates of new military diagnoses are in men and blacks or African Americans (blacks) (1). Blacks are disproportionally affected, and most new diagnoses occur among men who have sex with men (MSM). HIV preexposure prophylaxis (PrEP) is approximately 90% effective in preventing HIV infection when used properly (2), and an increasing number of active duty personnel have used HIV prevention services and PrEP in the military health system since the repeal of "Don't Ask, Don't Tell"* in 2011 (3). Military health system *and service* records were reviewed to describe HIV PrEP use among military personnel, and military health care providers were surveyed to assess HIV PrEP knowledge and attitudes. Among 769 service members prescribed PrEP during February 1, 2014-June 10, 2016, 60% received prescriptions from an infectious disease provider, 19% were black men, and 42% were aged >28 years. Half of surveyed military health care providers self-rated their PrEP knowledge as poor. DoD is developing new policy to address access to care challenges by defining requirements and establishing pathways for universal patient access to PrEP. Article	2018	Beskenazi, Amy; Feiler, Theresa M; Chen, Shaw-Ree; Cowles, Roberto; Holt, Sally; Valenti, William; McMahon, James M	Willingness to Take PrEP for HIV Prevention: The Combined Effects of Race/Ethnicity and Provider Trust.	AIDS Education and Prevention	-	-	-	1943-2755	10.1521/aeap.2018.30.1.1	https://dx.doi.org/10.1521/aeap.2018.30.1.1	Blacks and Hispanics/Latinos are disproportionately burdened by HIV compared to non-Hispanic Whites, as evidenced by higher HIV incidence, prevalence, and deaths attributable to AIDS. Increasing the use of *novel* prevention techniques such as Truvada for pre-exposure prophylaxis (PrEP) could greatly help in reducing these disparities by lowering HIV incidence among these higher risk groups. Trust in providers, which may differ by race and ethnicity, may influence willingness to take PrEP. This study explores the moderating effect of race/ethnicity on trust in one's primary care provider (PCP) on PrEP willingness. This study found a significant interaction between PCP trust and PrEP willingness, with those with greater trust having 2.26 times the adjusted odds of being willing to try PrEP. Results regarding the effects of race and ethnicity on these outcomes, however, were inconclusive. Results indicate the importance of fostering trust between PrEP-prescribing PCPs and their patients. Theses and Dissertations	2018	Brandão, Roberto Ruborn da Silva	Profilaxia Pré-Exposição ao HIV (PrEP) no contexto do processo de individualização e saúde	-	-	-	-	https://doi.org/10.11606/D.8.2018.tde-15062018-153500	https://escupita.capes.gov.br/escupita/publicsite/consultaSolrIn/rebuildSolrCore/searchTrabsSolrCoreIndexes.jsf?cspup=tmcdad_trabalho=42321132	A Profilaxia Pré-exposição ao HIV (PrEP) é uma nova estratégia de prevenção na qual os indivíduos consomem uma combinação de antiretrovirais diariamente para evitar a aquisição do vírus do AIDS. O objetivo desta estudo foi investigar o processo de individualização/ser e saúde. Analisamos o conteúdo de discussões de um grupo de usuários de PrEP, e de pessoas interessadas no assunto, numa rede social virtual com predominância de gays, bissexuais e outros homens que fazem sexo com homens. Os resultados e discussão foram distribuídos em três categorias: o contexto da sociedade de risco, as características do vírus e suas consequências para a saúde e os conteúdos da individualização. O segundo explora a produção dos dispositivos do *design* e do *gozar sexual* - mediados pela PrEP - na vida dos indivíduos. Os resultados apontam o desejo e experiência de uma nova forma de prevenção identificou autoproduções na individualização contemporânea. As considerações finais, por fim, refletem sobre as implicações às repostas sociais e políticas à epidemia do HIV/AIDS no atual contexto de quase-pandemias. Article	2018	Brinkley-Rubinstein, Lauren; Cloud, David; Drucker, Ernest; Zeller, Nickolas	Opioid Use Among Those Who Have Criminal Justice Experience: Harm Reduction Strategies for Lowers HIV Risk.	Current HIV/AIDS Reports	-	-	-	1548-3576	10.1007/s11904-018-0394-z	https://dx.doi.org/10.1007/s11904-018-0394-z	PURPOSE OF REVIEW: We reviewed the HIV and opioid literature relevant to harm reduction strategies for those with criminal justice experience. RECENT FINDINGS: Opioid use in the United States has risen at an alarming rate recently. This has led to increased numbers of people who inject drugs, placing new populations at risk for HIV, including those with criminal justice experience. Over the past decade, there has been a gradual decrease in the number of individuals under the supervision of the criminal justice system. However, concurrently, there has been a rise in the number of individuals incarcerated in jails in rural counties that are at the center of the current opioid epidemic. We provide a number of harm reduction strategies that could be implemented in correctional settings such as access and linkage to medication-assisted treatment, connection to syringe exchange programs and safe injection facilities (where available), and the repackaging of pre-exposure prophylaxis as a harm reduction tool. Article	2018	Brinkley-Rubinstein, Lauren; Peterson, Meghan; Arnold, Trisha; Nunn, Amy S; Beckwith, Curt G; Gustenhoven, Breana; Juneau, Eric; Lewis, Chantal; Chan, Philip A	Knowledge, interest, and anticipated barriers of pre-exposure prophylaxis uptake and adherence among gay, bisexual, and men who have sex with men who are incarcerated.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0205593	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6200206/	Criminal justice (CJ)-settings disproportionately include populations at high risk for acquiring HIV, and CJ-involved individuals are often at the intersection of multiple overlapping risk factors. However, few studies have examined attitudes about pre-exposure prophylaxis (PrEP) among incarcerated men who have sex with men (MSM). This study explored interest in, knowledge of, and barriers to PrEP uptake among gay, bisexual, and other men who have sex with men at the Rhode Island Department of Corrections. Using semi-structured interviews, 26 MSM were interviewed about PrEP knowledge, interest, and barriers to PrEP uptake during incarceration. Participants demonstrated low initial knowledge of PrEP but high interest after being told more about it. Participants self-identified risk factors for HIV acquisition, including condomless sex and substance use. In addition, participants preferred provision of PrEP prior to release. Post-release barriers to PrEP uptake and adherence included 1) concerns about costs of PrEP medications; 2) anticipated partner or family disapproval; 3) lack of access to transportation; 4) unstable housing. 5) compounding impacts of multiple hardships leading to a de-prioritization of PrEP and 6) fears re-incarceration. These results point to the need for future PrEP interventions among incarcerated populations that address incarceration and PrEP-related barriers during community re-entry via wraparound services that address PrEP and incarceration-related barriers. Article	2018	Brisson J.	Ethical public health issues for the use of informed PrEP	Global Public Health	-	-	-	17441692	10.1080/17441692.2017.1373139	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85028463636&doi=10.1080%2f17441692.2017.1373139&partnerID=40&md5=f3e5c3c80cdb6c86b9b1dbe3ade2cfb	This article presents the phenomenon of the use of informed pre-exposure prophylaxis (PrEP), also known colloquially as 'wild PrEP'. The refered ethical public health issues of the use of informal PrEP are discussed. From the approach of an ethical framework of risk reduction in public health, the main objective of this article is to encourage health-related practices and policies that do not stop the informal access to PrEP, but rather promote the wellbeing of users by providing them with the necessary knowledge and resources related to PrEP and HIV prevention (i.e. getting regularly tested for HIV if one is sexually active). The ethical issues related to the use of informal PrEP are discussed in relation to the following: the role of the state, the role of the pharmaceutical industry, and the role of public health actors in addressing the use of informal PrEP with the goal of promoting HIV prevention among individuals at high risk for HIV infection. © 2017, © 2017 Informa UK Limited, trading as Taylor & Francis Group	antiretroviral drugs; ethics; HIV; PrEP; public health	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Review
Article	2018	Brockhus J.M.; Scarsi K.K.; Seyles H.R.; Kilpatrick D.G.; Havens J.P.; Swindells S.; Bares S.H.	Midwest pharmacists' familiarity, experience, and willingness to provide pre-exposure prophylaxis (PrEP) for HIV	PLOS One	-	-	-	1932b203	10.1371/journal.pone.0207372	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056456277&doi=10.1371%2fjournal.pone.0207372&partnerID=40&md5=1eb64923f2f0fbad2f39e4d4664dcee9be	Introduction/Purpose: provision of pre-exposure prophylaxis (PrEP) through collaborative practice agreements with physicians could expand access to people at risk for HIV. We characterized pharmacists' familiarity with and willingness to provide PrEP services in Nebraska and Iowa. Methods: An invitation to complete an 18-question survey was emailed to 1,140 pharmacists in Nebraska and Iowa in June and July of 2016. Descriptive analyses and Pearson chi-square tests were used to determine to what extent demographics, familiarity and experiences were associated with respondents willingness to provide PrEP. Wilcoxon rank-sum tests compared ages and years of experience between groups of respondents. Results: One hundred forty pharmacists (12.3%) responded. Less than half were familiar with the use of PrEP (42%) or the CDC Clinical Guidelines for its use (25%). Respondents who were older (p = .003) were less likely to be familiar with PrEP. Pharmacists who were older (p = .01) and less likely to provide PrEP services as part of a collaborative practice agreement and after additional training. While familiarity with PrEP use or guidelines did not affect respondents' willingness to provide PrEP services, pharmacists who were more likely to be willing to provide PrEP services were younger (OR 2.77; p = 0.02), had more years of experience (OR 2.77; p = 0.02), and had HIV-related continuing education (OR 2.77; p = 0.02). Conclusions: Pharmacist respondents in Nebraska and Iowa had limited familiarity and experience with PrEP, but most indicated willingness to provide PrEP through collaborative practice agreements after additional training. Provision of PrEP-focused continuing education may lead to increased willingness to participate in PrEP programs. © 2018 Brockhus et al. Article	2018	Brooks R.A.; Allen V.C., Jr.; Regan R.; Mutchler M.G.; Cervantes-Tadeo R.; Lee S.-J.	HIV/AIDS conspiracy beliefs and intention to adopt preexposure prophylaxis among black men who have sex with men in Los Angeles	International journal of STD & AIDS	-	-	-	9564624	10.1177/0956462417727691	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041863504&doi=10.1177%2f0956462417727691&partnerID=40&md5=ddb6c330951fd5b83c0d9283ebd0fcc3	In the United States, black men who have sex with men (MSM) are the group most affected by the HIV/AIDS epidemic. Pre-exposure prophylaxis (PrEP) is an important new HIV prevention strategy that may help reduce new HIV infections among black MSM. This analysis examined the association between HIV/AIDS conspiracy beliefs and intention to adopt PrEP among 224 black MSM. The likelihood of adopting PrEP was assessed and more than half (60%) of the study population indicated a high intention to adopt PrEP. HIV/AIDS genocidal and treatment-related conspiracies were assessed using scales previously validated with black MSM. Almost two-thirds (63%) endorsed at least one of eight HIV/AIDS conspiracy beliefs presented. In multivariable analyses, black MSM who agreed with the genocidal or treatment-related conspiracy beliefs scales had a lower intention to adopt PrEP (Adjusted Odds Ratio AOR = 0.73, 95% CI = 0.54, 0.99 and AOR = 0.36, 95% CI = 0.23, 0.55, respectively). Our findings suggest that HIV/AIDS conspiracy beliefs may be a barrier to PrEP adoption among black MSM. Culturally appropriate interventions may be needed to address the influence that HIV/AIDS conspiracy beliefs may have on the adoption of PrEP among black MSM. Article	2018	Brown, A. E.; Nash, S.; Connor, N.; Kirwan, P. D.; Ogaz, D.; Crowford, S.; Angelis, D. De; Delpech, V. C.	Towards elimination of HIV transmission, AIDS and HIV-related deaths in the UK	HIV Medicine	-	-	-	1468-1293 1464-2662	10.1111/hiv.12617	https://onlinelibrary.wiley.com/doi/10.1111/hiv.12617	OBJECTIVES: Our objective was to present recent trends in the UK HIV epidemic (2007-2016) and the public health response. METHODS: HIV diagnoses and clinical markers were extracted from the HIV and AIDS Reporting System; HIV testing data in sexual health services (SHS) were taken from GUMCAD STI Surveillance System. HIV data were modelled to estimate the incidence in men who have sex with men (MSM) and post-migration HIV acquisition in heterosexuals. Office for National Statistics (ONS) data enabled mortality rates to be calculated. RESULTS: New HIV diagnoses in MSM declined by 29% between 2012 and 2016; heterosexuals as a result of decreasing numbers of migrants from high HIV prevalence countries entering the UK. Among MSM, the number of HIV diagnoses fell from 3570 in 2015 to 2010 in 2016 (and by 42% in London). The number of MSM tested for HIV in SHS increased annually; 28% of MSM who were tested in 2016 had been tested in the preceding year. In 2016, 78% of people started antiretroviral therapy within 90 days of diagnosis (33% in 2007). CONCLUSIONS: The dual successes of the HIV transmission decline in MSM and reduced mortality are attributable to frequent HIV testing and prompt treatment (combination prevention). Progress towards the elimination of HIV transmission, AIDS and HIV-related deaths could be achieved if combination prevention, including pre-exposure prophylaxis, is replicated for all populations.	epidemiology; treatment as prevention; HIV transmission; HIV testing; surveillance; deaths	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2018	Brown, William; Gignoux, Rebecca; Skerrill, Alan; Ibitoye, Mobolaji; Balan, Ivan; Hu, Tinzhe; Brown, Benjamin; Quispe, Luis; Sukwicha, Wichuda; Lama, Javier R; Carballo-Diéguez, Alex; Cranston, Ross D	Challenges and solutions implementing an SMS text message-based survey CASI and adherence reminders in an international biomedical HIV PrEP study (MTN 017)	Journal of Biomedical Informatics	-	-	-	1532-0480	10.1016/j.jbi.2018.02.018	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5926951/	BACKGROUND: We implemented a text message-based Short Message Service computer-assisted self-interviewing (SMS-CASI) system to aid adherence and monitor behavior in MTN-017, a phase 2 safety and acceptability study of vaginal ring with dapivirine (a non-nucleoside reverse transcriptase inhibitor) and oral tablets with emtricitabine/tenofovir disoproxil fumarate tablets. We sought to implement SMS-based daily reminders and conspicuous behavior monitoring, in four countries and five languages, and centralize data management/automated-backup. METHODS: We assessed features of five SMS programs against study criteria. After identifying the optimal program, we systematically implemented it in South Africa, Thailand, Peru, and the United States. The system consisted of four windows-based components and leveraged open-source software and SMS. The SMS-CASI was, designed for 160 character SMS. Reminders and reporting sessions were initiated by date/time triggered messages. System, questions, responses, and instructions were triggered by participant responses. RESULTS: There were 162,177 total messages sent 86,349 (60.73%), received 55,573 (39.09%), failed 255 (0.18%), 8,512 (5.98%) delayed. Of the message were 30.2% generated from either our SMS-CASI system or by participants. Implementation challenges included: high message costs; poor data access; slow data cleaning and analysis; difficulty reporting information to sites; a need for time-sensitive communication with participants; and changing requirements. We developed programming syntaxes to facilitate daily data cleaning and analysis, and a calendar template for reporting SMS behavior. Lastly, we redesigned secure email protocols to centralize data backup. We developed programming syntaxes to facilitate daily data cleaning and analysis, and a calendar template for reporting SMS behavior. Lastly, we redesigned text message language to increase privacy, and standardized hardware and software across sites, minimizing operational variability. CONCLUSION: We identified factors that and international implementation and operation of SMS-CASI for real-time adherence monitoring. The challenges and solutions we present can aid other researchers to develop and manage an international multilingual SMS-based adherence reminder and CASI system.	mHealth, Adherence, Short Message Service (SMS) text messaging, Computer-assisted Self-Interview, HIV, PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Buchbinder, Susan P	Maximizing the Benefits of HIV Preexposure Prophylaxis.	Topics in Antiviral Medicine	-	-	-	2161-5853	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5935264/	Preexposure prophylaxis (PrEP) with tenofovir/emtricitabine (daily indicates coformulation) is highly effective in preventing new HIV infections. PrEP efficacy is strongly associated with adherence. In clinical trials, PrEP has been more effective in men who have sex with men and HIV-serodiscordant heterosexual couples than in women, likely reflecting pharmacokinetic differences in drug concentrations in rectal versus disrupted flumarate in vaginal and rectal tissues, and poorer adherence in studies in women. Current guidelines recommend daily PrEP for men and women; however, PrEP taken at least 4 days per week for men may be as effective as daily PrEP, and women must take PrEP 6 to 7 days per week to maximize efficacy. Data are accumulating on the effectiveness of *periodized* PrEP for men who have sex with men, but it is not yet recommended in the United States. PrEP is underprescribed for younger individuals, black individuals, and Hispanic and Latino individuals. This article summarizes a presentation by Susan P. Buchbinder, MD, at the IAS-USA continuing education program, Improving the Management of HIV Disease, held in Chicago, Illinois, in May 2017. Article	2018	Bull L.; Dimitrijevic P.; Beverley S.; Scarborough A.; Mandalia S.; Doodeen O.; Barber T.; Reeves I.; McCormack S.; Raymont M.	Perceived need of, and interest in, HIV pre-exposure prophylaxis amongst men who have sex with men attending three sexual health clinics in London, UK	International journal of STD & AIDS	-	-	-	9564624	10.1177/0956462417738259	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85043163654&doi=10.1177%2f0956462417738259&partnerID=40&md5=7e4790cdd331540a6d3b3f1f4864e99f2	HIV pre-exposure prophylaxis (PrEP) has proven efficacy in reducing the risk of HIV infection in men who have sex with men (MSM), but has not yet been commissioned in the UK. The aim of this study was to investigate perceived need and benefit (or) experience of PrEP among HIV-negative MSM attending sexual health clinics. HIV-negative MSM attending sexual health clinics in London, UK were opportunistically invited to complete a questionnaire. Data collected comprised demographic data and sexual and drug use behaviours as well as questions regarding perceptions of risk and need for PrEP. Logistic regression analysis was undertaken to identify variables predicting acceptability of, and intention to use, PrEP. In addition, data were gathered on participants already taking PrEP. Eight hundred and forty-nine questionnaires were analysed. The median age of respondents was 35 years (IQR 28–41, range 18–78); 650 (77%) were of white ethnicity and 649 (77%) had a university education. Four hundred and fifty-six (54%) reported at least one episode of condomless anal sex in the preceding three months and 457 (52%) reported recreational drug use in the preceding three months and 437 (52%) had been diagnosed with a sexually transmitted infection within the preceding six months. Four hundred and sixty-three (66%) of 726 strongly agreed with the statement 'I think I would benefit from PrEP'. Multivariate analysis found that independent predictors for perceiving oneself to benefit from PrEP were: reporting condomless anal sex (OR = 2.16, 95% CI: 1.44, 3.24) and recreational drug use (OR = 1.66, 95% CI: 1.11, 2.48). Independent predictors for someone thinking they would benefit from taking PrEP: Eight percent of respondents (59/726) had already taken or were currently taking PrEP. The results suggest that individuals at risk are likely to perceive themselves as benefiting from PrEP. The majority perceived their risk of acquiring HIV and benefit from PrEP accurately. Overall they appeared to have little concern over the use of PrEP and generally positive attitudes. Further investigation is warranted to understand why those at risk do not perceive benefit from PrEP. © 2017, © The Author(s) 2017. Article	2018	Burman, Marice E	The informal use of antiretroviral medications for HIV prevention by men who have sex with men in South Florida: initiation, use practices, medications and motivations.	Culture, Health & Sexuality	-	-	-	1464-5351	10.1080/13691058.2017.1421709	https://dx.doi.org/10.1080/13691058.2017.1421709	Limited data suggest that some gay and other men who have sex with men are using antiretroviral medications informally, without a prescription, for HIV prevention. This qualitative study examined this phenomenon among gay and other men who have sex with men in South Florida. Participants initiated informal antiretroviral medication use as a means of protecting each other and because of the confidence in knowledge of antiretroviral medications shared by their friends and sex partners. The most commonly used medications included Truvada and Strikhil. Motivations for use included condomless sex, risk reduction, and fear of recent HIV exposure. Participants described positive and negative sentiments related to informal use, including concerns about informal antiretroviral medications offering sufficient protection against HIV, and limited knowledge about pre-exposure prophylaxis (PrEP). Because the antiretroviral medications used for PrEP have the potential to prevent HIV infection, future research must consider the informal antiretroviral medication use and related concerns, including adherence, diversion and viral resistance. Article	2018	Chan, Philip A.; Montgomery, Madeline C.; Rose, Jennifer; Tribuiano, Alec; Crowley, Christine; Medina, Martha M.; Patel, Rupa; Mayer, Kenneth; Kantor, Rami; Nunn, Amy S.	Statewide Evaluation of New HIV Diagnoses in Rhode Island: Implications for Prevention.	Public Health Reports	-	-	-	1468-2877 0033-3549	10.1177/0033354918777255	https://journals.sagepub.com/doi/10.1177/0033354918777255	OBJECTIVES: Patterns of HIV transmission may vary across demographic groups. Identifying and engaging these groups are necessary to prevent new infections and diagnose disease among people who are unaware of their infection. We evaluated data on people with new HIV diagnoses in Rhode Island from 2013 through 2015. We performed a descriptive analysis of HIV surveillance data and conducted a cluster analysis to identify subpopulations of people with newly diagnosed HIV. RESULTS: Of 163 people with new HIV diagnoses interviewed in Rhode Island from 2013 through 2015, 132 (79%) were male, 84 (58%) were nonwhite, 112 (67%) were men who have sex with men (MSM), 112 (67%) were born in the United States, and 61 (37%) were born in Rhode Island. LCA revealed 2 major classes. Of the 98 people in class 1, 90% were male, 83% were MSM, 80% were white, 94% were born in the United States, and 80% believed they acquired HIV in Rhode Island. Class 2 was 63% male and 69% Hispanic/Latino; 29% were born in the United States, and 61% believed they acquired HIV in Rhode Island. CONCLUSIONS: Most new HIV diagnoses in Rhode Island were among MSM born in the United States, and a substantial number were likely infected in state. People with newly diagnosed HIV who were foreign-born, including Hispanic/Latino and heterosexual groups, were less likely to have acquired HIV in Rhode Island than were MSM. HIV prevention approaches, including pre-exposure prophylaxis, should be adapted to the needs of specific groups. Rhode Island offers lessons for other states focused on eliminating HIV transmission. Theses and Dissertations	2018	Chandler, Cristian	Psychosocial associations of biobehavioral HIV prevention among Black men who have sex with men in the United States	-	-	-	University of Pittsburgh	-	NA	https://d-scholarship.pitt.edu/34408/	Black men who have sex with men (BMSM) experience the highest HIV incidence among at-risk groups; therefore, understanding the unique circumstances of BMSM is essential to addressing this significant public health issue. The theory of syndemic production, or the effect of co-occurring epidemics, was used to explore the result of psychosocial issues (substance use, intimate partner violence, sexual risk and depression) on HIV prevention and care outcomes. This dissertation analyzed data from the Promoting Our Worth, Equality and Resilience (POWER) study to explore the impact of individual-level syndemics on past-six-month screening behavior, PrEP use and HIV care continuum outcomes among BMSM. In the first analysis, BMSM under 30 were more likely to have been screened than BMSM aged 40 and older (AOR = 2.74, 95%CI: 1.74, 4.32). Further, despite the presence of a syndemic, men with two psychosocial issues were significantly more likely to report being screened for HIV than those who reported no psychosocial issues (AOR = 1.37, 95% CI: 1.04, 1.80). The second analysis explored differences among BMSM who reported PrEP-eligible HIV risk and BMSM who reported using PrEP. The results indicated that BMSM who were older (AOR = 1.04, 95% CI: 1.01, 1.07), had a higher income (AOR = 1.03, 95% CI: 1.01, 1.05), and had more than a high school education (AOR = 2.03, 95% CI: 1.03, 4.00) were more likely to report PrEP use. Additionally, compared to men who reported no psychosocial issues, BMSM were significantly more likely to report PrEP use when experiencing three (AOR = 5.65, 95% CI: 3.17, 10.08) or four psychosocial issues (AOR = 18.34, 95% CI: 5.01, 67.20). The third analysis focused on HIV-positive BMSM found that BMSM without insurance were less likely to report being in HIV care (AOR = 0.13, 95% CI: 0.03, 0.56) or using ART (AOR = 0.33, 95% CI: 0.20, 0.54). There were no significant associations between syndemic variables and HIV care outcomes. The results of these analyses suggest that individual factors cannot entirely explain disparities in HIV incidence and demonstrate the need to model the social and structural ecology of BMSM contributing to excess disease burden. Article	2018	Chang H.-H.; Kim S.-W.; Jung H.; Lee S.-A.; Park H.-K.; Kim S.; Lee J.M.; Choi J.Y.	Awareness and acceptance of HIV pre-exposure prophylaxis among medical personnel and men who have sex with men in Korea	Journal of Korean Medical Science	-	-	-	1011934	10.3346/jkms.2018.33.e91	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044147826&doi=10.3346%2fjkms.2018.33.e91&partnerID=40&md5=9201ab7e6894f4f69be2560464e4b4ff	Background: We aimed to investigate the awareness of human immunodeficiency virus (HIV) infection among high-risk individuals, including men who have sex with men (MSM) and medical personnel (MP) in Korea through a cross-sectional survey, identify possible obstacles hindering their access to pre-exposure prophylaxis (PrEP). Methods: In 2016, the five questionnaire survey was sent to randomly selected MSM and MP. To compare the changes in attitudes and knowledge of MSM, a second questionnaire survey was conducted in August 2017. Results: More than half of MSM (61.3% in 2016, 88.4% in 2017) were aware of PrEP. However, MP who offered PrEP had low knowledge regarding PrEP (23.4%). The background knowledge and perception of PrEP among MSM and MP at this survey was low (3.4% in 2016 and 5.7% in 2017, 1.9% in MP). The major obstacles that MSM reported were lack of insurance coverage (29% in 2016 and 32% in 2017), concern regarding adverse effects of PrEP (18% and 21%), and risk of exposing HIV-positive status to other people (15% and 10%). Among MP, lack of knowledge regarding the efficacy of PrEP was the most common obstacle (30%), followed by lack of insurance coverage (22%), and concern regarding adverse effects (20%). Conclusion: Our study showed that PrEP is required among MSM in Korea; however, most MP were not aware of PrEP. Lack of insurance coverage and knowledge regarding PrEP were major hindrances in the access to PrEP; therefore, further studies on how to make PrEP information more accessible are needed to help prevent HIV infection. © 2018 The Korean Academy of Medical Sciences. Irene; Johnson, Anna S.; Sullivan, Patrick S.	Trends in human immunodeficiency virus diagnoses among men who have sex with men in North America, Western Europe, and Australia, 2000-2014.	Annals of Epidemiology	-	-	-	1873-2585 1047-2797	10.1016/j.annepidem.2018.09.006	https://journals.lww.com/jaids/abstract/2020/12010/pre_exposure_prophylaxis_use_and_detected_sexually.6.aspx	PURPOSE: The aim of the article was to investigate recent trends in human immunodeficiency virus (HIV) diagnosis rates among men who have sex with men (MSM) in high-income countries in North America, Western Europe, and Australia. METHODS: Data on annual rates of HIV diagnoses among MSM aged 15 to 65 years from 2000 to 2014 were collected from 13 high-income countries. Joinpoint regression software was used to empirically determine country-specific trend periods. Trends in HIV diagnosis rates and in the proportion of diagnoses occurring in young MSM aged 15 to 24 years were analyzed using Poisson regression and log-binomial regression, respectively. RESULTS: Six countries experienced an increasing trend from 2000 to 2007-08 followed by either a stable or declining trend through 2014. Five countries had recently increasing trends, and two countries had one stable trend from 2000 to 2014. All 13 countries experienced increases in the proportion of diagnoses occurring in young MSM. CONCLUSIONS: Since 2008, half of the 13 high-income countries examined experienced decreasing trends. Still, some countries continue to experience increasing HIV trends, and young MSM are increasingly represented among new diagnoses. Efforts to support early sexual health promotion, reduce barriers to pre-exposure prophylaxis, and improve care engagement for young MSM are critical to addressing current HIV trends. Article	2018	Chapman Lambert, Crystal; Marrazzo, Jeanne; Amico, K Rivet; Mugavero, Michael J; Elopre, Latesha	PrEParing Women to Prevent HIV: An Integrated Theoretical Framework to PrEP Black Women in the United States.	Journal of the Association of Nurses in AIDS Care	-	-	-	1552-6917	10.1016/j.jana.2018.03.005	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7439521	Preexposure prophylaxis (PrEP) with optimal adherence has demonstrated efficacy in reducing HIV incidence in women. Black women are disproportionately burdened by the HIV epidemic, accounting for more than half of all new HIV cases in women, thereby making PrEP an ideal prevention strategy for this group. However, to date, PrEP uptake by women in the United States has been slow. Further domestic research is needed to understand the multilevel factors related to PrEP awareness, uptake, and implementation in Black women. Our purpose was to review the current status of HIV prevention in Black women. We summarize clinical trials germane to federal approval of PrEP; discuss important PrEP studies focused on women, including non-oral options; and review multilevel barriers to PrEP uptake. Lastly, we discuss the use of an integrated theoretical framework to organize multilevel factors related to PrEP uptake by Black women in order to guide intervention development. Theses and Dissertations	2018	Chen, Simiao	Economics of HIV Vaccines and HIV Vaccine Research and Development	-	-	Harvard University	-	-	NA	https://dash.harvard.edu/bitstream/handle/1/37945602/CHEN-DISSERTATION-2018.pdf?sequence=3&isAllowed=y	This thesis explores the economics of a prospective human immunodeficiency virus (HIV) vaccine in terms of: a) its cost-effectiveness in South Africa, and b) the opportunity cost of diverting vaccine R&D funds from other HIV prevention and control activities in South Africa. First, I use a mathematical and economic model of HIV vaccination in South Africa, exploring the cost-effectiveness of HIV vaccines with different attributes. I find that 1) vaccines with moderate initial efficacy but longer durations and smaller decay rates may have the same cost-effectiveness as a vaccine with high initial efficacy but short duration; 2) the vaccine's cost-effectiveness decreases only slightly with higher vaccine coverage but dramatically with lower prevalence rate; and 3) more than one-third of the total benefit of a vaccine comes from its positive externality.Second, I compare the HIV vaccination as a potential preventive intervention versus PrEP. I find that 1) a vaccine with 60% initial efficacy, an 8-year duration, and a decay rate of γ = 3 is less effective than PrEP in reducing HIV prevalence and incidence from 2021 to 2035; 2) if PrEP has an efficacy of 90%, then we should charge a Thai Trial vaccine below $63, and an HVTN702 vaccine below $100 to make it preferable to PrEP.Finally, I examine the economic return on investing in R&D of an HIV vaccine, by comparing the return (in terms of infections averted) to the same level of investment into increasing uptake of existing HIV preventive interventions instead (ART, MMC and PrEP). I find that 1) the attributes of an HIV vaccine, and the probability of realizing them through R&D investment, determines the attractiveness of such investment relative to spending on alternative HIV interventions; and 2) a vaccine is much more preferable if the initial coverage of alternative interventions is higher. Article	2018	Christine Tagliaferri Rael; Martinez, Michelle; Giguere, Rebecca; Bockting, Walter; MacCrate, Caitlin; Mellman, Will; Valente, Pablo; Greene, George J; Sherman, Susan; Footer, Katherine H A; Richard T D'Aquila; Carballo-Diéguez, Alex	Barriers and Facilitators to Oral PrEP Use Among Transgender Women in New York City	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2102-9	https://www.proquest.com/scholarly-journals/barriers-facilitators-oral-prep-use-among/docview/2019063721/se-2?accountid=8113	Transgender women may face a disparate risk for HIV/AIDS compared to other groups. In 2012, Truvada was approved for daily use as HIV pre-exposure prophylaxis (PrEP). However, there is a dearth of research about barriers and facilitators to PrEP in transgender women. This paper will shed light on transgender women living in New York City's perceived and actual challenges to using PrEP and potential strategies to overcome them. After completing an initial screening process, four 90-min focus groups were completed with n = 18 transgender women. Participants were asked what they like and dislike about PrEP. Participants identified the following barriers: uncomfortable side effects, difficulty taking pills, stigma, exclusion of transgender women in advertising, and lack of research on transgender women and PrEP. Facilitators included: reducing pill size, increasing the types of available HIV prevention products, and conducting scientific studies to evaluate PrEP in transgender women. Article	2018	Chua, Corrine Ying Xuan; Jain, Priya; Ballerini, Andrea; Bruno, Giacomo; Hood, R Lyle; Gupte, Manas; Gao, Song; Di Trani, Nicola; Susnjar, Antonia; Shelton, Kathryn; Bushman, Lane R; Folci, Marco; Filgueira, Carly S; Marzinke, Mark A; Anderson, Peter L; Hu, Ming; Nehete, Pramod; Arduino, Roberto C; Sastry, Jagannadha K; Grattoni, Alessandro	Transcutaneously refillable nanofluidic implant achieves sustained level of tenofovir diphosphate for HIV pre-exposure prophylaxis.	Journal of Controlled Release	-	-	-	1873-4995	10.1016/j.jconrel.2018.08.010	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6345255	Pre-exposure prophylaxis (PrEP) with antiretroviral (ARV) drugs are effective at preventing human immunodeficiency virus (HIV) transmission. However, implementation of PrEP presents significant challenges due to poor user adherence, low accessibility to ARVs and multiple routes of HIV exposure. To address these challenges, we developed the nanochannel delivery implant (NDI), a subcutaneously implantable device for sustained and constant delivery of tenofovir alafenamide (TAF) and emtricitabine (FTC) for HIV PrEP. Unlike existing drug delivery platforms with finite depots, the NDI incorporates ports allowing for transcutaneous refilling upon drug exhaustion. NDI-mediated drug delivery in rhesus macaques resulted in sustained release of both TAF and FTC for 83ā days, as indicated by concentrations of TAF, FTC and their respectively metabolites in plasma, PBMCs, rectal mononuclear cells and tissues associated with HIV transmission. Notably, clinically relevant preventative levels of tenofovir diphosphate were achieved as early as 3ā days after NDI implantation. We also demonstrated the feasibility of transcutaneous drug refilling to extend the duration of PrEP drug delivery in NHPs. Overall, the NDI represents an innovative strategy for long-term HIV PrEP administration in both developed and developing countries. Article	2018	Chuang D.-M.; Newman P.A.	Pre-exposure prophylaxis (PREP) awareness and acceptability among men who have sex with men in Taiwan	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2018.30.6.490	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060168696&doi=10.1521%2faeap.2018.30.6.490&partnerID=40&md5=56dae082419d70dd9bd85fd4128f3af4	Gay and other men who have sex with men (MSM) account for the vast majority of new HIV infections in Taiwan, yet utilization of pre-exposure prophylaxis (PrEP) remains low. We examined correlates of PrEP awareness and acceptability among MSM in Taiwan. A cross-sectional survey was conducted with 176 MSM (mean age = 27.4 years) recruited through community-based organizations in two cities. Less than half of participants (47.2%) were aware of PrEP; however, when it was described to them, the majority (72.2%) indicated PrEP acceptability. In multivariable analyses, condomless anal sex was negatively associated with PrEP awareness, and higher levels of vicarious stigma and anticipated PrEP disclosure to sexual partners were positively associated with PrEP acceptability. Our findings indicate the need for targeted interventions to increase PrEP awareness among MSM engaged in high-risk behaviors and implementation strategies that address sociocultural factors to accelerate PrEP utilization among MSM in Taiwan. © 2018 The Guilford Press. Article	2018	Clement M.E.; Seidelman J.; Wu J.; Alexis K.; McGee K.; Okeke N.L.; Samsa G.; McKellar M.	An educational initiative in response to identified PrEP prescribing needs among PCPs in the Southern U.S.	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1384534	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85030541377&doi=10.1080%2f09540121.2017.1384534&partnerID=40&md5=09eb78e399c01b661519ae5178557a68	Pre-exposure prophylaxis (PrEP) is an effective HIV prevention method, but many primary care physicians (PCPs) have not incorporated PrEP into practice. While PrEP may be a key strategy to reducing high HIV transmission rates in the southern US, knowledge about PrEP prescribing patterns among PCPs in this region is lacking. An online survey was sent to a large network of PCPs at an academic medical center in North Carolina in October 2015. The survey was repeated in September 2016, after an educational intervention that included on-site trainings at 14 PCP offices. Chi-square tests were used to compare PrEP prescribing patterns among providers. The initial survey was sent to 389 PCPs, with 115 (30%) responding. Of these, 78% reported seeing men who have sex with men (MSM). Only 17% had prescribed PrEP. The most frequently identified barrier was lack of knowledge (60%). When the survey was repeated after the educational initiative, 79 PCPs (20%) responded. Of these, 90% reported seeing MSM, and 35% had prescribed PrEP. PCPs who had attended a training were more likely to have prescribed PrEP (OR 4.84, CI 1.77–13.21). In conclusion, PrEP prescribing among PCPs in the southern US is low. A survey among PCPs identified lack of knowledge as a barrier to prescribing, motivating an institutional-wide educational campaign in response. Further efforts are needed to continue to raise awareness and educate PCPs in the South about PrEP. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Closson E.F.; Mitty J.A.; Malone J.; Mayer K.H.; Mimiaga M.J.	Exploring strategies for PrEP adherence and dosing preferences in the context of sexualized recreational drug use among MSM: a qualitative study	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1360992	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85028522420&doi=10.1080%2f09540121.2017.1360992&partnerID=40&md5=6bd91081200ce852854bef2670433837	The use of recreational drugs while having sex is associated with increased HIV incidence among men who have sex with men (MSM). Taking a daily antiretroviral pill, or pre-exposure prophylaxis (PrEP) is a biomedical intervention to prevent HIV. However, the efficacy of PrEP is closely tied with high levels of adherence. While PrEP has the potential to reduce HIV acquisition, the use of recreational drugs may impede adherence. We explored perceptions of PrEP utilization and regimen preferences among 40 HIV-negative, MSM who reported concurrent recreational drug use and condomless anal sex with a man. Semi-structured qualitative interviews were conducted and the data were analyzed using a qualitative descriptive approach. Participants perceived that it would be challenging to take PrEP while high on crystal meth, crack, powder cocaine, ecstasy and/or GHB. However, men identified strategies for using PrEP when they were not high on these drugs, including taking the pill when they started their day and integrating PrEP into an established routine, such as when taking other medications or preparing for sex. PrEP regimen preferences seemed to be shaped by the frequency in which participants used drugs and their ability to plan for sex. Taking PrEP everyday was appealing for those who regularly engaged in sexualized recreational drug use. Accounts depict these sexual interactions as frequent but unpredictable. A daily regimen would allow them to be prepared for sex without having to plan. An event-driven regimen was acceptable to men who occasionally used recreational drugs in the context of sex. For this group, sex usually occurred was generally prearranged. Patterns of sex and recreational drug use figured largely into participants' framings of how they would use PrEP. These behaviors will likely play a role in the uptake of and adherence to PrEP among this population. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Cohen, Stephanie E; Sachdev, Darpun; Lee, Sulggi A; Scheer, Susan; Bacon, Oliver; Chen, Miao-Jung; Okochi, Hideaki; Anderson, Peter L; Kearney, Mary F; Coffey, Susa; Scott, Hyman; Grant, Robert M; Havlir, Diane; Gandhi, Monica	Acquisition of tenofovir-susceptible, emtricitabine-resistant HIV despite high adherence to daily pre-exposure prophylaxis: a case report.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(18)30288-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6541554	BACKGROUND: Pre-exposure prophylaxis (PrEP) with emtricitabine and tenofovir disoproxil fumarate is highly protective against HIV infection. We report a case of tenofovir-susceptible, emtricitabine-resistant HIV acquisition despite high adherence to daily PrEP. METHODS: Adherence to PrEP was assessed by measuring concentrations of emtricitabine and tenofovir disoproxil fumarate or their metabolites in plasma, dried blood spots, and hair. After seroconversion, genotypic and phenotypic resistance of the acquired virus was determined by standard clinical tests and by single-genome sequencing of proviral genomes. HIV partner services identified the likely transmission partner. FINDINGS: A 21-year-old Latino man tested positive for HIV infection 13 months after PrEP initiation. He had a negative HIV antibody test, but detectable HIV RNA with 559 copies per mL. He reported good adherence to daily PrEP. He was linked to care and immediately started antiretroviral therapy, at which point his RNA was 1544 copies per mL and his HIV antibody test was positive. The HIV genotype revealed Met184Val, Leu74Val, Leu100Ile, and Lys103Asn mutations in reverse transcriptase, and the phenotype showed susceptibility to tenofovir disoproxil fumarate and resistance to emtricitabine. Segmental hair analysis of tenofovir disoproxil fumarate concentrations measured in 1 cm segments of hair from the scalp indicated consistently high adherence to PrEP in each of the 6 months before HIV diagnosis (0·0672-0·0889 ng/mg). Concentrations of tenofovir diphosphate (1012 fmol per punch) and emtricitabine triphosphate (0·266 fmol per punch) in a dried blood spot indicated high adherence over the preceding 6 weeks. Concentrations of emtricitabine (870·5 ng/mL) and tenofovir disoproxil fumarate (188·2 ng/mL) measured in plasma 3 months before HIV seroconversion confirmed adherence in the days preceding that visit. The likely transmission partner was not engaged in HIV primary care and had a similar viral genotype. INTERPRETATION: Acquisition of HIV virus that is susceptible to tenofovir disoproxil fumarate, but resistant to emtricitabine can occur despite high adherence to PrEP. Quarterly screening for HIV and sexually transmitted diseases facilitates early diagnosis in people on PrEP; when combined with prompt linkage to care and partner services this can prevent onward transmission of HIV. Article	2018	Coleman, Rosalind	Setting the scene, setting the targets. The Joint United Nations Programme on HIV/AIDS prevention targets of 2016 and estimating global pre-exposure prophylaxis targets.	Sexual Health	-	-	-	1448-5028	10.1071/SH18147	https://dx.doi.org/10.1071/SH18147	Commitment to ambitious and time-bound targets for HIV interventions has been part of the response from the beginning of the HIV epidemic. The Joint United Nations Programme on HIV/AIDS (UNAIDS) HIV primary prevention workA is built on five pillars that include offering pre-exposure prophylaxis (PrEP) to population groups at substantial risk of HIV infection. After a slow start, countries are now setting coverage targets for PrEP, but the weakness of epidemiological, demographic and behavioural data at subnational level in many countries where there is a high burden of new HIV infections, makes it difficult to define the locations and populations where to offer PrEP. This article reviews the history and challenges of PrEP target setting and suggests some possible ways of strengthening the process. Reviewing program data will identify gaps in reaching key and other priority populations for whom coverage targets were set and help to refine the offer of PrEP.	na	English	Australia	Asia and the Pacific	Switzerland	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Review
Article	2018	Collier K.L.; Colarossi L.G.; Sanders K.	A prep information and self-screening tool for women	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2018.30.1.13	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044073044&doi=10.1521%2faeap.2018.30.1.13&partnerID=40&md5=48c6c179c61d5a96a55469f66c1056ca	Although HIV pre-exposure prophylaxis (PrEP) is effective for women, studies show limited uptake among women to date. Barriers to women's PrEP uptake include their limited knowledge about PrEP and low perceived HIV risk. To address these barriers, we developed and pretested a printed palm card containing HIV prevention/PrEP information that addressed HIV prevention motivation with self-assessment questions about HIV risk. We conducted expert interviews (N = 8), focus groups with health, education, and social service providers (N = 13), and interviews with community women (N = 30) in New York City to assess attention to and acceptability of the card, comprehension of the information, and potential impact on prevention motivation. The card format and content were found to be acceptable and potentially motivational for preventive behaviors, as well as particularly relevant for women. Results of testing for language use, comprehension, and attention guided the final version of the card content. © 2018 The Guilford Press.	acesso restrito	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2018	Corl, Ammon; Bi, Ke; Luke, Claudia; Challa, Akshara Sree; Stern, Aaron James; Sinervo, Barry; Nielsen, Rasmus	The Genetic Basis of Adaptation following Plastic Changes in Coloration in a Novel Environment.	Current Biology	-	-	-	1879-0445 0960-9822	10.1016/j.cub.2018.06.075	https://www.sciencedirect.com/science/article/pii/S0960982218308996	Phenotypic plasticity has been hypothesized to precede and facilitate adaptation to novel environments 1-8, but examples of plasticity preceding adaptation in wild populations are rare (but see 9, 10). We studied a population of side-blotched lizards, Uta stansburiana, living on a lava flow that formed 22,500 years ago 11 to understand the origin of their novel melanic phenotype that makes them cryptic on the black lava. We found that lizards living on and off of the lava flow exhibited phenotypic plasticity in coloration but also appeared to have heritable differences in pigmentation. We sequenced the exomes of 104 individuals and identified two known regulators of melanin production, PREP and PRKAR1A, which had markedly increased levels of divergence between lizards living on and off the lava flow. The derived variants in PREP and PRKAR1A were only found in the lava population and were associated with increased pigmentation levels in an experimental cohort of hatchling lizards. Simulations suggest that the derived variants in the PREP and PRKAR1A genes arose recently and were under strong positive selection in the lava population. Overall, our results suggest that ancestral plasticity for coloration facilitated initial survival in the lava environment and was followed by genetic changes that modified the phenotype in the direction of the induced plastic response, possibly through de novo mutations. These observations provide a detailed example supporting the hypothesis that plasticity aids in the initial colonization of a novel habitat, with natural selection subsequently refining the phenotype with genetic adaptations to the new environment. Article	2018	Cornelisse, Vincent J; Fairley, Christopher K; Phillips, Tiffany; Walker, Sandra; Chow, Eric Pf	Fuckbuddy partnerships among men who have sex with men - a marker of sexually transmitted infection risk.	International Journal of STD & AIDS	-	-	-	1758-1052	10.1177/0956462417717647	https://dx.doi.org/10.1177/0956462417717647	Fuckbuddies' are a type of regular sexual partner with whom men have ongoing sexual contact, generally in the absence of romantic attachment. We surveyed 989 men who have sex with men (MSM) at the Melbourne Sexual Health Centre, Australia, with the aim of determining the frequency of 'fuckbuddy' partnerships among sexual health clinic attendees and assessing their sexual risk. The majority (60%) of 1139 regular partnerships were described as 'fuckbuddies'. Most MSM (63%) with a 'fuckbuddy' had multiple 'fuckbuddies'. MSM with 'fuckbuddies' were more likely to also have casual sexual partners (odds ratio OR 5.7; 95% confidence interval 3.6-8.9) and had more casual sexual partners (median of 4 versus 1, p < 0.001) and more rectal chlamydia (12.4% versus 5.7%; adjusted OR 2.3; p < 0.05) than MSM without 'fuckbuddies', and this persisted after adjusting for total numbers of sexual partners. Our findings suggest that patients with 'fuckbuddies' are at particular risk of sexually transmitted infections. We argue that clinicians should specifically ask about 'fuckbuddy' partnerships as part of their risk assessment during patient interviews, as these patients may benefit from HIV prevention strategies such as pre-exposure prophylaxis (PrEP). Article	2018	Cornelisse, Vincent J; Fairley, Christopher K; Stoove, Mark; Asselin, Jason; Chow, Eric P F; Price, Brian; Roth, Norman J; Willcox, Jeff; Tee, B K; Penn, Matthew; Chang, Christina C; Armishaw, Judith; Forgan-Smith, George; Wright, Edwina J	Evaluation of Preexposure (PrEP) Eligibility Criteria, Using Sexually Transmissible Infections as Markers of Human Immunodeficiency Virus (HIV) Risk at Enrollment in PrEPX, a Large Australian HIV PrEP Trial.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/ciy370	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6260154	Background: To determine participants' human immunodeficiency virus (HIV) risk, the Australian preexposure prophylaxis (PrEPX) trial used 6 eligibility criteria derived from the US Centers for Disease Control and Prevention PrEP guidelines. Participants who fulfilled no eligibility criteria could be enrolled if clinically assessed to need PrEP. This study evaluated whether PREPX eligibility criteria correlated with biological HIV risk markers-namely, syphilis, anorectal chlamydia, or anorectal gonorrhea (sexually transmitted infections STIs). Methods: We calculated adjusted odds ratios (aORs) to assess whether eligibility criteria predicted STI diagnoses at enrollment. Results: We included 1774 participants, of whom 10.2% tested positive for STIs. Eligibility criteria predicted STI diagnoses as follows: (1) aOR 2.5 (95% confidence interval CI, 1.4-4.4) for condomless anal intercourse (CLAI) with an HIV-positive regular sexual partner (RSP) with detectable viral load; (2) aOR 1.8 (95% CI, 1.3-2.5) for receptive CLAI with casual sexual partners; (3) aOR 1.8 (95% CI, 1.3-2.5) for previous STIs; (4) aOR 2.1 (95% CI, 1.4-3.0) for methamphetamine use; (5) aOR 0.8 (95% CI, .6-1.1) for unsuccessful condom use; and (6) aOR 1.0 (95% CI, .7-1.4) for insertive CLAI when uncircumcised. Of participants enrolled outside eligibility criteria, 7.1% had STIs. Conclusions: Eligibility criteria 1-4 predicted diagnoses of STIs, but eligibility criteria 5 and 6 did not. Our findings support the use of PrEP eligibility criteria recommended in current guidelines. Participants enrolled outside the eligibility criteria had substantial prevalence of STIs, suggesting that people who request PrEP but do not fulfill eligibility criteria may nonetheless need PrEP.	men who have sex with men; gay and bisexual men; syphilis; gonorrhea; chlamydia. Article	2018	Cornell, Morna; Dovel, Kathryn	Reaching key adolescent populations.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0000000000000457	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5956528	PURPOSE OF REVIEW: Adolescents and young people who fit within key populations face some of the greatest barriers to HIV care, but are frequently overlooked. We review the recent literature on these young, vulnerable populations including HIV risk factors, barriers to care, and strategies for engagement. RECENT FINDINGS: Common risk factors include age, risky sexual practices, poor education, and high levels of alcohol and drug abuse. Barriers to care include limited data, criminalization, and high levels of stigma. Strategies to increase engagement include incorporating adolescents into biological and behavioral surveys and the use of social media. Digital innovations for HIV prevention and testing show promise, and pre-exposure prophylaxis may be acceptable. At a policy level, decriminalizing same-sex activity and commercial sex work are priorities. Differentiated models of care including HIV self-testing, after-hour services, community-based delivery, and multimonth dispensing of antiretroviral therapy, should be combined into holistic care. SUMMARY: There has been limited success in reaching these key adolescent populations largely because of criminalization and stigma. Accurate, generalizable data are needed to inform the development of innovative strategies for holistic care. Article	2018	Correa J.; Ricart J.; Corti M.; Della Paolera D.; De Vedia L.; Repetto S.	Factors associated with the indication of pre-exposure prophylaxis for HIV prescribed by Argentine physicians; Factores asociados con la indicación de la profilaxis pre-exposición para HIV en médicos de Argentina	Prensa Médica Argentina	-	-	-	0032745X	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85077216316&partnerID=40&md5=25f2d51af9c90285c5b7d2dd24d8e64c	Pre-exposure prophylaxis (PrEP) is an effective measure to prevent HIV transmission. If the adherence is high, transmission rates are reduced by more than 90%. In Argentina, FTC-TDF is not yet approved for PrEP by the local regulatory agency. PrEP awareness, PrEP adoption, and factors associated with adoption among argentine physicians had not been studied to date. We designed a cross-sectional online survey conducted in August 2017 among argentine physicians and valored differents items about PrEP, (knowledge, attitudes, and beliefs associated with adoption). Univariate analysis was performed; the associations between categorical variables were analyzed by means of the chi2 test. The level of significance was considered with p <0.05. A total of 238 surveys were received from 81 centers in Argentina. Clinical scenarios associated with the highest prescription were: Serodiscordant couples 77%, sex workers 61%, transgender patients 32%, people who inject drugs 31%, and men who have sex with men (MSM) 23%. Factors associated with PrEP prescription between physicians were been chief of staff (p<0.05), been an infectious diseases specialist (p<0.05), assist more than 200 HIV seropositive patients per year (p<0.009) and having prescribed postexposure prophylaxis (PEP) (p<0.008). The authors concluded that in spite of not yet approved by the local regulatory agency, PrEP is been prescribed off- label by argentine physicians. Adopters were more likely to have experience providing HIV care, been chief of staff and ID specialist. These results could be used to plan future HIV prevention strategies in Argentina. © 2018, Ediciones Medicas del Sur S.R.L.. All rights reserved. Hepatitis C virus incidence in HIV-infected and in preexposure prophylaxis (PrEP)-using men having sex with men	Liver International	-	-	-	14783223	10.1111/liv.13922	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053197260&doi=10.1111%2fliv.13922&partnerID=40&md5=a040221087afd7206d56f5918e02093b	Background & Aims: HCV incidence still appears on the rise in HIV-infected MSM in France. We assessed the incidence of HCV infection in HIV-positive and in preexposure prophylaxis (PrEP)-using MSM. Methods: HIV-infected, HCV-negative MSM with serological follow-up in 2016 and HIV-negative, HCV-negative PrEP-using MSM enrolled from January 2016 to May 2017 in the French Dat'AIDS cohort were analysed to assess the incidence of a primary HCV infection. The incidence of HCV reinfection was also determined in patients having cured a previous infection. Results: Among 10 049 HIV-infected MSM followed in 2016, 681 patients were already HCV-infected when entering the study (prevalence 6.8%). Serological follow-up was available in 2016 for 4151 HCV-negative patients. Virological follow-up was available for 478 patients who had cured a previous infection. Fifty-seven HCV infections occurred in 2016 (42 primary infections, 15 reinfections). Incidence of primary HCV infection, reinfection and overall HCV infection was, respectively, 1.0, 3.1 and 1.2/100 person-years (PY). From January 2016 to May 2017, 930 HIV-negative subjects were enrolled for PrEP. Seventeen patients were already HCV-infected (prevalence 1.8%). Twelve HCV infections occurred during follow-up (10 primary infections, 2 reinfections) giving an incidence of primary infection of 1.0/100 PY and an overall incidence of 1.2/100 PY. Conclusions: The overall incidence of HCV infection and of a primary HCV infection in HIV-positive and in PrEP-using MSM appeared similar in France in 2016 to early 2017. HIV-positive and PrEP-using MSM probably share similar at-risk practices and both should be targeted for preventative interventions. © 2018 John Wiley & Sons A/S. Tropical Medicine and International Health (TM & IH)	-	-	-	1365-3156	10.1111/tmi.13129	https://dx.doi.org/10.1111/tmi.13129	OBJECTIVE: To explore the interest in taking PrEP among Western African men who have sex with men (MSM). METHODS: A cross-sectional survey was implemented at enrolment of HIV-negative MSM in a multiple centre community-based cohort study in four West African countries (Mali, Côte d'Ivoire, Burkina Faso, Togo). A standardised face-to-face questionnaire collected data on socio-demographic and behavioural characteristics over the previous 6 months. Descriptive analysis and multivariate logistic regression helped identify factors associated with the interest in taking PrEP. RESULTS: Of 564 participants, 87% were interested in taking PrEP. Interest in PrEP was associated with inconsistent condom use for anal sex (adjusted odds ratio (aOR): 2.11; 95% confidence interval (CI) 1.21-3.67), transactional sex (aOR: 2.02; 95% CI 1.11-3.71), searching for male sexual partners on the Internet in the previous month (aOR: 1.86; 95% CI 1.01-3.43), having a high level of self-esteem (aOR: 1.20; 95% CI 1.06-1.36), having at least one sexually transmitted infections at enrolment (aOR: 5.08; 95% CI 1.40-18.4) and not being aware of PrEP (aOR: 2.03; 95% CI 1.04-3.96). Participants having sex with HIV-positive male partners (aOR: 0.28; 95% CI 0.11-0.74), those being more sexually attracted to women than to men (aOR: 0.20; 95% CI 0.07-0.89) and those reporting psychological and material support from close friends (aOR: 0.33; 95% CI 0.15-0.73) were less interested in taking PreP. CONCLUSIONS: Western African HIV-negative MSM appear very interested in taking PrEP, especially those most at risk of HIV infection. PrEP implementation in a comprehensive prevention package should be considered urgently.	na	English	United Kingdom	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Quantitative
Article	2018	Cowan, Frances M.; Davey, Calum; Fearon, Elizabeth; Mushati, Phillis; Dirawo, Jeffrey; Chabata, Sungai; Cambiano, Valentina; Napierala, Sue; Hanisch, Dagmar; Wong-Gruenwald, Ramona; Masuka, Nyasha; Mabugo, Travor; Hatzold, Karin; Mugurungi, Owen; Busza, Joanna; Phillips, Andrew; Hargreaves, James R.	Targeted combination prevention to support female sex workers in Zimbabwe accessing and adhering to antiretrovirals for treatment and prevention of HIV (SAPPH-IRe): a cluster-randomised trial.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(18)30111-5	https://pubmed.ncbi.nlm.nih.gov/30030134/	BACKGROUND: Strengthening engagement of female sex workers with health services is needed to eliminate HIV. We assessed the efficacy of a targeted combination intervention for female sex workers in Zimbabwe. METHODS: We did a cluster-randomised trial from 2014 to 2016. Clusters were areas surrounding female sex worker clinics and were enrolled in matched pairs. Sites were randomly assigned (1:1) to receive usual care (free sexual-health services supported by peer educators, including HIV testing on demand, referral for antiretroviral therapy ART, and health education) or an intervention that supported additional regular HIV testing, on-site initiation of ART, pre-exposure prophylaxis, adherence, and intensified community mobilisation. The primary outcome was the proportion of all female sex workers with HIV viral load 1000 copies per mL or greater, assessed through respondent-driven sampling surveys. We used an adapted cluster-summary approach to estimate risk differences. This trial is registered with Pan African Clinical Trials Registry, number PACTR201312000722390. RESULTS: We randomly assigned 14 clusters to usual care or the intervention (seven in each group). 3612 female sex workers attended clinics in the usual-care clusters and 4619 in the intervention clusters during the study. Half as many were tested (1151 vs 2606) and diagnosed as being HIV positive (546 vs 1052) in the usual-care clusters. The proportion of all female sex workers with viral loads of 1000 copies per mL or greater fell in both study groups (from 421 30% of 1363 to 279 19% of 1443 in the usual-care group and from 399 30% of 1303 to 240 16% of 1439 in the intervention group), but with a risk difference at the end of the assessment period of only -2·8% (95% CI -8·1 to 2·5, p=0·23). Among HIV-positive women, the proportions with viral loads less than 1000 copies per mL were 590 (68%) of 869 in the usual-care group and 588 (72%) of 828 in the intervention group at the end of the assessment period, adjusted risk difference of 5·3% (95% CI -4·0 to 14·6, p=0·20). There were no adverse events. INTERPRETATION: Our intervention of a dedicated programme for female sex workers led to high levels of HIV diagnosis and treatment. Further research is needed to optimise programme content and intensity for the broader population. Article	2018	Coyer L.; Van Bilsen W.; Bil J.; Davidovich U.; Hoornenborg E.; Prins M.; Matser A.	Pre-exposure prophylaxis among men who have sex with men in the Amsterdam Cohort Studies: Use, eligibility, and intention to use	PLOS One	-	-	-	19326203	10.1371/journal.pone.0205663	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054888624&doi=10.1371%2fjournal.pone.0205663&partnerID=40&md5=8c73ea42378b9ce87fd6425b41615984	Objective: Currently, HIV pre-exposure prophylaxis (PrEP) is not covered by health insurance in the Netherlands. We examined time trends in use of PrEP, characteristics of PrEP users, PrEP eligibility and intention to use PrEP among HIV-negative men who have sex with men (MSM) participating in the Amsterdam Cohort Studies (ACS). Design: Prospective cohort study. Methods: We used data from four 6-monthly questionnaire waves, collected between 2015-2017. PrEP use over time was examined in logistic regression models using generalized estimating equations. Using descriptive statistics, we compared PrEP users before first-time initiation to non-PrEP-users. We used national guidelines to assess PrEP eligibility. Results: We included 687 MSM. Median age was 40 (IQR 33-47) years in 2015. Recent PrEP use was reported by 57/687 (8%) MSM. PrEP use increased over calendar time (P<0.001) to 7% in 2017. PrEP users did not differ from non-PrEP users in socio-demographic characteristics, but reported a significantly higher median number of casual sex partners, more often reported condomless anal sex and chemsex with casual partners, and more often had an sexually transmitted infection in the preceding 6 months (all P<0.05). PrEP eligibility increased over time, but the effect was not statistically significant (P = 0.075). PrEP eligibility criteria were met by 149/460 (32%) at wave 4, of whom 31/149 (21%) reported use of PrEP. The proportion with a high intention to use PrEP was greater among eligible than non-eligible MSM (51% vs. 24%, P<0.001). Conclusion: PrEP use increased over time but remained under 10%, even though 32% met the eligibility criteria, of whom 51% had a high intention to use PrEP. This suggests that a large proportion of Dutch MSM at risk could benefit from PrEP. © 2018 Coyer et al. Article	2018	Crosby, Richard A; Mena, Leandro; Smith, Rachel Vickers	Promoting positive condom use experiences among young black MSM: a randomized controlled trial of a brief, clinic-based intervention.	Health Education Research	-	-	-	1465-3648	10.1093/her/cyy010	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5961371	The aim of this study is to determine, among young Black men who have sex with men (YBMSM), the 12-month efficacy of a single-session, clinic-based intervention promoting condom use to enhance sexual pleasure (purpose 1) and the use of condoms from the start-to-finish of anal sex (purpose 2). A pre-test, post-test randomized controlled trial was conducted, using a 12-month period of follow-up observation, in STI clinics. Data from 394 YBMSM completing baseline and 12-month follow-up assessments were analyzed. The experimental condition comprised a one-to-one, interactive program (Focus on the Future) designed for tailored delivery. Regarding study purpose 1, in an age-adjusted linear regression model for 277 HIV-uninfected men, there was a significant effect of the intervention (Beta=0.13, P =0.036) relative to more favorable sexual experiences when using condoms. Regarding study purpose 2, in an adjusted logistic regression model, for HIV-uninfected men, there was a significant effect of the intervention (AOR=0.54, P =0.048) relative to using condoms from start-to-finish of anal sex. Significant effects for HIV-infected men were not observed. A small, but non-significant, effect was observed relative to men's self-report of always using condoms. This single-session program may be a valuable counseling tool for use in conjunction with pre-exposure prophylaxis-related care for HIV-uninfected YBMSM.	na	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Theses and Dissertations	2018	Dai, Minhao	USING THE INTEGRATIVE MODEL OF BEHAVIORAL PREDICTION TO UNDERSTAND GAY MEN'S BELIEFS, INTENTION, AND BEHAVIOR ON PREP UPTAKE	-	-	UKnowledge/Source Sets, University of Kentucky	-	na	10.13023/etd.2018.438	https://uknowledge.uky.edu/comm_etds/74	Antiretroviral treatment pre-exposure prophylaxis (PrEP) is an effective daily prevention medicine to reduce risks of HIV infections in high-risk populations. The current study examined PrEP uptake among gay men using the integrative model of behavioral prediction (IMBP) as the theoretical framework. Briefly, the IMBP states that attitude, norms, and behavioral control predict intention, which then predicts behavior. The intention-behavior relationship is moderated by actual control variables: skills and environmental constraints. To examine how IMBP variables affect PrEP uptake among gay men, I first conducted formative elicitation interviews with gay men; then I used the results from the interviews to construct the main survey. Then, the project recruited 500 gay men to participate in the survey, half of whom were PrEP takers and half of whom were not. The results of path modeling showed that attitudes and norms predicted behavioral intention, and intention predicted PrEP uptake among gay men. Results of moderation analyses testing the influence of skills and environmental constraints showed that HIV knowledge, lack of access to a doctor(s), and lack of health care system knowledge were significant moderators between intention and PrEP uptake. The practical implications, theoretical contributions, and empirical advancements were discussed. Article	2018	Dangerfield D.T., II; Carmack C.C.; Gilreath T.D.; Duncan D.T.	Latent classes of sexual positioning practices and sexual risk among men who have sex with men in Paris, France	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2267-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053279147&doi=10.1007%2fs10461-018-2267-2&partnerID=40&md5=d5eab4d653c0d02867fe0691d450090f	HIV/STI risk varies by sexual positioning practices; however, limited data have characterized the behavioral profiles of men who have sex with men (MSM) in France. This study used latent class analysis (LCA) to explore sexual risk profiles among MSM in Paris, France. LCA was used to classify sexual positioning and serosorting profiles among MSM in Paris (n = 496). Age, HIV status, relationship status, substance use, group sex, and PrEP history were used in a multinomial regression model predicting class membership. Three latent classes were identified: majority top/serosorters, versatile/low partners, and majority bottom/some serosorters. Majority top/serosorters had the highest probability of condomless serosorting; majority bottom/some serosorters had the highest mean number of partners (~ 12 partners) for condomless receptive anal intercourse. HIV-positive MSM were more likely to be classified as majority bottom/some serosorters than versatile/low partners (AOR 7.61; 95% CI 2.28, 25.3). Findings support the need for tailored and targeted interventions for highest-risk individuals. © Springer Science+Business Media, LLC, part of Springer Nature 2018. Article	2018	Dashwood T.; Tan D.H.S.	PrEParing for the unexpected: Mechanisms and management of HIV pre-exposure prophylaxis failure	Future Virology	-	-	-	17460794	10.2217/fvl-2018-0084	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054609725&doi=10.2217%2ffvl-2018-0084&partnerID=40&md5=f6660a49731f7d8c90ac151952200d04	Pre-exposure prophylaxis (PrEP) for HIV is a proven and effective tool for preventing HIV. However, there are instances where individuals taking PrEP have contracted HIV infection. Most of these cases are due to nonadherence to the drug, while other cases of apparent PrEP failure are due to unrecognized HIV infection at baseline. Importantly, there are also now at least three well-documented cases of PrEP failing despite adequate adherence; these are cases of PrEP 'breakthrough'. This article outlines the potential mechanisms of PrEP failure, as well as how to identify and manage these patients. Finally, we provide a perspective on the future of PrEP as a key tool in preventing HIV worldwide. © 2018 2018 Future Medicine Ltd. Article	2018	Davey, Calum; Cowan, Frances; Hargreaves, James	The effect of mobility on HIV-related healthcare access and use for female sex workers: A systematic review.	Social Science & Medicine	-	-	-	1873-5347 0277-9536	10.1016/j.socscimed.2018.06.017	https://pubmed.ncbi.nlm.nih.gov/29966821/	Female sex workers (FSW) experience a high HIV burden and are often mobile. FSW access to HIV-related healthcare is essential for equitable welfare and to reduce new HIV infections. We systematically reviewed the literature on mobility and HIV-related healthcare access and use among FSW. Outcome measures included: HIV/STI testing, STI treatment, PrEP (initiation or adherence), and ART (initiation or adherence). We summarised the results with a narrative synthesis. From 7417 non-duplicated citations, nine studies from Canada (3), Guatamala, Honduras (2), India, South Africa, and Vietnam were included. Only one of the studies was designed to address mobility and healthcare access, and only six reported adjusted effect estimates. Mobility was measured over four time-frames (from 'current' to 'ever'), as having lived or worked elsewhere or in another town/province/country. Three studies from Canada, Guatemala, and India found mobility associated with increased odds of poor initial access to healthcare (adjusted odds ratios (AOR) from 1.33, 95% CI 1.02, 1.75, to 2.27, 95% CI 1.09, 4.76), and one from Vietnam found no association (odds ratio (OR): 0.92, 95% CI 0.65, 1.28). The study from South Africa found no association with initiating ART (risk ratio: 0.86, 95% CI 0.65, 1.14). Two studies from Canada and Honduras found increased odds of ART interruption (AOR 2.74, 95% CI 0.89, 8.42; 5.19, 95% CI 1.38, 19.56), while two other studies from Canada and Honduras found no association with detectable viral load (OR 0.84, 95% CI 0.08, 8.33; AOR 0.79, 95% CI 0.41, 1.69). We found that mobility is associated with reduced initial healthcare access and interruption of ART, consistent with literature from the general population. Discordance between effects on adherence and viral load may be due to measurement of mobility. Future research should carefully construct measures of mobility and consider a range of HIV-related healthcare outcomes. Article	2018	Davey, Dvora Joseph; Farley E.; Towriss C.; Gomba Y.; Bekker L.-G.; Gorbach P.; Shoptaw S.; Coates T.; Myer L.	Risk perception and sex behaviour in pregnancy and breastfeeding in high HIV prevalence settings: Programmatic implications for PrEP delivery	PLOS One	-	-	-	19326203	10.1371/journal.pone.0197143	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046958966&doi=10.1371%2fjournal.pone.0197143&partnerID=40&md5=7ae5096e7d1a2f9ae0e40f8e55601802	HIV acquisition during pregnancy and breastfeeding significantly contributes toward paediatric HIV infection; however, little is known about risk behaviours in HIV-uninfected pregnant and postpartum women. We conducted twenty-six in-depth-interviews between July and December 2016 using a semi-structured interview guide among HIV-uninfected pregnant and recently postpartum women at-risk of HIV acquisition (defined as reporting 1 of the following: partner's serostatus unknown or HIV-infected, recent condomless sex in pregnancy, and/or alcohol use during pregnancy) who attended primary healthcare services. Our study contextualizes factors related to risky sexual behaviours during pregnancy and postpartum periods and assesses knowledge and hypothetical acceptability of pre-exposure prophylaxis (PrEP) in pregnancy. Translated and transcribed data were coded and analysed by three researchers using a thematic analysis approach. In interviews with HIV-uninfected pregnant/postpartum women at-risk of HIV acquisition, we identified common themes associated with sexual risk behaviours during pregnancy, including: lack of control over decisions in sex and condom use in pregnancy, low perceived risk (e.g. beliefs that their partner has the same HIV-negative serostatus), and socio-cultural beliefs around condom use during pregnancy (e.g. contact with sperm is essential for baby's development). PrEP knowledge was low among HIV-uninfected pregnant and breastfeeding women, and potential acceptability was good, though primary concerns were around the potential impact on the infant. While mothers presented a clear desire to protect themselves from HIV acquisition once pregnant, they also reported lack of control, and socio-cultural beliefs, like sex is good for the baby, that increased their risk of seroconversion. Mothers had limited PrEP awareness but reported hypothetical willingness to use PrEP because of concerns over HIV acquisition and onward mother to child transmission. © 2018 Joseph Davey et al. Article	2018	Davey, Dvora Joseph; Farley, Elise; Gomba, Yolanda; Coates, Thomas; Myer, Landon	Sexual risk during pregnancy and postpartum periods among HIV-infected and -uninfected South African women: Implications for primary and secondary HIV prevention interventions.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0192982	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5839542	BACKGROUND: HIV acquisition in pregnancy and breastfeeding contributes significantly toward pediatric HIV infection. However, little is known about how sexual behavior changes during pregnancy and postpartum periods which will help develop targeted HIV prevention and transmission interventions, including pre-exposure prophylaxis (PrEP). METHODS: Cross-sectional study in HIV-infected and uninfected pregnant and postpartum women in Cape Town, South Africa. Interviewers collected survey data on demographic, sexual behaviors, and alcohol use among pregnant and post-partum women. We report descriptive results of sexual behavior by trimester and postpartum period, and results of multivariable logistic regression stratified by pregnancy status. RESULTS: We enrolled 377 pregnant and postpartum women (56% pregnant, 40% HIV-infected). During pregnancy, 98% of women reported vaginal sex (8% anal sex, 44% oral sex) vs. 35% and 88% during the periods 0-6 and 7-12 months postpartum, respectively (p<0.05). More pregnant women reported having >1 partner in the past 12-months compared to postpartum women (18% vs. 13%, respectively, p<0.05). Sex frequency varied by trimester with greatest mean sex acts occurring during first trimester and >6-months postpartum (13 mean sex acts in first trimester; 17 mean sex acts >6-months postpartum). Pregnant women had increased odds of reporting condomless sex at last sex (aOR = 2.96;95%CI = 1.84-4.78) and ever having condomless sex in past 3-months (aOR = 2.65;95%CI = 1.30-5.44) adjusting for age, HIV status, and sex frequency compared to postpartum women. CONCLUSION: We identified that sexual behaviors and risk behaviors were high and changing during pregnancy and postpartum periods, presenting challenges to primary and secondary HIV prevention efforts, including PrEP delivery to pregnant and breastfeeding women.	na	English	United States	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Quantitative
Article	2018	Davey, Dvora Joseph; West, S.; Umutoni, V.; Taleghani, S.; Klausner, H.; Farley, E.; Shah, R.; Madni, S.; Orewa, S.; Kottamasu, V.; Rice, V.; Robbin, Z.; Wall, K. M.	A Systematic Review of the Current Status of Safer Conception Strategies for HIV Affected Heterosexual Couples in Sub-Saharan Africa.	AIDS and Behavior	-	-	-	1573-3254 1090-7165	10.1007/s10461-018-2170-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6466619/	We conducted a systematic review of safer conception strategies (SCS) for HIV-affected couples in sub-Saharan Africa to inform evidence-based safer conception interventions. Following PRISMA guidelines, we searched fifteen electronic databases using the following inclusion criteria: SCS research in HIV-affected couples; published after 2007; in sub-Saharan Africa; primary research; peer-reviewed; and addressed a primary topic of interest (SCS availability, feasibility, and acceptability, and/or education and promotion). Researchers independently reviewed each study for eligibility using a standardized tool. We categorize studies by their topic area. We identified 41 studies (26 qualitative and 15 quantitative) that met inclusion criteria. Reviewed SCSs included: antiretroviral therapy (ART), pre-exposure prophylaxis, timed unprotected intercourse, manual/self-insemination, sperm washing, and voluntary male medical circumcision (VMMC). SCS were largely unavailable outside of research settings, except for general availability (i.e., not specifically for safer conception) of ART and VMMC. SCS acceptability was impacted by low client and provider knowledge about safer conception services, stigma around HIV-affected couples wanting children, and difficulty with HIV disclosure in HIV-affected couples. Couples expressed desire to learn more about SCS; however, provider training, patient education, SCS promotions, and integration of reproductive health and HIV services remain limited. Studies of provider training and couple-based education showed improvements in communication around fertility intentions and SCS knowledge. SCS are not yet widely available to HIV-affected African couples. Successful implementation of SCS requires that providers receive training on effective SCS and provide couple-based safer conception counseling to improve disclosure and communication around fertility intentions and reproductive health. Article	2018	Davies N.; Heffron R.	Global and national guidance for the use of pre-exposure prophylaxis during peri-conception, pregnancy and breastfeeding	Sexual Health	-	-	-	14485028	10.1071/SH18067	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057008542&doi=10.1071%2fSH18067&partnerID=40&md5=f711ed2b10164bba359f516c59f37fa7	Pre-exposure prophylaxis (PrEP) is a well-established biomedical HIV prevention strategy and recommended to reduce HIV risk during peri-conception, pregnancy and breastfeeding. Efforts are needed to translate global recommendations into national guidelines and implementation strategies. This article presents the current status of policy guidance for the use of PrEP during peri-conception, pregnancy and breastfeeding, with a particular focus on high prevalence countries, including those in sub-Saharan Africa. PrEP clinical guidelines released by ministries of health or other national-level health bodies, with a particular focus on recommendations for PrEP use during peri-conception, pregnancy and breastfeeding, were reviewed and summarised. Among countries with PrEP guidelines and/or policy, pregnancy is recognised as a period with increased HIV vulnerability, and some recommend PrEP use specifically during pregnancy. Only one country notes that PrEP is contraindicated during pregnancy, recognising a gap in complete safety data from women using PrEP throughout pregnancy. PrEP is not contraindicated as a peri-conception HIV prevention strategy in any country, but only three countries have specific guidance for peri-conception HIV prevention. Multiple barriers to the implementation of PrEP during pregnancy and breastfeeding are discussed, including barriers at the policy, health systems, social and personal levels. Although pregnancy is a period of heightened risk and fertility rates are high in many settings with high HIV burden, few PrEP policies have included guidance for PrEP use specific to peri-conception, pregnancy and breastfeeding periods. This gap can be overcome by the development or adoption of national clinical guidelines and implementation strategies from exemplary countries. © 2018 CSIRO.	guidelines; HIV; PrEP; safer conception	English	United States	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	United States	Western and Central Europe and North America	Review
Article	2018	De Baetselier I.; Tsoumanis A.; Verbrugge R.; De Deken B.; Smet H.; Abdellati S.; Cuylaerts V.; Apers L.; Crucitti T.	Lymphogranuloma venereum is on the rise in Belgium among HIV negative men who have sex with men: Surveillance data from	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-018-3600-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058923657&doi=10.1186%2fs12879-018-3600-0&partnerID=40&md5=2a634c0e9d660cc91a868aaef5bd080a	Background: The number of cases of Lymphogranuloma venereum (LGV) is increasing in Europe. The described epidemic is mostly confined to HIV positive men who have sex with men (MSM). However, dissemination of LGV from HIV positive to HIV negative MSM could take place due to the implementation of pre-exposure prophylaxis (PrEP) and subsequent possible decrease in condom use. We describe here the LGV epidemiology in Belgium before the PrEP-era, starting from 2011 up to the end of the first half of 2017. Methods: A descriptive analysis of the socio-demographic and clinical characteristics of all LGV cases was performed. Fisher's exact test was used to compare symptomatic to asymptomatic patients. Logistic regression models were used to check for trends over time for: number of LGV cases, HIV status and symptoms. Results: The number of LGV cases rose by a factor four, from 21 in 2011 to 88 in 2016, and regression models showed a positive trend estimate of 14% increase per half year (p < 0.001). LGV decreased among HIV positive cases (odds ratio (OR): 0.79, p < 0.001) and increased among HIV negative cases (OR: 1.27, p < 0.001). In addition, a rise in the number of asymptomatic LGV cases (6.7%) was observed (OR:1.39, p = 0.047). Asymptomatic cases were also less likely to be HIV (p = 0.046) or Hepatitis C positive (p = 0.027). Conclusions: The rise of LGV in HIV negative MSM has now been documented. If we aim to halt the epidemic in HIV negative MSM, future public health strategies should include LGV testing of all Chlamydia trachomatis positive samples from MSM. © 2018 The Author(s). Article	2018	de Barbeyrac B.; Laurier-Nadalié C.; Touati A.; Le Roy C.; Imounga L.; Hénin N.; Peuchant O.; Bébéar C.; La Ruche G.; Ndeikoundam Ngangro N.	Observational study of anorectal Chlamydia trachomatis infections in France through the lymphogranuloma venereum surveillance network, 2010–2015	International journal of STD & AIDS	-	-	-	9564624	10.1177/0956462418785266	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049867611&doi=10.1177%2f0956462418785266&partnerID=40&md5=a51ae494c89c0f04bedfe72cd78eacd5	The objective of this article is to describe the epidemiology of lymphogranuloma venereum (LGV) and non-LGV Chlamydia trachomatis anorectal infections in France and to examine the characteristics of the affected populations via a voluntary sentinel surveillance system for LGV between 2010 and 2015. Anorectal samples positive for C. trachomatis (CT) were sent by the participating laboratories to the National Reference Center for CT for LGV identification. Biological and clinical data were collected by biologists and clinicians. There were 1740 LGV episodes and 2248 non-LGV episodes. Continuous monitoring highlighted a sharp increase in the number of LGV and non-LGV anorectal infections, which were 2.3-fold and 6.5-fold, respectively. Most of the infections occurred in men who have sex with men. LGV patients were older than non-LGV patients and were more frequently human immunodeficiency virus (HIV)-positive compared to non-LGV patients. Anorectal LGV was significantly associated with residence in Paris, HIV co-infection, concurrent syphilis and bloody anal discharge. Undocumented patient characteristics were strongly associated with anorectal LGV. The anorectal LGV epidemic is poorly controlled in France. Early detection and prompt treatment of patients and their sexual partners are required to prevent transmission in the context of pre-exposure prophylaxis (PrEP) for HIV infection. © The Author(s) 2018. Syndemics among individuals enrolled in the PrEP Brasil Study	Drug and Alcohol Dependence	-	-	-	0376-8716	10.1016/j.drugalcdep.2017.12.016	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044346422&doi=10.1016%2fj.drugalcdep.2017.12.016&partnerID=40&md5=5d79839f140e38d0f00be02c5445a4f3	Background: Concurrent psychosocial problems may synergistically increase the risk of HIV infection (syndemics), representing a challenge for prevention. We aimed to evaluate the prevalence and associated factors of syndemics among men who have sex with men (MSM) and transgender women (TGW) enrolled in the Brazilian pre-exposure prophylaxis demonstration study (PrEP Brasil Study). Methods: Secondary cross-sectional analysis of the PrEP Brasil Study was performed. Of 450 HIV-seronegative MSM/TGW enrolled in the PrEP Brasil Study– conducted at Rio de Janeiro and São Paulo, Brazil– 421 participants with complete data were included in the present analysis. Syndemics was defined as occurrence of ≥2 of the following conditions: polysubstance (≥2) use, binge drinking, positive depression screen, compulsive sexual behavior, and intimate partner violence (IPV). Results: The prevalence of recent polysubstance use was 22.8%, binge drinking 51.1%, positive depression screening 5.2%, compulsive sexual behavior 7.1%, and IPV 7.3%. Syndemics prevalence was 24.2%, and associated factors were younger age (adjusted Odds Ratio (aOR) 0.95, 95% Confidence Interval (95% CI) 0.92–0.98 per year increase), TGW vs. MSM (aOR 3.09, 95% CI: 1.2–8.0), and some college education or more vs. less than college (aOR 2.49, 95% CI: 1.31–4.75), and multiple male sexual partners in prior 3 months (aOR 1.69, 95% CI: 0.92–3.14). Conclusion: Given the high prevalence of syndemics, particularly of polysubstance use and binge drinking, PrEP delivery offers an opportunity to diagnose and intervene in mental and social well-being. © 2018 Elsevier B.V. Article	2018	De Clercq, Erik	Role of tenofovir alafenamide (TAF) in the treatment and prophylaxis of HIV and HBV infections.	Biochem Pharmacol	-	-	-	1873-2968 0006-2952	10.1016/j.bcp.2017.11.023	https://www.sciencedirect.com/science/article/abs/pii/S0006295217307098?via%3Dihub	Tenofovir (TFV) is the cornerstone of the treatment and prophylaxis of HIV infections. It has been routinely used in its prodrug form TDF (tenofovir disoproxil fumarate) combined with emtricitabine ((-)FTC) and other antiretroviral agents. TDF has now been replaced by TAF (tenofovir alafenamide) which allows better uptake by the lymphoid tissue. In combination with elvitegravir (E), cobicistat (C), emtricitabine (F), TAF can be advocated as an STR (single tablet regimen, Genvoya®) for the treatment of HIV infections. In this combination, E and C may in the future be replaced by bictegravir. The prophylaxis of HIV infection is momentarily based upon Truvada®, the combination of F with TDF, which in the future may also be replaced by TAF. TAF (Vemlidy®) has also replaced TDF (Viread®) for the treatment of hepatitis B virus (HBV) infections. Both TDF and TAF offer little or no risk for virus-drug resistance. As compared to TDF, TAF limits the risk for nephrotoxicity and loss of bone mineral density. What remains to be settled, however, before the universal use of TAF could be recommended, is its safety during pregnancy and its applicability in the treatment of tuberculosis, in combination with rifampicin.	na	English	United Kingdom	Western and Central Europe and North America	Belgium	Western and Central Europe and North America	Belgium	Western and Central Europe and North America	Review
Article	2018	Deeks, Emma D.	Darunavir/Cobicistat/Emtricitabine/Tenofovir Alafenamide: A Review in HIV-1 Infection.	Drugs	-	-	-	1179-1950 0012-6667	10.1007/s40265-018-0934-2	https://link.springer.com/article/10.1007/s40265-018-0934-2	Darunavir/cobicistat/emtricitabine/tenofovir AF (Symtuza(®)) is the first protease inhibitor (PI)-based single-tablet regimen (STR) available for the treatment of adults and adolescents (aged ≥ 12 years) with HIV-1 infection. It combines the PI darunavir (which has a high genetic barrier to resistance) with the pharmacokinetic booster cobicistat and the nucleos(t)ide reverse transcriptase inhibitors emtricitabine and tenofovir alafenamide (tenofovir AF), the latter being associated with less off-target tenofovir exposure than its predecessor tenofovir disoproxil fumarate (tenofovir DF). Over 48 weeks in phase 3 trials, darunavir/cobicistat/emtricitabine/tenofovir AF was noninferior to darunavir/cobicistat plus emtricitabine/tenofovir DF in establishing virological suppression in antiretroviral therapy (ART)-naïve adults and, likewise, was noninferior to an ongoing boosted PI, emtricitabine plus tenofovir DF regimen in preventing virological rebound in virologically-suppressed, ART-experienced adults. Resistance did not emerge to the STR components, with the exception being an emtricitabine resistance-associated mutation (RAM) M184I/V in one of seven recipients who experienced virological failure (although M184V was a minority variant at screening in this patient). Darunavir/cobicistat/emtricitabine/tenofovir AF was generally well tolerated, with renal and bone profile improvements but less favourable effects on some lipids versus tenofovir DF-based regimens. Thus, although longer-term and cost-effectiveness data would be beneficial, darunavir/cobicistat/emtricitabine/tenofovir AF is a welcome addition to the STRs available for the treatment of adults and adolescents with HIV-1 infection, being the first to combine the high genetic resistance barrier of darunavir with the renal/bone profile of tenofovir AF, thus expanding the patient population for whom an STR may be suitable. Article	2018	Delaugerre, C; Rodriguez, C; Capitant, C; Nere, ML; Mercier-Darty, M; Carette, D; Pialoux, G; Cotte, L; Charreau, I; Molina, JM	Drug resistance among patients who acquired HIV infection in a preexposure prophylaxis trial	AIDS	-	-	-	na	10.1097/QAD.0000000000001960	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-02092714/full	BACKGROUND: The IPERGAY ANRS trial showed that on-demand preexposure prophylaxis (PrEP) with tenofovir (TDF) and emtricitabine (FTC) was highly effective in preventing HIV infection among highly exposed MSM. Here, we analyzed drug resistance-associated mutations (RAMs) among all participants who acquired HIV infection during this trial. METHODS: Resistance was analyzed on frozen plasma at the time of HIV diagnosis among participants enrolled in the double-blind and open-label phases of the ANRS IPERGAY trial. Reverse transcriptase sequencing was performed, using population-based and ultradeep sequencing (454 GS Flex). Adherence was measured by pill counting and by plasma tenofovir and FTC assay. RESULTS: During the trial, 31 participants were diagnosed with HIV-1 infection (subtype B, 64.5%), using antigen/antibody immune assay in 29 cases and plasma HIV RNA assay in two. The median plasma HIV-1 RNA level was 5.52 log10copies/ml. Drug resistance was tested in 12 participants before starting PrEP, in six assigned to TDF/FTC group and in 13 assigned to placebo group. Primary resistance to nucleoside reverse transcriptase inhibitors (zidovudine) and/or nonnucleoside reverse transcriptase inhibitors was detected in six participants (19%; 95% confidence interval 7-42). No major or minor TDF-resistant or FTC-resistant variants were detected. CONCLUSION: No TDF or FTC resistance-associated mutations were found among participants who acquired HIV in the ANRS IPERGAY trial.	*antiviral resistance; *drug effect; *mutation; *procedures; *virology; Clinical Trials as Topic; Clinical trial (topic); DNA sequence; Double blind procedure; Double-Blind Method; Drug Resistance, Viral; Genetics; Genotype; HIV Infections *prevention & control, *virology; HIV Reverse Transcriptase genetics; HIV-1 *drug effects, genetics; High throughput sequencing; High-Throughput Nucleotide Sequencing; Human; Human immunodeficiency virus 1; Human immunodeficiency virus infection /prevention; Humans; Male; Mutation; Placebos administration & dosage; Pre-Exposure Prophylaxis *methods; Pre-exposure prophylaxis; Sequence Analysis, DNA; Treatment Failure; Treatment failure	English	United Kingdom	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Clinical
Theses and Dissertations	2018	Dennis, Ntombifuthi J.N	HIV Pre-Exposure Prophylaxis in the Real World: A Qualitative Exploration of Uptake and Adherence Among Women Who Engage in Sex Work in Gauteng, South Africa	-	-	Harvard University	-	-	NA	https://dash.harvard.edu/handle/1/37365184	Nearly 66% of new HIV infections in 2015 occurred in sub-Saharan Africa (1). This demonstrates the urgent need for the effective deployment of prevention modalities in the region. In recent years, an increasing allocation of resources has been diverted towards research aimed at HIV chemoprophylaxis in non-infected individuals. In outreach sites where oral PrEP is provided through mobile clinics, we conducted 24 in-depth interviews with women engaged in sex work identified through systematic random sampling and 9 in-depth interviews with healthcare providers identified through purposive sampling. Through an iterative process, data were analysed for recurring patterns or themes using a grounded theory approach. Results: Women's narratives indicated that uptake and adherence to oral PrEP is strongly influenced by forces outside of the women's control. Among factors identified in women's narratives include extreme economic adversity, uncooperative gatekeepers intimate partner violence, restricted focus of PrEP programs and fractured trust.Conclusions: This qualitative study indicates that there are complex and interconnected structural forces that actively shape women's engagement and retention in PrEP that are not currently being addressed in the conceptualization and roll-out of PrEP programs. To address uptake and adherence to PrEP we propose a rethink of the current PrEP HIV care model that provides a corrective lens for the current biomedical tunnel vision by integrating interventions that will address the confluent forces influencing uptake and adherence such as intimate partner violence, alcohol and drug addiction, abuse by police and the presence of extreme economic deprivation. Theses and Dissertations	2018	Denton, Paul Wesley	Mucosal HIV-1 Transmission in Humanized Mice	-	-	University of Texas Southwestern Medical Center	-	na	NA	http://hdl.handle.net/2152.5/260	HIV-1 infects ~6,800 people each and every day, transmitting predominantly through unprotected sexual contact. On a global scale, vaginal transmission now accounts for more than half of newly acquired HIV-1 infections. In developed countries intrarectal infection represents a major form of HIV-1 transmission. The social and economic toll of this disease has created an urgency to develop and implement novel approaches capable of preventing HIV-1 transmission. Yet this process has been hindered by the lack of adequate small animal models for pre-clinical efficacy and safety testing. Given the importance of mucosal HIV-1 transmission, the susceptibility of humanized mice to intrarectal and intravaginal HIV-1 infection was investigated. Human lymphocytes, including CD4+ T cells, generated in situ from hematopoietic stem cells reconstitute the gastrointestinal tract and the female reproductive tract of Bone marrow Liver Thymus (BLT) mice. The presence of human CD4+ T cells in these mucosal tissues renders BLT mice susceptible to both intrarectal and intravaginal HIV-1 transmission. Mucosally transmitted HIV-1 disseminates systemically in BLT mice. Effects of disseminated HIV-1 infection include a systemic loss of CD4+ T cells, particularly in gut associated lymphoid tissue, which closely mimics what happens in HIV-1 patients. The utility of humanized mice to study mucosal HIV-1 transmission is particularly highlighted by the demonstration herein that pre-exposure prophylaxis with antiretroviral drugs can prevent intrarectal HIV-1 transmission. This experimental finding has important implications for the clinical implementation of antiretroviral-based pre-exposure prophylactic measures to prevent the spread of AIDS. The goal of this dissertation project was to determine the suitability of the BLT mouse to serve as an animal model of HIV-1 transmission and as a model for assessing interventions aimed at preventing HIV-1 transmission. My conclusions are that BLT mice are susceptible to both intrarectal and intravaginal HIV-1 transmission and that pre-exposure prophylaxis with FDA approved antiretroviral drugs does prevent vaginal transmission in BLT mice. Thus, the BLT mouse system is an excellent candidate for pre-clinical evaluation of both microbicides and pre-exposure prophylactic regimens to prevent mucosal HIV-1 transmission. Griffithsin carrageenan fast dissolving inserts prevent SHIV HSV-2 and HPV infections in vivo	Nature Communications	-	-	-	20411723	10.1038/s41467-018-06349-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053878762&doi=10.1038%2fs41467-018-06349-0&partnerID=40&md5=e56ee6f4fc2d82d1a4cb92c93b30da3b	Human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) strategies with proven in vivo efficacy rely on antiretroviral drugs, creating the potential for drug resistance and complicated treatment options in individuals who become infected. Moreover, on-demand products are currently missing from the PrEP development portfolio. Griffithsin (GRFT) is a non-antiretroviral HIV entry inhibitor derived from red algae with an excellent safety profile and potent activity in vitro. When combined with carrageenan (CG), GRFT has strong activity against herpes simplex virus-2 (HSV-2) and human papillomavirus (HPV) in vitro and in vivo. Here, we report that GRFT/CG in a freeze-dried fast dissolving insert (FDI) formulation for on-demand use protects rhesus macaques from a high dose vaginal SHIV SF162P3 challenge 4 h after FDI insertion. Furthermore, the GRFT/CG FDI also protects mice vaginally against HSV-2 and HPV pseudovirus. As a safe, potent, broad-spectrum, on-demand non-antiretroviral product, the GRFT/CG FDI warrants clinical development. © 2018, The Author(s). Article	2018	Deutsch M.B.	Pre-Exposure Prophylaxis in Trans Populations: Providing Gender-Affirming Prevention for Trans People at High Risk of Acquiring HIV	LGBT Health	-	-	-	23258292	10.1089/lgbt.2018.0086	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055072598&doi=10.1089%2flgbt.2018.0086&partnerID=40&md5=dcfb30771c05b0ea7b5ac5a75a41bc33	Transgender (trans) people, particularly trans women of color, face alarmingly high rates of HIV. HIV pre-exposure prophylaxis (PrEP) with daily coformulated emtricitabine and tenofovir disoproxil fumarate is a promising biomedical HIV prevention modality; however, it has not yet been shown to be efficacious in the transgender population due to data limitations. Initial data suggest that barriers exist to PrEP uptake in the trans community, including lack of access to healthcare and concerns about interactions with hormone therapy. This article discusses these factors and reviews considerations for enhancing PrEP uptake and adherence in trans people at risk for HIV. © Copyright 2018, Mary Ann Liebert, Inc., publishers 2018. Article	2018	Di Ciaccio M.; Protiere C.; Rojas Castro D.; Suzan-Monti M.; Chas J.; Cotte L.; Siguier M.; Cua E.; Spire B.; Molina J.-M.; Preau M.	The ANRS-Ipergay trial, an opportunity to use qualitative research to understand the perception of the "participant"-physician relationship	AIDS Care	-	-	-	9540121	10.1080/09540121.2018.1468013	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047923240&doi=10.1080%2f09540121.2018.1468013&partnerID=40&md5=d9ca61ff7ef6cbd0bee98d1a14dac65b	The ANRS-IPERGAY trial consisted in providing sexual activity-based antiretroviral prophylaxis for HIV prevention (PrEP) with a package of prevention tools (counselling, condoms, HIV and sexually transmitted infections' screening) to highly exposed HIV-negative men who have sex with men (MSM). Few data exist concerning the patient-physician relationship in the particular context of PrEP, where physicians discuss sexual behaviours with MSM who are not classic patients, in that consultation is for prevention purposes, not for illness. This study took place during the open-label extension of ANRS-IPERGAY trial when all participants received PrEP. In this qualitative study, we examined how physicians perceived their relationship with participants in the ANRS-IPERGAY trial. Of all 30 physicians involved in the trial who were contacted by email to participate in an interview about their opinions and perceptions of ANRS-IPERGAY 18 volunteered to participate in the current sub-study. We performed a vertical analysis for each interview to identify the extract in each physician's discourse concerning their relationship with MSM participants, and conducted a horizontal analysis to construct the thematic tree and subsequently investigate differences and similitudes between themes. An analysis of all physicians' discourses showed that the participant-physician relationship during the trial could be described through 4 themes: (i) personal experience of the relationship, (ii) trust and non-judgement, (iii) positive relational climate and (iv) influence of physician's characteristics (age, gender, etc.) on relationship. We found that the particular context of PrEP led some physicians to adopt a patient-as-partner approach during consultations rather than a paternalist or hierarchical approach. Indeed, the close follow-up provided by the trial and the active role of patients in their own prevention care trajectory, are more compatible with the patient-as-partner approach. The prescription of PrEP may lead to an evolution in patient-physician relationships and may even modify the professional identity of physicians. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Doblecki-Lewis S.; Liu A.Y.; Feaster D.J.; Cohen S.E.; Elion R.; Bacon O.; Coleman M.; Cardenas G.; Kolber M.A.	Patterns and correlates of participant retention in a multi-city pre-exposure prophylaxis demonstration project	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001724	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054589674&doi=10.1097%2fQAI.0000000000001724&partnerID=40&md5=8ea64cc156be2421d4955321ce8ead2e	Background: Safe and effective use of pre-exposure prophylaxis (PrEP) depends on retention in care after initial engagement. Setting: The United States PrEP Demonstration Project offered daily oral tenofovir/emtricitabine to participants in San Francisco, Miami, and Washington, D.C. for 48 weeks from 2012 to 2014. Methods: The Demo Project participants' patterns of retention were assigned to 1 of 3 categories: Early loss to follow-up (ELTF) within the first 12 weeks of the study, retention throughout the study, or intermittent retention in which missed or delayed visits resulted in gaps in medication availability. For each group, baseline characteristics were tabulated. A two-step multivariable analysis was performed. Results: Overall, 366/554 (66.1%) of enrolled participants were retained for all study visits, 127/554 (22.9%) had intermittent retention, and 61/554 (11.0%) ELTF. In multivariable analysis, Miami compared with San Francisco site was associated with ELTF rather than full retention aOR 2.84; confidence interval (CI): 1.24 to 6.47 and also with intermittent rather than full retention (aOR 2.70; CI: 1.43 to 5.11). Younger age was associated with ELTF (aOR 1.80 for each 10-year decrement in age; CI: 1.26 to 2.57) and intermittent retention (aOR 1.47; CI: 1.17 to 1.84) compared with full retention. Factors associated with ELTF (but not intermittent retention) compared with full retention were black compared with white (aOR 3.32; CI: 1.09 to 10.16), reporting sex work (aOR 4.67; CI: 1.49 to 14.58), lack of regular employment (aOR 2.53; CI: 1.27 to 5.05), and lack of previous PrEP awareness (aOR 2.01; CI: 1.01 to 3.96). Conclusions: Tailored interventions addressing causes and risk factors for loss from PrEP care may improve retention and consistency of PrEP use. © 2018 Wolters Kluwer Health, Inc. Article	2018	Doll, Mimi; Fortenberry, J Dennis; Roseland, Denise; McAuliff, Kathleen; Wilson, Craig M; Boyer, Cherrie B	Linking HIV-Negative Youth to Prevention Services in 12 U.S. Cities: Barriers and Facilitators to Implementing the HIV Prevention Continuum.	Journal of Adolescent Health	-	-	-	1879-1972	10.1016/j.jadohealth.2017.09.009	https://dx.doi.org/10.1016/j.jadohealth.2017.09.009	PURPOSE: Linkage of HIV-negative youth to prevention services is increasingly important with the development of effective pre-exposure prophylaxis that complements behavioral and other prevention-focused interventions. However, effective infrastructure for delivery of prevention services does not exist, leaving many programs to address HIV prevention without data to guide program development/implementation. The objective of this study was to provide a qualitative description of barriers and facilitators of linkage to prevention services among high-risk, HIV-negative youth. DESIGN: Thematic analysis of structured interviews with staff implementing linkage to prevention services programs for youth aged 12-24 years. METHODS: Twelve adolescent medicine HIV primary care programs as part of larger testing research program focused on young sexual minority men of color. The study included staff implementing linkage to prevention services programs along with community-based HIV testing programs. The main outcomes of the study were key barriers/facilitators to linkage to prevention services. RESULTS: Eight themes summarized perspectives on linkage to prevention services: (1) relationships with community partners, (2) trust between providers and youth, (3) youth capacity to navigate prevention services, (4) pre-exposure prophylaxis specific issues, (5) privacy issues, (6) gaps in health records preventing tailored services, (7) confidentiality of care for youth accessing services through parents'/caretakers' insurance, and (8) need for health-care institutions to keep pace with models that prioritize HIV prevention among at-risk youth. Themes are discussed in the context of factors that facilitated/challenged linkage to prevention services. CONCLUSIONS: Several evidence-based HIV prevention tools are available; infrastructures for coordinated service delivery to high-risk youth have not been developed. Implementation of such infrastructures requires attention to community-, provider-, and youth-related issues.	424-433	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative

Article	2018	Downing M.J., Jr.; Antebi-Gruszka N.; Schrimshaw E.W.; Hirshfield S.	If You Film It Will They Watch? Factors Associated with Willingness to View Safer Sex Messaging in Internet-Based Sexually Explicit Media	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1971-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85033439498&doi=10.1007%2fs10461-017-1971-7&partnerID=40&md5=19c8adfb7c2f33815efa21133f8d79be	Research on the association between viewing condomless sex in sexually explicit media (SEM) and engaging in risk behavior suggests the need for SEM-based safer sex messaging (e.g., PrEP, condom use), though few studies have considered viewer willingness to watch SEM containing HIV/STI prevention messages. Online survey data from a racially diverse sample of 859 men and women were used to investigate factors associated with willingness to watch SEM with safer sex messaging. Analyses were conducted separately for three groups: heterosexual men and other men who only report sex with women, heterosexual women and other women who only report sex with men, and gay, bisexual, and other men who have sex with men. All three groups expressed some willingness to view safer sex messages in SEM and a majority viewed the SEM industry as having some responsibility to provide this type of messaging. Factors associated with greater willingness varied across the three groups. These findings have implications for the design and implementation of safer sex messaging in SEM. © 2017, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Drainoni, Mari-Lynn; Biancarelli, Dea L; Leech, Ashley A; Sullivan, Meg; Bazzi, Angela R	Implementing a Pre-Exposure Prophylaxis Intervention for Safer Conception among HIV Serodiscordant Couples: Recommendations for Health Care Providers.	Journal of Health Disparities Research and Practice	-	-	-	2166-5222	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6241314	Couples in HIV serodiscordant relationships frequently desire children. Although partners who are virally suppressed pose almost no risk of transmitting HIV to their partners, partners who are inconsistently on therapy may transmit HIV to their partners when attempting to conceive. Pre-exposure prophylaxis (PrEP) is an available safer conception strategy for these couples but is not consistently offered. We sought to better understand barriers to PrEP implementation for couples seeking conception and patient perceptions on what providers could do to encourage use. We conducted in-depth, qualitative interviews with 11 participants representing six couples taking PrEP for safer conception in a safety-net hospital in New England. Semi-structured qualitative interviews assessed the following: Relationship nature and contextual factors; attitudes and perceptions regarding PrEP for safer conception; experience within health care systems related to HIV and PrEP; and facilitators, barriers, and other experiences using PrEP for safer conception. Four key themes have important implications for implementation of PrEP for safer conception: Knowledge and understanding gaps regarding HIV and PrEP among both members of the couple, role of insurance and financing in decision-making, learning to manage and adhere to a treatment plan, and the need for providers to enhance knowledge and offer further support. Addressing barriers to safer conception strategies at multiple levels is needed to prevent HIV transmission within serodiscordant couples who desire children. Providers can play an important role in lowering these barriers through the use of multiple strategies.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2018	Dubé, Michael P.; Park, Sung Yong; Ross, Heather; Love, Tanzy M. T.; Morris, Sheldon R.; Lee, Ha Youn	Daily HIV pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate-emtricitabine reduced Streptococcus and increased Erysipelotrichaceae in rectal microbiota.	Scientific Reports	-	-	-	2045-2322	10.1038/s41598-018-33524-6	https://www.nature.com/articles/s41598-018-33524-6	Daily PrEP is highly effective at preventing HIV-1 acquisition, but risks of long-term tenofovir disoproxil fumarate plus emtricitabine (TDF-FTC) include renal decline and bone mineral density decrease in addition to initial gastrointestinal side effects. We investigated the impact of TDF-FTC on the enteric microbiome using rectal swabs collected from healthy MSM before PrEP initiation and after 48 to 72 weeks of adherent PrEP use. The V4 region of the 16S ribosomal RNA gene sequencing showed that Streptococcus was significantly reduced from 12.0% to 1.2% (p = 0.036) and Erysipelotrichaceae family was significantly increased from 0.79% to 3.3% (p = 0.028) after 48-72 weeks of daily PrEP. Catenibacterium mitsuokai, Holdemanella biformis and Turicibacter sanguinis were increased within the Erysipelotrichaceae family and Streptococcus agalactiae, Streptococcus oralis, Streptococcus mitis were reduced. These changes were not associated with host factors including PrEP duration, age, race, tenofovir diphosphate blood level, any drug use and drug abuse, suggesting that the observed microbiome shifts were likely induced by daily PrEP use. Long-term PrEP resulted in increases of Catenibacterium mitsuokai and Holdemanella biformis, which have been associated with gut microbiome dysbiosis. Our observations can aid in characterizing PrEP's side effects, which is likely to improve PrEP adherence, and thus HIV-1 prevention. Article	2018	Dubov A.; Altice F.L.; Fraenkel L.	An Information–Motivation–Behavioral Skills Model of PrEP Uptake	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2095-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046025462&doi=10.1007%2fs10461-018-2095-4&partnerID=40&md5=3c01bac5b31a69e17d24248139ed637e	Despite documented effectiveness of pre-exposure prophylaxis (PrEP), PrEP uptake remains low among at-risk populations. The 2015 CDC report estimates that about 1.2 million people in the US have indications for PrEP. However, only 49,158 or 4% of the targeted population are currently using PrEP. Efforts to optimize uptake of PrEP may be facilitated by the development of a comprehensive theoretical framework which can be used to understand reasons for poor uptake and to develop interventions to maximize PrEP uptake and adherence. This article reviews research on correlates of PrEP uptake and presents findings organized within an Information-Motivation-Behavioral Skills (IMB) model framework. In the context of PrEP uptake, the IMB model asserts that to the extent that at-risk groups are well-informed about PrEP, motivated to act on their knowledge, and have necessary behavioral skills to seek out and initiate PrEP regimen, they will successfully overcome obstacles to initiate and adhere to PrEP. The article proposes an adaptation the IMB model for PrEP uptake, provides empirical support for the adapted IMB model extracted from related research, and discusses its application in PrEP uptake interventions. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Dubov A.; Fraenkel L.; Yorick R.; Ogunbajo A.; Altice F.L.	Strategies to Implement Pre-exposure Prophylaxis with Men Who Have Sex with Men in Ukraine	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1996-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85037151925&doi=10.1007%2fs10461-017-1996-y&partnerID=40&md5=5e5aa286dd48c621bad33a4eba89463a	Ukrainian men who have sex with men (MSM) remain highly stigmatized group with HIV prevalence as high as 23%. Despite documented effectiveness of pre-exposure prophylaxis (PrEP), PrEP remains unavailable in Ukraine. The aim of this study was to elicit MSM preferences in order to inform program development to facilitate successful delivery of PrEP to Ukrainian MSM. 1184 MSM were recruited through social networking applications to complete a stated preference (choice-based conjoint) survey. Respondents completed 14 choice tasks presenting experimentally-varied combinations of five attributes related to PrEP administration (dosing frequency, dispensing venue, prescription practices, adherence support, and costs). Latent class analysis was used to estimate the relative importance of each attribute and preferences across nine possible PrEP delivery programs. Preferences clustered into five groups. PrEP affordability was the most influential attribute across groups, followed by dosing strategy. Only one group preferred injectable PrEP (n = 216), while the other four groups disliked daily PrEP and strongly preferred the 'on demand' option. One group (n = 258) almost exclusively considered cost in their decision making. One group (n = 151) had very low level of interest in PrEP initiation correlated with low self-perceived risk for HIV. The two most at-risk groups (n = 415) were also more sensitive to changes in program delivery. PrEP uptake among MSM is most likely to be successful when PrEP is affordable, its implementation is targeted, provided as "on-demand" with associated education, and when more thorough medical care and related testing is provided to at-risk populations. Its introduction will need affirmation by the Ukrainian government, and guidelines that reflect safety, efficacy, and patient preferences. © 2017, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Dubov A.; Galbo P., Jr; Altice F.L.; Fraenkel L.	Stigma and Shame Experiences by MSM Who Take PrEP for HIV Prevention: A Qualitative Study	American Journal of Men's Health	-	-	-	15579883	10.1177/1557988318797437	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055076148&doi=10.1177%2f1557988318797437&partnerID=40&md5=75913bfe86ba9ead1ddcea6d7f28348b	Pre-exposure prophylaxis (PrEP) uptake has been extremely low among key groups. PrEP-related stigma and shaming are potential barriers to uptake and retention in PrEP programs. There is a lack of literature describing PrEP stigma. In order to fill this gap, we recruited online 43 HIV-negative Men who have Sex with Men (MSM) who use PrEP. Semistructured interviews were conducted to explore their perceptions and experience of stigma related to PrEP use. Data were analyzed using Strauss and Corbin's grounded theory and constant comparison techniques to enhance understanding of the lived experiences of MSM who use PrEP. The participants experienced PrEP stigma as rejection by potential sexual partners, stereotypes of promiscuity or chemsex, and labeling of both the user and the medication. They connected PrEP stigma with HIV stigma, generational differences, moralization of condom use, and inability to embrace one's own sexuality. These findings point to a need to develop tailored interventions to address PrEP-related stigma and shaming for individuals, health-care professionals, and the MSM community-at-large. © The Author(s) 2018. Article	2018	Dunbar, Megan S; Kripke, Katharine; Haberer, Jessica; Castor, Delivette; Dalal, Shona; Mukoma, Wanjiru; Mullick, Saiqa; Patel, Pragna; Reed, Jason; Subedar, Hasina; Were, Daniel; Warren, Mitchell; Torjesen, Kristine	Understanding and measuring uptake and coverage of oral pre-exposure prophylaxis delivery among adolescent girls and young women in sub-Saharan Africa.	Sexual Health	-	-	-	1448-5028	10.1071/SH18061	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6429961	In response to World Health Organization (WHO) guidance recommending oral pre-exposure prophylaxis (PrEP) for all individuals at substantial risk for HIV infection, significant investments are being made to expand access to oral PrEP globally, particularly in sub-Saharan Africa. Some have interpreted early monitoring reports from new programs delivering oral PrEP to adolescent girls and young women (AGYW) as suggestive of low uptake. However, a lack of common definitions complicates interpretation of oral PrEP uptake and coverage measures, because various indicators with different meanings and uses are used interchangeably. Furthermore, operationalising these measures in real-world settings is challenged by the difficulties in defining the denominator for measuring uptake and coverage among AGYW, due to the lack of data and experience required to identify the subset of AGYW at substantial risk of HIV infection. This paper proposes an intervention-centric cascade as a framework for developing a common lexicon of metrics for uptake and coverage of oral PrEP among AGYW. In codifying these indicators, approaches to clearly define metrics for uptake and coverage are outlined, and the discussion on 'low' uptake is reframed to focus on achieving the highest possible proportion of AGYW using oral PrEP when they need and want it Recommendations are also provided for making increased investments in implementation research to better quantify the sub-group of AGYW in potential need of oral PrEP.and for improving monitoring systems to more efficiently address bottlenecks in the service delivery of oral PrEP to AGYW so that implementation can be taken to scale.	na	English	Australia	Asia and the Pacific	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2018	Dunn D.T.; Glidden D.V.; Stirrup O.T.; McCormack S.	The averted infections ratio: a novel measure of effectiveness of experimental HIV pre-exposure prophylaxis agents	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(18)30045-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048500138&doi=10.1016%2fS2352-3018%2818%2930045-6&partnerID=40&md5=8eb00fa696e901df1449973d0d3172da	Tenofovir disoproxil fumarate combined with emtricitabine is a highly effective oral pre-exposure prophylaxis (PrEP) agent for preventing the acquisition of HIV. This effectiveness has consequences for the design and analysis of trials assessing experimental PrEP regimens, which now generally include an active-control tenofovir disoproxil fumarate plus emtricitabine group, rather than a placebo group, as a comparator. Herein, we describe major problems in the interpretation of the primary measure of effectiveness proposed for these trials, namely the ratio of HIV incidence in the experimental agent group to that in the active-control group. We argue that valid interpretation requires an assumption about one of two parameters: either the incidence among trial participants had they not received PrEP or the effectiveness of tenofovir disoproxil fumarate plus emtricitabine within the trial. However, neither parameter is directly observed because of the absence of a no-treatment group, thus requiring the use of external evidence or subjective judgment. We propose an alternative measure of effectiveness based on the concept of averted infections, which incorporates one of these parameters. The measure is simple to interpret, has clinical and public health relevance, and is a natural preservation-of-effect criterion for assessing statistical non-inferiority. Its adoption could also allow the use of smaller sample sizes, currently a major barrier to the assessment of experimental PrEP regimens. © 2018 Elsevier Ltd	na	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Review
Article	2018	Duwal S.; Dickinson L.; Khoo S.; von Kleist M.	Hybrid stochastic framework predicts efficacy of prophylaxis against HIV: An example with different dolutegravir prophylaxis schemes	PLOS Computational Biology	-	-	-	1553734X	10.1371/journal.pcbi.1006155	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049362262&doi=10.1371%2fjournal.pcbi.1006155&partnerID=40&md5=76dac44f9ec8e6491b0ea5669814e4ee	To achieve the 90-90-90 goals set by UNAIDS, the number of new HIV infections needs to decrease to approximately 500,000 by 2020. One of the 'five pillars' to achieve this goal is pre-exposure prophylaxis (PrEP). Truvada (emtricitabine-tenofovir) is currently the only medication approved for PrEP. Despite its advantages, Truvada is costly and requires individuals to adhere to the once-daily regimen. To improve PrEP, many next-generation regimen, including long-acting formulations, are currently investigated. However, pre-clinical testing may not guide candidate selection, since it often fails to translate into clinical efficacy. On the other hand, quantifying prophylactic efficacy in the clinic is ethically problematic and requires to conduct long (years) and large (N>1000 individuals) trials, precluding systematic evaluation of candidates and deployment strategies. To prioritize- and help design PrEP regimens, tools are urgently needed that integrate pharmacological-, viral- and host factors determining prophylactic efficacy. Integrating the aforementioned factors, we developed an efficient and exact stochastic simulation approach to predict prophylactic efficacy, as an example for dolutegravir (DTG). Combining the population pharmacokinetics of DTG with the stochastic framework, we predicted that plasma concentrations of 145.18 and 722.23nM prevent 50- and 90% sexual transmissions respectively. We then predicted the reduction in HIV infection when DTG was used in PrEP, PrEP 'on demand' and post-exposure prophylaxis (PEP) before/after virus exposure. Once daily PrEP with 50mg oral DTG prevented 99–100% infections, and 85% of infections when 50% of dosing events were missed. PrEP 'on demand' prevented 79–84% infections and PEP >80% when initiated within 6 hours after virus exposure and continued for as long as possible. While the simulation framework can easily be adapted to other PrEP candidates, our simulations indicated that oral 50mg DTG is non-inferior to Truvada. Moreover, the predicted 90% preventive concentrations can guide release kinetics of currently developed DTG nano-formulations. © 2018 Duwal et al. http://creativecommons.org/licenses/by/4.0/	na	English	United States	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Quantitative
Article	2018	Eakle R.; Bourne A.; Mbogua J.; Mutanha N.; Rees H.	Exploring acceptability of oral PrEP prior to implementation among female sex workers in South Africa:	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25081	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042706954&doi=10.1002%2fjia2.25081&partnerID=40&md5=642893f3ef59865334889a8bc1796a07	Introduction: Female sex workers (FSWs) are at high-risk for HIV acquisition in South Africa, where the advent of new HIV prevention and treatment interventions represent the potential to significantly impact the epidemic. This paper focuses on aspects of PrEP acceptability as a new intervention within the context of a larger service delivery programme including the simultaneous rollout of early ART. This paper explores PrEP acceptability among the FGD participants as future potential users. Methods: FGDs were conducted in two clinic-based sites in Johannesburg and Pretoria. They aimed to explore community-level, multi-dimensional acceptability of PrEP within the context of imminent implementation alongside early ART in the TAPS Demonstration Project. Sex worker peer educators recruited participants from varying sex work locales. Facilitation was in English with adaptation by facilitators into local languages as needed. Transcripts were translated and transcribed into English. Thematic analysis was used to analyse the data. Results: Four FGDs were conducted in each site for a total of eight FDGs and 69 participants. Demographics were largely similar across the sites. Overall, there was strong acceptability of PrEP among participants and positive anticipation for the imminent delivery of PrEP in the local sex worker clinics. Themes arising from the discussions exploring aspects of PrEP acceptability included: awareness and understanding of PrEP; PrEP motivations including choice, control, and vulnerability, managing PrEP risks and worries; and, de-stigmatizing and empowering PrEP delivery. Participant discussions and recommendations highlighted the importance of developing clear education and messaging to accurately convey the concept of PrEP, and intervention integration into supportive and tailored services. Conclusions: Through the course of these FGDs, PrEP became a positive and highly anticipated prevention option among the FSWs participants who endorsed implementation in their communities. Effective integration of PrEP into existing services will include comprehensive health programming where ART is also available, appropriate messaging, and support. © 2018 The Authors. Article	2018	Eakle R.; Venter F.; Rees H.	Pre-exposure prophylaxis (PrEP) in an era of stalled HIV prevention: Can it change the game?	Retrovirology	-	-	-	17424690	10.1186/s12977-018-0408-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044828074&doi=10.1186%2fs12977-018-0408-3&partnerID=40&md5=c35be8ec5f1387b50f8283016bd05fef	Pre-exposure prophylaxis (PrEP) for HIV prevention has evolved significantly over the years where clinical trials have now demonstrated the efficacy of oral PrEP, and the field is scaling-up implementation. The WHO and UNAIDS have made PrEP implementation a priority for populations at highest risk, and several countries have developed guidelines and national plans accordingly, largely based on evidence generated by demonstration projects. PrEP presents the opportunity to change the face of HIV prevention by offering a new option for protection against HIV and disrupting current HIV prevention systems. Nevertheless, as with all new technologies, both practical and social requirements for implementation must be taken into account if there is to be sustained and widespread adoption, which will also apply to forthcoming prevention technologies. Defining and building success for PrEP within the scope of scale-up requires careful consideration. This review summarises where the PrEP field is today, lessons learned from the past, the philosophy and practicalities of how successful programming may be defined, and provides perspectives of costs and affordability. We argue that a successful PrEP programme is about effective intervention integration and ultimately keeping people HIV negative. © 2018 The Author(s). Article	2018	Eakle, Robyn; Mutanha, Nyaradzo; Mbogua, Judie; Sibanyoni, Maria; Bourne, Adam; Gomez, Gabriela; Venter, Francois; Rees, Helen	Designing PrEP and early HIV treatment interventions for implementation among female sex workers in South Africa: developing and learning from a formative research process.	BMJ Open	-	-	-	-	2044-6055	10.1136/bmjopen-2017-019292	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6009452	OBJECTIVES: The objective of this research was to design relevant, tailored oral pre-exposure prophylaxis (PrEP) and early antiretroviral (ART) interventions for female sex workers (FSWs) in South Africa. This paper examines the methods, process and outcomes of employing an inductive approach to formative research exploring intervention feasibility and acceptability. SETTING: Research was conducted in several sex work-related settings including five sites in and around clinics and stakeholder offices. PARTICIPANTS: Participants in this research included stakeholders, experts in the field and FSWs. This included at least 25 separate engagements, 14 local organisations and 8 focus group discussions (FGDs) with 69 participants, in addition to ad hoc meetings. RESULTS: The first set of outcomes consisted of five selected methods: (1) stakeholder consultations; (2) site assessments and selection; (3) field observations and mapping; (4) development of supportive structures to encourage retention and intervention adherence; (5) FGDs conducted with FSWs to explore specifics of acceptability. In terms of feasibility, two sites were selected in central Johannesburg and Pretoria out of five considered. The urban site contexts varied, necessitating adjustments to intervention implementation. There was overall support for PrEP and early ART from stakeholders and FSWs. Concerns included potential issues with adherence to PrEP (and early ART), possible reduction in condom use, resistance to antiretrovirals and burden on scarce resources. These concerns indicated where special attention should be focused on education, messaging and programming as well as development of supportive structures. CONCLUSIONS: The inductive approach allowed for a wide range of perspectives, defining population needs and accessibility. This research illustrated how similar sex work environments can vary and how implementation of interventions may not be uniform across contexts. Lessons learnt in details could assist in future project designs and implementation of new interventions where feasibility, social and cultural factors affecting acceptability must be considered. Article	2018	Eaton L.A.; Matthews D.D.; Bukowski L.A.; Friedman M.R.; Chandler C.J.; Whitfield D.L.; Sang J.M.; Stall R.D.	Elevated HIV prevalence and correlates of PrEP use among a community sample of black men who have sex with men	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001822	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054890168&doi=10.1097%2fQAI.0000000000001822&partnerID=40&md5=d8c729db59b64b699ee6d037c9df378b	Background: The HIV epidemic among black men who have sex with men (BMSM) demands urgent public health attention. Pre-exposure prophylaxis (PrEP) is a highly efficacious option for preventing HIV, but characteristics of PrEP use among community samples of BMSM are not well-understood. Methods: A serial cross-sectional survey assessment (N = 4184 BMSM reporting HIV-negative/unsure status) and HIV testing were conducted at Black Gay Pride events in 6 US cities in 2014, 2015, 2016, and 2017. Results: HIV prevalence was higher among BMSM selfreporting current PrEP use (1 of 3 participants) than BMSM not self-reporting current PrEP use (1 of 5 participants) 32.3%, N = 103/319 vs. 20.0%, N = 639/3,193, adjusted odds ratio (aOR) = 1.68, 95% confidence interval (CI): 1.31 to 2.15. BMSM reporting current PrEP use (N = 380) were more likely to report having a greater number of male sex partners (aOR = 1.02, 95% CI: 1.01 to 1.03), a sexually transmitted infection diagnosis (aOR = 2.44, 95% CI: 1.88 to 3.16), and stimulant drug use (aOR = 2.05, 95% CI, 1.21 to 3.47) when compared with BMSM not reporting current PrEP use (N = 3804). PrEP use increased from 4.7% (2014) to 15.5% (2017) (aOR = 1.19, 95% CI: 1.13 to 1.25). Among PrEP users, inability to afford health care coverage was associated with testing HIV-positive (aOR = 2.10, 95% CI: 1.24 to 3.56). Conclusions: The high prevalence of HIV infection among BMSM reporting PrEP use is concerning. It does not, however, challenge the efficacy of PrEP itself but rather the uptake of the surrounding preventative package including behavioral risk reduction support, sexually transmitted infection treatment, and medication adherence counseling. Further research to understand barriers to fully effective PrEP is needed to guide operational and behavioral interventions that close the gap on incident infection. © 2018 Wolters Kluwer Health, Inc. Article	2018	Elopre L.; McDavid C.; Brown A.; Shurbaji S.; Mugavero M.J.; Turan J.M.	Perceptions of HIV Pre-Exposure Prophylaxis among Young, Black Men Who Have Sex with Men	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2018.0121	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058058878&doi=10.1089%2fapc.2018.0121&partnerID=40&md5=0fc458c8fc93de1c760f28b073cc4eb7	We conducted in-depth interviews guided by the Andersen-Newman Health Service Utilization Framework to understand perceptions of pre-exposure prophylaxis (PrEP) with 25 young, black men who have sex with men (YBMSM) in the Southern United States. The mean age of participants was 24 years; 21 were insured; and 18 had a regular source of care. Five major themes emerged: (i) stigma related to being black, gay and living in the South; (ii) lack of discussion in the black community about HIV prevention and sexual health; (iii) stigma related to PrEP; (iv) medical mistrust; and (v) low perceived need to be on PrEP. This study presents formative qualitative work that underscores the need for behavioral interventions to address intersectional stigma and perceptions of risk among YBMSM in the South, so that PrEP is no longer viewed as a drastic step but rather as a routine HIV prevention strategy. © 2018, Mary Ann Liebert, Inc., publishers.	black men who have sex with men; PrEP; sexual silence; young	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Qualitative
Article	2018	Felsher M.; Szep Z.; Krakower D.; Martinez-Donate A.; Tran N.; Roth A.M.	"I don't need prep right now": A qualitative exploration of the barriers to prep care engagement through the application of the health belief model	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2018.30.5.369	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055080634&doi=10.1521%2faeap.2018.30.5.369&partnerID=40&md5=b2af31802f806f7383cdd8d9d6d95d32	The Health Belief Model has been useful for studying uptake of HIV prevention behaviors and has had limited application to understanding utilization of pre-exposure prophylaxis (PrEP), a biomedical strategy to reduce HIV acquisition. We recruited 90 persons undergoing HIV screening and educated them about PrEP. We followed up with 35 participants approximately 3 weeks later and quantitatively assessed PrEP uptake. No participant had initiated PrEP. We conducted in-depth interviews with 15 participants to explore situational factors impacting this decision. In this paper we provide an overview of PrEP-related engagement using qualitative data to contextualize (in)action. While participants perceived PrEP as beneficial, perceived benefits did not outweigh real-and perceived barriers, such as financial and time-related constraints. In order to promote PrEP uptake, cues to action that increase the benefits of PrEP during seasons of risk, and interventions that reduce real and perceived barriers are needed. © 2018 The Guilford Press. Article	2018	Fernandez, Sabrina	Preventing HIV Infection-What Pediatricians Should Know About HIV Pre-Exposure Prophylaxis.	Pediatric Annals	-	-	-	-	1938-2359	10.3928/19382359-20171214-03	https://dx.doi.org/10.3928/19382359-20171214-03	I recently diagnosed my first adolescent patient with new-onset HIV. As a primary care pediatrician, these cases are rare. I cried with the shock of the initial diagnosis, just as the patient did when I told him. One of my first thoughts was how could I have served him better. He had been inconsistent with condom use, and had several partners. I had encouraged safe sex practices, told him to talk to his partners about pregnancy prevention, and screened for sexually transmitted disease nearly every time he came into my office. However, there was one more thing I could have done that may have spared him this diagnosis in the first place. I could have prescribed HIV Pre-Exposure Prophylaxis (PrEP). This article is meant to introduce primary care pediatricians to the idea of HIV PrEP. The article reviews patient eligibility, how to prescribe HIV PrEP, as well as drug monitoring and follow-up. Article	2018	Fernando, Daniel	HIV Preexposure Prophylaxis	American Journal of Public Health	-	-	-	-	00900036	10.2105/AJPH.2018.304757	https://www.proquest.com/scholarly-journals/hiv-preexposure-prophylaxis-respond/docview/2135965900/se-2?accountid=8113	In that context, this article is more important in drawing attention to the limitations associated with prescription of PrEP (and other services) to qualified candidates. ...out of 5857 HIV-negative individuals tested for rectal sexually transmitted infections-who are excellent candidates for PrEP-only 2047 (35%) were prescribed PrEP. Primary care physicians (PCPs), in particular, are optimally positioned to provide PrEP, given their focus on health promotion, disease prevention, and longitudinal care. The Centers for Disease Control and Prevention estimate that 1.1 million individuals in the United States have indications for PrEP use,1 yet national pharmacy data suggest that only 100000 people used PrEP in 2017, with substantial demographic and geographic disparities in uptake.2,3 Multiple barriers to PrEP use exist among individuals at risk for HIV acquisition, including cost, perceived low risk of HIV acquisition, stigma, and medical or pharmaceutical mistrust.4 Barriers also exist among providers, including lack of familiarity with PrEP, inadequate training in HIV risk assessments, and concerns about potential risk compensation among PrEP users.5 Many of these barriers were likely minimized in our community health center, which specializes in care for sexual and gender minorities by providers who are familiar with conducting HIV risk assessments and prescribing PrEP; nevertheless, uptake was low. Examples from our own work include outreach to facilitate PrEP uptake among patients with recent diagnoses of rectal sexually transmitted infections or syphilis6 and automated algorithms that integrate electronic health records data to help providers identify patients who may benefit from PrEP.7 In addition to its potential effect on the HIV epidemic, PrEP may influence other key health outcomes. Genetic Variation of the Kinases That Phosphorylate Tenofovir and Emtricitabine in Peripheral Blood Mononuclear Cells	AIDS Research and Human Retroviruses	-	-	-	-	8892229	10.1089/aid.2017.0243	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046638870&doi=10.1089%2faid.2017.0243&partnerID=40&md5=689764259b2c0631a68364e330ca63f3	Tenofovir (TFV) disoproxil fumarate and emtricitabine (FTC) are used in combination for HIV treatment and pre-exposure prophylaxis (PrEP). TFV disoproxil fumarate is a prodrug that undergoes diester hydrolysis to TFV. FTC and TFV are nucleoside/nucleotide reverse transcriptase inhibitors that upon phosphorylation to nucleotide triphosphate analogs competitively inhibit HIV reverse transcriptase. We previously demonstrated that adenylate kinase 2, pyruvate kinase, muscle and pyruvate kinase, liver and red blood cell phosphorylate TFV in peripheral blood mononuclear cells (PBMC). To identify the kinases that phosphorylate FTC in PBMC, siRNAs targeted toward kinases that phosphorylate compounds structurally similar to FTC were delivered to PBMC, followed by incubation with FTC and the application of a matrix-assisted laser desorption ionization-mass spectrometry method and ultra high performance liquid chromatography-UV to detect the formation of FTC phosphates. Knockdown of deoxycytidine kinase decreased the formation of FTC-monophosphate, while siRNA targeted toward thymidine kinase 1 decreased the abundance of FTC-diphosphate. Knockdown of either cytidine monophosphate kinase 1 or phosphoglycerate kinase 1 decreased the abundance of FTC-triphosphate. Next-generation sequencing of genomic DNA isolated from 498 HIV-uninfected participants in the HIV Prevention Trials Network 069/AIDS Clinical Trials Group A5305 clinical study, revealed 17 previously unreported genetic variants of TFV or FTC phosphorylating kinases. Of note, four individuals were identified as simultaneous carriers of variants of both TFV and FTC activating kinases. These results identify the specific kinases that activate FTC in PBMC, while also providing further insight into the potential for genetic variation to impact TFV and FTC activation. © Copyright 2018, Mary Ann Liebert, Inc. 2018.	emtricitabine; kinase; nucleotide reverse transcriptase inhibitor; pharmacogenetics; tenofovir	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2018	Filgueiras, Sandra Lúcia; Maksud, Ivia	Da política à prática da profilaxia pós-exposição sexual ao HIV no SUS: sobre risco, comportamentos e vulnerabilidades	Sexualidad, Salud y Sociedad - Revista Latinoamericana	-	-	-	-	1984-6487	DOI: 10.1590/1984-6487.sess.2018.30.14.a	https://www.redalyc.org/articulo.oa?id=293362740014	The effects of the antiretroviral therapy on the HIV transmissibility intensified the diffusion of new biomedical technologies in the virus prevention. This article discusses risk perceptions and health practices, in narratives of both professionals and patients, about the Sexual Post-Exposure Prophylaxis ("sexual PEP"). The data are the result of a case study carried out in a public health service. Analysis was based on risks and vulnerability studies. The results showed that the epidemiological criteria are not sufficient to respond the prophylaxis indication, that the intersubjectivity spaces circumscribed by the sexual PEP are crossed by distinct logics of risk and by discriminatory moral standards. The concretization of health practices oriented by the perspective of sexuality exercise as an affirmation of a right keeps being a challenge. Article	2018	Fisher C.B.; Fried A.L.; Puri L.I.; Macapagal K.; Mustanski B.	"Free Testing and PrEP without Outing Myself to Parents:" Motivation to participate in oral and injectable PrEP clinical trials among adolescent men who have sex with men	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0200560	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050768902&doi=10.1371%2fjournal.pone.0200560&partnerID=40&md5=1b3acd00672c1767ebda3d1b6e15ec9d	Background Adolescent men who have sex with men (AMSM) account for disproportionately high numbers of new HIV diagnoses. Non-adherence to daily use limiting the effectiveness of oral PrEP (Truvada) has led to current trials with adult MSM testing Cabotegravir, a long-term injectable medication. Once comparative studies with young adult MSM have established relative safety and efficacy of these medications, there will be a need for such comparative trials involving adolescents. Trends in state laws and IRB protocol review indicate that many of these studies will permit youth to provide independent consent for participation. Understanding the motivations of AMSM to participate in HIV biomedical prevention studies is important to ensure their agreement is voluntary without misunderstanding and undue influence. This study examined AMSM attitudes toward participation in oral/injectable PrEP RCTs to inform protections of youth's rights and welfare in future studies. Methods We administered to 198 ethnically diverse U.S. AMSM, 14–17 years, a web-based survey including demographic and sexual health questions, description of a year-long oral versus injectable PrEP RCT and 26 Likert-type and one open-ended item assessing motivations for and against participation including: perceived benefits and risks of PrEP; free HIV/STI testing and counseling; confidentiality concerns; random assignment; and benefit to others. Results Sixty-two percent indicated they were likely to participate in the study. The majority endorsed daily HIV protection, free HIV/STI testing, sexual health counseling, not having to rely on partner's condom use, and altruism as reasons to participate. Reasons against participation included medication side effects, concern taking the pill daily and clinic visits would reveal their sexual orientation and behaviors to parents. Over half erroneously assumed they would be assigned to the condition best for them and 39% indicated free access to services would lead them to participate even if they did not want to. Multiple regression indicated these factors accounted for 55% of the variance in participation choice. Nether age or ethnicity yielded significance. Conclusions Results suggest future biomedical HIV prevention research will need to develop procedures to address AMSM's confidentiality concerns, enhance youth's understanding of random assignment, the continued importance of medication adherence and partner condom use during trial participation, and availability of alternative sexual health services to avoid the potentially undue influence of access to free sexual health services. © 2018 Fisher et al. Article	2018	Flash C.A.; Adegboyega O.O.; Yu X.; Avalos C.; Johnson S.; Mayer K.H.; Giordano T.P.	Correlates of linkage to HIV preexposure prophylaxis among HIV-testing clients	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001605	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051712901&doi=10.1097%2fQAI.0000000000001605&partnerID=40&md5=344d5d861ec461081b3ce63ccc478b4e	Background: Publicly funded HIV-testing sites can identify HIV preexposure prophylaxis (PrEP) candidates and provide PrEP linkage. Setting: Harris Health System's HIV clinic, HIV-testing program, and HIV-prevention program (HPP) in Houston, TX, a high HIVincidence city. Methods: A prospective assessment of individuals aged 18 years and older recruited from walk-in HIV testing from December 2013 to April 2015 included risk assessment, HIV testing, and self-administered survey, with follow-up surveys at 6 and 12 months and medical record review. Results: The mean age of our sample (n = 300) was 38.3 6 11.7 years. Men constituted 63.1% of the sample and 53.7% were black non-Hispanic, 26.3% Hispanic, and 14.7% white non-Hispanic. Most were uninsured (63.5%). Only 27% always used condoms, although 67% perceived personal HIV risk. Of 300 participants, 64 (21.3%) linked to PrEP care and 49 (16.3%) took PrEP. In multivariable analysis, compared with heterosexual men, women adjusted OR (aOR) 4.1, 95% CI: 1.5 to 11.1 and MSM (aOR 10.2, 95% CI: 3.4 to 31.0) were more likely to attend HPP and to take PrEP (aOR 3.0, 95% CI: 1.6 to 15.1 and 3.0, 95% CI: 1.1 to 8.3, respectively). Serodiscordance and PrEP interest correlated with program attendance (aOR 14.0, 95% CI: 6.1 to 32.3 and aOR 6.7, 95% CI: 1.8 to 25.4) and taking PrEP (aOR 13.1, 95% CI: 5.2 to 32.8 and 14.4, 95% CI: 1.8 to 166.9), respectively. Conclusions: Preexposure prophylaxis interest, being female or MSM, and serodiscordance correlated with PrEP linkage. Safety-net health systems can facilitate PrEP access in marginalized populations, but the PrEP initiation rates remain low. © 2017 The Authors. Article	2018	Flash, Charlene A; Frost, Elizabeth L T; Giordano, Thomas P; Amico, K Rivet; Cully, Jeffrey A; Markham, Christine M	HIV Pre-exposure Prophylaxis Program Implementation Using Intervention Mapping.	American Journal of Preventive Medicine	-	-	-	-	1873-2607	10.1016/j.amepre.2017.12.015	https://dx.doi.org/10.1016/j.amepre.2017.12.015	INTRODUCTION: HIV pre-exposure prophylaxis has been proven to be an effective tool in HIV prevention. However, numerous barriers still exist in pre-exposure prophylaxis implementation. METHODS: The framework of Intervention Mapping was used from August 2016 to October 2017 to describe the process of adoption, implementation, and maintenance of an HIV prevention program from 2012 through 2017 in Houston, Texas, that is nested within a county health system HIV clinic. Using the tasks outlined in the Intervention Mapping framework, potential program implementers were identified, outcomes and performance objectives established, matrices of change objectives created, and methods and practical applications formed. RESULTS: Results include the formation of three matrices that document program outcomes, change agents involved in the process, and the determinants needed to facilitate program adoption, implementation, and maintenance. Key features that facilitated successful program adoption and implementation were obtaining leadership buy-in, leveraging existing resources, systematic evaluation of operations, ongoing education for both clinical and nonclinical staff, and attention to emergent issues during launch. CONCLUSIONS: The utilization of Intervention Mapping to delineate the program planning steps can provide a model for pre-exposure prophylaxis implementation in other settings.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
Article	2018	Fletcher F.E.; Fisher C.; Buchberg M.K.; Floyd B.; Hotton A.; Ehioba A.; Donenberg G.	"Where Did This PrEP Come From?" African American Mother/Daughter Perceptions Related to Adolescent Preexposure Prophylaxis (PrEP) Utilization and Clinical Trial Participation	Journal of Empirical Research on Human Research Ethics	-	-	-	-	15562646	10.1177/1556264618755919	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042415267&doi=10.1177%2f1556264618755919&partnerID=40&md5=614a2b6bd695d85f99c21c7256802f68	Despite the demonstrated effectiveness of preexposure prophylaxis (PrEP) to reduce incident HIV infections, PrEP's potential as an HIV prevention strategy for adolescent populations is unknown. This study assessed perceptions of adolescent PrEP use and clinical trial participation among African American women and their adolescent daughters. We conducted focus group discussions with 15 African American mother/daughter pairs (N = 30). Findings suggest a general lack of PrEP awareness, favorable attitudes toward adolescent PrEP use, altruistic attitudes regarding research participation among daughters, and less favorable attitudes toward adolescent clinical trial participation among mothers. Study findings have the potential to inform strategies that provide equitable access to HIV scientific advances among African American women and girls and promote informed parent–child research decision making. © 2018, © The Author(s) 2018. Theses and Dissertations	2018	Francisco Miguel da Costa Grilo	HIV pre-exposure prophylaxis (PrEP): strategy with future?	-	-	Universidade do Porto	Universidade do Porto		NA	NA	https://hdl.handle.net/10216/114416	Introdução: Atualmente, estima-se que ocorram, globalmente, cerca de dois milhões de novas infeções pelo Vírus de Imunodeficiência Humana (VIH) por ano, apesar de décadas de Terapêutica Antirretroviral (TARV) de alta eficácia. Como tal, novas estratégias preventivas devem ser desenvolvidas de forma a impedir a progressão desta epidemia. A profilaxia de pré-exposição (PrEP) consiste num método biocomportamental que combina uma abordagem farmacológica com estratégias de promoção de comportamentos sexuais saudáveis. É dirigida a indivíduos com alto risco de adquirirem a infeção por VIH, como homens que têm sexo com homens (HSH), casais heterossexuais serodiscordantes, mulheres transsexuais, homens e mulheres heterossexuais que não usem o preservativo frequentemente e cujos parceiros sexuais sejam de alto risco, e utilizadores de drogas injetadas. Vários estudos randomizados foram realizados e demonstraram que a PrEP é uma medida segura, bem tolerada e eficaz na redução do risco de aquisição da infeção por VIH. Objetivos: O objetivo principal desta revisão bibliográfica é a análise da literatura mais recente relativa à PrEP, focando-se nos seus benefícios, desvantagens e desafios à sua implementação, procurando entender se é uma estratégia preventiva com futuro. Métodos: Uma pesquisa inicial foi efetuada no PubMed com recolha de artigos escritos em inglês e português no período entre 2011 e 2017. Apenas os que continham informação relativa aos tópicos abordados nesta revisão foram selecionados, tendo sido feito um esforço para usar a literatura mais recente (de 2016 a 2018). Adicionalmente, algumas notícias da internet, comunicados de imprensa e relatórios foram citados por referirem importantes desenvolvimentos relacionados com a PrEP. Discussão: Apesar de a PrEP ter evidência como uma medida preventiva eficaz, a sua implementação encontra-se num impasse e a sua utilização pelos indivíduos está aquém da esperada. Alguns fatores contribuem para isto, nomeadamente a compensação do risco, com consequente elevação da incidência de infeções sexualmente transmissíveis (ISTs), custo, estigma, falta de conhecimento da população sobre a PrEP e insegurança dos profissionais de saúde. Conclusão: Superar estas adversidades deve ser um objetivo atual. Governos e legisladores devem investir em formas de reduzir o custo da PrEP, aumentar o conhecimento da sua população alvo com medidas de sensibilização e realizar ações de formação aos profissionais de saúde, para evitar o estigma e desmistificar mitos e ideias erradas. Só enfrentando estas barreiras é que a PrEP pode ser implementada totalmente e conseguirá atingir o seu potencial preventivo. Article	2018	Franconi I.; Guaraldi G.	Pre-exposure Prophylaxis for HIV Infection in the Older Patient: What can be Recommended?	Drugs and Aging	-	-	-	-	1170229X	10.1007/s40266-018-0553-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046532275&doi=10.1007%2fs40266-018-0553-3&partnerID=40&md5=4bcad39409f6e553a5e6a33c915608e0	Over the past 15 years, a significant increase in new HIV/AIDS diagnoses has been observed in the elderly population. This new epidemiological shift has been attributed to a longer sex life, lifestyle and changes in sexual behavior, poor sexual health education, and misconceptions about the absence of sexually transmitted disease in later life. Although many biomedical and behavioral interventions have proven useful to prevent sexually transmitted infections and HIV, pre-exposure prophylaxis (PrEP) has been shown to be the most successful biomedical intervention to prevent HIV in high-risk individuals. This approach is based on delivering a fixed dose of tenofovir disoproxil fumarate (300 mg), alone or combined with emtricitabine (300/200 mg) daily or on demand, before and after sexual intercourse. Despite the consistent number of clinical trials proving the effectiveness and safety of this strategy, no studies have focused specifically on elderly people. These individuals, who may benefit substantially from (PrEP), are at a higher risk of experiencing side effects secondary to tenofovir exposure. This review critically discusses the efficacy and safety of PrEP in people aged over 50 years and translates the knowledge of tenofovir management in patients with HIV into monitoring and stopping rules to be used in this special population. We provide practical recommendations to properly identify PrEP candidates among older adults. Furthermore, we define correct case management before and during PrEP delivery, and we suggest stopping rules and alternative sexually transmitted infection prevention strategies. © 2018, Springer International Publishing AG, part of Springer Nature. Article	2018	Franks J.; Hirsch-Moverman Y.; Loquere A.S., Jr.; Amico K.R.; Grant R.M.; Dye B.J.; Rivera Y.; Gamboa R.; Mannheimer S.B.	Sex, PrEP, and Stigma: Experiences with HIV Pre-exposure Prophylaxis Among New York City MSM Participating in the HPTN 067/ADAPT Study	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-017-1964-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85034058888&doi=10.1007%2fs10461-017-1964-6&partnerID=40&md5=fa6798681adb6823a3d840aa03cee993	The HPTN 067/Alternative Dosing to Augment Pre-Exposure Prophylaxis Pill Taking (ADAPT) study evaluated daily and non-daily dosing schedules for oral pre-exposure prophylaxis (PrEP) to prevent HIV. A qualitative sub-study including focus groups and in-depth interviews was conducted among men who have sex with men participating in New York City to understand their experience with PrEP and study dosing schedules. The 37 sub-study participants were 68% black, 11% white, and 8% Asian; 27% were of Hispanic/Latino ethnicity. Mean age was 34 years. Themes resulting from qualitative analysis include: PrEP is a significant advance for HIV prevention; non-daily dosing of PrEP is congruent with HIV risk; and pervasive stigma connected to HIV and risk behavior is a barrier to PrEP adherence, especially for non-daily dosing schedules. The findings underscore how PrEP intersects with other HIV prevention practices and highlight the need to understand and address multidimensional stigma related to PrEP use. © 2017, The Author(s). Theses and Dissertations	2018	Fredericksen, Rob J; Mayer, Kenneth H; Gibbons, Laura E; Edwards, Todd C; Yang, Frances M; Walcott, Melonie; Brown, Sharon; Dant, Lydia; Loo, Stephanie; Gutierrez, Cristina; Paez, Edgar; Fitzsimmons, Emma; Wu, Albert W; Mugavero, Michael J; Mathews, William C; Lober, William B; Kitahata, Mari M; Patrick, Donald L; Crane, Paul K	Development and Content Validation of a Patient-Reported Sexual Risk Measure for Use in Primary Care	-	-	University of California	University of California	-	0884-8734	https://doi.org/10.1007/s11606-018-4496-5	https://escholarship.org/uc/item/69j9j6nm	BACKGROUND:Patient-provider sexual risk behavior discussions occur infrequently but may be facilitated by high-quality sexual risk screening tools. OBJECTIVE:To develop the Sexual Risk Behavior Inventory (SRBI), a brief computer-administered patient-reported measure. DESIGN:Qualitative item development/quantitative instrument validation. PARTICIPANTS:We developed SRBI items based on patient interviews (n = 128) at four geographically diverse US primary care clinics. Patients were diverse in gender identity, sex, sexual orientation, age, race/ethnicity, and HIV status. We compared sexual risk behavior identified by the SRBI and the Risk Assessment Battery (RAB) among patients (n = 422). APPROACH:We constructed an item pool based on validated measures of sexual risk, developed an in-depth interview guide based on pool content, and used interviews to elicit new sexual risk concepts. We coded concepts, matched them to item pool content, and developed new content where needed. A provider team evaluated item clinical relevance. We conducted cognitive interviews to assess item comprehensibility. We administered the SRBI and the RAB to patients. KEY RESULTS:Common, clinically relevant concepts in the SRBI included number of sex partners; partner HIV status; partner use of antiretroviral medication (ART)/pre-exposure prophylaxis (PrEP); and recent sex without barrier protection, direction of anal sex, and concern regarding HIV/STI exposure. While 90% reported inconsistent condom use on the RAB, same-day SRBI administration revealed that for over one third, all their partners were on ART/PrEP. CONCLUSION:The SRBI is a brief, skip-patterned, clinically relevant measure that ascertains sexual risk behavior across sex, sexual orientation, gender identity, partner HIV serostatus, and partner treatment status, furnishing providers with context to determine gradations of risk for HIV/STI. Article	2018	Freeborn K.; Portillo C.J.	Does pre-exposure prophylaxis for HIV prevention in men who have sex with men change risk behaviour? A systematic review	Journal of Clinical Nursing	-	-	-	-	9621067	10.1111/jocn.13990	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052511000&doi=10.1111%2fjocn.13990&partnerID=40&md5=06ce4d280b3eb021f81c8315c0fcf3f3	Aims and Objectives: To review the literature regarding PrEP and sexual behaviour change in MSM. Background: Pre-exposure prophylaxis for HIV has been available since 2012. Even so, pre-exposure prophylaxis has not been widely accepted among healthcare providers and men who have sex with men some of whom are convinced that pre-exposure prophylaxis decreases condom use and increases sexually transmitted infections. Design: A systematic review of the state of the evidence regarding the association of pre-exposure prophylaxis with condom use, sexually transmitted infection incidence and change in sexual risk behaviours in men who have sex with men. A structured search of databases resulted in 142 potential citations, but only 10 publications met inclusion criteria and underwent data abstraction and critical appraisal. Methods: An adapted Cochrane Collaboration domain-based assessment tool was used to critically appraise the methodological components of each quantitative study, and the Mixed Methods Appraisal Tool was used to critically appraise qualitative and mixed-methods studies. Results: Condom use in men who have sex with men using pre-exposure prophylaxis is influenced by multiple factors. Studies indicate rates of sexually transmitted infections in treatment and placebo groups were high. Pre-exposure prophylaxis did not significantly change sexually transmitted infection rates between baseline and follow-up. Reporting of sexual risk improved when questionnaires were completed in private by clients. Our review found that pre-exposure prophylaxis may provide an opportunity for men who have sex with men to access sexual health care, testing, treatment and counselling services. We did not find any conclusive evidence that pre-exposure prophylaxis users increase sexual risk behaviours. Conclusion: The perception among healthcare providers that pre-exposure prophylaxis leads to increased sexual risk behaviours has yet to be confirmed. In order to provide effective sexual health services, clinicians need to be knowledgeable about pre-exposure prophylaxis as an HIV prevention tool. Relevance to clinical practice: In an era where HIV prevention methods are rapidly improving, strategies for sexually transmitted infection testing, treatment, counselling and prevention remain vital to improve health. All healthcare providers are uniquely positioned to promote sexual health through the dissemination of accurate information. © 2017 John Wiley & Sons Ltd	behaviour; health promotion; HIV; inequalities in health; risk groups; sexual health; sexuality	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Theses and Dissertations	2018	Freeborn, Kellie	Sexual Risk Behavior in Men who have Sex with Men in an Era of Pre Exposure Prophylaxis (PrEP) for HIV Prevention.	-	-	University of California	University of California	-	NA	NA	https://escholarship.org/uc/item/68n7h92q	Background - Pre-exposure prophylaxis (PrEP) provides protection against HIV transmission but not against other sexually transmitted infections (STIs), which disproportionally affect men who have sex with men (MSM).This dissertation examines the association of PrEP initiation with subsequent patterns of condom use and STIs in MSM. A cohort of 525 MSM, 18 years and older, who self-identified as either high or low risk for HIV acquisition was followed for 13 months after initiating PrEP at a sexual health clinic in San Francisco. Dissertation Aims - 1) review the literature to examine if PrEP is associated with changes in risk behavior in MSM; 2) determine the reasons why MSM who self-identify as low risk for HIV request PrEP; and 3) determine how PrEP use affects condom use and STIs rates in MSM who self-identify as high risk for HIV.Methods – A systematic literature review was completed. The cohort was followed over 13 months subsequent to initiating PrEP. Questionnaires were used to examine condom use and biological assays were used to measure the frequency and type of STIs. Frequencies and descriptive analyses were completed, and multilevel logistic regression modeling was used to predict associations of condom use and STIs before and after initiation of PrEP. Framework analysis was used to identify themes and to develop a descriptive understanding of why low-risk MSM initiated and remained on PrEP. Findings - No conclusive evidence was found that PrEP use leads to increased sexual risk behaviors. Overall, condom use decrease peaked at ~ 6 months and returned to baseline rates at ~12 months. Disparities in condom use and STI rates were observed within sub-populations of MSM, and condom use was found to be influenced by perceived risk. In both the low- and high-risk cohorts, anal GC/CT and syphilis decreased and pharyngeal GC/CT either remained constant or increased. MSM do not use PrEP solely to replace condoms, rather PrEP provides, peace of mind, sexual pleasure and safety and security.Conclusion - In order to improve sexual health for MSM PrEP, STI screening and condom use education should be tailored to meet differing needs of sub populations. Sexual health discussion should include education on substance use, transmission of pharyngeal GC/CT and how MSM perceive sexual risk. Further research is needed to assess when more intensive counselling regarding condom use would be beneficial, how MSM perceive sexual risk and ways to reduce pharyngeal infections. Article	2018	Fu R.; Owens D.K.; Brandeau M.L.	Cost-effectiveness of alternative strategies for provision of HIV preexposure prophylaxis for people who inject drugs	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001747	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044225480&doi=10.1097%2fQAD.0000000000001747&partnerID=40&md5=c759b19049b16bc4660eb2d3ed7bafd1	Background: Oral HIV preexposure prophylaxis (PrEP) has been recommended as a means of HIV prevention among people who inject drugs (PWIDs) but, at current prices, is unlikely to be cost-effective for all PWID. Objective: To determine the cost-effectiveness of alternative strategies for enrolling PWID in PrEP. Design: Dynamic network model that captures HIV transmission and progression among PWID in a representative US urban center. Outcome measures: HIV infections averted, discounted costs and quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratios. Intervention: We assume 25% PrEP coverage and investigate four strategies: first, random PWID are enrolled (Unselected Enrollment); second, individuals are randomly selected and enrolled together with their partners (Enroll Partners); third, individuals with the highest number of sexual and needle-sharing partnerships are enrolled (Most Partners); fourth, individuals with the greatest number of infected partners are enrolled (Most Positive Partners). Results: PrEP can achieve significant health benefits: compared with the status quo of no PrEP, the strategies gain 1114 QALYs (Unselected Enrollment), 2194 QALYs (Enroll Partners), 2481 QALYs (Most Partners), and 3046 QALYs (Most Positive Partners) over 20 years in a population of approximately 8500 people. The incremental cost-effectiveness ratio of each strategy compared with the status quo (cost per QALY gained) is $272 000 (Unselected Enrollment), $158 000 (Enroll Partners), $124 000 (Most Partners), and $101 000 (Most Positive Partners). All strategies except Unselected Enrollment are cost-effective according to WHO criteria. Conclusion: Selection of high-risk PWID for PrEP can improve the cost-effectiveness of PrEP for PWID. © Copyright 2018 Wolters Kluwer Health, Inc. A Mobile Health Strategy to Support Adherence to Antiretroviral Preexposure Prophylaxis	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2017.0255	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044386304&doi=10.1089%2fapc.2017.0255&partnerID=40&md5=8415ffa0c0a4d0e3130e4063f97233de	Preexposure prophylaxis is a highly protective HIV prevention strategy, yet nonadherence can significantly reduce its effectiveness. We conducted a mixed methods evaluation of a mobile health intervention (iText) that utilized weekly bidirectional text or e-mail support messages to encourage preexposure prophylaxis (PrEP) adherence among participants in the multi-site iPrEx open-label extension study. A convenience sample of PrEP users from the San Francisco and Chicago sites participated in a 12-week pilot study. Fifty-six men who have sex with men enrolled; a quarter of them were less than 30 years of age, 13% were black/African American, 11% were Latino, and most (88%) completed some college. Two-Thirds opted for text message delivery. Of the 667 messages sent, only 1 individual requested support; initial nonresponse was observed in 22% and was higher among e-mail compared to text message recipients. Poststudy, a majority of participants would recommend the intervention to others, especially during PrEP initiation. Moreover, younger participants and men of color were more likely to report that they would use the iText strategy if it were available to them. Several participants commented that while they were aware that the messages were automated, they felt supported and encouraged that "someone was always there." Study staff reported that the intervention is feasible to administer and can be incorporated readily into clinic flow. A pre-post intervention regression discontinuity analysis using clinic-based pill counts showed a 50% reduction in missed doses 95% confidence interval (CI) 16-71; p = 0.008 and 77% (95% CI 33-92; p = 0.007) when comparing pill counts at quarterly visits just before and after iText enrollment. A mobile health intervention using weekly bidirectional messaging was highly acceptable and demonstrated promising effects on PrEP adherence warranting further evaluation for efficacy in a randomized controlled trial. © Jonathan D. Essay	2018	Galea, Jerome T; Baruch, Ricardo; Brown, Brandon	¡PrEP Ya! Latin America wants PrEP, and Brazil leads the way.	The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(18)30011-0	https://dx.doi.org/10.1016/S2352-3018(18)30011-0	Brazil has long been at the forefront of HIV treatment and prevention in Latin America. It was the first country in the region to make highly active antiretroviral therapy freely available 1 and participated in the iPrEx study, 2 which reported the efficacy of pre-exposure prophylaxis (PrEP) with daily oral emtricitabine and tenofovir disoproxil fumarate to prevent HIV acquisition in men who have sex with men (MSM) and transgender women. In The Lancet HIV, Beatriz Grinsztejn and colleagues 3 report another first in Latin America: a demonstration trial of PrEP among MSM and transgender women vulnerable to HIV under real-world conditions in the Brazilian public health system. The results, namely that PrEP was effective, drug adherence was good, and sexual risk compensation was not observed, will surprise few in the HIV prevention field. 3 Multiple studies show that MSM and transgender women are willing to use PrEP, have good drug adherence, and do not start having riskier sex. 4 However, we think the importance of this study should be to catalyse the rest of the region to implement PrEP. Article	2018	Gallay, Philippe A; Chatterji, Udayan; Kirchhoff, Aaron; Gandarilla, Angel; Pyles, Richard B; Baum, Marc M; Moss, John A	Protection Efficacy of C5A Against Vaginal and Rectal HIV Challenges in Humanized Mice.	Open Virology Journal	-	-	-	-	1874-3579	10.2174/1874357901812010001	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5842390	INTRODUCTION: In the absence of a vaccine, there is an urgent need for the identification of effective agents that prevent HIV transmission in uninfected individuals. Non-vaccine Biomedical Prevention (nBP) methods, such as topical or systemic pre-exposure prophylaxis (PrEP), are promising strategies to slow down the spread of AIDS. METHODS: In this study, we investigated the microbicidal efficacy of the viral membrane-disrupting amphipathic SWLRDIWDWICEVLSDFK peptide called C5A. We chose the bone marrow/liver/thymus (BLT) humanized mouse model as vaginal and rectal HIV transmission models. RESULTS: We found that the topical administration of C5A offers complete protection against vaginal and rectal HIV challenges in humanized mice. After demonstrating that C5A blocks genital HIV transmission in humanized mice, we examined the molecular requirements for its microbicidal property. We found that the removal of four amino acids on either end of C5A does not diminish its microbicidal efficacy. However, the removal of four amino acids at both the ends, abolishes its capacity to prevent vaginal or rectal HIV transmission, suggesting that the length of the peptide is a critical parameter for the microbicidal activity of C5A. Moreover, we demonstrated that the amphipathicity of the helical peptide as well as its hydrophobic surface represents key factors for the microbicidal activity of C5A in humanized mice. CONCLUSION: With its noncellular cytotoxic activity, its property of neutralizing both HSV and HIV, and its unique mechanism of action that disrupts the stability of the viral membrane, C5A represents an attractive multipurpose microbicidal candidate to be combined with other anti-HIV agents including antiretrovirals. Article	2018	Gandhi, Monica; Bacchetti, Peter; Rodrigues, Warren C.; Spinelli, Matthew; Koss, Catherine A.; Drain, Paul K.; Baeten, Jared M.; Mugo, Nelly R.; Ngure, Kenneth; Benet, Leslie Z.; Okochi, Hideaki; Wang, Guohong; Vincent, Michael	Development and Validation of an Immunoassay for Tenofovir in Urine as a Real-Time Metric of Antiretroviral Adherence.	EClinicalMedicine	-	-	-	-	2589-5370	https://doi.org/10.1016/j.eclinm.2018.08.004	https://pubmed.ncbi.nlm.nih.gov/30906930/	BACKGROUND: Pharmacologic adherence measures were critical to the interpretation of the tenofovir (TFV)-disoproxil-fumarate/emtricitabine (TDF/FTC) PrEP trials. These measures are being incorporated into PrEP demonstration projects, but currently-available metrics in plasma, cells, hair or urine involve expensive and time-intensive mass-spectrometry (MS)-based methods. No point-of-care method to assess PrEP adherence in real-time has yet been implemented. Antibody-based tests allow for low-cost, easy-to-perform, point-of-care drug detection. In this study, we developed an antibody-based TFV immunoassay and evaluated its test characteristics among individuals taking TDF/FTC. METHODS: We synthesized possible immunogens based on TFV's molecular structure, injected rabbits with the conjugated derivatives, and bled them monthly for subsequent ELISA-testing for TFV-specific antibodies. We purified an antibody with specific TFV binding and created dose-response curves for ELISA-quantification. We then quantified TFV in urine from human participants not taking TDF/FTC and from individuals taking daily TDF/FTC 300 mg/200 mg for 7 days with a 7-day washout period using ELISA with this TFV-specific antibody. ELISA results were compared with the gold-standard test for TFV detection/quantification using liquid-chromatography-tandem-MS (LC-MS/MS). FINDINGS: None of the urine samples from 115 participants not taking TDF/FTC showed ELISA- reactivity, indicating 100% specificity (95% CI 97-100%) of the immunoassay. Among participants taking TDF/FTC, 67 of 70 samples positive by LC-MS/MS were positive by the ELISA-immunoassay for an estimated diagnostic sensitivity of 96% (95% CI 88-99%). The precision of the assay was high (coefficient of variationb15%). The rank correlation between ELISA and LC-MS/MS values in the 70 quantitative urine TFV levels positive by LC-MS/MS across a wide range of concentrations among participants on TDF/FTC was high (r = 0.96). INTERPRETATION: Our antibody-based immunoassay for measuring TFV in urine performed well compared to the gold-standard of LC-MS/MS among individuals taking TDF/FTC. A sensitive and specific immunoassay paves the way for real-time monitoring/feedback on recent adherence to TFV-based regimens, which should optimize interpretation and outcomes during PrEP and ART roll-out. Article	2018	Gantenberg J.R.; King M.; Montgomery M.C.; Galárraga O.; Prosperi M.; Chan P.A.; Marshall B.D.L.	Improving the impact of HIV pre-exposure prophylaxis implementation in small urban centers among men who have sex with men: An agent-based modelling study	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0199915	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049597905&doi=10.1371%2fjournal.pone.0199915&partnerID=40&md5=45bf4b2a47ab3100ea8cae23dc8e9bd8	Objectives Identifying prescribing strategies that improve the efficiency of PrEP should increase its impact at the population level. This study identifies PrEP allocation criteria that most effectively reduce 10-year HIV incidence by 25%, in accordance with the US National HIV/AIDS Strategy's goal for the proportionate reduction in new diagnoses. Methods We used a discrete-time stochastic agent-based model to simulate several PrEP engagement strategies. The model represented MSM aged 15–74 in Rhode Island and was calibrated to statewide prevalence from 2009–2014. We simulated HIV transmission in the absence of PrEP and compared the following PrEP engagement scenarios: 1) allocation to the current patient population; 2) random allocation; 3) allocation to MSM with greater than 5 sexual partners in one year; 4) allocation to MSM with greater than 10 sexual partners in one year. For each scenario and coverage level we estimated the number and proportion of infections averted and the person-years on PrEP per averted infection. Results In 2014, HIV prevalence among MSM was between 4% and 5%. In the No PrEP scenario 826 new infections (95% simulation limits SL: 711, 955) occurred over 10 years, with an incidence rate of 3.51 per 1000 person-years (95% SL: 3.00, 4.08). Prevalence rose to 7.4% (95% SL: 6.7, 8.1). None of the PrEP scenarios reduced new HIV infections by 25% while covering less than 15% of the HIV-uninfected population. At 15% coverage, allocating PrEP to the current patient population, MSM with greater than 5 sexual partners in a year, and MSM with greater than 10 partners reduced new infections by at least 25%, requiring 161 (95% SL: 115, 289), 150 (95% SL: 107, 252), and 128 (95% SL: 100, 184) person-years on PrEP per averted infection, respectively. Conclusions Engaging MSM with high numbers of sexual partners would improve the population-level impact and efficiency of PrEP in settings where PrEP coverage remains low. However, the sustained population-level PrEP coverage needed to reduce new infections by 25% is substantially higher than current levels of PrEP uptake. © 2018 Gantenberg et al. Article	2018	Garner, Will; Wilson, Brigid M; Beste, Lauren; Maier, Marissa; Ohl, Michael E; Van Epps, Puja	Gaps in Preexposure Prophylaxis Uptake for HIV Prevention in the Veterans Health Administration.	American Journal of Public Health	-	-	-	-	1541-0048	10.2105/AJPH.2018.304788	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6215372	OBJECTIVES: To report demographics, regional variations, and indications for preexposure prophylaxis (PrEP) use for HIV prevention in the Veterans Health Administration (VHA). METHODS: We identified persons initiating tenofovir/emtricitabine for the PrEP indication in the United States between July 2012 and April 2016 in a VHA national database. We stratified PrEP use by provider type and VHA region. We calculated PrEP initiation rate for each region with VHA population data. RESULTS: Of the 825 persons who initiated PrEP during the observation period, 67% were White and 76% were men who have sex with men. People who inject drugs and transgender persons represented less than 1% each of the cohort. The majority of PrEP initiations were clustered in 3 states, leading with California (28%) followed by Florida (9%) and Texas (8%). The Southeast had one of the lowest PrEP rates at 10 PrEP initiations per 100 000 persons in care. Infectious disease specialists issued more than two thirds of index PrEP prescriptions. CONCLUSIONS: Uptake of PrEP in the VHA is uneven along geographic and risk categories. Understanding the reasons behind these gaps will be key in expanding the use of this important prevention tool. Article	2018	Garnett, Matthew; Hirsch-Moverman, Yael; Franks, Julie; Hayes-Larson, Eleanor; El-Sadr, Wafaa M; Mannheimer, Sharon	Limited awareness of pre-exposure prophylaxis among black men who have sex with men and transgender women in New York city	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1363364	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85027174218&doi=10.1080%2f09540121.2017.1363364&partnerID=40&md5=0be534a10efdb075cfc366b07e326caa	Awareness of Pre-exposure prophylaxis (PrEP) was assessed among a cohort of substance-using black men who have sex with men and transgender women (MSM/TGW) participating in the STAR Study, which recruited black MSM/TGW in New York City for HIV testing and linked HIV-infected individuals into care from July 2012 to April 2015. Sociodemographic, psychosocial, known HIV risk factors, and PrEP awareness were assessed among participants. Multivariable logistic regression was conducted to assess factors associated with PrEP awareness. Of 1673 participants, median age was 43 years and 25% were under age 30. Most participants (85.8%) reported having insufficient income for basic necessities at least occasionally, 54.8% were homeless, and 71.3% were unemployed. Awareness of PrEP was reported among 18.2% of participants. PrEP awareness was associated with younger age (adjusted odds ratio aOR 0.87, per 5 years), gay identity (aOR 2.46), higher education (aOR 1.70), more frequent past HIV testing (aOR 3.18), less HIV stigma (aOR 0.61), less hazardous/harmful alcohol use (aOR 0.61), and more sexual partners (aOR 1.04, per additional partner in past 30 days). In this substance-using black MSM/TGW cohort with high rates of poverty and homelessness, PrEP awareness was low. This study demonstrates the need for targeted dissemination of PrEP information to key populations to increase awareness and ultimately improve uptake and utilization of PrEP. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Garrett K.L.; Chen J.; Maas B.M.; Cottrell M.L.; Prince H.A.; Sykes C.; Schauer A.P.; White N.; Dumond J.B.	A pharmacokinetic/pharmacodynamic model to predict effective HIV prophylaxis dosing strategies for people who inject drugs	Journal of Pharmacology and Experimental Therapeutics	-	-	-	223565	10.1124/jpet.118.251009	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054370059&doi=10.1124%2fjpet.118.251009&partnerID=40&md5=120ac6da71ca3b3d75eb681bb68eb4a0	The goal of this work was to evaluate dosing strategies for tenofovir disoproxil fumarate (TDF), tenofovir alafenamide (TAF), and emtricitabine (FTC) for pre-exposure prophylaxis (PrEP) with injection drug use with a pharmacokinetic/pharmacodynamics analysis of concentration data generated from two single-dose clinical studies conducted in healthy women. Population pharmacokinetic models were developed using measured intracellular metabolite, endogenous nucleotide competitors, and extracellular parent drug concentrations. Intracellular metabolite concentrations were normalized to endogenous competitors and compared with an EC90 target for PrEP efficacy. Monte Carlo simulations were used to select effective dose strategies of single agents (TAF, TDF, and FTC) and combinations (TDF 1 FTC and TAF 1 FTC). Daily, intermittent, and event-driven dosing regimens at varying dosage amounts were explored. When combined, TDF + FTC and TAF + FTC both provided quick (0.5 hours) and durable (up to 84 and 108 hours, respectively) protection of >99% after a single dose. When dosed twice per week, protection remained at 100%. Single-agent regimens provided lower estimates of protection than either combination tested. Here, the application of pharmacokinetic modeling to in vitro target concentrations demonstrates the added utility of including FTC in a successful PrEP regimen. While no TAF-based PrEP data are currently available for comparison, this analysis suggests TAF 1 FTC could completely protect against percutaneous exposure with as little as two doses per week. © 2018 American Society for Pharmacology and Experimental Therapy. Article	2018	Getty, Carol-Ann; Subramaniam, Shrinidhi; Holtyn, August F; Jarvis, Brantley P; Rodewald, Andrew; Silverman, Kenneth	Evaluation of a Computer-Based Training Program to Teach Adults at Risk for HIV About Pre-Exposure Prophylaxis.	AIDS Education and Prevention	-	-	-	1943-2755	10.1521/aeap.2018.30.4.287	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6247787	This study developed a computer-based program to teach HIV prevention behaviors and raise awareness of pre-exposure prophylaxis (PrEP) among individuals at risk for HIV. The program was divided into modules containing educational material and multiple-choice questions. Participants received immediate feedback for responses and incentives for correct responses to multiple-choice questions. Participants trained on each module until they met speed and accuracy criteria. The modules were divided into: Course 1 (HIV), Course 2 (PrEP), and Course 3 (HIV risk behaviors). Tests of content from all three courses were delivered before and after participants completed each course. Test scores on the content delivered in the courses improved only after participants completed training on each course. HIV and PrEP knowledge was initially low and increased following completion of each part of the program. Computer-based training offers a convenient and effective approach to promoting HIV prevention knowledge, including use of PrEP. Theses and Dissertations	2018	Giguère, Katia	Mesure objective des rapports sexuels non protégés et caractérisation du sous-rapportage des rapports non protégés chez les travailleuses du sexe au Bénin à l'aide de marqueurs biologiques de l'exposition au sperme	-	-	Université Laval	-	NA	NA	http://hdl.handle.net/20.500.11794/34010	Les rapports sexuels non protégés (RSNP) sont un facteur de risque prédominant pour l'infection par le virus de l'immunodéficience humaine (VIH) et doivent donc être évalués de la façon la plus valide possible dans le cadre des études de prévention du VIH. À ce jour, le questionnaire demeure l'outil le plus utilisé pour documenter les comportements sexuels. Or, l'auto-rapportage des comportements sexuels est sujet à des biais de rappel et de désirabilité sociale. L'usage de biomarqueurs de l'exposition au sperme pourrait aider à pallier ces biais. L'antigène prostatique spécifique (PSA) et l'ADN chromosomique Y (ADNch-Y) sont les deux biomarqueurs de l'exposition au sperme les mieux caractérisés à ce jour. La PSA et l'ADNch-Y sont détectables jusqu'à respectivement deux et 14 jours suivant un RSNP. Dans le cadre d'une étude prospective de démonstration visant à vérifier la faisabilité d'implanter le traitement précoce comme prévention (early antiretroviral therapy : E-ART) et la prophylaxie pré-exposition (pre-exposure prophylaxis : PrEP) chez les travailleuses du sexe (TS) professionnelles de Cotonou au Bénin, le sous-rapportage des RSNP était anticipé de la part des participantes, de même qu'un potentiel changement dans les RSNP en cours de suivi dans le groupe PrEP. Nos objectifs étaient donc de valider l'autorapportage des RSNP à l'aide de la PSA et de l'ADNch-Y; de comparer le sous-rapportage des RSNP sur les périodes de rappel de deux et 14 jours; et d'évaluer les tendances de RSNP dans le groupe PrEP. Nous avons aussi pour objectif de comparer la capacité de détection du RSNP d'un nouveau test de détection, soit une PCR nichée ciblant la famille de gènes homologues testis-specific protein Y-encoded (n-TSPY), à celle de six autres méthodes couramment utilisées à des fins de détection de l'exposition récente au sperme. Au recrutement de l'étude E-ART/PrEP et sur une période de 24 mois de suivi, les RSNP survenus dans les deux et 14 derniers jours ont été évalués à chaque six mois par questionnaire et par détection de la PSA et de l'ADNch-Y. Lorsqu'une participante ne rapportait pas de RSNP dans les deux (ou 14) derniers jours, mais qu'elle était testée positive pour la PSA (ou l'ADNch-Y), elle était considérée comme ayant sous-rapporté les RSNP des deux (ou 14) derniers jours. Une régression de Poisson robuste a été utilisée pour comparer le sous-rapportage sur les deux périodes de rappel. Les tendances de RSNP en fonction des différentes mesures de RSNP ont été évaluées à l'aide d'une régression log-binomiale. Des équations d'estimation généralisée (Generalized estimating equation : GEE) ont été appliquées pour tenir compte de la dépendance des observations. Au recrutement, nous avons observé une prévalence d'environ 20% de sous-rapportage des RSNP chez les TS de Cotonou, mais aucune différence statistiquement significative du sous-rapportage des RSNP entre les deux périodes de rappel. Certains de nos résultats suggèrent que les performances relatives de chacun des biomarqueurs pour détecter les RSNP sur sa…	Relations sexuelles non protégées – Bénin; Travailleuses du sexe – Auto-évaluation – Bénin; Marqueurs biologiques; Biais dans les réponses; Antigène prostatique spécifique; Chromosome Y; ADN; Sperme	French	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	-	-	Quantitative
Article	2018	Gilmour, Judy; Henley, Rebecca; Lowe, Michele; Lowe, Michele, RN, MN	HIV, PEP and PrEP: A Guide for Acute Presentations	Emergency Nurse New Zealand	-	-	-	11762691	NA	https://www.proquest.com/scholarly-journals/hiv-pep-prep-guide-acute-presentations/docview/2449275463/se-2?accountid=8113	Treatment of HIV with ante retroviral medications has led to markedly improved outcomes for people living with HIV. However, in New Zealand the rate of newly reported transmissions has been increasing. New Zealand now follows a test and treat philosophy that sees the commencement of ante retroviral medication at the time of testing when high risk of exposure is identified. Patients are directed to emergency departments for testing and commencement of PEP (post exposure prophylaxis). This article discusses HIV in the New Zealand context and new initiatives to reduce HIV transmission. Article	2018	Gilson R.I.; Clutterbuck D.J.; Chen Z.E.	Demand for pre-exposure prophylaxis for HIV and the impact on clinical services: Scottish men who have sex with men perspectives	International journal of STD & AIDS	-	-	-	9564624	10.1177/0956462417723817	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041474278&doi=10.1177%2f0956462417723817&partnerID=40&md5=7128c8733619b4c245fe7b7eec9e7f31	There is a lack of data on ability and willingness of men who have sex with men (MSM) to self-fund HIV pre-exposure prophylaxis (PrEP). We aimed to explore how many eligible (PROUD study criteria) men may want PrEP and how many lower-risk MSM would be willing and able to self-fund this intervention. A self-completed anonymous questionnaire was distributed to MSM populations attending services. Of 377 participants, 81.5% were aware of PrEP. Fifty-three (15.5 %) were eligible, of whom 43 (81%) were very/extremely likely to want it. Of those ineligible, 229 (80%) were aware of PrEP and 106 (37.3%) were very/extremely likely to want it. Of eligible respondents 23% would be willing and able to pay at least £50 a month for PrEP. Of ineligible respondents this proportion was 21%. Our survey revealed high levels of awareness, understanding and willingness to take PrEP among MSM at high and lower risk of HIV acquisition. It indicated that over 70% of high-risk men would be unwilling or unable to self-fund PrEP, should it not be available on the NHS. For lower-risk MSM we estimated that capacity requirements for monitoring self-funded PrEP will be 50% higher than numbers eligible for PrEP. These factors will need to be taken into account when planning services. © 2017, © The Author(s) 2017. Article	2018	Giovenco, Danielle; Kuo, Caroline; Underhill, Kristen; Hoare, Jacqueline; Operario, Don	"The Time Has Arrived": Perceptions of Behavioral Adjustments in the Context of Pre-Exposure Prophylaxis Availability Among Adolescents in South Africa.	AIDS Education and Prevention	-	-	-	1943-2755 0899-9546	10.1521/aeap.2018.30.6.463	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6501564	Antiretroviral pre-exposure prophylaxis (PrEP) holds enormous potential to reduce HIV acquisition in key populations globally. We conducted an exploratory PrEP acceptability study using qualitative methodology among adolescents and service providers in the Western Cape Province of South Africa to inform future PrEP implementation challenges in South Africa and other high-prevalence African countries. Semistructured focus groups and in-depth individual interviews were conducted among 57 adolescents 16-17 years of age, living with and without HIV, and 25 clinical service providers. Adolescents and service providers expressed concerns that the availability of PrEP would lead to sexual disinhibition and a reduction in condom use among adolescents. Unexpected positive impacts included predictions that PrEP might encourage disclosure in serodiscordant partnerships and help normalize pill-taking in the community. Careful age, gender, and developmentally appropriate messaging will be needed to ensure adolescents understand partial efficacy and view PrEP as a component of combination prevention. Article	2018	Girometti N.; McCormack S.; Devitt E.; Gedela K.; Nwokolo N.; Patel S.; Suchak T.; McOwan A.; Whitlock G.	Evolution of a pre-exposure prophylaxis (PrEP) service in a community-located sexual health clinic: Concise report of the PrEPxpress	Sexual Health	-	-	-	14485028	10.1071/SH18055	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055577577&doi=10.1071%2fSH18055&partnerID=40&md5=bc44d75ec60ce95d862cb6ef140ea75b	Screening and treatment of sexually transmissible infections, including HIV, are free in the UK nations; pre-exposure prophylaxis (PrEP) became free in England in October 2017 through the PrEP Impact trial. Doctor-led PrEP clinics started at 56 Dean Street in September 2015, with the drug purchased privately at full price. The service was expanded to other staff to support initiation and monitoring of increasing numbers of attendees purchasing PrEP from online pharmacies. Nonetheless, when the clinic was given a target of 1700 for the PrEP Impact trial, it was clear this could not be achieved in a timely manner through 56 Dean Street alone. To prepare for the trial, all staff with HIV testing competencies were trained in good clinical practice and trial-specific procedures, and a patient group directive was approved to facilitate nurse prescribing and dispensing. Electronic pro formas to capture eligibility for starting or continuing PrEP were adapted for the Dean Street Express clinic, with some information collected directly from service users using touch screens. These interventions, together with an update to the 2016 information leaflet developed by the community, enabled enrolment and follow-up of 1700 participants in 4 months. PrEP advice and monitoring were easily accommodated in the 56 Dean Street sexual health service, but did require additional training and approval for nurse prescribing and dispensing drug in order to achieve the target, which still fell short of the demand. © 2018 CSIRO. Article	2018	Glidden D.V.; Mulligan K.; McMahan V.; Anderson P.L.; Guanira J.; Chariyalertsak S.; Buchbinder S.P.; Bekker L.-G.; Schechter M.; Grinsztejn B.; Grant R.M.	Metabolic effects of preexposure prophylaxis with coformulated tenofovir disoproxil fumarate and emtricitabine	Clinical Infectious Diseases	-	-	-	10584838	10.1093/cid/ciy083	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048510668&doi=10.1093%2fcid%2fciy083&partnerID=40&md5=b11c9a19bcb9caec28531e431c3a3768	Background Antiretroviral drugs have been associated with changes in lipids, fat mass and dat distribution. Tenofovir disoproxil fumarate (TDF) has been shown to have a more favorable metabolic profile than other drugs in its class. However, the metabolic effects of TDF in preexposure prophylaxis (PrEP) are unknown. Methods We evaluated the effects of TDF/emtricitabine (FTC) on lipids and body composition in a blinded, placebo-controlled PrEP trial. Participants enrolled in a metabolic subcohort (N = 251, TDF/FTC; N = 247, placebo) consented to fasting lipid panels, dual-energy X-ray absorptiometry scans for body composition, and pharmacologic testing of drug metabolites at baseline and every 24 weeks thereafter. Results Lean body mass was stable and unaffected by TDF/FTC. Body weight increased in both groups but was lower on TDF/FTC through week 72. This difference was explained by lower fat accumulation on TDF/FTC. The net median percent difference (standard error, P value) for TDF/FTC vs placebo at week 24 was -0.8% (0.4%, P =.02),+0.3% (0.4%, P =.46), and -3.8% (1.4%, P =.009) for total, lean, and fat mass, respectively. There was no apparent differential regional fat accumulation on TDF/FTC. Decreases in cholesterol, but not triglycerides, were seen in TDF/FTC participants, with detectable drug levels compared to placebo. Conclusions TDF/FTC for PrEP showed cholesterol reductions and appeared to transiently suppress the accumulation of weight and body fat compared to placebo. There was no evidence of altered fat distribution or lipodystrophy during daily oral TDF/FTC PrEP. © The Author(s) 2018. Article	2018	Gnatienko N.; Wagman J.A.; Cheng D.M.; Bazzi A.R.; Raj A.; Blokhina E.; Toussova O.; Forman L.S.; Lioznov D.; Bridden C.; Sullivan M.; Bryant K.; Samet J.H.; Tsui J.I.	Serodiscordant partnerships and opportunities for pre-exposure prophylaxis among partners of women and men living with HIV in St. Petersburg, Russia	PLOS One	-	-	-	19326203	10.1371/journal.pone.0207402	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056566686&doi=10.1371%2fjournal.pone.0207402&partnerID=40&md5=75aeb56255ea62ef37729a21602fa133	Objective To describe the frequency of being partnered and having an HIV-negative partner, and whether this differed by gender, among a cohort of persons living with HIV (PLWH) who have ever injected drugs; to describe awareness of HIV pre-exposure prophylaxis (PrEP) and perceived partner interest in PrEP. Setting Secondary analyses of an observational cohort study of PLWH who have ever injected drugs in St. Petersburg, Russia. Methods Primary outcomes were 1) being partnered and 2) being in a serodiscordant partnership. The main independent variable was gender. Multivariable GEE logistic regression models were fit for binary outcomes, adjusted for age, income, education, and recent opioid use. Descriptive analyses were performed for partners' HIV status, substance use, sex risk behaviors, and awareness of PrEP for a subset of participants. Results At baseline, 50% (147/296) reported being in a partnership, and of those, 35% were in a serodiscordant partnership. After adjustment, women had significantly higher odds of being partnered compared to men (aOR = 3.12; 95% CI: 1.77, 5.51), but there were no significant gender differences in the odds of being in a serodiscordant partnership (aOR = 0.58; 95% CI: 0.27, 1.24). Among a sub-sample of participants queried (n = 56), 25% were aware of PrEP for prevention of sexual HIV transmission and 14% for prevention of injection-related transmission. Conclusion Although half of our sample were partnered and one third of these partnerships were serodiscordant, PrEP awareness was low. Substantial opportunities for HIV prevention exist among PLWH who have ever injected drugs in Russia and their HIV-negative partners. Given the high proportion of HIV-negative partners among this ART-naïve sample, efforts to address the associated inherent risks, such as couples-based interventions, are needed to increase condom use, PrEP awareness, or uptake of other HIV-prevention modalities (e.g., ART for the HIV-positive partner). Article	2018	Goedel W.C.; King M.R.F.; Lurie M.N.; Nunn A.S.; Chan P.A.; Marshall B.D.L.	Effect of racial inequities in pre-exposure prophylaxis use on racial disparities in HIV incidence among men who have sex with men: A modeling study	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001817	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054888860&doi=10.1097%2fQAI.0000000000001817&partnerID=40&md5=bd39a6595ab08c5765f47599253e6a3a	Background: Pre-exposure prophylaxis (PrEP) uptake has been slow among African American men who have sex with men (AAMSM) in the United States. We used an agent-based model (ABM) to simulate race-specific PrEP coverage to estimate their impact on racial disparities in HIV incidence among MSM in Atlanta, GA. Methods: An ABM was constructed to simulate HIV transmission in a dynamic network of 10,000 MSM over 10 years, beginning in 2015. We modeled a base scenario with estimated PrEP coverage of 2.5% among AAMSM and 5.0% among white MSM (WMSM). We then compared HIV incidence over 10 years and calculated a disparity ratio of AAMSM to WMSM incidence rates across varying PrEP scale-up scenarios, with equal and unequal coverage among AAMSM and WMSM. Results: Assuming current coverage remains constant, the model predicts HIV incidence rates of 2.95 and 1.76 per 100 person-years among AAMSM and WMSM, respectively, with a disparity ratio of 1.68. If PrEP coverage was to increase 6-fold without addressing inequities in PrEP uptake, the model predicts incidences of 2.65 and 1.34, corresponding to a mean decrease of 10.4% and 24.0% in HIV incidence, respectively. This stronger benefit for WMSM increased the disparity ratio to 1.98. Equal PrEP coverage among AAMSM and WMSM resulted in lower incidence rates overall with lower disparity ratios. Conclusions: Lower uptake among AAMSM relative to WMSM may limit the population-level impact of PrEP use among AAMSM, which may ultimately culminate in wider racial disparities in HIV incidence among MSM. © 2018 Wolters Kluwer Health, Inc. Article	2018	Goedel W.C.; Schneider J.A.; Hambrick H.R.; Kreski N.T.; Morganstein J.G.; Park S.H.; Mgbako O.; Duncan D.T.	Are Anal Sex Roles Associated with Preferences for Pre-Exposure Prophylaxis Administration Modalities Among Men Who Have Sex with Men?	Archives of Sexual Behavior	-	-	-	40002	10.1007/s10508-017-1083-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85035764393&doi=10.1007%2fs10508-017-1083-5&partnerID=40&md5=d1094f13d08eb1698dcb9e88637012ca	The current study sought to examine awareness of, willingness to use, and preferences for available and theoretical administration modalities for HIV pre-exposure prophylaxis (PrEP) and the association of anal sex roles with these concepts among a sample of men who have sex with men (MSM) in Paris, France. Broadcast advertisements were placed on a popular geosocial-networking smartphone application for MSM to direct users to complete a Web-based survey. MSM answered questions on their recent engagement in condomless anal intercourse and awareness of and willingness to use PrEP in the form of once daily and event-driven pill regimens, long-acting injections, and penile and rectal microbicides as well as sexual roles. Multinomial regression models were fit to assess the association between behaviorally classified anal sexual role and preference for one of these biomedical prevention modalities. A total of 482 HIV-uninfected MSM completed the survey, 48.1% of whom engaged in some form of condomless anal intercourse in the preceding 3 months. Most respondents (85.3%) had heard of once daily PrEP, but fewer respondents had heard of other PrEP modalities. Assuming equal effectiveness, long-acting injections were the most commonly preferred (21.8%). Behaviorally defined "bottom" and "versatile" MSM more frequently preferred long-acting injections (32.9% of "bottoms" and 25.3% of "versatiles"). The development of long-acting injections to deliver antiretroviral drugs and topical microbicides may offer more convenient and acceptable options for HIV prevention among MSM, as MSM in this sample were willing to use them and would prefer to use them over currently available pill regimens. © 2017, Springer Science+Business Media, LLC. Article	2018	Golub S.A.; Lelutiu-Weinberger C.; Surace A.	Experimental Investigation of Implicit HIV and Preexposure Prophylaxis Stigma: Evidence for Ancillary Benefits of Preexposure Prophylaxis Use	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001592	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061851354&doi=10.1097%2fQAI.0000000000001592&partnerID=40&md5=08cb29774b7e11d8d6b027cd2af52eca	Background: Preexposure prophylaxis (PrEP) stigma (ie, negative attitudes toward PrEP users) has been widely documented and is considered a significant barrier to implementation. However, few studies have examined PrEP stigma using implicit measures designed to reduce demand characteristics in responding. This study examined implicit PrEP- and HIV-related stigma among gay and bisexual men using geospatial social networking applications (ie, "hookup apps"). Methods: Participants were presented with 4 simulated online profiles (pretested for comparability) paired with each of the following characteristics: HIV negative, HIV positive, on PrEP, or substance user. Participants rated the profiles on attractiveness, desirability, trustworthiness, likelihood of condom use, and riskiness of sex. Results: There was no evidence of PrEP-related stigma, ie, participants did not rate profiles of PrEP users more negatively than profiles of HIV-negative individuals not disclosing PrEP use. However, profiles of HIV-positive individuals were rated significantly less attractive and desirable than HIV-negative or PrEP profiles. When the sample was split by history of PrEP use, negative ratings of HIV-positive profiles remained only among participants who had never taken PrEP. Participants with any history of PrEP use demonstrated no difference in ratings by HIV status. Conclusion: These data provide the first empirical evidence for lower HIV stigma among PrEP users. Individuals who have used PrEP may "see" HIV-positive individuals differently than those without a history of PrEP use. The lack of evidence for PrEP-related stigma is encouraging and suggests that negative stereotypes about PrEP users may not extend to negative implicit judgments about them on social networking sites. Article	2018	Golub, Sarit A	PrEP Stigma: Implicit and Explicit Drivers of Disparity	Current HIV/AIDS Reports	-	-	-	15483568	10.1007/s11904-018-0385-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042174282&doi=10.1007%2fs11904-018-0385-0&partnerID=40&md5=642403ab99659080769b5b08e9c6b96f	Purpose of Review: Despite its promise as an HIV prevention strategy, PrEP uptake remains slow, especially among highest priority populations. One factor that may be impeding implementation and driving disparities is PrEP-related stigma. This paper reviews the role of PrEP-related stigma in PrEP access, adherence, and persistence and examines its antecedents and consequences. Recent Findings: Although PrEP stigma is often experienced at the community level (i.e., by potential and current users), it can be reinforced and even amplified by public health programs, policy, and research. PrEP stigma disproportionately impacts disadvantaged groups and impedes scalability by influencing behavior of both patients and providers. Summary: Reducing PrEP stigma and its negative impact on the epidemic requires a significant shift in perspective, language, and programs. Such a shift is necessary to ensure broader reach of PrEP as a prevention strategy and improve its utilization by the individuals who need it most. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Gonçalves R.B.; Marreiros A.; Augusto G.F.	Portuguese health care providers' knowledge, attitudes, and acceptability of HIV pre-exposure prophylaxis	HIV and AIDS Review	-	-	-	17301270	10.5114/hivar.2018.80256	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058843546&doi=10.5114%2fhivar.2018.80256&partnerID=40&md5=0ca90c68acfb9ceb0ec6957d229fec1d	Introduction: Evidence shows that pre-exposure prophylaxis (PrEP) is highly effective in preventing sexually acquired human immunodeficiency virus (HIV) infection. Whilst its implementation is limited to the US and some countries where demonstration projects have taken place, PrEP has recently been introduced in Portugal. Successful implementation of PrEP requires actively engaging and involving of health care providers (HCP) in Portugal, yet little is known about their knowledge, attitudes, and acceptability towards this novel intervention. Material and methods: An online survey of convenience-sampled Portuguese HCP was conducted in January 2016, prior to PrEP implementation, to determine their knowledge, attitudes, practices, and acceptability of PrEP. Results: A total of 96 respondents nationwide took part in the study, of whom the majority were females (60.3%), specialist physicians/junior doctors (39%/53%), working in the field of HIV for 1 to 5 years (42.3%). Over half (51%) considered having an average or high knowledge of PrEP, and this was more common amongst infectious diseases specialists. Major concerns regarding PrEP implementation included a rise in sexually transmitted infections and increased antiretroviral resistance. Despite only 31.3% being asked about PrEP in the future, the majority (75%) considered that PrEP should be made available in Portugal. The main barrier to PrEP implementation was the lack of knowledge and information to HCP. Conclusions: Portuguese HCP demonstrated variable degrees of knowledge around PrEP, yet most would support its introduction in the country. Concerns were raised about potential consequences of PrEP roll out as well as implementation challenges that ought to be addressed before PrEP introduction. © 2018 Termedia Publishing House Ltd.. Article	2018	Goodreau, Steven M; Hamilton, Deven T; Jenness, Samuel M; Sullivan, Patrick S; Valencia, Rachel K; Wang, Li Yan; Dunville, Richard L; Barrios, Lisa C; Rosenberg, Eli S	Targeting Human Immunodeficiency Virus Pre-Exposure Prophylaxis to Adolescent Sexual Minority Males in Higher Prevalence Areas of the United States: A Modeling Study	Journal of Adolescent Health	-	-	-	1054139X	10.1016/j.jadohealth.2017.09.023	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85039063550&doi=10.1016%2fj.jadohealth.2017.09.023&partnerID=40&md5=a45921c7ca6151167fb8eacfbf8da843	Purpose: Pre-exposure prophylaxis (PrEP) is an effective and safe intervention to prevent human immunodeficiency virus (HIV) transmission in men who have sex with men; current Centers for Disease Control and Prevention guidelines indicate its use among high-risk adults. Adolescent sexual minority males (ASMM) also have significant HIV risk, but implementation strategies are likely to differ for this population. We aimed to estimate impact and efficiency of PrEP for ASMM in higher prevalence US settings, using a variety of implementation strategies and assumptions about coverage, adherence, and background prevalence. Methods: We develop a stochastic, dynamic, network-based model, parametrized using numerous ASMM behavioral and clinical data sources. We simulate 10 years with and without PrEP, comparing percent of incident infections averted (impact) and number of person-years on PrEP per infection averted (efficiency). Results: Our main scenario (PrEP for 16- to 18-year-old ASMM, initiating PrEP 6 months after first anal intercourse, 40% coverage, adherence profiles from the ATN 113 trial; 2.9% background HIV prevalence among ASMM) prevents 27.8% of infections, with 38 person-years on PrEP per infection averted. Expanding implementation to cover younger ages or earlier initiation has small effects on impact and efficiency. Targeting highest risk ASMM increases efficiency, but requires querying sexual histories. Across levels examined, coverage and adherence do not have major impacts on efficiency, whereas background prevalence does. Conclusions: PrEP can have a large impact on HIV incidence among ASMM in the United States, especially in settings with high prevalence. However, willingness of, and support for, providers will be central to achieving the coverage needed to make this a success. © 2017 The Society for Adolescent Health and Medicine	Adolescent sexual minority males; Bisexual males; HIV; Homosexual males; Mathematical modeling; Pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Govender E.; Abdool Karim Q.	Understanding women and men's acceptability of current and new HIV prevention technologies in KwaZulu-Natal, South Africa	AIDS Care	-	-	-	9540121	10.1080/09540121.2018.1488027	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048739120&doi=10.1080%2f09540121.2018.1488027&partnerID=40&md5=880791cedfc069673cbefc13866d7ece	Despite significant advances to the HIV epidemic, prevention remains a challenge globally. Adolescent girls and young women in southern and Eastern Africa are still at high risk of acquiring HIV infection with limited prevention options. The expanding product pipeline of novel drugs and delivery approaches has highlighted the importance of acceptability and uptake of these anti-retroviral based products to realize their full prevention potential. Community engagement is now imperative to inform both product development and uptake; with research directed to understand what potential users are willing to use given the broader cultural-gender context in which HIV prevention product choices are made/negotiated. We conducted ten gender specific discussion groups with 112 participants in three of the eight highest HIV prevalence districts in urban, peri-urban, and rural KwaZulu-Natal. The participants where purposively selected according to age, location and sex. The data was analysed thematically in terms of the key enablers and barriers of accepting three key HIV dosing strategies; the oral pill, the vaginal ring and the injectable among men and women. The study found that women are willing to consider HIV prevention options that align with their current sexual and reproductive health routines, offers the longest duration of protection, and requires minimal/no partner involvement, in contrast most men were not supportive of their partners using of any form of PrEP, irrespective of dosing strategies and formulations as it raised questions of infidelity and side effects on men. The findings is indicative of the complexities of women's product choices, which are often embedded in a system of personal preference on an intrapersonal level, but also of male dominance, gender norms and cultural contexts at an interpersonal level. Understanding this intrapersonal-interpersonal interplay can enhance PrEP messaging and promotion; further highlighting the need to expand biomedical innovations for women initiated technologies. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	acceptability; HIV prevention; Pre-exposure prophylaxis; South Africa; women	English	United Kingdom	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Qualitative
Theses and Dissertations	2018	Grab, Sheila	DESIGN, DEVELOPMENT AND EVALUATION OF AN EXTENDED RELEASE VAGINAL FILM PLATFORM FOR HIV PREVENTION	-	-	University of Pittsburgh	-	-	NA	http://d-scholarship.pitt.edu/33702/	The human immunodeficiency virus (HIV) is a global health pandemic and over 70% of those living with HIV are found in Sub-Saharan Africa. In this region, the main method of transmission is through heterosexual contact and women account for the majority of those living with the virus. Topical pre-exposure prophylaxis is the vaginal or rectal application of a microbicide product prior to sexual intercourse to protect against HIV infection. Microbicides can be formulated into dosage forms such as; tablets, gels, films and rings. Acceptability studies have identified the film, a traditionally fast release, coitally dependent formulation as an acceptable dosage form to women. Although this dosage form is found to be safe, effective and preferred among women, there are barriers to daily and coitally dependent product usage for some women. In efforts to overcome barriers of both dosage form and dosing regimen acceptability, we propose that the vaginal film can provide a platform for extended drug delivery. We hypothesized that vaginal residence time of polymeric films could be manipulated through physical film properties and polymeric makeup of the film, which can be used to extend the dosing interval of films for the delivery of potent antiretrovirals. Increased volume films were manufactured through altering film thickness. These films were able to accommodate a hydrophilic agent, tenofovir (TFV), a hydrophobic agent, dapivirine (DPV) and a combination of dapivirine and MK-2048. Model films containing TFV and DPV were assessed in the non-human primate and showed that increased volume films can extend vaginal retention time compared to their thin film counterparts. Another approach to formulate extended release films was through a design of experiments using a combination of polymers to enhance vaginal retention. A panel of films was manufactured and characterized. A lead film platform was selected and when tested in the non-human primate was able to deliver MK-2048 vaginally at levels above the IC50 for this compound for up to 30 days. Overall, this work provided strong evidence for the application of the polymeric film as an extended release platform for the vaginal delivery of antiviral agents for HIV prevention. Article	2018	Grace, D; Jollimore, J; MacPherson, P; Strang, MJP; Tan, DHS	The Pre-Exposure Prophylaxis (PrEP)-Stigma Paradox: Learning from Canada's First Wave of PrEP Users	AIDS Patient Care and STDs	-	-	-	1087-2914	10.1089/apc.2017.0153	https://pubmed.ncbi.nlm.nih.gov/29185801/	With the emergence of daily oral tenofovir disoproxil fumarate and emtricitabine-based pre-exposure prophylaxis (PrEP) use in Canada, questions have emerged concerning the impacts of this HIV prevention tool on gay men's social and sexual lives. We conducted small focus groups and individual qualitative interviews with 16 gay men in Toronto who were part of the first wave' of Canadian PrEP users. Participants were on PrEP for at least one year as part of a demonstration project (November 2014-June 2016). These participants accessed PrEP before regulatory approval by Health Canada in February 2016. The mean age of participants was 37.6 years (SD 11.02); 94% completed secondary education, and 69% were white. Sex-stigma emerged as a complex theme in men's accounts of PrEP use across three overlapping domains: (1) PrEP-related stigma, including discussions of concealment and stigma from friends, family, and sexual partners, (2) PrEP as a perceived tool for combating HIV-related stigma, where some men said that they no longer discussed HIV status with sexual partners, and (3) PrEP as illuminating structural stigma, where it was attributed to unmasking stigma related to sex and sexuality. For some participants, PrEP has allowed for liberating sex and a self-described return to normalcynormal, exciting, pleasurable sex that was no longer reliant on condom use. Paradoxically, some men said that PrEP use both led them to experience stigmatizing reactions within their social and sexual networks, while also helping to remove stigma, shame, and fear related to HIV, sexuality, and sex with gay men living with HIV. Article	2018	Grant, Robert M; Mannheimer, Sharon; Hughes, James P; Hirsch-Moverman, Yael; Loquere, Avelino; Chitwarakorn, Anupong; Curlin, Marcel E; Li, Maoji; Amico, K Rivet; Hendrix, Craig W; Anderson, Peter L; Dye, Bonnie J; Marzinke, Mark A; Piwowar-Manning, Estelle; McKinstry, Laura; Elharrar, Vanessa; Stirratt, Michael; Rooney, James F; Eshleman, Susan H; McNicholl, Janet M; van Griensven, Frits; Holtz, Timothy H	Daily and Nondaily Oral Preexposure Prophylaxis in Men and Transgender Women Who Have Sex With Men: The Human Immunodeficiency Virus Prevention Trials Network 067/ADAPT Study.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/cix1086	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5961078	Background: Nondaily dosing of oral preexposure prophylaxis (PrEP) may provide equivalent coverage of sex events compared with daily dosing. Methods: At-risk men and transgender women who have sex with men were randomly assigned to 1 of 3 dosing regimens: 1 tablet daily, 1 tablet twice weekly with a postsex dose (time-driven), or 1 tablet before and after sex (event-driven), and were followed for coverage of sex events with pre- and postsex dosing measured by weekly self-report, drug concentrations, and electronic drug monitoring. Results: From July 2012 to May 2014, 357 participants were randomized. In Bangkok, the coverage of sex events was 85% for the daily arm compared with 84% for the time-driven arm (P = .79) and 74% for the event-driven arm (P = .02). In Harlem, coverage was 66%, 47% (P = .01), and 52% (P = .01) for these groups. In Bangkok, PrEP medication concentrations in blood were consistent with use of ≥2 tablets per week in >95% of visits when sex was reported in the prior week, while in Harlem, such medication concentrations occurred in 48.5% in the daily arm, 30.9% in the time-driven arm, and 16.7% in the event-driven arm (P < .0001). Creatinine elevations were more common in the daily arm (P = .050), although they were not dose limiting. Conclusions: Daily dosing recommendations increased coverage and protective drug concentrations in the Harlem cohort, while daily and nondaily regimens led to comparably favorable outcomes in Bangkok, where participants had higher levels of education and employment. Healthcare providers' understanding of HIV serodiscordance in South Africa and Uganda: implications for HIV prevention in sub-Saharan Africa	African Journal of AIDS Research	-	-	-	16085906	10.2989/16085906.2018.1462217	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046709720&doi=10.2989%2f16085906.2018.1462217&partnerID=40&md5=7a11d21e017a2dae15dbd6c2aba0806e	HIV transmission within stable heterosexual HIV serodiscordant couples accounts for almost half the new incident infections in South Africa and Uganda. Advances in HIV prevention provide opportunities to reduce transmission risk within serodiscordant partnerships (e.g., antiretroviral treatment (ART), pre-exposure prophylaxis (PrEP), medical male circumcision, and couples-based HIV counselling and testing). These interventions require a clinical encounter with a provider who recognises prevention opportunities within these partnerships. We explored healthcare provider understanding of HIV serodiscordance in a reproductive counselling study with providers in eThekwini district, South Africa, and Mbarara district, Uganda. In eThekwini, in-depth interviews (29) and focus group discussions (2) were conducted with 42 providers (counsellors, nurses and doctors) from public sector clinics. In Mbarara, in-depth interviews were conducted with 38 providers (medical officers, clinical officers, nurses, peer counsellors and village health workers). Thematic analysis was conducted using NVivo software. In eThekwini, many providers assumed HIV seroconcordance among client partners and had difficulty articulating how serodiscordance occurs. Mbarara providers had a better understanding of HIV serodiscordance. In the two countries, providers who understood HIV serodiscordance were better able to describe useful HIV-prevention strategies. Healthcare providers require training and support to better understand the prevalence and mechanisms of HIV serodiscordance to implement HIV-prevention strategies for HIV serodiscordant couples. © 2018, © 2018 NISC (Pty) Ltd.	antiretroviral treatment; HIV counselling; HIV knowledge; HIV transmission; reproductive health	English	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Qualitative

Retention, engagement, and adherence to pre-exposure prophylaxis for men who have sex with men and transgender women in PrEP Brasil: 48 week results of a demonstration study	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(18)30008-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042160626&doi=10.1016%2fS2352-3018%2818%2930008-0&partnerID=40&md5=371ed48ec7c37442129649a4c72d9ac4	Background: PrEP Brasil was a demonstration study to assess feasibility of daily oral tenofovir diphosphate disoproxil fumarate plus emtricitabine provided at no cost to men who have sex with men (MSM) and transgender women at high risk for HIV within the Brazilian public health system. We report week 48 pre-exposure prophylaxis (PrEP) retention, engagement, and adherence, trends in sexual behaviour, and incidence of HIV and sexually transmitted infections in this study cohort. Methods: PrEP Brasil was a 48 week, open-label, demonstration study that assessed PrEP delivery at three referral centres for HIV prevention and care in Rio de Janeiro, Brazil (Fundação Oswaldo Cruz), and São Paulo, Brazil (Universidade de São Paulo and Centro de Referência e Treinamento em DST e AIDS). Eligible participants were MSM and transgender women who were HIV negative, aged at least 18 years, resident in Rio de Janeiro or São Paulo, and reported one or more sexual risk criteria in the previous 12 months (eg, condomless anal sex with two or more partners, two or more episodes of anal sex with an HIV-infected partner, or history of sexually transmitted infection STI diagnosis). Participants were seen at weeks 4, 12, 24, 36, and 48 for PrEP provision, clinical and laboratory evaluation, and HIV testing. Computer-assisted self-interviews were also done at study visits 12, 24, 36, and 48, and assessed sexual behaviour and drug use. PrEP retention was defined by attendance at the week 48 visit, PrEP engagement was an ordinal five-level variable combining presence at the study visit and drug concentrations, and PrEP adherence was evaluated by measuring tenofovir diphosphate concentrations in dried blood spots. Logistic regression models were used to quantify the association of variables with high adherence (≥4 doses per week). The study is registered with ClinicalTrials.gov, number NCT01989611. Findings: Between April 1, 2014, and July 8, 2016, 450 participants initiated PrEP, 375 (83%) of whom were retained until week 48. At week 48, 277 (74%) of 375 participants had protective drug concentrations consistent with at least four doses per week: 183 (82%) of 222 participants from São Paulo compared with 94 (63%) of 150 participants from Rio de Janeiro (adjusted odds ratio 1·88, 95% CI 1·06–3·34); 119 (80%) of 148 participants who reported sex with HIV-infected partners compared with 158 (70%) of 227 participants who did not (1·78, 1·03–3·08); 67 (87%) of 77 participants who used stimulants compared with 210 (71%) of 298 participants who did not (2·23, 1·02–4·92); and 232 (80%) of 289 participants who had protective concentrations of tenofovir disphosphate at week 4 compared with 42 (54%) of 78 participants who did not (3·28, 1·85–5·80). Overall, receptive anal sex with the last three partners increased from 45% at enrolment to 49% at week 48 (p=0·17), and the mean number of sexual partners in the previous 3 months decreased from 11·4 (SD 28·94) at enrolment to 8·3 (19·55) at week 48 (p<0·0013). Two individuals seroconverted during follow-up (HIV incidence 0·51 per 100 person-years, 95% CI 0·13–2·06); both of these patients had undetectable tenofovir concentrations at seroconversion. Interpretation: Our results support the effectiveness and feasibility of PrEP in a real-world setting. Offering PrEP at public health-care clinics in a middle-income setting can retain high numbers of participants and achieve high levels of adherence without risk compensation in the investigated populations. Article	2018	Grov C.; D'angelo A.B.; Flynn A.W.P.; Lopez-Rios J.; Pantalone D.W.; Holloway I.W.; Whitfield T.H.F.; Parsons J.T.	How do gay and bisexual men make up for missed PrEP doses, and what impact does missing a dose have on their subsequent sexual behavior?	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2018.30.4.275	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056740542&doi=10.1521%2faeap.2018.30.4.275&partnerID=40&md5=b58ef03ec92e4c330ce3de7e8d7a356c	HIV pre-exposure prophylaxis (PrEP) is being adopted by members of key populations, such as gay and bisexual men (GBM). Since adherence to a daily PrEP regimen ensures a maximum protection, it is critical to understand GBM's behavioral responses to having missed PrEP doses. We report on qualitative interviews with GBM taking PrEP. We identified three behavioral responses: (1) 59% continued with their next scheduled dose; (2) 49% described "making up" for a missed dose by taking medication as soon as possible; and (3) 11% reported "doubling" the next PrEP dose. Participants provided potentially contradictory narratives about their sexual behavior after a missed dose: (1) 54% described making no changes; (2) 49% described adjusting their sexual behavior to reduce HIV risk; and (3) 10% said their decision would be contingent upon how many doses were missed. For PrEP prescribers, our data provide a useful lens to understand patients' lived experiences with PrEP. © 2018 The Guilford Press. Article	2018	Grov C.; Kumar N.	HIV Pre-Exposure Prophylaxis (PrEP) Is Coming to Europe, but Are Gay Men Ready to Accept It? Qualitative Findings from Berlin, Germany	Sexuality Research & Social Policy	-	-	-	18689884	10.1007/s13178-017-0278-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85014731814&doi=10.1007%2fs13178-017-0278-9&partnerID=40&md5=5b53b869c1b5f78614778a76118eca3b	In 2016, the European Medicines Agency approved the marketing of Truvada for use as pre-exposure prophylaxis (PrEP) in European Union (EU) member states. As individual countries throughout the EU make decisions about whether to adopt PrEP and fund it via governmental insurance, it is vital to understand key populations' knowledge of and attitudes toward PrEP. In 2015, 20 gay men completed face-to-face audio-recorded interviews, describing their knowledge of and attitudes toward PrEP (mean age 35.9; 35% HIV-positive, 65% HIV-negative). We found that in spite of PrEP not yet having been approved for marketing in Germany, all but one of the participants were aware of PrEP and knew the difference between PrEP and post-exposure prophylaxis (PEP; which is approved for use in Germany). By and large, attitudes were favorable about PrEP, especially among HIV-negative participants. Next, there appeared to be an already high demand for PrEP with several participants going to great lengths to gain access to PrEP; two described intentions to obtain PEP for use as PrEP, one was obtaining PrEP via another country (where it was legal), and a fourth participant was discretely distributing PrEP out of his home. Our findings appear to validate anecdotal evidence suggesting high demand for PrEP and that some are already finding ways to obtain it without governmental approval. Our findings suggest that participants were prepared to see the rollout of PrEP in Berlin, pending its approval. © 2017, Springer Science+Business Media New York. Article	2018	Grov, Christian; Jonathan Rendina, H; Patel, Viraj V; Kelvin, Elizabeth; Anastos, Kathryn; Parsons, Jeffrey T	Prevalence of and Factors Associated with the Use of HIV Serosorting and Other Biomedical Prevention Strategies Among Men Who Have Sex with Men in a US Nationwide Survey	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2084-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044068190&doi=10.1007%2fs10461-018-2084-7&partnerID=40&md5=37c91215ea7f2c42ea40d4e24c4cf616	PrEP and treatment-as-prevention (TasP) are biomedical strategies to reduce HIV transmission. Some men who have sex with men (MSM) are combining biomedical strategies with HIV serosorting—termed "biomed matching" when both partners are either on PrEP or TasP, or "biomed sorting" when one partner is using PrEP and the other TasP. Nevertheless, there is limited data on the extent of biomed matching/sorting in large geographically diverse samples. In 2016–2017, 5021 MSM from across the US were surveyed about their HIV status and HIV viral load/PrEP use, as well as that of their recent casual male partners. For each participant, we calculated the proportion of his partners who were (1) HIV-positive and undetectable, (2) HIV-positive and detectable/unknown, (3) HIV unknown/undiscussed, (4) HIV-negative on PrEP, (5) HIV-negative, not on PrEP. In total, 66.6% (n = 3346) of participants were HIV-negative and not on PrEP, 11.9% (n = 599) on PrEP, 14.1% (n = 707) HIV-positive and undetectable, 1.1% (n = 55) HIV-positive and viral load detectable/unknown, and 6.2% (n = 313) HIV unsure/unknown. A participant's own HIV and PrEP status/was significantly associated with that of his partners (all p < 0.001), evincing evidence of both serosorting and biomed matching. Among men on PrEP and those who were HIV-undetectable, there was also some evidence to suggest these participants dually engaged in biomed matching as well as biomed sorting. We found evidence of biomed matching and sorting, which may compound its effectiveness for those using it (i.e., both partners bring biomedical protection). Unintended consequences of biomed matching/sorting include that men not using a biomedical strategy may be less likely to benefit from a partner's use of the strategy—potentially further driving disparities in HIV infections. Public health campaigns might be well served to highlight not only the benefits that biomedical HIV prevention strategies provide for their users (e.g., "being on PrEP protects me from getting HIV"), but also the benefits that a user brings to his partners (e.g., "my use of PrEP means my partners won't get HIV"), and the benefits of being with a partner who is using a biomedical strategy (e.g., "my partner's use of PrEP/TasP protects me from HIV"). © 2018, Springer Science+Business Media, LLC, part of Springer Nature. HIV prevention strategies and risk of infection: A model-based analysis	Epidemiology and Infection	-	-	-	-	-	-	-	9502688	10.1017/S0950268818000845	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85045297930&doi=10.1017%2fS0950268818000845&partnerID=40&md5=43f5ffbc3f7668c7351ab69b84ba1ab8	Risk populations for HIV infections tend to neglect condom use, making alternative preventive approaches necessary. Accordingly, we modelled the risk of sexual HIV transmission for condom use vs. use of rapid diagnostic test (RDT) systems with subsequent exclusion of potential sexual partners with a syreinfo or falsely positive test from unprotected sex with and without the use of HIV pre-exposure prophylaxis (PrEP) in a bio-statistical approach. We combined a previously described model of transmission risk for HIV-exposed individuals with a newly suggested model of risk of HIV exposure for sexually active HIV-negative individuals. The model was adapted for several stages of infection and different strategies of HIV infection prevention. HIV prevention with RDTs can reduce the transmission risk by up to 87% compared with having sex without any prevention and up to 80% compared with condom use. Nevertheless, RDT-based prevention strategies demonstrate a lack of protection in several stages of infection. Especially in the first 3 months after infection, the risk of transmitting HIV to unprotected sexual partners is prone to unprotected sexual contacts substantially reduces HIV transmission risk. Combination of different prevention strategies is advisable for high-risk groups. © 2018 Cambridge University Press. Article	2018	Hambrick, H Rhodes; Park, Su Hyun; Schneider, John A; Meyer, Kenneth H; Carrico, Adam W; Sherman, Scott E; Duncan, Dustin T	Poppers and PrEP: Use of Pre-exposure Prophylaxis Among Men Who Have Sex with Men Who Use Inhaled Nitrites.	AIDS and Behavior	-	-	-	-	-	-	-	1573-3254	10.1007/s10461-018-2139-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8226412/	Men who have sex with men (MSM) commonly use inhaled nitrites, or poppers, though their use is a risk factor HIV seroconversion. Pre-exposure prophylaxis, or PrEP, is effective for HIV prevention, but is not widely used, and little is known regarding PrEP use and acceptability among MSM who use inhaled nitrites. We surveyed 500 MSM in Paris, France in 2016 about popper use, sexual behaviors including condomless anal sex (CAS), and PrEP use and acceptability. Participants were 18 years old (IQR: 25–39), 90% were born in France, and 90% identified as gay. Most (70%) reported popper use in the past 3 months. Using multivariate adjusted logistic regression, we found that popper users were more likely than non-users to consider themselves candidates for PrEP (adjusted relative risk ratio (aRRR) = 2.73, 95% CI 1.54–4.83), but they were not more likely to be current (aRRR = 1.54, 95% CI 0.71–3.33) or past (aRRR = 1.37, 95% CI 0.46–4.28) PrEP users. Mediation analyses indicated that increased CAI and sensewriting partly explained the relationship between popper use and PrEP candidacy. There was considerable interest in alternate proposed PrEP delivery modalities, particularly long-acting injectable PrEP: adjusted risk ratio (aRR) = 1.43, 95% CI 1.15–1.79. Article	2018	Hamilton, Dewan T; PhD, MPH; Goodreau, Steven M; PhD, Jenness, Samuel M; PhD, Sullivan, Patrick S; PhD, DVM, Wang, Li Yan, MBA, MA, Danielle, Richard C, MPH; Burriss, Lisa C, DRPH; Jenkins-Moore, Eli S, PhD	Potential Impact of HIV Pre-exposure Prophylaxis Among Black and White Adolescent Sexual Minority Males	American Journal of Public Health	-	-	-	-	-	-	-	900836	10.2105/AJPH.2018.304471	https://www.proquest.com/scholarly-journals/potential-impact-hiv-pre-exposure-prophylaxis-among/docview/2717140103/se-2?accountid=8117	Objectives. To assess the potential impact of preexposure prophylaxis (PrEP) on the HIV epidemic among Black and White adolescent sexual minority males (ASMM). Methods. We used a network model and race-specific data from recent trials to simulate HIV transmission among a population of Black and White 13- to 16-year-old ASMM over 20 years. We examined the combined effects of universal (impact) and the number needed to treat to prevent an infection (efficiency) under multiple coverage and adherence scenarios. Results. At modeled coverage and adherence, PrEP could avert 3% to 20% of HIV infections among Black ASMM over 20 years, depending on PrEP efficacy. Because of higher HIV incidence, PrEP was substantially more impactful among Black ASMM than among White ASMM. The number needed to treat was more favorable among Black ASMM (number needed to treat = 23–32) compared with White ASMM (146–227). Conclusions. PrEP can reduce HIV incidence among both Black and White ASMM but is far more efficient for Black ASMM because of higher incidence. Public Health Implications. Black ASMM communities suffer disproportionate HIV burden; despite imperfect adherence, PrEP programs could prevent HIV efficiently in these communities. Article	2018	Hammack P.L.; Meyer I.H.; Krueger E.A.; Lightfoot M.; Frost D.M.	HIV testing and pre-exposure prophylaxis (PrEP) use, familiarity, and attitudes among gay and bisexual men in the United States: A national probability sample of three birth cohorts	PLOS One	-	-	-	-	-	-	-	19526203	10.1371/journal.pone.0202906	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051047364&doi=10.1371%2fjournal.pone.0202906&partnerID=40&md5=74c581164e49a03f1f01e0bae7191699	The study examined HIV testing and use, familiarity, and attitudes toward pre-exposure prophylaxis (PrEP) among HIV-negative gay and bisexual men in the United States. A national probability sample (N = 420) of three age cohorts (18–25, 34–41, and 52–59 years) completed a survey between March, 2016 and March, 2017. Most men did not meet CDC recommendations for HIV testing, and 25.2% of men in the younger cohort had never tested. Only 4.1% used PrEP across cohorts. Visiting an LGBT clinic and searching for LGBT resources online were both associated with PrEP use. Men in the middle cohort were more familiar with PrEP (79%) than men in the younger (52%) and older (57%) cohorts. Bisexual and non-urban men were less familiar with PrEP. Attitudes were positive among most men (68.4%) familiar with PrEP. Findings suggest that most men are potentially at risk for HIV do not meet CDC guidelines for testing, and PrEP use continues to be minimal. Efforts to educate gay and bisexual men about HIV risk and prevention need to be reinvigorated and expanded to include non-gay-identified and non-urban men. © 2018 Hammack et al. Article	2018	Hammond, Mohamed A; Yeacher, Stefanie; Jin, Fengyi; Bourne, Adam; Haire, Bridget; Maher, Lisa; Lea, Toby; Prestage, Garrett	The new MTV generation: Using methamphetamine, Truvada™, and Viagra™ to enhance sex and stay safe.	International Journal of Drug Policy	-	-	-	-	-	-	-	1873-4758	10.1016/j.drugpo.2018.02.021	https://dx.doi.org/10.1016/j.drugpo.2018.02.021	INTRODUCTION: Gay and bisexual men (GBM) often use illicit drugs to enhance sexual pleasure, commonly referred to as 'chemsex' or 'party n play'. In particular, the use of methamphetamine and Viagra™ and other erectile dysfunction medications, both together and separately are strongly predictive of subsequent HIV infection. Truvada™, as pre-exposure prophylaxis (PrEP), virtually eliminates HIV transmission during condomless anal intercourse (CLAI). HIV-negative GBM in intensive sex partying networks may be adding PrEP to their drug regimen to actively reduce the possibility of HIV infection. Methods: The Following Love Undergoing Change study is an online prospective observational study of GBM who use methamphetamine, Viagra™ and other erectile dysfunction medications (collectively, MTV). METHODS: The Following Love Undergoing Change study is an online prospective observational study of gay and illicit drug use among men who have sex with men (GBM). Between January and July 2017, 1031 GBM provided details about their use of MTV. Binary logistic, multiple regression analysis were used to estimate adjusted odds ratios (aOR) and associated 95% confidence intervals (95%CI). RESULTS: Concurrent MTV use was reported by 6.0% of participants, 3.1% used methamphetamine and Viagra™ or other erectile dysfunction medications (MV only) and 11.2% used Truvada™ as PrEP (T only). In multivariate analysis, compared to use of 'MV only', MTV was independently associated with CLAI with casual partners (aOR = 4.78,95%CI = 2.42-32.34), and Truvada™ (aOR = 4.7,95%CI = 1.43-8.56) in the previous six months. Compared to use of 'T only', MTV was independently associated with CLAI (aOR = 3.78,95%CI = 2.42-32.34), and Truvada™ (aOR = 3.31,95%CI = 1.32-8.00). Greater social engagement with other gay men (aOR = 1.44,95%CI = 1.20-1.76) and having more sexual partners (aOR = 2.30,95%CI = 1.18-4.82) were independently associated with use of MTV compared to use of 'MV only' or 'T only'. CONCLUSIONS: GBM in intensive sex partying networks are increasingly adding PrEP alongside other drugs they use to enhance sexual experiences. Interventions that promote the use of PrEP during chemsex could mitigate HIV risk.	-	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Editorial	2018	Hampel B.; Reinacher M.; Fehr J.S.	HIV pre-exposure prophylaxis (PrEP): Is it time to rethink HIV prevention in sweden? Article	2018	Hancock K.; Barton J.; Ngare K.; Celum C.; Mugo N.; Tindimwebwa E.; Heffron R.	Safer conception among HIV-1 serodiscordant couples in East Africa: understanding knowledge, attitudes, and experiences	AIDS Care	-	-	-	-	-	-	-	9540121	10.1080/09540121.2018.1427251	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042227568&doi=10.1080%2f09540121.2018.1427251&partnerID=40&md5=9551e35a3d1080356ed2f9a758a0f4	For HIV-1 serodiscordant couples, HIV-1 exposure and risk of transmission is heightened during pregnancy attempts, but safer conception strategies can reduce risk. As safer conception programs are scaled up, understanding couples' preferences and experiences can be useful for programmatic recommendations. We followed 1013 high-risk, heterosexual HIV-1 serodiscordant couples from Kenya and Uganda for two years in an open-label delivery study of integrated pre-exposure prophylaxis (PrEP) and antiretroviral therapy (ART), the Partners Demonstration Project. We used descriptive statistics to describe the safer conception strategies exposures to characterize women who reported use of a safer conception strategy by their first annual visit. HIV-1 infection was the study visit. Multivariable logistic regression identified factors associated with safer conception strategy use. Results: Of 1057 women enrolled, 679 (64%) desired children in the future. At the first annual visit, 59% of women recognized PrEP, 50% ART, 58% timed conditions sex, 23% self-insemination, and fewer than 10% recognized male circumcision, sperm washing, or ovulation testing. Safer conception strategy use was reported by 19% of women overall, including 29% of women who desired children in the future. Factors associated with safer conception strategy use included: desire to conceive, male partner HIV status disclosure, and follow-up 12- and 24-months after enrollment. Women will be asked to complete a questionnaire and offered HIV testing. Additional complications of this study include identifying comparable populations of YWSS in the DREAMS+PrEP and non-DREAMS comparison sites, and retention of YWSS over the 24-month period. The primary outcome is HIV incidence among YWSS HIV-negative at study enrollment measured by repeat, rapid HIV testing over 24 months. Inference will be based on plausibility that DREAMS+PrEP had an impact on HIV incidence. A process evaluation will be conducted to understand intervention implementation, and document any contextual factors determining the success or failure of intervention delivery. Discussion: HIV prevention products of known efficacy are available. Innovative studies are needed to provide evidence of how to optimize product use through combination interventions to achieve population impact within different contexts. We describe the design of such a study. © 2018 The Author(s).	-	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2018	Hanssen, Bernadette; Hargreaves, James R; Cheyska, Tarisai; Chabata, Sungai; Mushati, Phillis; Floyd, Sian; Birdthistle, Isolde; Buzes, Joanna; Cowan, Frances	Evaluating the impact of DREAMS on HIV incidence among young women who sell sex: Protocol for a non-randomised study in Zimbabwe	BMC Public Health	-	-	-	-	-	-	-	14712458	10.1186/s12889-018-5085-6	https://escholarship.org/uc/item/7sn0q760	Background: "Determined, Resilient, AIDS-free, Mentored and Safe" (DREAMS) is a package of biomedical, social and economic interventions offered to adolescent girls and young women aged 10-24 years with the aim of reducing HIV incidence. In four of the six DREAMS districts in Zimbabwe, DREAMS includes an offer of oral pre-exposure prophylaxis (DREAMS+PrEP), alongside interventions to support demand and adherence, to women aged 18-24 who are at highest risk of HIV infection, including young women who sell sex (YWSS). This evaluation study addresses the question: does the delivery of DREAMS+PrEP through various providers reduce HIV incidence among YWSS Zimbabwe? We describe our approach to designing a rigorous study to assess whether DREAMS+PrEP had an impact on HIV incidence. Methods: The study design is a non-randomised, controlled, prospective cohort study. The study population is young women who sell sex in the sex-working scene for the target populations for DREAMS+PrEP. There are a small number of DREAMS districts (N = 6), and 41 DREAMS+PrEP is being implemented by various providers. The study will use a cohort analysis approach to compare HIV incidence among YWSS in DREAMS+PrEP districts (N = 3) with HIV incidence among YWSS in non-DREAMS districts (N = 3). Eligible participants will be identified through a respondent-driven sampling approach (RDS), and followed up (census) at baseline, 12- and 24-months after enrollment. Women will be asked to complete a questionnaire and offered HIV testing. Additional complications of this study include identifying comparable populations of YWSS in the DREAMS+PrEP and non-DREAMS comparison sites, and retention of YWSS over the 24-month period. The primary outcome is HIV incidence among YWSS HIV-negative at study enrollment measured by repeat, rapid HIV testing over 24 months. Inference will be based on plausibility that DREAMS+PrEP had an impact on HIV incidence. A process evaluation will be conducted to understand intervention implementation, and document any contextual factors determining the success or failure of intervention delivery. Article	2018	Heumann, Christine L	Biomedical Approaches to HIV Prevention in Women.	Current Infectious Disease Reports	-	-	-	-	-	-	-	1523-3847	10.1007/s11908-018-0618-9	https://pubmed.ncbi.nlm.nih.gov/29666937/	PURPOSE OF REVIEW: Effective HIV prevention techniques for women are of critical importance, as nearly half of all HIV infections globally are in women. This article reviews the recent literature on biomedical approaches to HIV prevention in women. RECENT FINDINGS: In trials in which women were adherent to oral pre-exposure prophylaxis (PrEP), PrEP was equally efficacious in men and women. However, in studies of oral PrEP exclusively in women, adherence was low, and it was not efficacious. In trials of topical PrEP, including vaginal tenofovir gel and the monthly dapivirine ring, efficacy was also dependent upon adherence. Treatment as prevention (TasP) is a very effective HIV prevention strategy, though limited in that it is not controlled by the HIV-uninfected partner. Adherence is an important factor in the efficacy of biomedical interventions for HIV prevention in women; continued research is needed to identify the most efficacious and acceptable agents for women. Oral PrEP is currently recommended for the following groups of HIV-negative women: heterosexual women in ongoing sexual relationships with a partner infected with or at substantial risk of HIV infection and women who inject drugs and share injection or drug preparation equipment. Article	2018	Hevey M.A.; Walsh J.L.; Petroll A.E.	Pop combination, HIV and STI testing rates, and delivery of preventive care in a clinic-based cohort	AIDS Education and Prevention	-	-	-	-	-	-	-	8999546	10.1521/aeap.2018.30.5.393	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056707764&doi=10.1521%2faeap.2018.30.5.393&partnerID=40&md5=2176772a0b524a67a9c1c2798ad5dbe	HIV pre-exposure prophylaxis (PrEP) has been demonstrated to be a safe and effective method of reducing HIV incidence. Questions remain regarding PrEP's efficacy and outcomes in real-world clinical settings. This study examined the effectiveness of a clinic-based intervention to increase PrEP uptake and subsequent delivery of preventive care (pop combination; HIV testing and STI testing). One hundred thirty-four patients were seen between 2010 and 2016 over 305 visits. One hundred sixteen patients (87%) started daily PrEP and of those, 58 (76%) attended at least one 6-month follow-up visit. Over 80% of PrEP patients completed all recommended STI screening after starting PrEP. Only 40% of patients had all appropriate immunizations at baseline; 79% had all appropriate immunizations at study completion. This study demonstrated high rates of both retention and of attaining recommended preventive care in a clinical setting outside of the rigors of clinical trials. © 2018 The Guilford Press.	-	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2018	Hill, Bianca S; Patel, Viraj V; Haughton, Lorlette J; Blackstock, Ore J	Leveraging Social Media to Explore Black Women's Perspectives on HIV Pre-exposure Prophylaxis.	Journal of the Association of Nurses in AIDS Care	-	-	-	-	-	-	-	1552-6917	10.1016/j.jana.2017.06.010	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5788230/	Pre-exposure prophylaxis (PrEP) remains an under-utilized HIV prevention tool among men who have sex with men (MSM). To more comprehensively elucidate barriers and facilitators to PrEP use among US MSM, we conducted a systematic review of peer-reviewed published articles and content analysis of online posts about PrEP. We searched peer-reviewed databases (Medline, Web of Science, Google Scholar) using MESH headings and keywords about PrEP and/or HIV prevention from 2005 to 2015. We included original studies among MSM in the US that reported on barriers, facilitators, or other factors related to PrEP use. We also searched online posts and associated comments (news articles, opinion pieces, blogs and other social media posts) in diverse venues (Facebook, Slate Outward, Huffington Post Gay Voices, Queerty, and Joy PrEP Experience blog) to identify posts about PrEP. We used content analysis to identify themes and compare potential differences between the peer-reviewed literature and online posts. We identified 25 peer-reviewed articles and 28 online posts meeting inclusion criteria. We identified 48 unique barriers and 66 facilitators to using PrEP. These 94 themes fit into an overarching framework of 5 categories: (1) Individual; (2) Provider; (3) Dyadic; (4) Community; and (5) Structural. Most themes were identified in both the peer-reviewed literature and online posts. Within the 5 categories, analysis of online posts revealed 16 identification of a greater number of unique themes. Thirty-eight themes were identified in the online posts that were not identified in the peer-reviewed literature. We identified barriers and facilitators to PrEP in online posts that were not identified in a systematic review of the peer-reviewed literature. By incorporating data both from a systematic review of peer-reviewed articles and from online posts, we have identified additional novel information about barriers to and facilitators of PrEP use. Traditional research approaches may not comprehensively capture current factors important for designing and implementing PrEP-related interventions. Theses and Dissertations	2018	Ho, Ming-Chun	Evidence-Based Study of Medication Compliance Project in Hiv Prevention Using Pre-Exposure Prophylaxis (Prep) Antivirals for HIV-Negative Males	-	-	San Jose State University	-	NA	https://doi.org/10.31979/etd.gx2q-979x	https://doi.org/10.31979/etd.gx2q-979x https://scholarworks.sjsu.edu/etd_doctoral/81	In 2012, emtricitabine/tenofovir was the only Food and Drug Administration-approved medication for pre-exposure prophylaxis (PrEP) used in human immunodeficiency virus (HIV) prevention. To date, there is little research on open-label and mixed-payer characteristics supporting medication compliance of men who have sex with men (MSM). The purpose of this research was to describe individual demographic variables associated with PrEP medication adherence and to examine the effect of a follow-up phone call from a nurse once a month for 3 months. A total of 30 MSM were recruited and data were collected using a demographic questionnaire, medication adherence tool and follow-up phone calls. Data were analyzed using a statistical package. Spearman's rho correlations demonstrated high medication adherence in single men (rs (28) = −.375, p < .05) with no mental health issues (rs (28) = .426, p < .05) and a higher educational level (rs (28) = −.431, p < .05). A between group Chi-square demonstrated men with high medication adherence and medium medication adherence did not statistically differ over 3 months (χ^2 (2, N = 28) = .668, p = .71). Individuals who exhibited higher PrEP use in an open-label and mixed-payer structure appeared to be young, single, well educated, and employed Caucasian gay males with multiple partners. More information will be needed from ethnically diverse populations, especially non-Caucasians. Finally, clinical nurses, by supplying accountability by phone calls, could improve PrEP compliance by providing planned monthly reminders. Article	2018	Hodges-Mameletzis, Ioannis; Dalal, Shona; Msimanga-Radebe, Busisiwe; Rodolph, Michelle; Baggaley, Rachel	Going global: the adoption of the World Health Organization's enabling recommendation on oral pre-exposure prophylaxis for HIV.	Sexual Health	-	-	-	1448-5028	10.1071/SH18125	https://dx.doi.org/10.1071/SH18125	In September 2015, the World Health Organization (WHO) launched evidence-based guidelines by recommending that any person at substantial HIV risk should be offered oral pre-exposure prophylaxis (PrEP) containing tenofovir disoproxil fumarate (TDF) as an additional prevention choice. Since 2017, PrEP medicines have also been listed in the WHO's Essential Medicines List, including TDF/emtricitabine (FTC) and TDF in combination with lamivudine (3TC). A descriptive policy review and analysis of countries adopting WHO's 2015 recommendation on oral PrEP was conducted. As of June 2018, we identified 35 countries that had some type of policy on oral PrEP, and an additional five countries where a specific policy on PrEP is currently pending. A total of 19 high-income countries (HICs) and 21 low- and middle-income countries (LMICs) have adopted or have a pending policy. Most countries that have adopted or pending PrEP are in the European (42.9%) or African (30.0%) region. TDF/FTC is the most commonly recommended PrEP drug in the guidelines reviewed, although seven countries, namely in sub-Saharan Africa (6/7), are also recommending the use of TDF/3TC for PrEP. In sum, by the end of 2018, at least 40 countries (20.6%) are anticipated to have adopted WHO's oral PrEP recommendation. Nonetheless, policy uptake does not reflect broader programmatic coverage of PrEP services, which remain limited across all settings, irrespective of income status. Enhancing global partnerships is needed to support and track ongoing policy adoption and to ensure that policy is translated into meaningful implementation of PrEP services.	antiretroviral, policy, PrEP, prevention	English	Australia	Asia and the Pacific	Switzerland	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Review
Article	2018	Hoenigl M.; Jain S.; Moore D.; Collins D.; Sun X.; Anderson P.L.; Corado K.; Blumenthal J.S.; Daar E.S.; Milam J.; Dubé M.P.; Morris S.	Substance use and adherence to HIV preexposure prophylaxis for men who have sex with men	Emerging Infectious Diseases	-	-	-	10806040	10.3201/eid2412.180400	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056697285&doi=10.3201%2feid2412.180400&partnerID=40&md5=87b1b6f8d0cd76798dcd1a45b51e7a31	The effectiveness of oral HIV preexposure prophylaxis (PrEP) strongly depends on maintaining adherence. We investigated the association between substance use and PrEP adherence, as well as incident sexually transmitted infections (STIs) in a high-risk cohort of 394 participants (391 men who have sex with men and 3 transgender women) who were enrolled in a PrEP demonstration project. We assessed baseline and ongoing substance use over a 48-week period for stimulants and nonstimulant substances and for each substance separately. We measured PrEP adherence by using dried blood spots to obtain levels of tenofovir diphosphate. No differences in these levels were found between substance users and nonsubstance users. Baseline stimulant use was strongly associated (odds ratio 3.4; p<0.001) with incident STIs during the study. Thus, PrEP adherence was not decreased by substance use. Because substance users had increased rates of STIs, indicating higher-risk behavior, they might be excellent candidates for PrEP. © 2018, Centers for Disease Control and Prevention (CDC). Article	2018	Hojilla J.C.; Mehrotra M.; Truong H.-H.M.; Glidden D.V.; Amico K.R.; McMahan V.; Vlahov D.; Chariyalertsak S.; Guanira J.V.; Grant R.M.	HIV sero disclosure among men who have sex with men and transgender women on HIV pre-exposure prophylaxis	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1394437	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85032392039&doi=10.1080%2f09540121.2017.1394437&partnerID=40&md5=6b923ca8d21dacbea82d261a7c8b3458	HIV pre-exposure prophylaxis (PrEP) might lead individuals to view serodisclosure as unnecessary. We examined the prevalence of non-disclosure and lack of knowledge of partner status in a global cohort of men who have sex with men (MSM) and transgender women (TW) enrolled in the iPrEx Open Label Extension (OLE). We calculated prevalence ratios by fitting a logistic model and estimating predicted probabilities using marginal standardization. Prevalence of non-disclosure and lack of knowledge of partner status were highest in Thailand (73% and 74%, respectively) and lowest in the USA (23% and 37%, respectively). In adjusted analyses, PrEP use was not significantly associated with non-disclosure or lack of knowledge of partner status (p-values>0.05). We found that relationship characteristics were significantly associated with both outcomes. Non-disclosure was higher among casual (adjusted prevalence ratio aPR 1.54, 95% confidence interval 1.24–1.84) and transactional sex partners (aPR 2.03, 1.44–2.62), and among partners whom participants have known only minutes or hours before their first sexual encounter (aPR 1.62, 1.33–1.92). Similarly, participants were less likely to know the HIV status of casual partners (aPR 1.50, 1.30–1.71), transactional sex partners (aPR 1.62, 1.30–1.95), and those they have known for only days or weeks (aPR 1.13, 0.99–1.27) or minutes or hours (aPR 1.27, 1.11–1.42). Our findings underscore the role of dyadic factors in influencing serodisclosure. Comprehensive risk reduction counseling provided in conjunction with PrEP that address relationship characteristics are needed to help patients navigate discussions around HIV status. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Hojilla J.C.; Vlahov D.; Crouch P.-C.; Dawson-Rose C.; Freeborn K.; Carrico A.	HIV Pre-exposure Prophylaxis (PrEP) Uptake and Retention Among Men Who Have Sex with Men in a Community-Based Sexual Health Clinic	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-2009-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038121130&doi=10.1007%2fs10461-017-2009-x&partnerID=40&md5=307d76c01902c575caa03c3bd8878600	In a community-based clinic serving men who have sex with men in San Francisco, California, this study characterized key steps of the pre-exposure prophylaxis (PrEP) cascade and identified correlates of retention in care. In total, 344 patients were evaluated for PrEP. Three-fourths (78%) of those who sought PrEP services initiated PrEP. The overall cumulative incidence of discontinuing PrEP at 13 months was 38%. Men with a sexually transmitted infection (STI) were 44% less likely to be retained (adjusted hazard ratio aHR 0.56, 95% confidence interval 0.33–0.95). Comprehensive retention efforts for men with STIs are crucial to optimize the benefits of PrEP. © 2017, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Hojilla J.C.; Vlahov D.; Glidden D.V.; Amico K.R.; Mehrotra M.; Hance R.; Grant R.M.; Carrico A.W.	Skating on thin ice: Stimulant use and sub-optimal adherence to HIV pre-exposure prophylaxis	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25103	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055257076&doi=10.1002%2fjia2.25103&partnerID=40&md5=3dd4cc15468b0bde46eee8c5aa55ddb1	Stimulant and heavy alcohol use are prevalent and associated with elevated risk for HIV seroconversion among men who have sex with men (MSM) and transgender women. In addition, each can pose difficulties for antiretroviral adherence among people living with HIV. Scant research has examined the associations of stimulant and heavy alcohol use with adherence to daily oral pre-exposure prophylaxis (PrEP) among MSM and transgender women. To address this gap in the literature, we evaluated the hypothesis that stimulant use and binge drinking are prospectively associated with sub-optimal PrEP adherence. Methods: We analysed data from participants in a nested case-cohort in the iPrEx open label extension. Stimulant use (i.e. powder cocaine, crack-cocaine, cocaine paste, methamphetamine, cathinone) and binge drinking (i.e. ≥5 drinks in a single day) in the last 30 days were assessed. Baseline urine was tested for stimulants using immunoassays to reduce misclassification. Sub-optimal adherence was defined as tenofovir drug concentrations in dried blood spots less than 700 fmol per punch, indicative of less than four doses per week. We tested the prospective association of stimulant use and binge drinking with sub-optimal adherence at the 4-week follow-up visit. Results and Discussion: Data from 330 participants were analysed. The majority of the participants were MSM (89%) with a median age at baseline of 29 years (interquartile range 24 to 39). Approximately 16% (52/330) used stimulants and 22% (72/ 330) reported binge drinking in the last 30 days. Stimulant users had fivefold greater odds of sub-optimal PrEP adherence compared to non-users in adjusted analysis (adjusted odds ratio aOR 5.04; 95% CI 1.35 to 18.78). Self-reported binge drinking was not significantly associated with sub-optimal adherence after adjusting for stimulant use and baseline confounders (aOR 1.16 0.49 to 2.73). Depressive symptoms, being transgender, and number of sex partners were also not significantly associated with sub-optimal PrEP adherence (p > 0.05). Conclusions: Stimulant use is a risk factor for sub-optimal PrEP adherence in the month following PrEP initiation. Comprehensive prevention approaches that reduce stimulant use may optimize PrEP adherence. Creating adherence plans that specifically address PrEP dosing in the context of ongoing stimulant use should also be considered. © 2018 The Authors. Article	2018	Holt M.; Lea T.; Mao L.; Kolstee J.; Zablotska I.; Duck T.; Allan B.; West M.; Lee E.; Hull P.; Grulich A.; De Wit J.; Prestage G.	Community-level changes in condom use and uptake of HIV pre-exposure prophylaxis by gay and bisexual men in Melbourne and Sydney, Australia: results of repeated behavioural surveillance in 2013–17	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(18)30072-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048016050&doi=10.1016%2fS2352-3018%2818%2930072-9&partnerID=40&md5=416c8f6f04e10731e51e9bbd5258fc51	Background: Pre-exposure prophylaxis (PrEP) has been rapidly rolled out in large, publicly funded implementation projects in Victoria and New South Wales, Australia. Using behavioural surveillance of gay and bisexual men, we analysed the uptake and effect of PrEP, particularly on condom use by gay and bisexual men not using PrEP. Methods: We collected data from the Melbourne and Sydney Gay Community Periodic Surveys (GCPS), cross-sectional surveys of adult gay and bisexual men in Melbourne, VIC, and Sydney, NSW. Recruitment occurred at gay venues or events and online. Eligible participants were 18 years or older (face-to-face recruitment) or 16 years or older (online recruitment), identified as male (including transgender participants who identified as male); and having had sex with a man in the past 5 years or identified as gay or bisexual, or both. Using multivariate logistic regression, we assessed trends in condom use, condomless anal intercourse with casual partners (CAIC), and PrEP use by gay and bisexual men, controlling for sample variation over time. Findings: Between Jan 1, 2013, and March 31, 2017, 27 011 participants completed questionnaires in the Melbourne (n=13 051) and Sydney (n=13 960) GCPS. 16 827 reported sex with casual male partners in the 6 months before survey and were included in these analyses. In 2013, 26 (1%) of 2692 men reported CAIC and were HIV-negative and using PrEP, compared with 167 (5%) of 3660 men in 2016 and 652 (16%) of 4018 men in 2017 (p<0·0001). Consistent condom use was reported by 1360 (46%) of 2692 men in 2013, 1523 (42%) of 3660 men in 2016, and 1229 (31%) of 4018 men in 2017 (p<0·0001). In 2013, 800 (30%) of 2692 men who were HIV-negative or untested and not on PrEP reported CAIC, compared with 1118 (31%) of 3660 men in 2016, and 1166 (29%) of 4018 in 2017 (non-significant trend). Interpretation: A rapid increase in PrEP use by gay and bisexual men in Melbourne and Sydney was accompanied by an equally rapid decrease in consistent condom use. Other jurisdictions should consider the potential for community-level increases in CAIC when modelling the introduction of PrEP and in monitoring its effect. Article	2018	Holt, Martin; Draper, Bridget L; Pedrana, Alisa E; Wilkinson, Anna L; Stoové, Mark	Comfort Relying on HIV Pre-exposure Prophylaxis and Treatment as Prevention for Condomless Sex: Results of an Online Survey of Australian Gay and Bisexual Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2097-2	https://www.proquest.com/scholarly-journals/comfort-relying-on-hiv-pre-exposure-prophylaxis/docview/2016176968/se-2?accountid=8113	HIV-negative and untested gay and bisexual men from Victoria, Australia (n = 771) were surveyed during August–September 2016 about their comfort having condomless sex with casual male partners in scenarios in which pre-exposure prophylaxis (PrEP) or treatment as prevention were used. Men not using PrEP were most comfortable with the idea of condomless sex with HIV-negative partners (31%), followed by partners using PrEP (23%). PrEP users were more comfortable with the idea of condomless sex with these partner types (64 and 72%, respectively). Very few men not taking PrEP were comfortable with condomless sex with HIV-positive partners (3%), even with undetectable viral loads (6%). PrEP users were more comfortable with condomless sex with HIV-positive partners (29%), and those with undetectable viral loads (48%). Being on PrEP, having recent condomless sex with casual partners or a HIV-positive regular partner were independently associated with comfort having condomless sex. Theses and Dissertations	2018	Hong, Yangsun; Rojas, Hernando; Hull, Shawnika J.	Experience of Intersectionality and Perceived Social Influence of Mass Media for PrEP : The Importance of Social Context and Communicative Action	-	-	University of Wisconsin-Madison	-	NA	NA	https://www.proquest.com/dissertations-theses/experience-intersectionality-perceived-social/docview/2462171642/se-2?accountid=8113	This dissertation has two goals. First, it aims to identify and test the mechanisms through which individuals' social locations influence their health behavior by constructing social context related to health behavior. Based on theoretical integration of models in multiple disciplines, I specify and test a social process model of health behavior in the context of PrEP engagement for women with HIV risk. Using intersectionality as an approach, this multilevel health behavior model focuses on how disadvantaged social experiences of groups with multiple marginalization, in terms of race, gender, and socioeconomic status, influence social contextual and psychosocial predictors of health behavior. The model also explores how state-level structural support influences the social mechanisms. I found that experiences of discrimination as an upstream societal factor constrains chances to build and maintain social contextual opportunities to have social connections to discuss health, to have trust in medical services, and obtain social support. Thus, experience of discrimination links one's marginalized social locations and their social contextual conditions that affect adoption of health behavior. Moreover, state-level policy support for marginalized groups contributes to social contextual factors and psychosocial predictors of behavioral intention for PrEP information seeking. Another important purpose of this study is to identify social contextual factors, which can be modified by health communication intervention to promote health behavior. This study found that talking about health with others positively affects PrEP awareness, perceived norms about PrEP uptake, and self-efficacy, which are predictors of behavior. Based on these findings, this dissertation also aims to suggest and test a health communication strategy for social-structural intervention. This study highlights the role of mass media as a social institution in shaping individuals' perceptions of social context, particularly social values and social norms, by providing shared experiences and understanding among people. Accordingly, mass media intervention is a powerful tool to resolve social barriers, such as lack of awareness and negative social norms, that potentially discourage considering PrEP as a method of self-protection for women at risk of HIV. Adopting the influence of presumed influence hypothesis, I expect that mass media coverage of PrEP indirectly shapes perception of positive social norms about PrEP uptake based on their perception of media influence on others. This study found that perception of others' exposure to PrEP media campaign positively affects their perception of campaign influence on others, which shapes positive normative perceptions about PrEP uptake. Moreover, this study explores whether this strategy motivates not only individual PrEP-related behavior but also encourages social actions regarding PrEP such as communicative and community activities. The results indicate that perceived social norms about PrEP in turn influence their intentions for PrEP engagement at the individual and social levels. Beyond a provider-recipients tradition of health promotion communication that focuses on how individuals interpret the campaign information and then how campaign exposure changes behavior, this study enlightens the indirect influence of media-based health communication in shaping individuals' perceptions of social environment as well as health behaviors. Article	2018	Hood J.E.; Eljallad T.; Abad J.; Connolly M.; Heumann C.; Fritz J.; Roach M.; Lukomski D.; Golden M.R.	Getting pre-exposure prophylaxis to high-risk transgender women: Lessons from Detroit, USA	Sexual Health	-	-	-	14485028	10.1071/SH18063	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056130304&doi=10.1071%2fSH18063&partnerID=40&md5=199699d4e8bf6f1c8e48af0fb4675d49	Background: Pre-exposure prophylaxis (PrEP) is a highly effective HIV prevention strategy, but it is unclear how best to deliver PrEP to key populations. Drawing upon a cross-sectional survey of transgender women (TW) in Detroit, USA, and experience of a PrEP clinic that serves this population, this manuscript describes the following: (1) the risk profile of Detroit TW; (2) the proportion of TW with at least one PrEP indication; and (3) perceptions of and experiences with PrEP among TW in Detroit. Methods: Between August 2017 and March 2018, 126 TW completed an online PrEP survey. Survey responses were summarised using descriptive statistics and multivariable relative risk regression. Results: Among participants who reported a negative or unknown HIV status (76% of all participants), 56% reported risk behaviour(s) consistent with PrEP indication guidelines, 17% reported currently taking PrEP and another 4% reported discontinued PrEP use. Among participants who met an indication for PrEP but were not currently taking PrEP, 64% indicated that they were not interested in taking PrEP. Approximately 60% of participants who were not currently taking PrEP reported that they would be more likely to take PrEP if it were provided at a clinic that also provided hormone replacement therapy. Conclusions: Although a substantial proportion of TW in our survey were on PrEP, interest in PrEP among high-risk TW who were not taking it was low. Specialised clinical infrastructure that is responsive to the specific needs of TW may be needed to expand PrEP to this oftentimes marginalised and high-risk population. © 2018 CSIRO. Article	2018	Hoornenborg E.; Coyer L.; Van Laarhoven A.; Achterbergh R.; De Vries H.; Prins M.; Van Der Loeff M.S.	Change in sexual risk behaviour after 6 months of pre-exposure prophylaxis use: Results from the Amsterdam pre-exposure prophylaxis demonstration project	AIDS	-	-	-	2699370	10.1097/QAD.0000000000001874	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050230580&doi=10.1097%2fQAD.0000000000001874&partnerID=40&md5=a911c3a948da1f75ccdc51cf827df416	Objective: HIV pre-exposure prophylaxis (PrEP) use may lead to higher STI incidence via behavioural risk compensation. We examined changes in sexual behaviour between baseline and 6 months after PrEP initiation among MSM and transgender women (TGW). Design: Prospective, open-label demonstration study at a large sexually transmitted infection (STI) clinic in Amsterdam, the Netherlands. Methods: Participants answered questions about sexual behaviour in the preceding 3 months, including number of anal sex partners and frequency of anal sex with and without condom by partner type and were tested for STI. Sexual behaviour at baseline was compared with 6 months after PrEP initiation using Wilcoxon signed rank tests. Logistic regression was used to identify factors associated with an increase in receptive condomless anal sex acts (rCASa) with casual partners. Results: Data were available for 328 (99%) MSM and 2 (1%) TGW. The number of receptive and insertive condomless anal sex acts (CASa) increased (baseline: median 11, interquartile range 4-23; 6 months: median 14, interquartile range 6-26, P < 0.001), whereas the number of anal sex partners (P = 0.2) and anal sex acts (P = 0.8) remained unchanged. Prevalence of STI was stable. Older age, prior engagement in chemsex, recent use of postexposure prophylaxis and choosing a daily PrEP regimen at baseline were associated with an increase in rCASa with casual partners. Conclusion: Over the first 6 months after initiation of PrEP, an increase in insertive and receptive CASa was observed. Long-term follow-up data are needed and STI incidence needs to be closely monitored. © 2018 Wolters Kluwer Health, Inc. All rights reserved. Article	2018	Hoornenborg, Elske; Achterbergh, Roel Ca; van der Loeff, Maarten F Schim; Davidovich, Udi; van der Helm, Jannie J; Hogewoning, Arjan; van Duijnhoven, Yvonne Thp; Sonder, Gerard Jb; de Vries, Henry Jc; Prins, Maria	Men who have sex with men more often chose daily than event-driven use of pre-exposure prophylaxis: Baseline analysis of a demonstration study in Amsterdam	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25105	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050239200&doi=10.1002%2fjia2.25105&partnerID=40&md5=53570824bb69a30f505e2454ecd85896	The Amsterdam PrEP project is a prospective, open-label demonstration study at a large sexually transmitted infection (STI) clinic. We examined the uptake of PrEP; the baseline characteristics of men who have sex with men (MSM) and transgender persons initiating PrEP; their choices of daily versus event-driven PrEP and the determinants of these choices. Methods: From August 2015 through May 2016, enrolment took place at the STI clinic of the Public Health Service of Amsterdam, the Netherlands. MSM or transgender persons were eligible if they had at least one risk factor for HIV infection within the preceding six months. Participants were offered a choice between daily or event-driven use of tenofovir/emtric-itabine. Baseline data were analysed using descriptive statistics and multivariable analysis was employed to determine variables associated with daily versus event-driven PrEP. Results: Online applications were submitted by 870 persons, of whom 587 were invited for a screening visit. Of them, 415 were screened for eligibility and 376 initiated PrEP. One quarter (103/376, 27%) chose event-driven PrEP. Prevalence of bacterial STI was 19.0% and mean condomless anal sex (CAS) episodes in the preceding three months were 11. In multivariable analysis, older age (≥45 vs. ≤34, aOR 2.1, 95% CI 1.2 to 3.9), being involved in a steady relationship (aOR 1.7, 95% CI 1.0 to 2.7), no other daily medication use (aOR 0.6, 95% CI 0.3 to 0.9), and fewer episodes of CAS (per log increase aOR 0.7, 95% CI 0.6 to 0.9) were determinants for choosing event-driven PrEP. Discussion: PrEP programmes are becoming one of the more important intervention strategies with the goal of reducing incident HIV-infection and we were unable to accommodate many of the persons applying for this study. Offering a choice of dosing regimen to PrEP users may enable further personalization of HIV prevention strategies and enhance up-take, adherence and cost-effectiveness. Conclusions: The majority of participants preferred daily versus event-driven use. Within this majority, a high number of CAS episodes before PrEP initiation was reported and we observed a high prevalence of STI. Determinants of choosing event-driven PrEP were older age, fewer CAS episodes, no other daily medication use, and involved in a steady relationship. © 2018 The Authors. Article	2018	Hotton A.L.; Keene L.; Corbin D.E.; Schneider J.; Voisin D.R.	The relationship between Black and gay community involvement and HIV-related risk behaviors among Black men who have sex with men	Journal of Gay and Lesbian Social Services	-	-	-	10538720	10.1080/10538720.2017.1408518	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85039053551&doi=10.1080%2f10538720.2017.1408518&partnerID=40&md5=fb3a141abc73581a890a6614d59d2da0	Black gay men must navigate identities and stigmas related to being gay and Black, and report higher HIV incidence relative to their White male counterparts although they report lower rates of drug use and risky sexual behaviors. This study examined whether closeness to the gay or Black community correlated with HIV-related risk and protective behaviors. Data were drawn from uConnect, a population-based cohort study of young Black men who have sex with men (YBMSM) on Chicago's South Side. The sample consists of 618 Black MSM ranging in age from 16 to 29. Cross-sectional measures for this study include Black and gay community closeness, drug use, sexual risk behaviors, HIV testing, and health promotion behaviors. Closeness with the gay community was associated with greater pre-exposure prophylaxis (PrEP) knowledge as well as participating in health promotion programs along with higher rates of transactional sex and having sex under the influence of substances, and increased odds of self-reported HIV seropositivity. Involvement in the Black community was associated with lower odds of reporting being HIV positive. Findings suggest that programs and initiatives are needed to help promote the positive aspects of the Black and gay communities, while minimizing the negative correlates of such involvements. © 2018 Taylor & Francis Group, LLC.	community; health outcomes; HIV; involvement; young Black MSM	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2018	Hu Y.; Zhong X.-N.; Peng B.; Zhang Y.; Liang H.; Dai J.-H.; Zhang J.-Y.; Huang A.-L.	Associations between perceived barriers and benefits of using HIV pre-exposure prophylaxis and medication adherence among men who have sex with men in Western China	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-018-3497-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056627024&doi=10.1186%2fs12879-018-3497-7&partnerID=40&md5=10153c4ab4f87d3d52a2d47a73a003ff	Background: To investigate the associations between the perceived barriers and benefits of using HIV pre-exposure prophylaxis medication, including worries about the side effects, disliking taking drugs, perceived burden of taking medication, positive expectations as to the efficacy of the drugs, favourable doctor-patient relationships, and medication adherence among men who have sex with men (MSM) to provide a target for improving medication adherence and reducing HIV infection among MSM. Methods: MSM were recruited in western China from April 2013 to October 2014, administered oral tenofovir (TDF) daily and followed up every 12 weeks for 2 years. At each follow-up, the medication rate was calculated based on the self-reported number of missed doses over 2 weeks, and then, the medication adherence was evaluated. The barriers and benefits perceived during medication were obtained by a self-administered questionnaire, and their effects on medication adherence were analysed by linear mixed models. Results: A total of 411 participants were enrolled in this study, and 1561 follow-up observation points were obtained. The average medication rate was 0.62 ± 0.37, and the medication rate increased with longer follow-up (P < 0.05). The medication rate was higher among MSM who were divorced (compared to those who were unmarried, P < 0.0001). MSM with more positive expectations as to the efficacy of the drugs showed higher rates of medication (P < 0.0001), while those who were more worried about side effects had a lower medication rate (P = 0.0208). In contrast, the dislike of taking the drugs and the burden perceived during medication had no effects on the actual medication rate of taking TDF (P > 0.05). Conclusion: How to obtain and maintain high medication adherence among MSM is the key to the PrEP intervention strategy for effective reduction of HIV infection. For MSM in China, we should deepen their understanding of the effectiveness and safety of PrEP and increase their confidence in PrEP, thereby improving their medication adherence. Article	2018	Huang X.; Hou J.; Song A.; Liu X.; Yang X.; Xu J.; Zhang J.; Hu Q.; Chen H.; Chen Y.; Meyers K.; Wu H.	Efficacy and safety of oral TDF-based pre-exposure prophylaxis for men who have sex with men: A systematic review and meta-analysis	Frontiers in Pharmacology	-	-	-	16639812	10.3389/fphar.2018.00799	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068051558&doi=10.3389%2ffphar.2018.00799&partnerID=40&md5=b741390d81db6da20096303820a86ac4	Background: Pre-exposure prophylaxis (PrEP) is used as an HIV prevention method by people at substantial risk of HIV infection. This systematic review and meta-analysis evaluates current clinical evidence for use of oral TDF-based PrEP among men who have sex with men. Methods: A comprehensive literature search in PubMed, web of science, Google Scholar and ClinicalTrials.gov was performed. A random-effects meta-analysis was conducted using the event rate (ER) for estimation of the incidence of HIV and grade 3 or 4 adverse events (AE) among PrEP arm and using risk ratio (RR) for comparison of incidence of HIV and grade 3 or 4 AE between PrEP recipients and PrEP non-users. Blood-based adherence levels were also divided into three categories with reference to previous meta-analysis. Subgroup meta-analysis was also performed to evaluate whether blood-based adherence levels moderated the effect of TDF-based PrEP on HIV incidence. Narrative review was used due to inconsistent measurements of risk behavior and drug resistance. This review is registered on the PROSPERO database (CRD42017077965). Results: Fourteen studies were included in the review. Oral TDF-based PrEP significantly reduced HIV incidence with minimum drug resistance and tolerable safety risks (HIV incidence, ER = 1.1%, 95% CI 0.6-2.0%, p < 0.001, RR = 0.244, 95% CI 0.111-0.537, p < 0.001 and grade 3 or 4 AEs, ER = 13.0%, 95% CI 9.9-16.9%, p < 0.001, RR = 1.059, 95% CI 0.824-1.362, p = 0.653). Oral TDF-based PrEP was more effective in reducing HIV incidence with high levels of blood-based PrEP adherence (ER, 0.4%) compared to moderate adherence (2.9%; p < 0.001). Most studies found no association between PrEP use and self-reported sexual behavior. Conclusion: Oral TDF-based PrEP is an effective intervention to prevent against HIV infection among MSM. Well-designed implementation science studies that integrate sociobehavioral and biomedical interventions are needed to identify optimal PrEP delivery models in different populations to translate biomedical efficacy into real-world efficacy. © 2018 Huang, Hou, Song, Liu, Yang, Xu, Zhang, Hu, Chen, Chen, Meyers and Wu. Article	2018	Huang Y.-L.A.; Tao G.; Samandari T.; Hoover K.W.	Laboratory testing of a cohort of commercially insured users of HIV preexposure prophylaxis in the United States, 2011-2015	Journal of Infectious Diseases	-	-	-	221899	10.1093/infdis/jix595	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044453431&doi=10.1093%2finfdis%2fjix595&partnerID=40&md5=028807e5103539fc7e7ceaff9df072f2	To ensure the health and safety of persons taking antiretroviral medication as preexposure prophylaxis (PrEP) against human immunodeficiency virus (HIV) infection, Centers for Disease Control and Prevention guidelines recommend initial and follow-up laboratory testing. We assessed the rates of recommended testing, using a commercial insurance claims database. Before taking PrEP, 45% of users were tested for HIV, 55% for syphilis, 43% for chlamydia/gonorrhea, and 38% for hepatitis B, and 31% had creatinine level measured. By 6 months after PrEP initiation, 38% were tested for HIV, 49% for syphilis, and 39% for chlamydia/gonorrhea, and 37% had their creatinine level measured. Although laboratory testing was less frequent than recommended, testing rates increased over the study period. © The Author(s) 2017. Essay	2018	Huang, Ya-Lin A; Zhu, Weiming; Smith, Dawn K; Harris, Norma; Hoover, Karen W	HIV Preexposure Prophylaxis, by Race and Ethnicity - United States, 2014-2016.	MMWR Recommendations and Reports	-	-	-	1545-861X	10.15585/mmwr.mm6741a3	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6193685	Preexposure prophylaxis (PrEP) with a daily, oral pill containing antiretroviral drugs is highly effective in preventing acquisition of human immunodeficiency virus (HIV) infection (1-4). The combination of tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) is the only medication approved by the Food and Drug Administration (FDA) for PrEP. PrEP is indicated for men and women with sexual or injection drug use behaviors that increase their risk for acquiring HIV (5). CDC analyzed 2014-2016 data from the IQVIA Real World Data - Longitudinal Prescriptions (IQVIA database) to estimate the number of persons prescribed PrEP (users) in the United States and to describe their demographic characteristics, including sex and race/ethnicity. From 2014 to 2016, the annual number of PrEP users aged ≥16 years increased by 470%, from 13,748 to 78,360. In 2016, among 32,853 (41.9%) PrEP users for whom race/ethnicity data were available, 68.7% were white, 11.2% were African American or black (black), 13.1% were Hispanic, and 4.5% were Asian. Approximately 7% of the estimated 1.1 million persons who had indications for PrEP were prescribed PrEP in 2016, including 2.1% of women with PrEP indications (6). Although black men and women accounted for approximately 40% of persons with PrEP indications (6), this study found that nearly six times as many white men and women were prescribed PrEP as were black men and women. The findings of this study highlight gaps in effective PrEP implementation efforts in the United States. Article	2018	Hughes S.D.; Sheon N.; Andrew E.V.W.; Cohen S.E.; Doblecki-Lewis S.; Liu A.Y.	Body/Selves and Beyond: Men's Narratives of Sexual Behavior on PrEP	Medical Anthropology: Cross-Cultural Studies in Health and Illness	-	-	-	1459740	10.1080/01459740.2017.1416608	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056574799&doi=10.1080%2f01459740.2017.1416608&partnerID=40&md5=e889ffad3a4f9f5b4921213db0fe43de	Although pre-exposure prophylaxis (PrEP) has dramatically impacted HIV prevention, deep engagement with PrEP-takers' own accounts of their sexual behavior is still rare. We report findings from semi-structured interviews with male participants of the US PrEP Demonstration Project. In their narratives, interviewees variously foregrounded their individual selves, interactions with sexual partners, and the biopolitical and historical context of their lives. PrEP served to discursively integrate the multiple selves populating these stories. We argue that medical anthropological notions can help make sense of men's accounts, and PrEP's role in them, advancing a holistic conception of personhood that includes but transcends concern with HIV. © 2018, © 2018 Taylor & Francis. Article	2018	Ibrahim M.E.; Brooks K.M.; Castillo-Mancilla J.R.; McHugh C.; Morrow M.; Brothers J.; Mawhinney S.; Hosek S.; Huhn G.; Anderson P.L.	Short communication: Bioequivalence of tenofovir and emtricitabine after coencapsulation with the proteus ingestible sensor	AIDS Research and Human Retroviruses	-	-	-	8892229	10.1089/aid.2018.0081	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055077374&doi=10.1089%2faid.2018.0081&partnerID=40&md5=b0769d02fa6baeb00511eacec86a9df3	Adherence to tenofovir disoproxil fumarate/emtricitabine (TDF/FTC, Truvada®) is the primary determinant of HIV pre-exposure prophylaxis (PrEP) efficacy. Despite its importance, limitations exist in current methods of adherence quantification, restricting their implementation in the clinic. Proteus Discover (Proteus Digital Health®) can measure the time of each dose using an ingestible sensor that is coencapsulated with medication. In this study, the bioequivalence of coencapsulated TDF/FTC with the Proteus sensor was compared relative to unencapsulated drug. This was a 1:1 randomized cross-over study in which healthy participants received a single dose of unencapsulated and coencapsulated TDF/FTC. A 14-day washout separated each period. Blood was collected at predose and at 0.25, 0.5, 1, 2, 4, 6, 10, 24, 48, and 72 h postdose. Plasma concentrations were determined by LC-MS/MS methods, with a 10 ng/mL lower limit of quantitation (LLOQ) for both tenofovir (TFV) and FTC. Noncompartmental analysis was carried out with Phoenix® WinNonlin® for maximum concentrations (Cmax), area under the concentration-time curve from time 0 to the last measured time point (AUClast) and AUC extrapolated to infinity (AUCinf). Geometric mean ratios were calculated for each parameter and bioequivalence was defined as the 90% confidence interval (CI) of each ratio being within 80%-125%. Twenty-four participants (11 males; 19 white, 3 African American, and 2 Hispanic) completed both visits. Mean ± SD age was 28 ± 4 years and weight was 74 ± 14 kg. The 90% CIs for TFV Cmax, AUClast, and AUCinf were 89%-119%, 94%-111%, and 96%-111%, respectively. The 90% CIs for FTC Cmax, AUClast, and AUCinf were 96%-120%, 96%-108%, and 96%-108%, respectively. Bioequivalence was observed for the coencapsulation of TDF/FTC with the Proteus ingestible sensor, as assessed by a rigorously conducted pharmacokinetic study. Future studies will evaluate the utility and effectiveness of the sensor system as a tool to monitor PrEP adherence in clinical settings. © Copyright 2018, Mary Ann Liebert, Inc., publishers.	adherence; bioequivalence; digital medicine; pharmacokinetics; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2018	Iniesta, Carlos	Awareness, knowledge, use, willingness to use and need of Pre-Exposure Prophylaxis (PrEP) during World Gay Pride 2017	PLOS One	-	-	-	NA	https://doi.org/10.1371/journal.pone.0216376	https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0204738	Objective To assess the awareness, knowledge, use, and willingness to use and need of PrEP among men who have sex with men (MSM) and transgender women (TW) who attended World Gay Pride (WGP) 2017 in Madrid. Design and methods Online survey. Participants were recruited through gay-oriented dating apps and HIV Non-Governmental Organizations' social media. Inclusion criteria included being MSM or TW, age 18 years old or above, and having attended WGP in Madrid. Information regarding the participant's awareness and knowledge, use or willingness to use, and need for PrEP was collected, as well as sociodemographic characteristics. Participants were considered to be in need of PrEP if they met one of the following indication criteria: having practiced unprotected anal intercourse with more than 2 partners, having practiced chemsex, or having engaged in commercial sex—all in the preceding 6 months. Descriptive and multivariable analyses with logistic regression were conducted. Results 472 participants met the inclusion criteria and completed the questionnaire. The mean age was 38, 97.7% were MSM, 77% had a university education, and 85% were living in Spain, mostly in big cities. Overall, 64% of participants were aware of PrEP, but only 33% knew correctly what PrEP was. 67% of HIV-negative participants were willing to take PrEP, although only 5% were taking it during WGP, mostly due to lack of access. 43% of HIV-negative respondents met at least one PrEP indication criteria. For HIV-negative men living in Spain, university education and living in big cities was associated with PrEP awareness. Lower education level and meeting PrEP criteria was associated with willingness to use PrEP. Conclusions Our study shows that among MSM attending WGP 2017 in Madrid, there was limited PrEP awareness, low accuracy of PrEP knowledge, and a high need and willingness to use PrEP. Health authorities should strengthen existing preventive strategies and implement PrEP. Article	2018	Ishiekwene, Celestine; Thomas-Powell, Sherry; Ghitan, Monica; Kuhn-Basti, Margaret; Chapnick, Edward; Yu Shia Lin	Evaluation of the awareness, knowledge and use of pre-exposure prophylaxis (PrEP) among the serodiscordant partners of HIV infected individuals on ART in an urban HIV clinic	Cogent Medicine	-	-	-	NA	10.1080/2331205X.2018.1475124	https://www.proquest.com/scholarly-journals/evaluation-awareness-knowledge-use-pre-exposure/docview/2170827177/se-2?accountid=8113	The awareness, knowledge and acceptance of pre-exposure prophylaxis (PrEP) among at risk group greatly depend on the collaborative efforts of CDC, health care workers and other government and non-governmental organizations. We conducted a cross-sectional study to evaluate the knowledge of PrEP among HIV patients and indirect assessment of the use of PrEP by their serodiscordant sexual partners. Two (4%) of the study participants whose partner(s) were at risk had discussed the use of PrEP with their partner(s) but none of their partners was on PrEP. The study revealed that awareness of PrEP may be slowly increasing but the uptake of PrEP is low. Awareness of PrEP does not translate to knowledge of PrEP. This is why there is need for health care professionals especially primary care physicians including HIV providers to incorporate PrEP counseling programs in the care of PLWHA and their families. Article	2018	Jacot, TA; Clark, MR; Adedipe, OE; Godbout, S; Peele, AG; Ju, S; Schwartz, JL; Thurman, AR; Doncel, GF	Development and clinical assessment of new objective adherence markers for four microbicide delivery systems used in HIV prevention studies	Clinical and Translational Medicine	-	-	-	2001-1326	10.1186/s40169-018-0213-6	https://onlinelibrary.wiley.com/doi/10.1186/s40169-018-0213-6	BackgroundAdherence is critical for successful topical, vaginally delivered anti-retroviral (ARV)-based HIV pre-exposure prophylaxis (PrEP). Quantitating systemic or tissue ARV levels through LC-MS/MS is currently viewed as the most reliable measure of adherence. However, for placebo-controlled trials, this is a high cost analysis that measures adherence only in the drug treatment group. A desirable marker of adherence is one that is measured in both placebo and drug treatment groups using a simple on-site clinical laboratory test, which allows necessary interventions for supporting participant adherence. Our objective was to develop adherence markers for four vaginal placebo products currently used as microbicide delivery systems: gel, film, insert, and intravaginal ring. Excipient and spectroscopy-based approaches were used for preclinical development of the placebo markers and subsequently validated by the CONRAD 135 study. The study collected vaginal swabs collected each day for 1week post vaginal application of gel, film, or insert in the clinic with or without sex. Intravaginal rings were collected after 1day, 7, and 30days of use.ResultsPlacebo gel, film, and insert in vaginal swabs were successfully detected by specific excipient colorimetric or probe-based assays for hydroxyethylcellulose, glycerin, and sorbitol respectively, as well as spectroscopy-based prediction models. The range of detection for gel, film, and insert in swabs collected up to 16h post vaginal application was 70-100% of the total swabs per time point, with some markers showing potential for longer duration. Decreasing residual glycerin levels and increasing bioanalyte penetration of vaginally used intravaginal rings showed significant changes between 1 and 30days of use.ConclusionsWe demonstrated clinical proof-of-concept that adherence markers for placebo product can be measured using simple, lower cost approaches. Measuring adherence in both placebo and drug arms of a HIV PrEP study would better inform future trial designs. Article	2018	Jaiswal J.; Griffin M.; Singer S.N.; Greene R.E.; Acosta I.L.Z.; Kaudeyr S.K.; Kapadia F.; Halkitis P.N.	Structural barriers to pre-exposure prophylaxis use among young sexual minority men: The P18 cohort study	Current HIV Research	-	-	-	1570162X	10.2174/1570162X16666180730144455	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055640863&doi=10.2174%2f1570162X16666180730144455&partnerID=40&md5=4f5364d6526c5befbc67a7a5c2adbb60	Background: Despite decreasing rates of HIV among many populations, HIV-related health disparities among gay, bisexual and other men who have sex with men persist, with disproportional percentages of new HIV diagnoses among racial and ethnic minority men. Despite increasing awareness of HIV pre-exposure prophylaxis (PrEP), PrEP use remains low. In addition to exploring individual-level factors for this slow uptake, structural drivers of PrEP use must also be identified in order to maximize the effectiveness of biomedical HIV prevention strategies. Method: Using cross-sectional data from an ongoing cohort study of young sexual minority men (N=492), we examine the extent to which structural-level barriers, including access to health care, medication logistics, counseling support, and stigma are related to PrEP use. Results: While almost all participants indicated awareness of PrEP, only 14% had ever used PrEP. PrEP use was associated with lower concerns about health care access, particularly paying for PrEP. Those with greater concerns talking with their provider about their sexual behaviors were less likely to use PrEP. Conclusion: Paying for PrEP and talking to one's provider about sexual behaviors are concerns for young sexual minority men. In particular, stigma from healthcare providers poses a significant barrier to PrEP use in this population. Providers need not only to increase their own awareness of and advocacy for PrEP as an effective risk-management strategy for HIV prevention, but also must work to create open and non-judgmental spaces in which patients can discuss sexual behaviors without the fear of stigma. © 2018 Bentham Science Publishers. Article	2018	Jalil, Emilia M.; Grinsztejn, Beatriz; Velasque, Luciane; Ramos Makkeda, Alessandra; Luz, Paula M.; Moreira, Ronaldo I.; Kamel, Luciana; Fernandes, Nilo M.; Ferreira, Ana Cristina G.; Hoagland, Brenda; Wagner, Sandra; Liu, Albert; McFarland, Willi; Buchbinder, Susan; Veloso, Valdilea G.; Wilson, Erin	Awareness, Willingness, and PrEP Eligibility Among Transgender Women in Rio de Janeiro, Brazil.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000001839	https://journals.lww.com/jaids/fulltext/2018/12010/awareness,_willingness,_and_prep_eligibility_among.6.aspx	BACKGROUND: HIV epidemics disproportionately affect transwomen worldwide. Trans-specific guidance, outreach, and interventions to increase pre-exposure prophylaxis (PrEP) use among transwomen are scarce. SETTING: Rio de Janeiro, Brazil. METHODS: We measured awareness and willingness to use PrEP and examined factors associated with those outcomes among transwomen in Rio de Janeiro and estimated how many transwomen would be eligible for PrEP. Data originate from Transcender study, a respondent-driven sampling survey conducted from August 2015 to January 2016. We performed regression models for PrEP awareness and willingness. RESULTS: One hundred thirty-one (38.0%) of 345 participants had heard of PrEP. Among transwomen who self-reported as HIV-negative, 162 (76.4%, N = 212 with available data) reported willingness to use it and 163 (66.8%, N = 244) met PrEP behavioral eligibility criteria. Transwomen with health access in the previous 6 months who reported HIV-infected sexual partner and with 8+ years of schooling had increased odds of PrEP awareness. Lower PrEP awareness was associated with condomless anal intercourse and newly diagnosed HIV infection. Younger age and perceiving themselves at risk of HIV infection increased the odds of PrEP willingness. Lower odds of PrEP willingness were associated with concerns about long-term effects of PrEP and with difficulties in getting access to health care due to transphobia. CONCLUSION: Combination of low awareness, high willingness, and substantial PrEP eligibility corroborates transwomen as a key population for HIV prevention. PrEP is a promising and empowering strategy for HIV prevention among transwomen, but trans-specific recommendations are needed to effectively implement PrEP in this population. Article	2018	Janes, Holly; Corey, Lawrence; Ramjee, Gita; Carpp, Lindsay N; Lombard, Carl; Cohen, Myron S; Gilbert, Peter B; Gray, Glenda E	Weighing the Evidence of Efficacy of Oral PrEP for HIV Prevention in Women in Southern Africa.	AIDS Research and Human Retroviruses	-	-	-	1931-8405	10.1089/AID.2018.0031	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6080090	As oral tenofovir-based regimens for preexposure prophylaxis (PrEP) are adopted as standard of care for HIV prevention, their utilization in clinical trials among women in southern Africa will require an accurate estimate of oral PrEP efficacy in this population. This information is critical for women in choosing this prevention strategy, and in public health policy making. Estimates of the efficacy of oral PrEP regimens containing tenofovir have varied widely across trials that enrolled women, with some studies reporting high efficacy and others reporting no efficacy. Although poor adherence is strongly associated with lack of efficacy, other factors, such as mode of transmission (sexual vs. parenteral), predominant HIV subtype (C vs. non-C), intensity of exposure, and percentage of stable serodiscordant couples, may also contribute to the variation in efficacy estimates. In this article, we evaluate the evidence for PrEP efficacy in women and propose potential explanations for the observed differences in efficacy among studies. Our review emphasizes the need to continue to refine estimates of efficacy and effectiveness of tenofovir-based oral PrEP so as to best develop the next generation of HIV prevention tools, and to inform public policies directed toward HIV prevention.	preexposure prophylaxis, oral PrEP efficacy, HIV prevention, southern African women, adherence	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review

Theses and Dissertations	2018	Jaramillo, Jahn	Perceptions of Pre-Exposure Prophylaxis (PrEP) and Acceptability of Peer Navigation Among HIV-Negative Latinx and Black Men Who Have Sex with Men (MSM) in Western Washington	-	-	University of Washington	-	NA	NA	https://digital.lib.washington.edu/researchworks/bitstream/handle/1773/42888/Jaramillo_washington_0250O_18463.pdf?sequence=1&isAllowed=y	HIV PrEP (pre-exposure prophylaxis) is an effective biomedical approach for HIV prevention. However, PrEP is an underutilized resource among Latinx and Black men who have sex with men (MSM) in the United States. Peer navigation approaches are being widely scaled up to support PrEP uptake and adherence, though it remains unclear what strategies work best to effectively address the diverse social and cultural needs of Latinx and Black MSM. This study is based on qualitative research conducted on a subset of 66 Latinx and Black MSM residing in Western Washington who participated in an online CAPI REDCap survey. We conducted semi-structured in-depth interviews with 21 men selected through purposive sampling methods to evaluate the intersectionality of race, ethnicity, sexual orientation, and other identities men possessed and how this related to their views on PrEP in general, and on peer navigation specifically. Thematic analysis was used to identify and analyze emergent themes. Four major themes emerged as relevant to PrEP interest and uptake: 1) disclosure concerns for bisexual/gay masculine identified men; 2) specific challenges for Latinx MSM, including migration status and need for advocacy; 3) specific challenges for Black MSM, including discrimination and need lack of trust; and 4) special considerations for younger men, including limited knowledge and experience discussing sexual health and an interest in more comprehensive peer intervention content. Interest in peer navigation was high among study participants, particularly for men with limited social support or English proficiency and for men who had moved from out of state or another country. Several potential approaches to improve peer navigation were identified, including developing culturally congruent programming to match peers with men based on various identity considerations and identified needs, employing social media such as chatrooms and informational phone lines as complementary combination strategies, and incorporating trauma-informed care into a peer navigation program for Latinx and Black MSM. Tailored peer navigation approaches may help MSM of color by increasing resilience to societal stigma at the individual level, enhancing social support at the interpersonal level and serving as a bridge to providers at the structural level. These strategies could ultimately reduce racial/ethnic HIV disparities, if implemented. Article	2018	John, Steven A; Starks, Tyrel J; Rendina, H Jonathon; Grov, Christian; Parsons, Jeffrey T	Should I Convince My Partner to Go on Pre-Exposure Prophylaxis (PrEP)? The Role of Personal and Relationship Factors on PrEP-Related Social Control among Gay and Bisexual Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1835-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021108263&doi=10.1007%2fs10461-017-1835-1&partnerID=40&md5=cbb386900b9e36145d528593828362b2	An estimated 35–68% of new HIV infections among gay, bisexual, and other men who have sex with men (GBM) are transmitted through main partnerships. Pre-exposure prophylaxis (PrEP) is highly effective in reducing HIV seroconversion, yet PrEP uptake has been modest. PrEP-naïve GBM with HIV-negative, PrEP-naïve main partners enrolled in One Thousand Strong (n = 409), a U.S. national cohort of GBM, were asked about (1) the importance of partner PrEP use and (2) their willingness to convince their partner to initiate PrEP. On average, participants thought partner PrEP was only modestly important and were only moderately willing to try to convince their partner to initiate PrEP. Personal PrEP uptake willingness and intentions were the strongest indicators of partner PrEP outcomes. Being in a monogamish relationship arrangement (as compared to a monogamous arrangement) and the experience of intimate partner violence victimization were associated with increased willingness to persuade a partner to initiate PrEP. © 2017, Springer Science+Business Media, LLC. Article	2018	John, Steven A; Whitfield, Thomas H F; Rendina, H Jonathon; Parsons, Jeffrey T; Grov, Christian	Will Gay and Bisexual Men Taking Oral Pre-exposure Prophylaxis (PrEP) Switch to Long-Acting Injectable PrEP Should It Become Available?	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1907-2	https://www.proquest.com/scholarly-journals/will-gay-bisexual-men-taking-oral-pre-exposure/docview/2020258261/se-2?accountid=8113	Oral pre-exposure prophylaxis (PrEP) is highly effective at reducing HIV transmission risk and is CDC recommended for many gay, bisexual, and other men who have sex with men (GBM). We sought to investigate awareness of and preference for using long-acting injectable PrEP (LAI-PrEP) among GBM currently taking oral PrEP (n = 104), and identify their concerns. About half of GBM had heard of LAI-PrEP, and 30.8% specifically preferred LAI-PrEP. GBM with more concerns about the level of protection and drug half-life of LAI-PrEP had lower odds of preferring LAI-PrEP. Given that daily pill adherence is a challenge for some on PrEP, it is important to investigate the degree to which those on PrEP might consider LAI-PrEP as an alternative.Resumo alternativo:La Profilaxis pre-Exposición (PrEP) es altamente efectiva en reducir el riesgo de transmisión del VIH y es recomendada por los Centros de Control y Prevención de Enfermedades (CDC, por su sigla en inglés) para hombres homosexuales, bisexuales, y otros hombres que tienen relaciones sexuales con hombres (HGB). Buscamos investigar el grado de conciencia sobre y la preferencia por usar la PrEP inyectable de acción prolongada (LAI-PrEP, por su sigla en inglés) entre HGB que están actualmente tomando la PrEP oralmente (n = 104), e identificar sus preocupaciones al respecto. Aproximadamente la mitad de los HGB había oído sobre la LAI-PrEP (LAI-PrEP, por su sigla en inglés) y el 30.8% prefirió específicamente la LAI-PrEP. HGB con más preocupación sobre el nivel de protección y la vida-media de la LAI-PrEP tuvieron menor probabilidad de preferir la LAI-PrEP. Dado que la adherencia al tratamiento con un medicamento diario es un desafío para algunas personas que toman la PrEP, es importante investigar hasta qué punto las personas que toman la PrEP considerarían la LAI-PrEP como una alternativa. Article	2018	Jonas K.J.; Yaemim N.	HIV Prevention After Discontinuing Pre-Exposure Prophylaxis: Conclusions From a Case Study	Frontiers in Public Health	-	-	-	22962565	10.3389/fpubh.2018.00137	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074599809&doi=10.3389%2ffpubh.2018.00137&partnerID=40&md5=7fd3352d3857c2b231d3a09f2fb6b02f	Pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate in combination with emtricitabine (FTC) is a highly effective form of HIV prevention. Endeavors of health-care providers and activists in many countries over the world are directed at making access to PrEP possible, or increasing PrEP use among men-who-have-sex-with-men (MSM). We argue while this effort is necessary, we also need to consider modes of HIV prevention after a period of PrEP use. PrEP uptake is not a one-way street, meaning that individuals may discontinue PrEP use, either voluntarily and involuntarily. Voluntary discontinued PrEP use in conjunction with decreased or no HIV risk exposure is unproblematic, but involuntary discontinuations with continuous high level of HIV risk exposure calls for tailored post-PrEP use HIV prevention. We present a case study of an MSM individual who discontinued PrEP for medical reasons (renal function) and seroconverted soon afterward, to illustrate the need for tailored HIV prevention post-PrEP. Furthermore, we provide additional contexts of PrEP discontinuation leading to populations that are in need for post-PrEP types of HIV prevention. Subsequently, we present suggestions for modes of post-PrEP HIV prevention based on knowledge–communication–choice model. Community organization and health-care providers should consider and prepare their HIV prevention consulting protocols for such types of clients and add post-PrEP HIV prevention measures to their consulting offer. © Copyright © 2018 Jonas and Yaemim.	counselling; HIV; pre-exposure prophylaxis; prevention; public health	English	Switzerland	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Qualitative
Article	2018	Jotwani, Vasantha, MD; Scherzer, Rebecca, PhD; Glidden, David V, PhD; Mehrotra, Megha, MPH; Defechereux, Patricia, PhD; Liu, Albert, MD, MPH; Gandhi, Monica, MD, MPH; Bennett, Michael, PhD; Coca, Steven G, MD; Parikh, Chirag R, MD, PhD; Grant, Robert M, MD; Shlipak, Michael G, MD, MPH	Pre-exposure Prophylaxis With Tenofovir Disoproxil Fumarate/Emtricitabine and Kidney Tubular Dysfunction in HIV-Uninfected Individuals: JAIDS	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001654	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-with-tenofovir/docview/2075664379/se-2?accountid=8113	Background: Pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) is becoming increasingly adopted for HIV prevention. Tenofovir can cause proximal tubular damage and chronic kidney disease in HIV-infected persons, but little is known regarding its nephrotoxic potential among HIV-uninfected persons. In this study, we evaluated the effects of PrEP on urine levels of the following: α1-microglobulin (α1m), a marker of impaired tubular reabsorption; albuminuria, a measure of glomerular injury; and total proteinuria. Setting: The Iniciativa Profilaxis Pre-Exposicion (iPrEx) study randomized HIV-seronegative men and transgender women who have sex with men to oral TDF/FTC or placebo. The iPrEx open-label extension (iPrEx-OLE) study enrolled former PrEP trial participants to receive open-label TDF/FTC. Methods: A cross-sectional analysis compared urine biomarker levels by study arm in iPrEx (N = 100 treatment arm, N = 100 placebo arm). Then, urine biomarker levels were compared before and after PrEP initiation in 109 participants of iPrEx-OLE. Results: In iPrEx, there were no significant differences in urine α1m, albuminuria, or proteinuria by treatment arm. In iPrEx-OLE, after 24 weeks on PrEP, urine α1m and proteinuria increased by 21% 95% confidence interval (CI): 10 to 33 and 18% (95% CI: 8 to 28), respectively. The prevalence of detectable α1m increased from 44% to 65% (P < 0.001) and estimated glomerular filtration rate declined by 4 mL/min/1.73 m2 (P < 0.001). There was no significant change in albuminuria (6%; 95% CI: −7% to 20%). Conclusion: PrEP with TDF/FTC was associated with a statistically significant rise in urine α1m and proteinuria after 6 months, suggesting that PrEP may result in subclinical tubule dysfunction. Pharmacokinetics and Pharmacodynamics of Tenofovir Reduced-Glycerin 1% Gel in the Rectal and Vaginal Compartments in Women: A Cross-Compartmental Study With Directly Observed Dosing	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001655	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054066383&doi=10.1097%2fQAI.0000000000001655&partnerID=40&md5=300a3d0461be49a3c2acd53f0b8c6a60	Background: Evidence is lacking regarding whether vaginal preexposure prophylaxis with topical tenofovir (TFV) reduces the risk of rectal HIV acquisition. Setting: Bronx, NY. Methods: MTN-014 was a phase 1, cross-over, randomized sequence trial comparing the cross-compartment pharmacokinetics and pharmacodynamics of daily TFV reduced-glycerin 1% gel after 14 days each of rectal and vaginal application, with directly observed dosing and a 6-week washout period between phases. Results: Fourteen HIV-uninfected women enrolled; 91% of doses were observed and 13 women completed all study procedures. TFV and TFV diphosphate (TFV-DP) were detected in most samples collected from the dosing compartment. After vaginal dosing, TFV was detected in 10/14 samples of rectal fluid (RF) (median 4.4 ng/sponge) and 1/13 rectal tissue samples (0.2 ng/mg); TFV-DP was detected in 2/13 rectal tissue samples at 59.8 and 76.5 fmol/mg. After rectal dosing, TFV was detected in 9/14 samples of vaginal fluid (median 1.1 ng/swab) and in 6/14 vaginal tissue samples (median below limit of quantification); TFV-DP was detected in 3/14 vaginal tissue samples at 17.3, 87.6, and 77.1 fmol/mg. Neither cervicovaginal lavage fluid nor RF collected 24 hours after rectal or vaginal dosing resulted in a statistically significant suppression of viral replication. Conclusions: In this study of 14 days each of vaginal and rectal application of TFV reduced-glycerin 1% gel, we found only a small degree of cross-compartment distribution of TFV in RF and vaginal fluids and no pharmacodynamic activity in ex vivo testing. Although high TFV concentrations in the dosing compartment may be protective, low cross-compartment tissue concentrations are not likely to be protective. Copyright © 2018 The Author(s). Article	2018	Kahle E.M.; Sullivan S.; Stephenson R.	Functional knowledge of pre-exposure prophylaxis for HIV prevention among participants in a web-based survey of sexually active gay, bisexual, and other men who have sex with men: Cross-sectional study	JMIR Public Health and Surveillance	-	-	-	23692960	10.2196/publichealth.8089	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041071494&doi=10.2196%2fpublichealth.8089&partnerID=40&md5=124508bf9a916f61b5fb9dc4c2edd9ce	Background: Awareness of pre-exposure prophylaxis (PrEP) for HIV prevention is increasing, but little is known about the functional knowledge of PrEP and its impact on willingness to use PrEP. Objective: The objective of this study was to assess the functional knowledge of PrEP among a sample of gay, bisexual, and other men who have sex with men (MSM) participating in a Web-based survey of sexually active MSM. Methods: Men at least 18 years old, residing in the United States, and reporting sex with a man in the previous 6 months were recruited through social networking websites. PrEP functional knowledge included the following 4 questions (1) efficacy of consistent PrEP use, (2) inconsistent PrEP use and effectiveness, (3) PrEP and condom use, and (4) effectiveness at reducing sexually transmitted infections (STIs). Ordinal logistic regression was used to identify respondent characteristics associated with PrEP functional knowledge. In a subsample of participants responding to HIV prevention questions, we compared willingness to use PrEP by response to PrEP functional knowledge using logistic regression analysis adjusted for age, race and ethnicity, and education level. Results: Among 573 respondents, PrEP knowledge was high regarding adherence (488/573, 85.2%), condom use (532/573, 92.8%), and STIs (480/573, 83.8%), but only 252/573 (44.0%) identified the correct efficacy. Lower functional PrEP knowledge was associated with minority race/ethnicity (P=.005), lower education (P=.01), and not having an HIV test in the past year (P=.02). Higher PrEP knowledge was associated with willingness to use PrEP (P=.009). Younger age was not associated with higher PrEP functional knowledge or willingness to use PrEP. Conclusions: PrEP knowledge was generally high in our study, including condom use and consistent use but may be lacking in higher risk MSM. The majority of respondents did not correctly identify PrEP efficacy with consistent use, which could impact motivation to seek out PrEP for HIV prevention. Targeted messaging to increase PrEP knowledge may increase PrEP use. Article	2018	Kambutse I.; Igiraneza G.; Ogbuagu O.	Perceptions of HIV transmission and preexposure prophylaxis among health care workers and community members in Rwanda	PLOS One	-	-	-	19326203	10.1371/journal.pone.0207650	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057168332&doi=10.1371%2fjournal.pone.0207650&partnerID=40&md5=5f3147e50566b0d8a06df40556cb8b0d	There are too many new HIV infections globally with 1.8 million persons infected in 2016 alone. Pre-exposure prophylaxis (PrEP) holds potential to decrease new infections and is synergistic with efforts currently in place to achieve an end to the AIDS epidemic in Sub-Saharan African, but uptake is limited. Given its novelty, assessing the beliefs and attitudes of healthcare professionals and members of the community towards HIV transmission and PrEP will be helpful to inform implementation efforts. Study was a random survey of 201 community members and 51 healthcare providers, carried out at multiple community sites in Huye district, Southern Province, Rwanda and at Kigali University Teaching Hospital (KUTH). The study findings are that there are still misconceptions about HIV in the community with some respondents believing that HIV is due to punishment from God (5.4%), poverty (3.0%), smoking cigarettes (1.0%), drinking alcohol (2.0%), punishment from ancestors (1.0%) and witchcraft (1.5%), and that its transmission is by mosquito bites (10.9%), sharing food or drinks with a HIV infected person (6.5%) or as a result of carelessness (47.8%). More than 50% of respondents from both groups had insufficient knowledge regarding PrEP, but expressed some interest in PrEP (82.6% of the respondents from the community and 86.5% of the health workers). However, some healthcare workers felt that promotion of safe sex practices (74.5%), HIV testing and treating HIV infected patients (60.4%) would work better than PrEP to decrease new HIV infections. Barriers to PrEP implementation included perceived stigma, delayed access to prevention services at the health facilities while personal-level concerns included lack of family support, reluctance to take a medication daily and fear of being perceived as having HIV. This study showed that health care workers and community members are willing to utilize PrEP in Rwanda, but many challenges exist including limited knowledge about PrEP, stigma, provider and system level service delivery barriers at health facilities among others. More studies are needed to assess ways of addressing and /or eliminating these barriers. © 2018 Kambutse et al. Theses and Dissertations	2018	Kamugisha, Leonard	The role of a mass media campaign in uptake of HIV counselling and testing among young people in five Southern Africa countries	-	-	South African National ETD Portal	-	NA	NA	https://hdl.handle.net/10539/25366	Southern Africa forms the epicentre of the HIV epidemic and young people commonly get diagnosed long after infection. Despite the evidence that HIV Counselling and Testing (HCT) can reduce risky sexual behaviors and prevent HIV, uptake of testing in young people remains limited and this is especially true in Southern Africa. In the last few years, effective interventions for HIV prevention have been implemented, including treatment as prevention and pre-exposure prophylaxis. In the context of very high prevalence of HIV among young people in Southern Africa, it is critical that countries attain higher levels of HCT. Demand creation is one of the means to increase uptake of HCT. This study investigated the relationship between exposure to a mass media campaign and uptake of HIV counselling and testing among young people in five countries of Southern Africa (Lesotho, Mozambique, South Africa, Swaziland and Zambia) for the period 2008 to 2012. A secondary data analysis from a multi-country study was undertaken. Methods: Secondary data on young people aged 15-24 years from a post-only crosssectional observational multi-country study that was undertaken in 2012 to evaluate the One Love Campaign, a regional behavior change media campaign coordinated by Soul City Institute for Development Communication was undertaken. The exposure variable was exposure to One Love campaign (in the form of television film series; locally produced radio drama series, television public service announcements and a television series in South Africa. In other participating countries the programme also comprised talk shows broadcast by national- and community broadcasters; booklets, billboards used to trigger discussion during community dialogues and community outreach events) with the outcome of interest being HIV testing, with a number of covariates such as socio-demographic characteristics (e.g age, education level, nationality, sex, marital status, socio-economic status (defined as wealth quintile), whether respondent had children or not, and country of residence. Bivariate and multivariate analysis was conducted to establish the relationship between exposure to One Love campaign and HIV testing among the study population. vii Results: A total of eight-thousand-six-hundred and thirteen young people (n=8613) participated in the study. There was nearly equal distribution of respondents between those that had had an HIV test (52.0%) and those that had not (48.0%). Exposure to One Love through multiple media, was positively associated with HIV testing (aOR=2.34, 95% CI 1.94- 2.81), and there was a dose response. Other factors associated with having an HIV test included being female (aOR= 1.95, 95% CI 1.75 - 2.18); having living child (aOR=4.23, 95% CI 3.57-5.01); being the aged 18-20 years (aOR=2.24, 95% CI 1.95 - 2.58) or group 20-24 years (aOR=4.14, 95% CI 3.57 - 4.81) and having secondary or tertiary education (aOR= 2.67, 95% CI 1.92 - 3.68). Increased wealth until quintile 4 was negatively associated with having an HIV test, (aOR= 0.93, 95% CI 0.77 - 1.12). Conclusion: Overall the findings of this study show that exposure to more than one medium in the campaign has greater odds of testing. The results of this study provide important information on the relationship between exposure to a media campaign and HIV testing among young people. Social and behaviour change communication strategies that use multi-media are necessary to achieve improved HIV testing among young people. Article	2018	Kapadia S.N.; Wu C.; Mayer K.H.; Wilkin T.J.; Rivet Amico K.; Landovitz R.J.; Andrade A.; Chen Y.Q.; Chege W.; McCauley M.; Gulick R.M.; Schackman B.R.	No change in health-related quality of life for at-risk U.S. Women and men starting HIV pre-exposure prophylaxis (PrEP): Findings from HPTN 069/ACTG A5305	PLOS One	-	-	-	19326203	10.1371/journal.pone.0206577	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059210649&doi=10.1371%2fjournal.pone.0206577&partnerID=40&md5=70b944161c12ef5d90077411410c805b	Introduction Tenofovir (TDF)-containing PrEP is effective for HIV prevention, but its effect on health-related quality of life (QOL) is unknown. Using data from HPTN 069/ACTG A5305, a randomized study of potential PrEP regimens comparing maraviroc alone, or together with TDF or emtricitabine (FTC), to TDF + FTC (control), we evaluated the impact of these regimens on QOL in at-risk HIV-uninfected U.S. women and men. Methods QOL was measured at baseline (before starting medications) and every 8 weeks through week 48 using the EQ-5D-3L. Responses were converted to a scale from 0.0 (death) to 1.0 (perfect health), using published valuation weights. Mean scores were compared between groups at each time point using nonparametric testing. Multivariable linear regression was used to adjust for potential confounders. Results We analyzed 186 women (median age 35 years, 65% black, 17% Hispanic) and 405 men (median age 30 years, 28% black, 22% Hispanic), including 9 transgender participants analyzed based on sex-at-birth. Mean baseline QOL was 0.91 for women and 0.95 for men. There were minimal changes in mean QOL over time for any regimen (women: p = 0.29; men: p = 0.14). There were no significant differences between participants who continued the regimen compared to participants who discontinued early (women: p = 0.61; men: p = 0.1). Mean QOL did not differ significantly by regimen at any time point, both unadjusted and after adjustment for age, race/ethnicity, adherence, and use of alcohol, marijuana, opiates, and other substances. Conclusions QOL in at-risk individuals starting candidate PrEP regimens in a clinical trial is similar to the general population and maintained over time. This finding did not vary among regimens or when adjusted for demographics, adherence, and substance use. Our findings are the first to show that starting a candidate PrEP regimen in at-risk HIV-uninfected U.S. women and men was not associated with significant changes in QOL. Article	2018	Kapogiannis B.G.; Nelson R.M.; Siberry G.K.; Lee S.; Hazra R.	Advancing HIV biomedical prevention research for at-risk adolescents	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001853	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056324807&doi=10.1097%2fQAI.0000000000001853&partnerID=40&md5=14151d8f484987a25bbee8e12685e0a2	Despite significant additions to the HIV prevention toolbox, infection rates across the United States continue to rise among vulnerable adolescents and young adults. Access to these interventions by youth at risk for HIV is limited by the lack of data about their safety and use, compounding the myriad contextual barriers to effectively preventing HIV in this group. The NIH-funded Adolescent Trials Network implemented an innovative approach to the inclusion of adolescents at risk for HIV infection who consented for their own participation in the first adolescent study of HIV preexposure prophylaxis (PrEP). This model of mature minor consent was supported by state-based adolescent treatment statutes that extend an adolescent's ability to consent to participation in research with a sufficient prospect of clinical benefit from the intervention to justify the potential risks, and a balance of benefits and risks that is at least as favorable as available evidence-based alternatives. Important data on the safety and patterns of PrEP use by at-risk adolescents prompted the FDA to revise the label. The expanded indication of PrEP for HIV prevention in adolescents is hoped to inform clinical guidelines and provides a powerful tool to reduce new infections in the United States among vulnerable at-risk adolescents. Lessons learned from this years-long iterative endeavor have implications for improving access to the rapidly evolving landscape of HIV prevention modalities, including recently implemented studies of long-acting PrEP formulations designed to reduce the burden of daily adherence required by oral PrEP, a major clinical pitfall for adolescent clinicians and their patients. © 2018 Wolters Kluwer Health, Inc. Article	2018	Karim, SSA; Passmore, JAS; Baxter, C	The microbiome and HIV prevention strategies in women	Current Opinion in HIV and AIDS	-	-	-	1746-630X	10.1097/COH.0000000000000431	https://pubmed.ncbi.nlm.nih.gov/29059077/	Purpose of review HIV prevention approaches that women can use and control are a priority. Results from topical and oral preexposure prophylaxis (PrEP) HIV prevention trials have produced inconsistent results in women. One of the main behavioural factors impacting effectiveness of PrEP has been suboptimal adherence. In this review, we examine biological factors that modulate topical PrEP efficacy, with particular focus on the vaginal microbiome. Recent findings Genital inflammation is an independent risk factor for HIV acquisition in women. Using 16S rRNA sequencing of the vaginal microbiota, anaerobic bacteria linked with bacterial vaginosis have been shown to be associated with both genital inflammation and HIV risk. Using proteomics, it was recently discovered that a dysbiotic vaginal microbiome, comprising less than 50% Lactobacillus spp., directly influenced topical PrEP efficacy. Gardnerella vaginalis, the dominant vaginal species in dysbiotic women, was able to directly degrade tenofovir, but not dapivirine, an antiretroviral also being developed for topical PrEP. Summary The link between bacterial vaginosis-associated organisms with HIV risk and altered tenofovir gel effectiveness underscores the importance of good vaginal health and good adherence for women to benefit maximally from topical PrEP. Altering the vaginal microbiome is one of the new directions being pursued for HIV prevention. Article	2018	Kasaie P.; Berry S.A.; Shah M.S.; Rosenberg E.S.; Hoover K.W.; Gift T.L.; Chesson H.; Pennington J.; German D.; Flynn C.P.; Beyrer C.; Dowdy D.W.	Impact of providing preexposure prophylaxis for human immunodeficiency virus at clinics for sexually transmitted infections in Baltimore city: An agent-based model	Sexually Transmitted Diseases	-	-	-	1485717	10.1097/OLQ.0000000000000882	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056497266&doi=10.1097%2fOLQ.0000000000000882&partnerID=40&md5=063c0e5013bd03cf05219c4ce248ab39	Background Preexposure prophylaxis (PrEP) greatly reduces the risk of human immunodeficiency virus (HIV) acquisition, but its optimal delivery strategy remains uncertain. Clinics for sexually transmitted infections (STIs) can provide an efficient venue for PrEP delivery. Methods To quantify the added value of STI clinic-based PrEP delivery, we used an agent-based simulation of HIV transmission among men who have sex with men (MSM). We simulated the impact of PrEP delivery through STI clinics compared with PrEP delivery in other community-based settings. Our primary outcome was the projected 20-year reduction in HIV incidence among MSM. Results Assuming PrEP uptake and adherence of 60% each, evaluating STI clinic attendees and delivering PrEP to eligible MSM reduced HIV incidence by 16% 95% uncertainty range, 14%-18% over 20 years, an impact that was 1.8 (1.7-2.0) times as great as that achieved by evaluating an equal number of MSM recruited from the community. Comparing strategies where an equal number of MSM received PrEP in each strategy (ie, evaluating more individuals for PrEP in the community-based strategy, because MSM attending STI clinics are more likely to be PrEP eligible), the reduction in HIV incidence under the STI clinic-based strategy was 1.3 (1.3-1.4) times as great as that of community-based delivery. Conclusions Delivering PrEP to MSM who attend STI clinics can improve efficiency and effectiveness. If high levels of adherence can be achieved in this population, STI clinics may be an important venue for PrEP implementation. © 2018 Lippincott Williams & Wilkins. Article	2018	Kay, Katherine; Shah, Dhaval K.; Rohan, Lisa; Bies, Robert	Physiologically-based pharmacokinetic model of vaginally administered dapivirine ring and film formulations.	British Journal of Clinical Pharmacology	-	-	-	1365-2125 0306-5251	10.1111/bcp.13625	https://pubmed.ncbi.nlm.nih.gov/29714824/	AIMS: A physiologically-based pharmacokinetic (PBPK) model of the vaginal space was developed with the aim of predicting concentrations in the vaginal and cervical space. These predictions can be used to optimize the probability of success of vaginally administered dapivirine (DPV) for HIV prevention. We focus on vaginal delivery using either a ring or film. METHODS: A PBPK model describing the physiological structure of the vaginal tissue and fluid was defined mathematically and implemented in MATLAB. Literature reviews provided estimates for relevant physiological and physicochemical parameters. Drug concentration-time profiles were simulated in luminal fluids, vaginal tissue and plasma after administration of ring or film. Patient data were extracted from published clinical trials and used to test model predictions. RESULTS: The DPV ring simulations tested the two dosing regimens and predicted PK profiles and area under the curve of luminal fluids (29 079 and 33 067 mg h l(-1) in groups A and B, respectively) and plasma (0.177 and 0.211 mg h l(-1)) closely matched those reported (within one standard deviation). While the DPV film study reported drug concentration at only one time point per patient, our simulated profiles pass through reported concentration range. CONCLUSIONS: HIV is a major public health issue and vaginal microbicides have the potential to provide a crucial, female-controlled option for protection. The PBPK model successfully simulated realistic representations of drug PK. It provides a reliable, inexpensive and accessible platform where potential effectiveness of new compounds and the robustness of treatment modalities for pre-exposure prophylaxis can be evaluated. Article	2018	Kecojevic A.; Basch C.; Basch C.; Kernan W.	Pre-exposure prophylaxis youtube videos: Content evaluation	JMIR Public Health and Surveillance	-	-	-	23692960	10.2196/publichealth.7733	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076911634&doi=10.2196%2fpublichealth.7733&partnerID=40&md5=9b39c4e094fbf2618e6140aa35830ce9	Background: Antiretroviral (ARV) medicines reduce the risk of transmitting the HIV virus and are recommended as daily pre-exposure prophylaxis (PrEP) in combination with safer sex practices for HIV-negative individuals at a high risk for infection, but are underused in HIV prevention. Previous literature suggests that YouTube is extensively used to share health information. While pre-exposure prophylaxis (PrEP) is a novel and promising approach to HIV prevention, there is limited understanding of YouTube videos as a source of information on PrEP. Objective: The objective of this study was to describe the sources, characteristics, and content of the most widely viewed PrEP YouTube videos published up to October 1, 2016. Methods: The keywords "pre-exposure prophylaxis" and "Truvada" were used to find 217 videos with a view count >100. Videos were coded for source, view count, length, number of comments, and selected aspects of content. Videos were also assessed for the most likely target audience. Results: The total cumulative number of views was >2.3 million, however, a single Centers for Disease Control and Prevention video accounted for >1.2 million of the total cumulative views. A great majority (181/217, 83.4%) of the videos promoted the use of PrEP, whereas 60.8% (132/217) identified the specific target audience. In contrast, only 35.9% (78/217) of the videos mentioned how to obtain PrEP, whereas less than one third addressed the costs, side effects, and safety aspects relating to PrEP. Medical and academic institutions were the sources of the largest number of videos (66/217, 30.4%), followed by consumers (63/217, 29.0%), community-based organizations (CBO; 48/217, 22.1%), and media (40/217, 18.4%). Videos uploaded by the media sources were more likely to discuss the cost of PrEP (P<.001), whereas the use of PrEP was less likely to be promoted in videos uploaded by individual consumers (P=.002) and more likely to be promoted in videos originated by CBOs (P=.009). The most common target audience for the videos was gay and bisexual men. Conclusions: YouTube videos can be used to share reliable PrEP information with individuals. Further research is needed to identify the best practices for using this medium to promote and increase PrEP uptake. © Aleksandar Kecojevic, Corey Basch, Charles Basch, William Kernan. Expanding the Menu of HIV Prevention Options: A Qualitative Study of Experiences with Long-Acting Injectable Cabotegravir as PrEP in the Context of a Phase II Trial in the United States	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-2017-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85039736006&doi=10.1007%2fs10461-017-2017-x&partnerID=40&md5=7f1705a0e25a1acd05b1a415e82435e7	Adherence challenges with oral pre-exposure prophylaxis have stimulated interest in alternate modes of administration including long-acting injections. We conducted 30 in-depth interviews with 26 male trial participants and 4 clinical providers in a Phase IIa study (ÉCLAIR) evaluating the use of long-acting cabotegravir (CAB-LA) injections in New York and San Francisco. Interviews exploring attitudes and experiences with CAB-LA were audiotaped, transcribed, and analyzed using thematic content analysis. Despite a high frequency of some level of side effects, almost all participants reported being interested in continuing with CAB-LA, versus a daily oral, due to its convenience and the perceived advantage of not worrying about adhering to pills. Providers reinforced the importance of CAB-LA as a prevention option and the need for guidelines to assist patient decision-making. Further research is needed on the acceptability of CAB-LA among women and men at higher risk for HIV in different settings. © 2017, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Khan, Arshad Bashir; Thakur, Ram Sharnagat	Design and evaluation of mucoadhesive vaginal tablets of tenofovir disoproxil fumarate for pre-exposure prophylaxis of HIV.	Drug Development and Industrial Pharmacy	-	-	-	1520-5762 0363-9045	10.1080/03639045.2017.1399272	https://pubmed.ncbi.nlm.nih.gov/29082767/	OBJECTIVE: To design and evaluate novel, feasible, safe, mucoadhesive intravaginal tablets of tenofovir disoproxil fumarate (TDF). SIGNIFICANCE: It may provide pre-exposure prophylaxis for women against HIV. METHODS: TDF intravaginal tablets were formulated employing poylvinylpyrrolidone (PVP) as the matrix forming polymer and various mucoadhesive polymers such as carbopol 934, 940, chitosan, and sodium carboxymethylcellulose (SCMC). Wet granulation was used. The evaluation involved testing drug-excipient compatibility, precompression parameters such as percentage yield, bulk density and tapped density of the granules, Carr's index, Hausner ratio, angle of repose, post compression parameters such as color, shape, physical dimensions, weight variation, hardness, friability, swelling index, assay, in vitro dissolution study and ex vivo mucoadhesion studies. RESULTS: Based on in vitro evaluation, C1 was selected as the best formulation and evaluated further for release kinetics, curve fitting analysis, absorption studies using liquid chromatography-mass spectrometry (LC-MS) technique and histopathological assessment in female Sprague-Dawley rats. C1 followed Higuchi model kinetics. Accelerated stability study was as per ICH guidelines by keeping C1 at 40 ± 2 °C and 75 ± 5% RH for six months. CONCLUSIONS: C1 was selected as the best formulation due to better swelling index (65.93% at 24 h), prolonged release of 100.62% cumulative drug release (CDR) at 24 h), superior mucoadhesion force (35.93 × 10(2) dynes/cm(2)) and retention time (16 h). The study revealed that C1 remained stable for six months. C1 showed nil systemic absorption which is desirable and according to histopathological study, C1, exhibited minimal damage on the rat vaginal epithelium indicating safety. Article	2018	Khaw, Carole; Richardson, Daniel; Matthews, Gail; Read, Tim	Looking at the positives: proactive management of STIs in people with HIV.	AIDS Research and Therapy	-	-	-	1742-6405	10.1186/s12981-018-0216-9	https://aidsrestherapy.biomedcentral.com/articles/10.1186/s12981-018-0216-9	Patients who are HIV-positive and co-infected with other sexually transmitted infections (STIs) are at risk of increased morbidity and mortality. This is of clinical significance. There has been a dramatic increase in the incidence of STIs, particularly syphilis, gonorrhoea, Mycoplasma genitalium and hepatitis C virus (HCV) in HIV-positive patients. The reasons for this are multifactorial, but contributing factors may include effective treatment for HIV, increased STI testing, use of HIV pre-exposure prophylaxis and use of social media to meet sexual partners. The rate of syphilis-HIV co-infection is increasing, with a corresponding increase in its incidence in the wider community. HIV-positive patients infected with syphilis are more likely to have neurological invasion, causing syndromes of neurosyphilis and ocular syphilis. HIV infection accelerates HCV disease progression in co-infected patients, and liver disease is a leading cause of non-AIDS-related mortality among patients who are HIV-positive. Since several direct-acting antivirals have become subsidised in Australia, there has been an increase in treatment uptake and a decrease in HCV viraemia in HIV-positive patients. The incidence of other sexually transmitted bacterial infections such as Neisseria gonorrhoeae and M. genitalium is increasing in HIV patients, causing urethritis, proctitis and other syndromes. Increasing antimicrobial resistance has also become a major concern, making treatment of these infections challenging. Increased appropriate testing and vigilant management of these STIs with data acquisition on antimicrobial sensitivities and antimicrobial stewardship are essential to prevent ongoing epidemics and emergence of resistance. Although efforts to prevent, treat and reduce epidemics of STIs in patients living with HIV are underway, further advances are needed to reduce the significant morbidity associated with co-infection in this patient setting. Article	2018	Khurana, Nidhi; Yaylali, Emine; Farnham, Paul G; Hicks, Katherine A; Allaire, Benjamin T; Jacobson, Evin; Sansom, Stephanie L	Impact of Improved HIV Care and Treatment on PrEP Effectiveness in the United States, 2016-2020.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001707	https://dx.doi.org/10.1097/QAI.0000000000001707	BACKGROUND: The effect of improving diagnosis, care, and treatment of persons living with HIV (PLWH) on pre-exposure prophylaxis (PrEP) effectiveness in the United States has not been well established. METHODS: We used a dynamic, compartmental model that simulates the sexually active US population. We investigated the change in cumulative HIV incidence from 2016 to 2020 for 3 HIV care-continuum levels and the marginal benefit of PrEP compared with each. We also explored the marginal benefit of PrEP for individual risk groups, and as PrEP adherence, coverage and dropout rates varied. RESULTS: Delivering PrEP in 2016 to persons at high risk of acquiring HIV resulted in an 18.1% reduction in new HIV infections from 2016 to 2020 under current care-continuum levels. Achieving HIV national goals of 90% of PLWH with diagnosed infection, 85% of newly diagnosed PLWH linked to care at diagnosis, and 80% of diagnosed PLWH virally suppressed reduced cumulative incidence by 34.4%. Delivery of PrEP in addition to this scenario resulted in a marginal benefit of 11.1% additional infections prevented. When national goals were reached, PrEP prevented an additional 15.2% cases among men who have sex with men, 3.9% among heterosexuals, and 3.8% among persons who inject drugs. CONCLUSIONS: The marginal benefit of PrEP was larger when current HIV-care-continuum percentages were maintained but continued to be substantial even when national care goals were met. The high-risk men who have sex with men population was the chief beneficiary of PrEP. Article	2018	Klevens R.M.; Martin B.M.; Doherty R.; Fukuda H.D.; Cranston K.; DeMaria A., Jr.	Factors Associated with Pre-exposure Prophylaxis in a Highly Insured Population of Urban Men Who Have Sex with Men, 2014	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1879-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85027490642&doi=10.1007%2fs10461-017-1879-2&partnerID=40&md5=10561fc878141b477c070fe377054dd5	In the United States, an estimated 25% of men who have sex with men (MSM) have indications for receiving pre-exposure prophylaxis to prevent HIV infection (PrEP), but <4% reported PrEP use in the past 12 months. We evaluate factors associated with having heard of, willingness to use, and use of PrEP in a venue-based, time-spaced sample of 316 urban, highly insured Boston MSM in the 2014 NHBS. We found that 53.7% of respondents reported receiving usual medical care from a doctor's office or health maintenance organization, 57.6% had an indication for PrEP, 66.6% had heard of PrEP, 53.6% reported willingness to use PrEP, and 5.8% reported use of PrEP in the past 12 months. In multivariable analyses, an indication for PrEP was statistically associated with having heard of, willingness to use, and use of PrEP in the past 12 months. Findings guide statewide efforts to evaluate and promote PrEP. © 2017, Springer Science+Business Media, LLC. Article	2018	Knapper C.; Birley H.; Couzens Z.; Jones A.T.; Parker I.	How to do it: Setting up a PrEP service in an integrated sexual reproductive health service setting	Sexually Transmitted Infections	-	-	-	13684973	10.1136/sextrans-2018-053561	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049246705&doi=10.1136%2fsextrans-2018-053561&partnerID=40&md5=28849bc2008947b1c004828b5ec15949	Pre-exposure prophylaxis for HIV (PrEP) has been shown to reduce transmission of HIV in a number of trials; however, there is limited evidence regarding the optimal way to deliver PrEP through pre-existing UK services, particularly through fully integrated drop-in sexual health service models. PrEP in the form of Truvada was launched in Wales in July 2017. We set up a PrEP service to be delivered via our drop-in integrated sexual reproductive health service. In the first 5 months of PrEP service provision, we found unforeseen levels of comorbidity, polypharmacy and renal impairment in our cohort of PrEP patients. As a result, we have altered our service model and all patients are now followed up in booked appointment PrEP clinics run by members of the HIV team. Those patients with estimated glomerular filtration rate (eGFR) of 60-70 mL/min or with eGFR of 60-80 mL/min and with comorbidities impacting on renal function are monitored every 4-6 weeks initially, and PrEP has been incorporated into our pre-existing virtual HIV renal clinic for discussion with a renal physician. The PrEP team clinicians report that monitoring and managing the PrEP cohort is now easier in its appointment-only format, although some patients have reported that they would prefer a drop-in system. © Article author(s) (or their employer(s) unless otherwise stated in the text of the article) 2018. Article	2018	Ko N.-Y.; Wu H.-J.; Strong C.; Li C.-W.; Ku W.-W.; Hsu S.-T.	Differences in awareness of and willingness to use pre-exposure prophylaxis and anticipated condom use among serodiscordant couples in Taiwan	AIDS Care	-	-	-	9540121	10.1080/09540121.2018.1481195	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047795801&doi=10.1080%2f09540121.2018.1481195&partnerID=40&md5=b962b977185cf97c540a48a605f173d8	Pre-exposure prophylaxis (PrEP) has proven to be effective in reducing the risk of HIV transmission in uninfected individuals who engaged in sexual activity with HIV-infected partners. Serodiscordant couples are the key targets of PrEP implementation. The study aimed to compare awareness of and willingness to use PrEP and anticipated condom use among 112 HIV-serodiscordant couples: 32 heterosexuals couples, 70 men who have sex with men (MSM) couples, and 10 people who inject drugs (PWID) couples. A cross-sectional study was conducted in an AIDS designated hospital in Taiwan. The PrEP survey for discordant couples included questions on awareness of non-occupational post-exposure prophylaxis (nPEP) and PrEP, attitudes toward PrEP, anticipated condom use if using PrEP, and sexual behaviors. Overall, 46.2% were aware of PrEP, only 33% were willing to take PrEP, and 44.6% would continue condom use if they were taking PrEP. Among the three key populations, MSM couples had the highest awareness of and willingness to use PrEP. Awareness of and willingness to use PrEP did not differ by HIV status, with moderate agreement (Cohen's Kappa coefficient: 0.56) between HIV-serodiscordant partners. Both HIV-serodiscordant partners' willingness to use PrEP was significantly associated with being MSM (adjusted odds ratio (AOR), 4.28 1.28–14.30, p = 0.018), previous receipt of nPEP (AOR, 6.98 1.23–39.65, p = 0.028), anticipated condom use (AOR, 0.14 0.05–0.41, p < 0.001), and income ≧ NT$30,000 per month (AOR, 2.25 (0.99–5.04), p = 0.05). Policy makers need to consider the differences among key populations to scale up PrEP implementation. More efforts should be focused on improving awareness of and willingness to use PrEP among heterosexual and PWID serodiscordant couples to scale up PrEP implementation in Taiwan. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	awareness; HIV prevention; Pre-exposure prophylaxis; serodiscordant couples; willingness	English	United Kingdom	Western and Central Europe and North America	Taiwan	Asia and the Pacific	Taiwan	Asia and the Pacific	Quantitative
Article	2018	Koester K.A.; Erguera X.A.; Kang Dufour M.-S.; Udoh I.; Burack J.H.; Grant R.M.; Myers J.J.	"Losing the Phobia:" Understanding How HIV Pre-exposure Prophylaxis Facilitates Bridging the Serodivide Among Men Who Have Sex With Men	Frontiers in Public Health	-	-	-	22962565	10.3389/fpubh.2018.00250	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067019007&doi=10.3389%2ffpubh.2018.00250&partnerID=40&md5=1e9c718a6b24b53881b6ee7f306f349f	The use of HIV serostatus information has played a pivotal role in partner selection norms. A phenomenon known as serosorting is the practice of selecting a partner based on a perception that they are of the same HIV status in order to avoid transmission from one partner to the other. An understudied aspect of serosorting is that it has a divisive effect—one accepts or rejects a potential partner based on a singular characteristic, the partner's HIV status, and thus excludes all others. This division has been formally referred to as the HIV serodivide. In this study, we explored partner selection strategies among a group of HIV-negative, young men who have sex with men (n = 29) enrolled in a PrEP demonstration project in Northern California. We found that trends in serosorting were in fact shifting, and that a new and opposite phenomenon was emerging, something we labeled "seromixing" and that PrEP use played a part in why norms were changing. We present three orientations in this regard: (1) maintaining the phobia: in which men justified the continued vigilance and exclusion of people living with HIV as viable sex or romantic partners, (2) loosening/relaxation of phobia: among men who were reflecting on their stance on serosorting and its implications for future sexual and/or romantic partnerships, and (3) losing the phobia: among men letting go of serosorting practices and reducing sentiments of HIV-related stigma. The majority of participants spoke of changing or changed attitudes about intentionally accepting rather than rejecting a person living with HIV as a sex partner. For those who maintained strict serosorting practices, their understandings of HIV risk were not erased as a result of PrEP use. These overarching themes help explain how PrEP use is contributing to a closing of the HIV serodivide. © Copyright © 2018 Koester, Erguera, Kang Dufour, Udoh, Burack, Grant and Myers. Article	2018	Koren D.E.; Nichols J.S.; Simoncini G.M.	HIV Pre-Exposure Prophylaxis and Women: Survey of the Knowledge, Attitudes, and Beliefs in an Urban Obstetrics/Gynecology Clinic	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0030	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058025079&doi=10.1089%2fapc.2018.0030&partnerID=40&md5=b0fa8a59d4d7994340a7a2ef0b74cfc	Uptake of HIV pre-exposure prophylaxis (PrEP) is low among women at risk for HIV acquisition. Of 468,000 women, whom the United States Centers for Disease Control and Prevention estimates to be eligible for PrEP, only 10,000 unique women have begun therapy through the third quarter of 2015. These data suggest insufficient HIV prevention efforts. This study, conducted at the site of an urban academic medical center with an emergency department HIV prevalence rate of 4%, assesses the knowledge, attitudes, and beliefs of women toward PrEP. A self-administered survey was conducted among women at a family planning obstetrics/gynecology clinic at Temple University Hospital (Philadelphia, PA). Participants assessed their HIV acquisition risk and answered eight questions regarding knowledge, attitudes, and beliefs toward PrEP. Three hundred eighty-nine surveys met inclusion criteria. Sixty-five percent of women were black, and 73% were between 18 and 33 years of age. The median self-perceived risk score was 0 (interquartile range = 2) using a Likert scale. Thirty-three percent of women believed that PrEP could work, and 27% knew that such a regimen existed. Concerns existed toward cost (44%) and side effects (39%). Fifty-seven percent of women surveyed stated that they would take a medication to prevent HIV, and 64% felt comfortable discussing the subject with her doctor. Our data demonstrate a lack of PrEP knowledge, although willingness for uptake among women at risk for HIV acquisition, and a need for directed education and outreach. © 2018, Mary Ann Liebert, Inc., publishers.	attitudes; beliefs; HIV prevention; knowledge; pre-exposure prophylaxis; women	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Early adopters of human immunodeficiency virus preexposure prophylaxis in a population-based combination prevention study in rural Kenya and Uganda	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciy390	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057547289&doi=10.1093%2fcid%2fciy390&partnerID=40&md5=ab82ec75c171c2422477296cd356867f	Background. Global guidelines recommend preexposure prophylaxis (PrEP) for individuals with substantial human immunodeficiency virus (HIV) risk. Data on PrEP uptake in sub-Saharan Africa outside of clinical trials are limited. We report on "early adopters" of PrEP in the Sustainable East Africa Research in Community Health (SEARCH) study in rural Uganda and Kenya. Methods. After community mobilization and PrEP education, population-based HIV testing was conducted. HIV-uninfected adults were offered PrEP based on an empirically derived HIV risk score or self-identified HIV risk (if not identified by score). Using logistic regression, we analyzed predictors of early PrEP adoption (starting PrEP within 30 days vs delayed/no start) among adults identified for PrEP. Results. Of 21 212 HIV-uninfected adults in 5 communities, 4064 were identified for PrEP (2991 by empiric risk score, 1073 by self-identified risk). Seven hundred and thirty-nine individuals started PrEP within 30 days (11% of those identified by risk score; 39% of self-identified); 77% on the same day. Among adults identified by risk score, predictors of early adoption included male sex (adjusted odds ratio 1.53; 95% confidence interval, 1.09–2.15), polygamy (1.92; 1.27–2.90), serodiscordant spouse (3.89; 1.18–12.76), self-perceived HIV risk (1.66; 1.28–2.14), and testing at health campaign versus home (5.24; 3.33–8.26). Among individuals who self-identified for PrEP, predictors of early adoption included older age (2.30; 1.29–4.08) and serodiscordance (2.61; 1.01–6.76). Conclusions. Implementation of PrEP incorporating a population-based empiric risk score, self-identified risk, and rapid initiation, is feasible in rural East Africa. Strategies are needed to overcome barriers to PrEP uptake, particularly among women and youth. © The Author(s) 2018. Similar tenofovir hair concentrations in men and women after directly observed dosing of tenofovir disoproxil fumarate/emtricitabine: Implications for preexposure prophylaxis adherence monitoring	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001935	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060232378&doi=10.1097%2fQAD.0000000000001935&partnerID=40&md5=b147263f5d09e36e4df2e258fea87c3b	Objectives: Women likely require higher adherence than men to preexposure prophylaxis (PrEP) with tenofovir disoproxil fumarate (TDF)/emtricitabine (FTC) for similar efficacy. Pharmacologic metrics of adherence predict efficacy better than self-report, but expected drug levels (adherence benchmarks) must be established using directly observed therapy. We sought to evaluate whether tenofovir hair concentrations differ between women and men receiving directly observed TDF/FTC. Methods: We assessed tenofovir hair concentrations in HIV-uninfected volunteers randomized to receive 100%, 67%, or 33% of daily dosing of TDF/FTC for 12 weeks (DOT-DBS, NCT02022657). Hair samples were collected at dosing weeks 4, 8, and 12 and every 3 weeks during a 12-week washout. Tenofovir concentrations in the proximal 1.5 cm of hair (representing 6 weeks of exposure) were analyzed using liquid chromatography/tandem mass spectrometry. Linear regression was used to model tenofovir hair concentrations in terms of sex, doses over the prior 6 weeks, and number of days since last dose. Results: A total of 264 hair samples were analyzed from 23 female and 24 male participants. Female participants had similar tenofovir hair concentrations to men (estimated fold-difference 0.92, 95% CI 0.75 - 1.13, P ¼ 0.43). The estimated fold-difference in tenofovir levels for female versus male participants did not appreciably change when age (0.93, 95% CI 0.76 - 1.15), weight (0.89, 95% CI 0.71 - 1.11), or race/ ethnicity (0.95, 95% CI 0.77 - 1.17) were added to the model. Conclusion: Women and men have similar adherence benchmarks for tenofovir in hair samples. As pharmacokinetic metrics are increasingly used for PrEP monitoring, these findings provide guidance for assessing adherence via hair concentrations. © 2018 Wolters Kluwer Health, Inc. Article	2018	Koss, Catherine A; Hosek, Sybil G; Bacchetti, Peter; Anderson, Peter L; Liu, Albert Y; Horng, Howard; Benet, Leslie Z; Kuncze, Karen; Louie, Alexander; Saberi, Parya; Wilson, Craig M; Gandhi, Monica	Comparison of Measures of Adherence to Human Immunodeficiency Virus Preexposure Prophylaxis Among Adolescent and Young Men Who Have Sex With Men in the United States.	Clinical Infectious Diseases	-	-	-	-	1537-6591	10.1093/cid/cix755	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5850042	Background: Young men-who-have-sex-with-men (MSM) are disproportionately impacted by human immunodeficiency virus (HIV). Preexposure prophylaxis (PrEP) could reduce HIV acquisition among youth, but suboptimal adherence threatens effectiveness. Optimal metrics of PrEP adherence among adolescents have remain undefined. Methods: The Adolescent Trials Network 110/113 studies provided daily oral PrEP with tenofovir (TFV) disoproxil fumarate/emtricitabine over 48 weeks to a diverse population of MSM (aged 15-22 years). Self-reported adherence was assessed and PrEP drug concentrations measured from hair and dried blood spot (DBS) samples; 23% of participants received Wisepill electronic monitoring devices. The average number of PrEP doses per week taken was estimated, and concordance between measures assessed. Results: Among 243 participants, hair samples were collected at 1186/1238 (96%) person-visits. The concordance of TFV levels in hair and TFV-diphosphate in DBS around thresholds consistent with taking ≥4 and 7 PrEP doses/week was high (76% and 80%). Hair and DBS concentrations correlated poorly with self-report and Wisepill metrics. Through week 12, 40%-60% of participants (by hair and DBS), ≤31% (Wisepill), and >85% (self-report) were estimated to have taken ≥4 PrEP doses/week (a threshold associated with protection among MSM). For all measures except self-report, adherence declined over time, with half of participants taking <2 doses/week by week 48. Conclusions: Among youth on PrEP, adherence waned over time. Self-report overestimated adherence, and use of Wisepill was limited. Hair collection was highly acceptable and provided similar interpretations to DBS. Incorporation of either metric in future PrEP studies among youth could identify suboptimal adherence and trigger interventions.	adherence, adolescent, HIV prevention, preexposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

HIV health care providers are ready to introduce pre-exposure prophylaxis in Central and Eastern Europe and neighbouring countries: data from the Euroguidelines in Central and Eastern Europe (ECEE) Network Group	HIV Medicine	-	-	-	-	14642662	10.1111/hiv.12641	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050500214&doi=10.1111%2fhiv.12641&partnerID=40&md5=165a0cc916a39c39be74c4b26135a3b9	Objectives: Pre-exposure prophylaxis (PrEP) for HIV infection has been introduced in only a few European countries. We investigated the potential to provide PrEP in the Central and Eastern European region, and in neighbouring countries. Methods: The Euroguidelines in Central and Eastern Europe (ECEE) Network Group was formed in February 2016 to review standards of care for HIV infection in the region. Information related to PrEP was collected through on-line surveys. Respondents were recruited by ECEE members based on their involvement in HIV care. Results: Seventy-six respondents from 23 countries participated in the survey. Twenty-six (34.2%) respondents reported that PrEP tenofovir disoproxil fumarate (FTC) was registered by the drug registration authority in their country. Fifty-three (70.7%) respondents reported being aware of 'informal' PrEP use in their country. If they had access to PrEP, 56 (74.7%) would advise its use in their practice. Forty-five (59.2%) respondents had concerns regarding PrEP use, and 10 (13.3%) expressed the need for more training. Most of the respondents (88.2%) would provide PrEP to people with high-risk behaviours. Conclusions: PrEP is already used informally in some countries in the region. Physicians are keen to use PrEP if and when it is accessible. Obstacles towards implementing PrEP in those countries were mostly related to lack of national guidelines, drug registration and governmental strategy. © 2018 British HIV Association	central Europe; EACS; eastern Europe; Euroguidelines; HIV; pre-exposure prophylaxis	English	United Kingdom	Western and Central Europe and North America	Poland	Western and Central Europe and North America	Poland	Western and Central Europe and North America	Review

Perspectives of South African youth in the development of an implant for HIV prevention	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25170	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053187581&doi=10.1002%2fjia2.25170&partnerID=40&md5=278e1d3ed5935c8d80d8d7391110de8f	Introduction: Implants are a new dosage form in development for HIV pre-exposure prophylaxis (PrEP) with potential for high adherence given that they are provider-administered and are intended for long-acting protection. Integrating end-user preference into early stage product development may further overcome challenges with future product uptake and adherence. Hence, we sought to optimize the design of a PrEP implant in early-stage development by gathering opinions about implant attributes from potential end-users in South Africa. Methods: We conducted 14 focus group discussions (FGDs) with young women and men aged 18 to 24 in Cape Town and Soshanguve, South Africa, inviting participants into discussion as co-designers. FGDs were homogenous by gender and previous implant experience. During FGDs, we showed prototype devices and followed a semi-structured guide with questions on history of contraceptive implant use, preferences for physical characteristics of an implant, implant biodegradability, insertion process, participant-driven ideas for implant design, and social adoption considerations. FGDs were facilitated in English, isiXhosa, Tswana, isiZulu, or Tsonga, audio-recorded, transcribed into English, and qualitatively coded and analysed. Results: In this qualitative sample of 105 youth (68 women and 37 men), 58 participants were from Soshanguve and 47 from Cape Town, and 23% had previously used contraceptive implants. Participants expressed preferences for several implant design features; specifically, longer duration (≥6 months) was more important to most participants than the size or number of devices implanted. A majority preferred a flexible versus stiff implant to minimize palpability, thereby increasing discreetness and comfort. Nearly all participants favoured a biodegradable implant to avoid removal and thus reduce clinic visits. Concerns about the implant centred on its possible side effects and the "plastic" look of the prototype displayed for demonstration. Conclusions: This study offers preliminary insights into an implant for HIV prevention that provides long-lasting protection may be well received among young South Africans. Additionally, flexibility, discreetness, and biodegradability may increase acceptability of the implant. Such end-user feedback is being incorporated into current implant designs in the hope of creating an effective long-acting PrEP product that is likely to achieve high uptake and adherence in target populations. © 2018 RTI International. Theses and Dissertations	2018	Kuennemeier, Brian; Schiemann, Jack	Truvada as Pre-Exposure Prophylaxis (PrEP) and Intimacy Among Gay Men in San Francisco	-	-	Wright Institute	Wright Institute	-	NA	NA	https://www.proquest.com/dissertations-theses/truvada-as-pre-exposure-prophylaxis-prep-intimacy/docview/2117544597/se-2?accountid=8113	Pre-Exposure Prophylaxis (PrEP) is a new HIV prevention strategy that takes existing medications used for the maintenance of HIV and gives them to HIV-negative individuals to prevent new HIV infections. Applications of this technology have been enacted in several populations, but of particular interest are gay men and other men who have sex with men (MSM) due to the significant impact that HIV has had on this population. This study is a qualitative examination of how the use of Truvada as PrEP has affected the experience of intimacy for HIV-negative gay men living in San Francisco. An interpretative phenomenological analysis (IPA) was utilized to examine data from 9 interviews with gay men in San Francisco who have been using this particular chemoprophylaxis for at least one year. This study found that PrEP significantly decreases feelings of fear and anxiety related to HIV and sex, which allowed them to experience more emotional and sexual intimacy in their relationships. Article	2018	Kusejko K.; Marzel A.; Hampel B.; Bachmann N.; Nguyen H.; Fehr J.; Braun D.L.; Battegay M.; Bernasconi E.; Calmy A.; Cavassini M.; Hoffmann M.; Böni J.; Yerly S.; Klimkait T.; Perreau M.; Rauch A.; Günthard H.F.; Kouyos R.D.	Quantifying the drivers of HIV transmission and prevention in men who have sex with men: a population model-based analysis in Switzerland	HIV Medicine	-	-	-	-	14642662	10.1111/hiv.12660	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051135628&doi=10.1111%2fhiv.12660&partnerID=40&md5=b7c408a8394067738c29824bb1715c62	Objectives: Despite the huge success of antiretroviral therapy (ART), there is an ongoing HIV epidemic among men who have sex with men (MSM) in resource-rich countries. Understanding the driving factors underlying this process is important for curbing the epidemic. Methods: We simulated the HIV epidemic in MSM in Switzerland by stratifying a mathematical model by CD4 count, the care cascade and condom use. The model was parametrised with clinical, epidemiological and behavioural data from the Swiss HIV Cohort Study and surveys in the HIV-negative population. Results: According to our model, 3.4% of the cases that would otherwise have occurred in 2008–2015 were prevented by early initiation of ART. Only 0.6% of the cases were attributable to a change in condom use in the HIV-positive population, as less usage is mainly seen in virally suppressed MSM. Most new infections were attributable to transmission from recently infected undiagnosed individuals. It was estimated that doubling the diagnosis rate would have resulted in 11.8% fewer cases in 2001–2015. Moreover, it was estimated that introducing pre-exposure prophylaxis (PrEP) for 50% of those MSM not using condoms with occasional partners would have resulted in 22.6% fewer cases in 2012–2015. Conclusions: By combining observational data on the relevant epidemiological and clinical processes with a mathematical model, we showed that the 'test and treat' approach is most effective in reducing the number of new cases. Only a moderate population-level effect was estimated for early initiation of ART and a weak effect for the change in condom use of diagnosed MSM. Protecting HIV-negative individuals who are not using condoms with PrEP was shown to have a major impact. © 2018 British HIV Association	condom use; HIV diagnosis; HIV epidemic; men who have sex with men; pre-exposure prophylaxis; treatment as prevention	English	United Kingdom	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Quantitative
Article	2018	Kwakwa H.A.; Bessias S.; Sturgis D.; Walton G.; Wahome R.; Gaye O.; Jackson M.	Engaging United States Black Communities in HIV Pre-exposure Prophylaxis: Analysis of a PrEP Engagement Cascade	Journal of the National Medical Association	-	-	-	-	279684	10.1016/j.jnma.2017.12.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85040768555&doi=10.1016%2fj.jnma.2017.12.006&partnerID=40&md5=9c0bc6b135ca924c6fe56258a8e93771	Background/Purpose: National PrEP utilization analyses show US non-Hispanic Blacks accessing PrEP at disproportionately low rates given the higher HIV prevalence among Blacks, and in comparison to utilization by non-Hispanic Whites. Women also are underrepresented among PrEP utilizers, especially Black women. We examine the process of accessing PrEP for a majority Black population in an urban community health center setting. Methods: In the Philadelphia city health centers, patients referred for PrEP were followed through six steps of accessing PrEP: referral, patient contact by a PrEP team, maintained interest by patients, scheduling of screening appointments, attending screening appointments, and initiating PrEP. Chi-squared tests were performed at each stage to identify gender differences in drop-off at each step. Results: Between August 2014 and December 2015, 14% of 785 patients referred for PrEP initiated. Women constituted 37.8% of referrals. A smaller majority of Blacks initiated (84.6% of females, 69.5% of males) than were referred (94.5% of females, 88.1% of males). Prior knowledge of PrEP was associated with screening (68% of those with prior knowledge screened, compared with 29.6% of those without prior knowledge,X2 p<0.0001). Higher initiation:referral ratios were noted for self-referrals, and for those referred by clinicians, peers and partners. Conclusions: In a diverse cohort in a community health center setting, myriad barriers resulted in a 14% initiation rate for persons at elevated risk for HIV who were referred for PrEP. These barriers led to disproportionately fewer non-Hispanic Blacks and women initiating PrEP. Efforts to better engage Blacks and women in PrEP care are urgently needed, and may include better dissemination of PrEP-related information in Black communities and to women, and training of clinicians serving Black and female populations to improve competency in provision of PrEP care. © 2018	Black; Cascade; Engagement; HIV; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Essay	2018	Kwan, TH; Wong, NS; Lui, GCY; Lee, KCK; Lee, SS	Acceptability of an incentivised PrEP programme for men who have sex with men at high risk of HIV infection in Hong Kong: an implementation study	The Lancet	-	-	-	-	0140-6736	10.1016/S0140-6736(18)32706-5	https://www.proquest.com/scholarly-journals/acceptability-incentivised-prep-programme-men-who/docview/2125626777/se-2?accountid=8113	Background In Hong Kong, pre-exposure prophylaxis (PrEP) was first launched as a pilot study for men who have sex with men (MSM) at high risk of HIV infection. However, the community's acceptance of such programme might affect policy making in its implementation as a service. Therefore, we aimed to examine the feasibility of an incentivised mode of PrEP delivery in the MSM community. Methods We did a implementation study of daily co-formulated tenofovir disoproxil fumarate 300 mg plus emtricitabine 200 mg (TDF/FTC). We prescribed oral tablets of TDF/FTC to PrEP-naive, HIV-negative, high-risk MSM for 30 weeks through a pilot clinic in Hong Kong. We assessed MSM that self-referred or were referred by collaborating community organisations or HIV services using a survey about their eligibility and, if applicable, reasons for not joining the study. The key inclusion criteria were recent history of condomless anal sex and HIV negative on testing, whereas HBsAg-positive patients and those with impaired renal functions were excluded. The primary measures were acceptance rate and associated socio-behavioural factors. Consenting MSM were required to pay a fixed price at each visit but the follow-up interval was increased over time, such that the unit cost of TDF/FTC became lower for participants who remained on the programme. The actual cost of TDF/FTC was equivalent to HK$25 (US$3·20) per tablet or 13% of the market price upon completion. The study was approved by the Joint Chinese University of Hong Kong–New Territories East Cluster Clinical Research Ethics Committee. This study is registered with the Centre for Clinical Research and Biostatistics Clinical Trials Registry, number CUHK_CCRB00533, and the Chinese Clinical Trial Registry, number ChiCTR-OPC-16009603. Findings Between Sep 21, 2017, and May 23, 2018, 292 MSM were assessed. Among 247 MSM who showed interest in the study, 196 (79%) had engaged in high-risk behaviours in the preceding 6 months. Among 229 high risk MSM, 196 (86%) indicated willingness to join the study, of which 71 ultimately enrolled. 49 (98%) of 50 MSM who used drugs during sex were interested in joining the programme (p=0·004). There were no significant associations between risky behaviours, such as the practice of condomless sex, and PrEP acceptance. The most common reason for not being interested in the study was the drug cost (24 53% of 45), concern about side-effects (13 29%), low perceived risk (ten 22%), and feeling troublesome about taking daily medications (nine 20%). Interpretation An incentivised mode of PrEP delivery was moderately well accepted by high risk MSM in Hong Kong. The gap between awareness and their access to PrEP would need to be addressed in the future if programme expansion is considered, since price can be a major deterrent for some eligible people despite the lowered price. Community education on PrEP together with pre-PrEP counselling is crucial for successful implementation. Funding AIDS Trust Fund (MSS 264 R), Hong Kong. Article	2018	Kwan, Tsz Ho; Lee, Shui Shan	Predictors of HIV Testing and Their Influence on PrEP Acceptance in Men Who Have Sex with Men: A Cross-Sectional Study.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-017-1978-0	https://dx.doi.org/10.1007/s10461-017-1978-0	HIV testing is the gateway to biomedical means of prevention and treatment. Identifying predictors of HIV testing is important to inform future preventive interventions. Of 444 men who have sex with men without known HIV infection enrolled in a study in Hong Kong, 64% had ever been HIV-tested. Testers were generally older, better educated, had a higher monthly income, and more likely self-identified as gay. Testers often used Internet and frequented saunas for sex networking, compared with non-testers attending bars, massage centres and public toilets. HIV testing habit also varied with the profile of body image type and preferred type in sex networking. Higher acceptance of pre-exposure prophylaxis (PrEP) was observed among testers. Overall, socioeconomic status played an important role in both HIV testing and access to PrEP. Interventions targeting sex networking venues and alternative means of testing provision are needed to increase coverage of HIV testing. Article	2018	Lalley-Chareczko L.; Clark D.; Conyngham C.; Zuppa A.; Moorthy G.; Mounzer K.; Koenig H.	Delivery of TDF/FTC for pre-exposure prophylaxis to prevent HIV-1 acquisition in young adult men who have sex with men and transgender women of color using a urine adherence assay	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001772	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057625253&doi=10.1097%2fQAI.0000000000001772&partnerID=40&md5=810f48eed8a0cb8c56b06a175c2acb20	Background: Pre-exposure prophylaxis (PrEP) for HIV prevention with daily tenofovir and emtricitabine is effective when taken consistently. Currently, there is no objective way to monitor PrEP adherence. Urine has been shown to be highly correlated with plasma tenofovir levels, with urine tenofovir levels .1000 ng/mL demonstrating recent (1-2 days) adherence to PrEP. Setting: This study was conducted at an urban community health center in Philadelphia, Pennsylvania. Methods: PrEP was administered to 50 young men who have sex with men and transgender women of color using weekly, biweekly, and/or monthly dispensation schedules. Primary objectives were retention at 48 weeks (in care at week 48 and completing ≥50% of medication pickups) and adherence assessed by urine tenofovir levels. Risk behaviors and sexually transmitted infection diagnoses were also collected. Results: Seventy percent of participants were retained in care at 48 weeks. The proportion of subjects with urine tenofovir consistent with recent adherence was 80, 74.4, 82.4, 82.4, and 69.7% at weeks 4, 12, 24, 36, and 48, respectively. Sixty-one sexually transmitted infections were diagnosed over 231 screenings throughout 48 weeks, with no significant change between the first and second 24-week periods (P = 0.43; 0 seroconversions). At week 48, more than half of subjects reported an increase or no change in condom use, an increase in their ability to discuss HIV with partners, and no change in number of sexual partners from baseline. Conclusions: These data demonstrate PrEP can be successfully delivered to a high-risk population with high program retention and medication adherence measured by urine tenofovir levels. © 2018 Wolters Kluwer Health, Inc. Article	2018	Lam, RPK; Balsari, S; Hung, KKC; Hsiao, KH; Leung, LP; Leaning, J	How Do Doctors and Nurses in Emergency Departments in Hong Kong View Their Disaster Preparedness? A Cross-Sectional Territory-Wide Online Survey	Disaster Medicine and Public Health Preparedness	-	-	-	-	1935-7893	10.1017/dmp.2017.71	https://pubmed.ncbi.nlm.nih.gov/28829007/	Objectives: To assess the level of all-hazards disaster preparedness and training needs of emergency department (ED) doctors and nurses in Hong Kong from their perspective, and identify factors associated with high perceived personal preparedness. Design: This study was a cross-sectional territory-wide online survey conducted from 9 September to 26 October, 2015. Participants: The participants were doctors from the Hong Kong College of Emergency Medicine and nurses from the Hong Kong College of Emergency Nursing. Methods: We assessed various components of all-hazards preparedness using a 25-item questionnaire. Backward logistic regression was used to identify factors associated with perceived preparedness. Results: A total of 107 responses were analyzed. Respondents lacked training in disaster management, emergency communication, psychological first aid, public health interventions, disaster law and ethics, media handling, and humanitarian response in an overseas setting. High perceived workplace preparedness, length of practice, and willingness to respond were associated with high perceived personal preparedness. Conclusions: Given the current gaps in and needs for increased disaster preparedness training, ED doctors and nurses in Hong Kong may benefit from the development of core-competency-based training targeting the under-trained areas, measures to improve staff confidence in their workplaces, and efforts to remove barriers to staff willingness to respond. Article	2018	Lambrescak E.; Mariot P.; Dahlouk S.Y.; Rabahi N.; Lesage A.-C.; Bourguignon J.; Taouk M.; Zeitoun J.-D.; Atienza P.; Etienney I.	Prophylactic use of Truvada® and the role of the proctologist; Information sur la prise prophylactique de Truvada® en proctologie	Hepato-Gastro et Oncologie Digestive	-	-	-	-	21153310	10.1684/hpg.2018.1643	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054482193&doi=10.1684%2fhpg.2018.1643&partnerID=40&md5=16872782ba5dce9794565d430f458801	The use of antiretroviral drugs for HIV, on demand, for prophylaxis, has been approved for marketing in France since March 2017. The vast majority of beneficiaries are homosexual men. In addition to the presentation of these patients under Prep to proctologic emergencies, programmed proctological consultations are very often proposed by infectious physicians. There are currently no recommendations regarding the content of these consultations. This mini-review attempts to shed light on these new practices, with a sharing of our experience based on the epidemiology of human Papilloma Virus (HPV) lesions. The key elements for these patients are: information on HPV contamination and other sexually transmitted infections (STIs), a careful clinical examination, the treatment of observed lesions and their monitoring. Many questions arise regarding the indication for an HPV vaccine in these patients, the possibility of an increase in the resistance of other STIs and the pace of follow-up to offer them. Article	2018	Lancki N.; Almirol E.; Alon L.; McNulty M.; Schneider J.A.	Preexposure prophylaxis guidelines have low sensitivity for identifying seroconverters in a sample of young Black MSM in Chicago	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001710	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041456459&doi=10.1097%2fQAD.0000000000001710&partnerID=40&md5=73b08eaf95678a7b37415ae330332e39	Background: Identification of clients at greatest risk of acquiring HIV is critical for preexposure prophylaxi (PrEP) implementation. Young black MSM (YBMSM) have high incidence of HIV. We examined published guidelines in identifying eligible PrEP candidates, including seroconverters, in a representative cohort of YBMSM. Methods: The uConnect cohort included YBMSM aged 16-29 years during PrEP roll-out in Chicago from 2013 and 2016. YBMSM with indications for PrEP were determined using Center for Disease Control and Prevention (CDC) guidelines, the HIV incidence risk index for MSM (HIRI-MSM) scoring tool, and Gilead recommendations with calculation of sensitivities, specificities, and area under the curve (AUC) for HIV seroconversion over 18 months. Incidence rate ratios (IRRs) using Poisson regression were modeled to compare individual and network factors associated with seroconversion. Results: In the study cohort, 300 HIV uninfected YBMSM contributed 390.4 person-years of follow-up mean age (SD), 22.3 years (3.07). HIV incidence was 8.5 cases per 100 person-years (95% confidence interval, 6.0-11.9). One network factor was associated with seroconversion: having partners more than 10 years older (IRR-=-4.4, 95% confidence interval, 1.6-11.8). Overall, 49% of the cohort had an indication for PrEP using CDC guidelines; 72% using HIRI-MSM, and 86% using Gilead recommendations. HIV seroconverters (n-=-33) were identified as PrEP eligible prior to seroconversion with sensitivities/AUCs for CDC (52%/0.51), HIRI-MSM (85%/0.57), and Gilead guidelines (94%/0.54). Conclusion: Low sensitivity of CDC guidelines and limited AUC of HIRI-MSM and Gilead screening tools are of concern for PrEP implementation among most at risk populations such as YBMSM. Consideration of demographics, local epidemiology, and network factors may better guide identification of clients who could benefit most from PrEP. © 2018 Wolters Kluwer Health, Inc. Article	2018	Landovitz, RJ; Li, S; Grinsztejn, B; Dawood, H; Liu, AY; Magnus, M; Hosseinipour, MC; Panchia, R; Cottle, L; Chau, G; Richardson, P; Marzinke, MA; Hendrix, CW; Eshleman, SH; Zhang, Y; Tolley, E; Sugarman, J; Kofron, R; Adeyeye, A; Burns, D; Rinehart, AR; Margolis, D; Spreen, WR; Cohen, MS; McCauley, M; Eron, JJ	Safety, tolerability, and pharmacokinetics of long-acting injectable cabotegravir in low-risk HIV-uninfected individuals: HPTN 077, a phase 2a randomized controlled trial	PLOS Medicine	-	-	-	-	NA	10.1371/journal.pmed.1002690	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01667796/full	BACKGROUND: Cabotegravir (CAB) is a novel strand-transfer integrase inhibitor being developed for HIV treatment and prevention. CAB is formulated both as an immediate-release oral tablet for daily administration and as a long-acting injectable suspension (long-acting CAB CAB LA) for intramuscular (IM) administration, which delivers prolonged plasma exposure to the drug after IM injection. HIV Prevention Trials Network study 077 (HPTN 077) evaluated the safety, tolerability, and pharmacokinetics of CAB LA in HIV-uninfected males and females at 8 sites in Brazil, Malawi, South Africa, and the United States. CONCLUSIONS: In this study, CAB LA was well tolerated at the doses and dosing intervals used. ISRs were common, but infrequently led to product discontinuation. CAB LA 600 mg every 8 weeks met pharmacokinetic targets for both male and female study participants. The safety and pharmacokinetic results observed support the further development of CAB LA, and efficacy studies of CAB LA for HIV treatment and prevention are in progress. TRIAL REGISTRATION: ClinicalTrials.gov Registry: ClinicalTrials.gov Trial number: NCT02178800. METHODS AND FINDINGS: HPTN 077 was a double-blind, placebo-controlled phase 2a trial. Healthy individuals age 18-65 years at low HIV risk were randomized (3:1) to receive CAB or placebo (PBO). In the initial oral phase, participants received 1 daily oral tablet (CAB or PBO) for 4 weeks. Those without safety concerns in the oral phase continued and received injections in the injection phase (Cohort 1: 3 injections of CAB LA 800 mg or 0.9% saline as PBO IM every 12 weeks for 3 injection cycles; Cohort 2: CAB LA 600 mg or PBO IM for 5 injection cycles; the first 2 injections in Cohort 2 were separated by 4 weeks, the rest by 8 weeks). The primary analysis included weeks 5 to 41 of study participation, encompassing the injection phase. The cohorts were enrolled sequentially. Primary outcomes were safety and tolerability. Secondary outcomes included pharmacokinetics and events occurring during the oral and injection phases. Between February 9, 2015, and May 27, 2016, the study screened 443 individuals and enrolled 110 participants in Cohort 1 and 89 eligible participants in Cohort 2. Participant population characteristics were as follows: 66% female at birth; median age 31 years; 27% non-Hispanic white, 41% non-Hispanic black, 24% Hispanic/Latino, 3% Asian, and 6% mixed/other; and 6 transgender men and 1 transgender woman. Twenty-two (11%) participants discontinued the oral study product; 6 of these were for clinical or laboratory adverse events (AEs). Of those who received at least 1 CAB LA injection, 80% of Cohort 1 and 92% of Cohort 2 participants completed all injections; injection course completion rates were not different from those in the PBO arm. Injection site reactions (ISRs) were common (92% of Cohort 1 and 88% of Cohort 2 participants who received CAB LA reported any ISR). ISRs were mostly Grade 1 (mild) to Grade 2 (moderate), and 1 ISR event (Cohort 1) led to product discontinuation. Grade 2 or higher ISRs were the only AEs reported more commonly among CAB LA recipients than PBO recipients. Two Grade 3 (severe) ISRs occurred in CAB recipients, 1 in each cohort, but did not lead to product discontinuation in either case. Seven incident sexually transmitted infections were diagnosed in 6 participants. One HIV infection occurred in a participant 48 weeks after last injection of CAB LA: CAB was not detectable in plasma both at the time of first reactive HIV test and at the study visit 12 weeks prior to the first reactive test. Participants in Cohort 2 (unlike Cohort 1) consistently met prespecified pharmacokinetic targets of at least 95% of participants maintaining CAB trough concentrations above PA-IC90, and 80% maintaining trough concentrations above 4× PA-IC90. Study limitations include a modest sample size, a short course of injections, and a low-risk study population.	*HIV test; *cabotegravir; *drug safety; Adolescent; Adult; Adverse drug reaction; Aged; Anti-HIV Agents *administration & dosage, adverse effects, blood, *pharmacokinetics; Article; Brazil; Cohort analysis; Controlled study; Delayed-Action Preparations; Diagnosis; Disease course; Double blind procedure; Double-Blind Method; Drug Administration Schedule; Drug Monitoring; Drug efficacy; Drug therapy; Drug withdrawal; Female; HIV Infections diagnosis, *prevention & control, transmission, virology; Hispanic; Human; Human immunodeficiency virus infection; Human tissue; Humans; IC90; Injection site reaction; Injections, Intramuscular; Major clinical study; Malawi; Male; Middle Aged; Outcome assessment; Pharmacokinetics; Phase 2 clinical trial; Placebo; Plasma; Pyridones *administration & dosage, adverse effects, blood, *pharmacokinetics; Randomized controlled trial; Recipient; Rest; Risk Assessment; Risk Factors; Risk assessment; Sample size; Sexually transmitted disease; Side effect; Sodium chloride; South Africa; Tablet; Transgender; Treatment Outcome; Trough concentration; United States; Young Adult; Young adult	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2018	Leblanc, Natalie M.; Mitchell, Jason	Providers' Perceptions of Couples' HIV Testing and Counseling (CHTC): Perspectives From a U.S. HIV Epicenter.	Couple & Family Psychology	-	-	-	-	2160-4096 2160-410X	10.1037/cfp0000097	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6179155/	Current epidemiology demonstrate the significance of couple-based HIV transmission among vulnerable U.S. populations and its contribution to health disparity in HIV prevalence. Couples HIV testing and counseling (CHTC) can be used to address couple-based HIV risk in the U.S. Though a globally recognized service, the literature lacks U.S.-based healthcare providers' (HCP) perspectives of CHTC. To address this research gap, a qualitative descriptive design was used to ascertain HCPs' perceptions about CHTC. Semi-structured in-depth interviews were conducted with 22 HCPs who were experienced with engaging patients or clients across the HIV care continuum. Overall, HCPs supported CHTC among different U.S. POPULATIONS: Content and thematic analysis revealed HCPs perceived CHTC to be an evolution from current HIV testing approaches and a mechanism to screen people who may not otherwise. CHTC was perceived to have biomedical and bio-behavioral merit that warranted consideration for implementation within health service settings and among populations with heightened HIV risk. This strategy was perceived to be a mechanism for introducing PrEP and conception health into one's practice. CHTC also signaled patients reorienting perceptions of personal health as being linked to the health of another individual. Providers recognized that couples have evolved to be increasingly non-heteronormative and thought that CHTC should be offered to all couples. However, participants also noted that HCPs in the U.S. need to be comfortable with promoting sexual health among various populations for implementation of CHTC to be successful. Article	2018	Leech A.A.; Burgess J.F.; Sullivan M.; Kuohung W.; Horný M.; Drainoni M.-L.; Christiansen C.L.; Linas B.P.	Cost-effectiveness of preexposure prophylaxis for HIV prevention for conception in the United States	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002014	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056401261&doi=10.1097%2fQAD.0000000000002014&partnerID=40&md5=6232d36c99d13c2758b0ae57d1166186	Objective:The aim of this study was to investigate the value of coformulated Tenofovir disoproxil fumarate and emtricitabine (TDF/FTC) for preexposure prophylaxis (PrEP) for conception in the U.S. and to identify scenarios in which 'Undetectable=Untransmittable' (U=U) may not be adequate, and rather, PrEP or assisted reproduction would improve outcomes.Design:We developed a Markov cohort simulation model to estimate the incremental benefits and cost-effectiveness of PrEP compared with alternative safer conception strategies, including combination antiretroviral therapy (cART) alone for the HIV-infected partner and assisted reproductive technologies. We modelled various scenarios in which HIV RNA suppression in the male partner was less than perfect.Setting:U.S. healthcare sector perspective.Participants:Serodiscordant couples in the U.S. was composed of an HIV-infected male and HIV-uninfected female seeking conception.Intervention:Economic analysis.Main outcome measure(s):Cumulative risks of HIV transmission to women and babies, maternal life expectancy, discounted quality-adjusted life years (QALY), discounted lifetime medical costs and incremental cost-effectiveness ratios.Results:cART with condomless intercourse limited to ovulation was the preferred HIV prevention strategy among women seeking to conceive with an HIV-infected partner who is HIV-suppressed. PrEP was not cost-effective for women who had partners who were virologically suppressed. When the probability of male partner HIV suppression was low and we assumed generic pricing of PrEP, PrEP was cost-effective, and sometimes even cost-saving compared with cART alone.Conclusion:From a U.S. healthcare sector perspective, when the male partner was not reliably suppressed, PrEP became economically attractive, and in some cases, cost-saving. © 2019 Lippincott Williams and Wilkins. Article	2018	LeGrand S.; Knudtson K.; Benkeser D.; Muessig K.; McGee A.; Sullivan P.S.; Hightow-Weidman L.	Testing the Efficacy of a Social Networking Gamification App to Improve Pre-Exposure Prophylaxis Adherence (P3: Prepared, Protected, emPowered): Protocol for a Randomized Controlled Trial	JMIR Research Protocols	-	-	-	-	19290748	10.2196/10448	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070275630&doi=10.2196%2f10448&partnerID=40&md5=4b67e401cfb7a7870f38ab9b5177729b	Background: HIV prevalence is high among young men who have sex with men (YMSM) and young transgender women who have sex with men (YTWSM), particularly among minorities. Despite its proven efficacy and safety, the uptake of and adherence to pre-exposure prophylaxis (PrEP) among YMSM and YTWSM is currently limited. To date, evidence-based interventions to promote and sustain PrEP adherence have been limited and not shown to be highly efficacious. Given the widespread adoption of smartphones, mobile apps can be utilized to increase PrEP adherence for many YMSM and YTWSM. Objective: The study consists of a formative research phase to develop an app-based intervention, P3 (Prepared, Protected, emPowered), to increase PrEP adherence, and a randomized controlled trial (RCT) to test its efficacy. P3 is a mobile app built on an established health platform, which includes social networking and game-based components to encourage PrEP adherence among YMSM and YTWSM. P3+ includes all P3 features plus adherence counseling delivered via two-way text messaging (short message service, SMS) through the app. Methods: The formative research phase includes usability testing to assess users' comprehension of P3's educational content, understanding and use of intervention features, and overall impressions of app functionality, followed by app refinements. A subsequent field trial will identify and resolve any remaining technical challenges. A three-arm RCT (P3, P3+, and standard of care) will then be conducted at 6 iTech subject recruitment venues to assess intervention efficacy and to conduct a comparison of costs to deliver the 2 intervention arms. Results: This is an ongoing research project with initial results from the formative work expected in 2020 and those from the RCT in 2021. Conclusions: P3 aims to provide an engaging, interactive experience that is highly appealing for the target population, leveraging technology already heavily integrated into the lives of young people, and thus meeting users' needs in a familiar, stimulating way. If efficacious, P3 could be a sustainable, easily disseminated, lower-cost PrEP intervention for YMSM and YTWSM. Further, the research aims to determine the processes that are essential to developing and implementing future health-related gamification interventions. ©Sara LeGrand, Kelly Knudtson, David Benkeser, Kathryn Muessig, Andrew Mcgee, Patrick S Sullivan, Lisa Hightow-Weidman. Article	2018	LeVasseur, Michael T; Goldstein, Neal D; Tabb, Loni P; Olivieri-Mui, Brianne L; Welles, Seth L	The Effect of PrEP on HIV Incidence Among Men Who Have Sex With Men in the Context of Condom Use, Treatment as Prevention, and Seroadaptive Practices.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000001555	https://dx.doi.org/10.1097/QAI.0000000000001555	BACKGROUND: HIV preexposure prophylaxis (PrEP) is an effective tool in preventing HIV infection among high-risk men who have sex with men (MSM). It is unknown how effective PrEP is in the context of other implemented HIV prevention strategies, including condom use, seroadaption, and treatment as prevention (TasP). We evaluate the impact of increasing uptake of PrEP in conjunction with established prevention strategies on HIV incidence in a high-risk population of MSM through simulation. METHODS: Agent-based simulation models representing the sexual behavior of high-risk, urban MSM in the United States over the period of 1 year were used to evaluate the effect of PrEP on HIV infection rates. Simulations included data for 10,000 MSM and compared increasing rates of PrEP uptake under 8 prevention paradigms: no additional strategies, TasP, condom use, seroadaptive behavior, and combinations thereof. RESULTS: We observed a mean of 103.2 infections per 10,000 MSM in the absence of any prevention method. PrEP uptake at 25% without any additional prevention strategies prevented 30.7% of infections. In the absence of PrEP, TasP, condom use, and seroadaptive behavior independently prevented 27.1%, 48.8%, and 37.7% of infections, respectively, and together prevented 72.2%. The addition of PrEP to the 3 aforementioned prevention methods, at 25% uptake, prevented an additional 5.0% of infections. CONCLUSIONS: To achieve a 25% reduction in HIV infections by 2020, HIV prevention efforts should focus on significantly scaling up access to PrEP in addition to HIV testing, access to antiretroviral therapy, and promoting condom use. Article	2018	Li J.; Peng L.; Gilmour S.; Gu J.; Ruan Y.; Zou H.; Hao C.; Hao Y.; Lau J.T.-F.	A mathematical model of biomedical interventions for HIV prevention among men who have sex with men in China	BMC Infectious Diseases	-	-	-	-	14712334	10.1186/s12879-018-3516-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057545827&doi=10.1186%2fs12879-018-3516-8&partnerID=40&md5=7ae79d44d34c256f9e55661e85abd890	Background: The new HIV treatment guidelines in China recommend antiretroviral therapy (ART) for all people living with HIV, but significant gaps in implementation still exist. Pre-exposure prophylaxis (PrEP) can effectively reduce the risk of HIV transmission among men who have sex with men (MSM). This study assessed the epidemiological impact and cost effectiveness of PrEP, enhanced biomedical interventions and their combination among MSM in China. Methods: A deterministic mathematical model was developed and projected over 20 years to assess the impact of PrEP, biomedical interventions and their combinations. Incidence and prevalence of HIV were measured, and cost-effectiveness was assessed using incremental cost (international dollars, Int.) per quality-adjusted life year (QALY) gained. Results: A total of 0.78 million new HIV infections were estimated to occur over the next 20 years if no additional interventions are implemented among MSM. The PrEP-only strategy covering 25-75% of HIV-negative high-risk MSM can prevent 0.09-0.20 million (12.1-25.7%) new infections, at a cost of 17,277-18,452 Int./QALY. The optimal cost-effectiveness path is from test-and-treat to the combination strategy of test-and-treat and PrEP. Some strategies could almost eliminate new HIV infections over the next 20 years. Conclusions: PrEP, test-and-treat, and their combinations among MSM are effective and cost-effective relative to current policy. PrEP is an important and cost-effective addition to current policy in China. © 2018 The Author(s). Article	2018	Lichtenstein, Bronwen; Kay, Emma Sophia; Klinger, Ian; Mutchler, Matt G	Ricky and Lucy: gender stereotyping among young Black men who have sex with men in the US Deep South and the implications for HIV risk in a severely affected population.	Culture, Health & Sexuality	-	-	-	-	1464-5351	10.1080/13691058.2017.1347280	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5775064	HIV disproportionately affects young Black men who have sex with men in the USA, with especially high rates in the Deep South. In this Alabama study, we interviewed 24 pairs of young Black men who have sex with men aged 19-24 and their close friends (n = 48) about sexual scripts, dating men and condom use. Three main themes emerged from the study: the power dynamics of 'top' and 'bottom' sexual positions for condom use; gender stereotyping in the iconic style of the 'I Love Lucy' show of the 1950s; and the sexual dominance of 'trade' men. Gender stereotyping was attributed to the cultural mores of Black families in the South, to the preferences of 'trade' men who exerted sexual and financial control and to internalised stigma relating to being Black, gay and marginalised. The findings suggest that HIV prevention education for young Black men who have sex with men is misguided if gendered power dynamics are ignored, and that funded access to self-protective strategies such as pre-exposure prophylaxis and post-exposure prophylaxis could reduce HIV risk for this severely affected population. Article	2018	Lillie, Tiffany A.; Baer, James; Adams, Darrin; Zhao, Jinkou; Wolf, R. Cameron	Think global, act local: the experience of Global Fund and PEPFAR joint cascade assessments to harmonize and strengthen key population HIV programmes in eight countries.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25125	https://onlinelibrary.wiley.com/doi/full/10.1002/jia2.25125	INTRODUCTION: The Global Fund and the US President's Emergency Plan for AIDS Relief (PEPFAR) are major donors to HIV services with key populations (KPs) to achieve the UNAIDS 95-95-95 epidemic control goals. The programmes they fund are not always well aligned or coordinated, decreasing their effectiveness. Joint assessments are designed and led by LINKAGES, a project funded by PEPFAR and the US Agency for International Development, to improve coordination among donors and on-the-ground implementation of KP HIV programmes. Joint assessments help identify barriers that prevent KPs from accessing interventions along the cascade of prevention, diagnosis and treatment services, and provide recommendations to improve and align programmes. Detailed reports from eight assessments in Malawi, Cameroon, Swaziland, Haiti, Angola, Nepal, Côte d'Ivoire and Botswana were analysed for thematic challenges, and recommendations are presented. The purpose of the paper is to identify commonalities across KP HIV programmes that were found through the assessments so others can learn and then strengthen their programmes to become more effective. DISCUSSION: The joint cascade assessments offered countries feedback on HIV programme challenges and recommendations for strengthening them at national, subnational and local levels. Shared intervention areas included: (1) robust population size estimates to inform service delivery targets and to budget resources for KP outreach; (2) accessible and KP-friendly services most relevant to individuals to increase retention in the HIV cascade; (3) decentralized, community-based services for HIV testing and antiretroviral therapy, and new approaches including self-testing and PrEP; (4) addressing structural issues of stigma, discrimination and violence against KPs to create a more enabling environment; and (5) more effective and continual tracking of KPs across the cascade, and coordinated, harmonized monitoring tools and reporting systems between donor-funded and national programmes. CONCLUSIONS: The assessment teams and country stakeholders viewed the assessments as a best practice for coordinating donor-funded programmes that may overlap or inefficiently serve KPs. Global and national HIV programmes need investments of time, resources, and commitment from stakeholders to continually course-correct to align and improve programmes for sustained impact. The type of continued partnership demonstrated by the joint assessments is key to address HIV among KPs globally. Article	2018	Lim S.H.; Akbar M.; Wickersham J.A.; Kamarulzaman A.; Altice F.L.	The management of methamphetamine use in sexual settings among men who have sex with men in Malaysia	International Journal of Drug Policy	-	-	-	-	9553959	10.1016/j.drugpo.2018.02.019	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044533745&doi=10.1016%2fj.drugpo.2018.02.019&partnerID=40&md5=96c13e46e3e9c0ee663b1222eb8b7fb2	Background: The intentional use of illicit drugs for sexual purposes (also known as 'chemsex') is well known within the MSM communities in Malaysia although research in this population is scarce primarily because both drug use and homosexuality are illegal and stigmatised in Malaysia. Methods: From April to December 2014, interviews were conducted with twenty men (age range 21–43) living in Greater Kuala Lumpur who had sexual intercourse with other men in the past 6 months and who used illicit drugs at least monthly in the past 3 months. Fourteen men were recruited via gay social networking smartphone applications or websites while six were referred by the participants. Data were analsed using thematic analytic approach. Findings: The average duration of illicit drug use was 6.4 years (range 1–21) and all participants were using methamphetamine ("ice" or crystal meth) with frequency of use ranged from daily to once a month. Participants came from diverse ethnic, economic, and occupational backgrounds. Most participants used an inhalation apparatus ("bong") to consume methamphetamine and injection was rare in the sample. The primary motivation of methamphetamine use was to increase sexual capacity, heighten sexual pleasure and enhance sexual exploration and adventurism. Socializing with friends ("chilling"), and increased energy for work were secondary motivations. Participants emphasized the need to control the use of methamphetamine and some have established rules to control the amount and duration of use and a minority of men have maintained condom use during anal sex while under the influence of methamphetamine. Participants who professed to be in control of their drug use characterized themselves as functional users regardless of the health and social consequences from continuing use. Overall, participants perceived themselves differently from the traditional opioid users and reported limited access to sexual health and substance use treatment services. Conclusion: There is a need to increase access to HIV prevention services such as PrEP and PEP, professional support, and substance abuse treatment for drug-using MSM. A more open and friendly environment towards drug-using MSM may help them access and engage with the health services. © 2018	HIV; Homosexuality; Illicit drugs; Malaysia	English	United Kingdom	Western and Central Europe and North America	malaysia	Asia and the Pacific	malaysia	Asia and the Pacific	Qualitative
Article	2018	Liu C.; Ding Y.; Ning Z.; Gao M.; Liu X.; Wong F.Y.; He N.	Factors influencing uptake of pre-exposure prophylaxis: Some qualitative insights from an intervention study of men who have sex with men in China	Sexual Health	-	-	-	-	14485028	10.1071/SH17075	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041426700&doi=10.1071%2fSH17075&partnerID=40&md5=3b144168c58c400838933ee696b3c61e	Background: Pre-exposure prophylaxis (PrEP) is a biomedical approach for preventing the acquisition of HIV in populations at substantial risk for HIV. However, its uptake among men who have sex with men (MSM) is low in China. The study aimed to identify factors that might influence MSM's uptake and use of PrEP. Methods: In-depth interviews were conducted with 32 self-identified MSM from a PrEP intervention study evaluating daily oral tenofovir disoproxil fumarate (TDF) to prevent HIV infection. Of these men, 11 were presently using the 'TDF' group; 8 from the 'change-over' group (i.e. initially used PrEP but subsequently quitted); and 13 from the non-user group. Data were analysed using thematic approach. Results: Perception of low HIV risk, mistrust of the national PrEP program, and concerns of side effects were the main reasons for not wanting to use PrEP. Also, lack of main sexual partner's support, difficulties in adhering to the daily TDF regimen, and the inconvenient schedules in securing the medicine were the major reasons for not wanting to use or quitting the use of PrEP. On the other hand, perceived high HIV risk, beliefs in efficacy of PrEP, and worries of transmitting HIV to families were the major motives for PrEP uptake. Conclusions: Findings suggest that PrEP implementation strategies should first address issues including but not limited to accurate self-assessment of HIV risk, mistrust and limited knowledge about medical trials and PrEP, and ease of accessing PrEP. © CSIRO 2018.	biomedical approach; HIV prevention.; tenofovir disoproxil fumarate	English	United States	Western and Central Europe and North America	China	Asia and the Pacific	NA	NA	Qualitative
Article	2018	Lovelock M.	Sex, death and austerity: resurgent homophobia in the British tabloid press	Critical Studies in Media Communication	-	-	-	-	15295036	10.1080/15295036.2018.1442013	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044022893&doi=10.1080%2f15295036.2018.1442013&partnerID=40&md5=a73b4e178b726fd2ad3ad9fece71f0d2	This article explores how the current context of neoliberal austerity has come to shape representations of gay identity in the British tabloid press. Focusing on the reporting of two news events by the Daily Mail and the Sun between July 2016 and July 2017, the High Court ruling on the provision of the HIV prevention drug PrEP by the National Health Service and the rise of so-called "chemsex" amongst gay men, I argue that the right-wing tabloids have reformulated traditional homophobic scripts in ways that correspond with the contemporary social and political context of neoliberal austerity. My analysis therefore expands scholarly understandings of how austerity ideologies shape normative understandings of "good" and "bad" behavior through the specific context of gay identity. I argue that the right-wing tabloids have come to circulate a negatively coded vision of gay life characterized by drug addiction and promiscuous, "risky" sex, which is constructed as the antithesis of the idealized, respectable and responsible subject of neoliberal austerity. Amidst the uncertainties of neoliberalism, these representations manufacture and sell a seemingly transcendental, conservative, heteronormative consensus around sexual moralities under austerity. © 2018, © 2018 National Communication Association.	austerity; chemsex; Homophobia; neoliberalism; tabloid press	English	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Qualitative
Article	2018	Luo, Wei; Katz, David A.; Hamilton, Deven T.; McKenney, Jennie; Jenness, Samuel M.; Goodreau, Steven M.; Stekler, Joanne D.; Rosenberg, Eli S.; Sullivan, Patrick S.; Cassels, Susan	Development of an Agent-Based Model to Investigate the Impact of HIV Self-Testing Programs on Men Who Have Sex With Men in Atlanta and Seattle.	JMIR Public Health and Surveillance	-	-	-	-	2369-2960	10.2196/publichealth.9357	https://pubmed.ncbi.nlm.nih.gov/29959112/	BACKGROUND: In the United States HIV epidemic, men who have sex with men (MSM) remain the most profoundly affected group. Prevention science is increasingly being organized around HIV testing as a launch point into an HIV prevention continuum for MSM who are not living with HIV and into an HIV care continuum for MSM who are living with HIV. An increasing HIV testing frequency among MSM might decrease future HIV infections by linking men who are living with HIV to antiretroviral care, resulting in viral suppression. Distributing HIV self-test (HIVST) kits is a strategy aimed at increasing HIV testing. Our previous modeling work suggests that the impact of HIV self-tests on transmission dynamics will depend not only on the frequency of tests and testers' behaviors but also on the epidemiological and testing characteristics of the population. OBJECTIVE: The objective of our study was to develop an agent-based model to inform public health strategies for promoting safe and effective HIV self-tests to decrease the HIV incidence among MSM in Atlanta, GA, and Seattle, WA, cities representing profoundly different epidemiological settings. METHODS: We adapted and extended a network- and agent-based stochastic simulation model of HIV transmission dynamics that was developed and parameterized to investigate racial disparities in HIV prevalence among MSM in Atlanta. The extension comprised several activities: adding a new set of model parameters for Seattle MSM; adding new parameters for tester types (ie, regular, risk-based, opportunistic-only, or never testers); adding parameters for simplified pre-exposure prophylaxis uptake following negative results for HIV tests; and developing a conceptual framework for the ways in which the provision of HIV self-tests might change testing behaviors. We derived city-specific parameters from previous cohort and cross-sectional studies on MSM in Atlanta and Seattle. Each simulated population comprised 10,000 MSM and targeted HIV prevalences are equivalent to 28% and 11% in Atlanta and Seattle, respectively. RESULTS: Previous studies provided sufficient data to estimate the model parameters representing nuanced HIV testing patterns and HIV self-test distribution. We calibrated the models to simulate the epidemics representing Atlanta and Seattle, including matching the expected stable HIV prevalence. The revised model facilitated the estimation of changes in 10-year HIV incidence based on counterfactual scenarios of HIV self-test distribution strategies and their impact on testing behaviors. CONCLUSIONS: We demonstrated that the extension of an existing agent-based HIV transmission model was sufficient to simulate the HIV epidemics among MSM in Atlanta and Seattle, to accommodate a more nuanced depiction of HIV testing behaviors than previous models, and to serve as a platform to investigate how HIV self-tests might impact testing and HIV transmission patterns among MSM in Atlanta and Seattle. In our future studies, we will use the model to test how different HIV self-test distribution strategies might affect HIV incidence among MSM. Article	2018	Lu-Ping ZHANG; Yue-Hong HAN; Gui-Rong CHENG; Wen-Jie ZHANG; Xia ZHAO; Xiao-Mei YU	A Study on the Preventive Drugs for Exposure to AIDS	Journal of Kunming Medical University	-	-	-	-	2095-610X	10.3969/j.issn.100304706.2018.02.028	http://dx.doi.org/10.3969/j.issn.1003-4706.2018.02.028	The prevention of occupational exposure to HIV has been carried out in China for many years, and achieved remarkable results. However, the practice of preventive drugs among people with non occupational exposure has many difficulties. Although the high-risk groups show high willingness and demand, their awareness of the preventive drugs is low due to the fear of increasing unprotected sex after the use of the drug. Other factors negatively affecting the application of the drugs are the cost and the side effects. In order to provide preventive treatment on time for the high-risk groups, the awareness of non occupational exposure prophylaxis should be raised. Article	2018	Luz P.M.; Benzaken A.; Alencar T.M.D.; Pimenta C.; Veloso V.G.; Grinsztejn B.	PrEP adopted by the brazilian national health system: What is the size of the demand?: What is the size of the demand?	Medicine (United States)	-	-	-	-	257974	10.1097/MD.0000000000010602	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047765430&doi=10.1097%2fMD.0000000000010602&partnerID=40&md5=970105f8c5f9561dfedab2dcf2b71179	Background:Brazil's response to the HIV epidemic now includes free access to preexposure prophylaxis (PrEP) to populations at substantial risk for HIV infection including men who have sex with men (MSM). We used nationally representative demographic, epidemiologic, and surveillance data to offer estimates for the number of MSM at substantial risk for HIV infection who might be eligible and willing to use PrEP in Brazil.Methods:Starting from the age/sex-stratified population, we calculated the number of men aged 15 to 64 years, in 5-year age groups, and the proportion of those who report sex with other men during their lifetime. We focused on 11 cities (representing all regions) that are responsible for a significant fraction of the HIV burden of the country and used city-specific HIV prevalence estimates to infer the fraction of MSM who are HIV-negative. We then derived the proportion of HIV-negative MSM under substantial risk for HIV infection defined as having unprotected receptive anal intercourse in the 6 months before study participation. Finally, PrEP uptake among the eligible was inferred from the PrEP Brazil study.Results:Our results show that PrEP demand in these 11 cities is 66,120 men aged 15 to 64 years. When we consider the lower and upper bounds for the available parameters, we find that PrEP demand in these 11 cities might vary from 33,378 to 97,962 men. If PrEP is restricted to those aged 15 to 49 years, demand drops by 20%. PrEP demand varies considerably by city, mostly because of the differences in population size and city-specific HIV prevalence.Discussion:We have shed light on the probable size of PrEP demand in Brazil certain that the incorporation of PrEP as part of Brazil's combination prevention for populations at substantial risk for HIV infection is a necessary challenge. PrEP will not only prevent HIV infections, it will also expand testing among the most vulnerable with the added benefit of offering combination prevention for the uninfected and immediate treatment for those already infected. As such, expected added benefits of PrEP will be earlier linkage to care, prompt treatment initiation leading to health benefits and decreased transmission. © 2018 the Author(s). Article	2018	Luz, Paula M; Osher, Benjamin; Grinsztejn, Beatriz; Maclean, Rachel L; Losina, Elena; Stern, Madeline E; Struchiner, Claudio J; Parker, Robert A; Freedberg, Kenneth A; Mesquita, Fabio; Walensky, Rochelle P; Veloso, Valdilea G; Paltiel, A David	The cost-effectiveness of HIV pre-exposure prophylaxis in men who have sex with men and transgender women at high risk of HIV infection in Brazil.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25096	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5878414	INTRODUCTION: Men who have sex with men (MSM) and transgender women (TGW) in Brazil experience high rates of HIV infection. We examined the clinical and economic outcomes of implementing a pre-exposure prophylaxis (PrEP) programme in these populations. METHODS: We used the Cost-Effectiveness of Preventing AIDS Complications (CEPAC)-International model of HIV prevention and treatment to evaluate two strategies: the current standard of care (SOC) in Brazil, including universal ART access (No PrEP strategy); and the current SOC plus daily tenofovir/emtricitabine PrEP (PrEP strategy) until age 50. Mean age (31 years, SD 8.4 years), age-stratified annual HIV incidence (age ≤ 40 years: 4.3/100 PY; age > 40 years: 1.0/100 PY), PrEP effectiveness (43% HIV incidence reduction) and PrEP drug costs ($23/month) were from Brazil-based sources. The analysis focused on direct medical costs of HIV care. We measured the comparative value of PrEP in 2015 United States dollars (USD) per year of life saved (YLS). Willingness-to-pay threshold was based on Brazil's annual per capita gross domestic product (GDP; 2015: $8540 USD). RESULTS: Lifetime HIV infection risk among high-risk MSM and TGW was 50.5% with No PrEP and decreased to 40.1% with PrEP. PrEP increased per-person undiscounted (discounted) life expectancy from 36.8 (20.7) years to 41.0 (22.4) years and lifetime discounted HIV-related medical costs from $4100 to $8420, which led to an incremental cost-effectiveness ratio (ICER) of $2530/YLS. PrEP remained cost-effective (<1x GDP) under plausible variation in key parameters, including PrEP effectiveness and cost, initial cohort age and HIV testing frequency on/off PrEP. CONCLUSION: Daily tenofovir/emtricitabine PrEP among MSM and TGW at high risk of HIV infection in Brazil would increase life expectancy and be highly cost-effective. Article	2018	Machekano, Rhoderick; Tiam, Appolinaire; Kassaye, Seble; Tukei, Vincent; Gill, Michelle; Mohai, Florence; Nchepe, Masepeli; Mokone, Majoalane; Barasa, Janet; Mohale, Sesomo; Letsie, Mosilinyane; Guay, Laura	HIV incidence among pregnant and postpartum women in a high prevalence setting.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0209782	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6310250/#:~:text=The%20estimated%20HIV%20incidence%20rate,CI%3A%200.83%E2%80%932.10).	In sub-Saharan Africa, most women who test HIV negative at the first antenatal care encounter are rarely tested again during pregnancy and postpartum, yet data suggests that pregnancy is associated with increased risk of HIV acquisition compared to non-pregnant women. We describe HIV incidence during pregnancy and postpartum in Lesotho, a high prevalence setting, and factors associated with HIV seroconversion. We enrolled a cohort of HIV negative women presenting at health facilities for antenatal care and followed them through delivery up to 24 months postpartum. Women were repeatedly tested for HIV according to the Lesotho Ministry of Health routine rapid HIV testing guidelines and responded to risk behavior questionnaire every three months. We estimated HIV incidence and associated 95% confidence intervals. We used mixed effects Cox regression models to identify independent factors associated with seroconversion accounting for repeated assessment. The estimated overall HIV incidence rate was 1.58 (95% CI: 1.05-2.28) per 100 person- years. The estimated HIV incidence rate during pregnancy (2.61 per 100 person-years, 95% CI: 1.28-5.14) was almost double the estimated HIV incidence during postpartum (1.36 per 100 person-years, 95% CI: 0.83-2.10). Women's age (14-24 years compared to 25-45 years), multiple sexual partnerships, urethral discharge and no condoms nor pre-exposure prophylaxis were independently associated with HIV infection. There is an increased need for counseling and support of HIV-uninfected pregnant and breastfeeding women to stay HIV-negative, including provision of pre-exposure prophylaxis during this high-risk period, particularly among adolescent and young women. Theses and Dissertations	2018	Mafunda, Martin Canaan	Multiscale Modelling of HIV/AIDS Transmission Dynamics	-	-	University of Venda	University of Venda	-	NA	NA	http://hdl.handle.net/11602/1256	Infectious diseases remain a major public health concern. Well-known for causing sickness and death, enormous pain and suffering, increased time spent on patient care and huge economic losses due to lost production. Infectious diseases continue to be a scourge without equal. In this work, we address the following research question: Can we use a multiscale model of HIV/AIDS transmission dynamics to assess the comparative effectiveness of health interventions that are implemented at different scale domains? To achieve the set objectives of the study, we use multiscale modelling approach, a new and emerging computational high-throughput technique for mathematically studying problems that have many characteristics across several scales. To be more specific, we perform these tasks in addressing the research question. First, we develop a within-host submodel and use it to show it's associated limitations which only a multiscale model can resolve. Second, we develop a between-host submodel and use it to motivate the need for multiscale modelling of the HIV/AIDS disease system. Finally, we link the two submodels to produce a nested HIV/AIDS multiscale model that affords us the opportunity to compare effectiveness of five preventive and treatment HIV/AIDS health interventions. Analysis of the multiscale model shows that it is possible to jointly study two key aspects (immunology and epidemiology) of infectious diseases. The multiscale model provides the means for making meaningful comparative effectiveness on available preventive and treatment health interventions. Consequently, we employ the multiscale model to show that impact of HIV/AIDS packages increases as more interventions are integrated into the packages. Specifically, the study shows that combined HAART and male circumcision is more effective than an intervention involving HAART alone. Overall, our study successfully illustrates the utility of multiscale modelling methodology as a tool for assessing the comparative effectiveness of HIV/AIDS preventive and treatment interventions. For purposes of informing public health policy, we use the study results to infer that condom use, male circumcision and pre-exposure prophylaxis are more effective in controlling the transmission dynamics of HIV/AIDS at the start of the epidemic as compared to when the disease is endemic in the community while the converse is also true for HAART. Article	2018	Maheu-Giroux, Mathieu; Baral, Stefan; Vesga, Juan F; Diouf, Daouda; Diabaté, Souleymane; Alary, Michel; Abo, Kouamé; Boily, Marie-Claude	Anal Intercourse Among Female Sex Workers in Côte d'Ivoire: Prevalence, Determinants, and Model-Based Estimates of the Population-Level Impact on HIV Transmission.	American Journal of Epidemiology	-	-	-	-	1476-6256	10.1093/aje/kwx244	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5860370	Current evidence suggests that anal intercourse (AI) during sex work is common in sub-Saharan Africa, but there have been few studies in which the contribution of heterosexual AI to human immunodeficiency virus (HIV) epidemics has been investigated. Using a respondent-driven sampling survey of female sex workers (FSWs; n = 466) in Abidjan, Côte d'Ivoire, in 2014, we estimated AI prevalence and frequency. Poisson regressions were used to identify AI determinants. Approximately 20% of FSWs engaged in AI during a normal week (95% confidence interval: 15, 26). Women who performed AI were generally younger, had been selling sex for longer, were born in Côte d'Ivoire, and reported higher sex-work income, more frequent sex in public places, and violence from clients than women not reporting AI. Condom use was lower, condom breakage/slippage more frequent, and use of water-based lubricants was less frequently reported for AI than for vaginal intercourse. Using a dynamic transmission model, we estimated that 22% (95% credible interval: 11, 37% of new HIV infections could have been averted among FSWs during 2000-2015 if AI had been substituted for vaginal intercourse. Despite representing a small fraction of all sex acts, AI is an underestimated source of HIV transmission. Increasing availability and uptake of condoms, lubricants, and pre-exposure prophylaxis for women engaging in AI could help mitigate HIV risk.	anal sex, HIV/AIDS, Côte d'Ivoire, female sex worker, mathematical model, respondent-driven sampling, West Africa	English	United States	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Quantitative
Article	2018	Maksut, Jessica L.; Eaton, Lisa A.; Siembida, Elizabeth J.; Fabius, Chanee D.; Bradley, Alison M.	Health care discrimination, sex behavior disclosure, and awareness of pre-exposure prophylaxis among Black men who have sex with men	Stigma and Health	-	-	-	-	2376-6972, 2376-6972	10.1037/sah0000102	https://www.proquest.com/scholarly-journals/health-care-discrimination-sex-behavior/docview/1940533239/se-2?accountid=8113	Background: Perceived healthcare-related discrimination and disclosure of same-sex sex behaviors to healthcare providers may act as barriers to awareness of pre-exposure prophylaxis (PrEP) for Black/African-American men who have sex with men (BMSM). Given the elevated rates of HIV transmission among young BMSM in particular, age is likely an important factor for determining the correlates of PrEP awareness unique to BMSM of different ages. Method: 147 BMSM (M age = 30.6 years, SD = 10.3 years) located in the Southeastern United States were recruited from gay-identified bars, clubs, bathhouses, parks, and street locations, via online classifieds (e.g., Craigslist) and social media (e.g., Facebook). Participants completed surveys that included questions about demographic characteristics, perceived healthcare-related discrimination, disclosure of same-sex sex behavior to healthcare providers, and PrEP awareness. Results: Perceived healthcare-related discrimination was significantly, negatively associated with PrEP awareness, and same-sex sex behavior disclosure to healthcare providers was significantly, positively related to awareness of PrEP among BMSM. A moderation analysis, with participant age as the moderator, revealed that higher perceived healthcare-related discrimination was significantly, negatively associated with PrEP awareness beginning at 30.2 years of age, and that the relationship strengthened as age increased. Discussion: Perceived healthcare-related discrimination plays a particularly important role in PrEP awareness for BMSM who are 30 years of age and older. Discrimination in healthcare settings may impact BMSM's ability, particularly those who are older, to access PrEP information. Healthcare professionals must establish procedures for identifying appropriate patients for PrEP, and prioritize addressing the psychosocial factors that impede PrEP awareness for their BMSM patients. Article	2018	Malone J.; Syvertsen J.L.; Johnson B.E.; Mimiaga M.J.; Mayer K.H.; Bazzi A.R.	Negotiating sexual safety in the era of biomedical HIV prevention: relationship dynamics among male couples using pre-exposure prophylaxis	Culture, Health & Sexuality	-	-	-	-	13691058	10.1080/13691058.2017.1368711	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029427168&doi=10.1080%2f13691058.2017.1368711&partnerID=40&md5=78010d0e709c7e358e72691a9eeb90ec	Up to two-thirds of new cases of HIV transmission between gay, bisexual and other men who have sex with men in the USA are attributed to primary relationships. Understanding the relationship dynamics and sexual agreements of male-male couples can provide insight into HIV transmission patterns and prevention needs in this population. The daily use of antiretroviral pre-exposure prophylaxis (PrEP) is highly effective in preventing HIV, but its negotiation and use within social and intimate relationship contexts remain understudied. We conducted semi-structured qualitative interviews with 20 male couples (n = 40 men) in which at least one partner was either using or in the process of initiating PrEP. Congruent with a theoretical focus on social theories of relationships and negotiated risk, couples were interviewed about relationship dynamics, trust, communication and sexual health practices, including their perception and use of PrEP. Overall, we found that couples showed heightened trust and communication when establishing open, sexual agreements and demonstrated high awareness of sexual risks and health practices in the context of PrEP use. This study demonstrates how understanding relationship dynamics can better inform HIV prevention and sexual health promotion efforts for male couples at risk of HIV. © 2017, © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Marcus J.L.; Levine K.; Grasso C.; Krakower D.S.; Powell V.; Bernstein K.T.; Boswell S.; Mayer K.H.	HIV preexposure prophylaxis as a gateway to primary care	American Journal of Public Health	-	-	-	-	900036	10.2105/AJPH.2018.304561	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053854896&doi=10.2105%2fAJPH.2018.304561&partnerID=40&md5=4395b56a058b6276d2673c4b6551c20b	Objectives. To determine whether HIV preexposure prophylaxis (PrEP) use is associated with use of non-HIV-related health care. Methods. We conducted a cross-sectional study of potential PrEP candidates at a Boston, Massachusetts, community health clinic during 2012 to 2016, comparing the proportion of PrEP users and non-PrEP users receiving primary care. Results. Of 5857 PrEP candidates, 2047 (35%) were prescribed PrEP. After adjustment for demographics and number of visits, more PrEP users received influenza vaccination (prevalence ratio PR = 1.28; 95% confidence interval CI = 1.20, 1.37), tobacco screening (PR = 1.06; 95% CI = 1.02, 1.09), and depression screening (PR = 1.07; 95% CI = 1.04, 1.11) compared with non-PrEP users. After additional adjustment for diabetes, hypertension, and overweight or obesity, more PrEP users received glucose testing (PR = 1.64; 95% CI = 1.56, 1.72) but fewer received hemoglobin A1c testing (PR = 0.81; 95% CI = 0.71, 0.93) compared with non-PrEP users. Conclusions. PrEP use was associated with receipt of influenza vaccination, tobacco and depression screening, and glucose but not hemoglobin A1c testing. Among PrEP users receiving routine care, the benefits of PrEP may extend to behavioral health, mental health, and prevention and treatment of other infectious and chronic diseases. © 2018 American Public Health Association Inc. Behavioural and demographic correlates of undiagnosed HIV infection in a MSM sample recruited in 13 European cities	BMC Infectious Diseases	-	-	-	-	14712334	10.1186/s12879-018-3249-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054930876&doi=10.1186%2fs12879-018-3249-8&partnerID=40&md5=384dfabd72d190d0297e2c170de87e6c	Background: Reducing the number of people with undiagnosed HIV infection is a major goal of HIV control and prevention efforts in Europe and elsewhere. We analysed data from a large multi-city European bio-behavioural survey conducted among Men who have Sex with Men (MSM) for previously undiagnosed HIV infections, and aimed to characterise undiagnosed MSM who test less frequently than recommended. Methods: Data on sexual behaviours and social characteristics of MSM with undiagnosed HIV infection from Sialon II, a bio-behavioural cross-sectional survey conducted in 13 European cities in 2013/2014, were compared with HIV-negative MSM. Based on reported HIV-testing patterns, we distinguished two subgroups: MSM with a negative HIV test result within 12 months prior to the study, i.e. undiagnosed incident infection, and HIV positive MSM with unknown onset of infection. Bivariate and multivariate associations of explanatory variables were analysed. Distinct multivariate multi-level random-intercept models were estimated for the entire group and both subgroups. Results: Among 497 participants with HIV-reactive specimens, 234 (47.1%) were classified as previously diagnosed, 106 (21.3%) as incident, and 58 (11.7%) as unknown onset based on self-reported status and testing history. MSM with incident HIV infection were twice as likely (odds ratio (OR) = 2.22, 95% confidence interval (95%CI): 1.17-4.21) to have used recreational substances during their last anal sex encounter and four times more likely (OR = 3.94, 95%CI: 2.14-7.27) not to discuss their HIV status with the last anal sex partner(s). MSM with unknown onset of HIV infection were 3.6 times more likely (OR = 3.61, 95%CI: 1.74-7.50) to report testing for a sexually transmitted infection (STI) during the last 12 months. Conclusions: Approximately one third of the study participants who are living with HIV were unaware of their infection. Almost two-third (65%) of those with undiagnosed HIV appeared to have acquired the infection recently, emphasizing a need for more frequent testing. Men with the identified behavioural characteristics could be considered as primary target group for HIV Pre-Exposure Prophylaxis (PrEP) to avoid HIV infection. The increased odds of those with unknown onset of HIV infection to have had an STI test in the past year strongly suggests a lost opportunity to offer HIV testing. © 2018 The Author(s). Article	2018	Marquard, Jenna L.; Saver, Barry; Kandaswamy, Swaminathan; Martinez, Vanessa I.; Simoni, Jane M.; Stekler, Joanne D.; Ganesan, Deepak; Scanlan, James	Designing a wrist-worn sensor to improve medication adherence: accommodating diverse user behaviors and technology preferences.	JAMIA Open	-	-	-	-	2574-2531	10.1093/jamiaopen/ooy035	https://academic.oup.com/jamiaopen/article/1/2/153/5084465	OBJECTIVES: High medication adherence is important for HIV suppression (antiretroviral therapy) and pre-exposure prophylaxis efficacy. We are developing sensor-based technologies to detect pill-taking gestures, trigger reminders, and generate adherence reports. MATERIALS AND METHODS: We collected interview, observation, and questionnaire data from individuals with and at-risk for HIV (N = 17). We assessed their medication-taking practices and physical actions, and feedback on our initial design. RESULTS: While participants displayed diverse medication taking practices and physical actions, most (67%) wanted to use the system to receive real-time and summative feedback, and most (69%) wanted to share data with their physicians. Participants preferred reminders via the wrist-worn device or mobile app, and summative feedback via mobile app or email. DISCUSSION: Adoption of these systems is promising if designs accommodate diverse behaviors and preferences. CONCLUSION: Our findings may help improve the accuracy and adoption of the system by accounting for user behaviors, physical actions, and preferences.	medication adherence; HIV infections; smartphone; gestures; human engineering	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2018	Marrazzo, Jeanne M.	BIOMEDICAL PREVENTION OF HIV IN WOMEN: CHALLENGES AND APPROACHES, WITH PARTICULAR REFERENCE TO THE VAGINAL MICROBIOME.	Transactions of the American Clinical and Climatological Association	-	-	-	-	0065-7778	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6116616/	Although great progress has been made in treating HIV-1 infection globally, incidence remains high in many locales, especially sub-Saharan Africa. Two-thirds of the burden of disease is there, and among those infected, 60% are women. Pre-exposure prophylaxis, the administration of a drug to prevent acquisition of infection, has proven to be a promising prevention modality for HIV-1 when administered as a daily oral regimen of tenofovir disoproxil fumarate/emtricitabine. However, data suggest that oral tenofovir disoproxil fumarate/emtricitabine may not achieve protective concentrations in the cervicovaginal tissue as rapidly as it does in the rectum. Moreover, a relative paucity of the beneficial vaginal bacteria Lactobacillus crispatus, along with a commensurate increase in the vaginal anaerobes that characterize bacterial vaginosis, strongly increases risk of HIV-1 acquisition and may even modify efficacy of topical tenofovir when used as pre-exposure prophylaxis. bacterial vaginosis, a globally prevalent infection that increases women's risk of HIV-1 acquisition, and presents serious other reproductive health risks and management challenges, presumably involves survival of treatment-resistant biofilm communities. Methods to effect sustained improvement in the vaginal microenvironment are urgently needed. Article	2018	Marshall, Brandon D L; Goedel, William C; King, Maximilian R F; Singleton, Alyson; Durham, David P; Chan, Philip A; Townsend, Jeffrey P; Galvani, Alison P	Potential effectiveness of long-acting injectable pre-exposure prophylaxis for HIV prevention in men who have sex with men: a modelling study.	The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(18)30097-3	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6138558	BACKGROUND: Oral pre-exposure prophylaxis (PrEP) prevents HIV infection in men who have sex with men (MSM); however, adherence is an ongoing concern. Long-acting injectable PrEP is being tested in phase 3 trials and could address challenges associated with adherence. We examined the potential effectiveness of long-acting injectable PrEP compared with oral PrEP in MSM. METHODS: We used an agent-based model to simulate HIV transmission in a dynamic network of 11â245 MSM in Atlanta, GA, USA. We used raw data from studies in macaque models and pharmacokinetic data from safety trials to estimate the time-varying efficacy of long-acting injectable PrEP. The effect of long-acting injectable PrEP on the cumulative number of new HIV infections over 10 years (2015-24) was compared with no PrEP and daily oral PrEP across a range of coverage levels. Sensitivity analyses were done with varying maximum efficacy and drug half-life values. FINDINGS: In the absence of PrEP, the model predicted 2374 new HIV infections (95% simulation interval SI 2345-2412) between 2015 and 2024. The cumulative number of new HIV infections was reduced in all scenarios in which MSM received long-acting injectable PrEP compared with oral PrEP. At a coverage level of 35%, compared with no PrEP, long-acting injectable PrEP led to a 44% reduction in new HIV infections (1044 new infections averted 95% SI 1018-1077) versus 33% (792 infections averted 763-821) for oral PrEP. The relative benefit of long-acting injectable PrEP was sensitive to the assumed efficacy of injections received every 8 weeks, discontinuation rates, and terminal drug half-life. INTERPRETATION: Long-acting injectable PrEP has the potential to produce larger reductions in HIV transmission in MSM than oral PrEP. However, the real-world, population-level impact of this approach will depend on uptake of this prevention method and its effectiveness, as well as retention of patients in clinical care. FUNDING: National Institute on Drug Abuse and National Institute of Mental Health.	agent-based modeling, pre-exposure prophylaxis, men who have sex with men, cabotegravir, HIV, microsimulation	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Martínez Fernández, Iván	La implementación de la profilaxis preexposición en España sin las mujeres	Feminismo/s	-	-	-	-	NA	doi.org/10.14198/fem.2018.31.05	https://doi.org/10.14198/fem.2018.31.05	El objetivo del presente artículo es la exposición sucinta de la exclusión de las mujeres en la resolución del 27 de Julio de 2017 en el que se explicita el convenio de colaboración entre la Dirección General de Salud Pública, Calidad e Innovación y la empresa Gilead Servicios S.L.U. Este convenio es la formalización de la entrada e implementación de la profilaxis preexposición ante el VIH en el territorio nacional. La profilaxis preexposición ante el VIH es una novedosa intervención biomédica de carácter preventivo aplicada en personas que no viven con el VIH, que contiene como parte fundamental la ingesta diaria de un medicamento llamado Truvada, formado por dos componentes farmacológicos, emtricitabine y tenofovir, y capaz de inhibir la reproducción exponencial del virus en el caso de que se produzca la exposición de los tejidos del mismo al VIH sin variar de forma radical los hábitos sexuales. Article	2018	Martinez O.; Isabel Fernandez M.; Wu E.; Carballo-Diéguez A.; Prado G.; Davey A.; Levine E.; Mattera B.; Lopez N.; Valentin O.; Murray A.; Sutton M.	A couple-based HIV prevention intervention for Latino men who have sex with men: Study protocol for a randomized controlled trial	Trials	-	-	-	-	17456215	10.1186/s13063-018-2582-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044998624&doi=10.1186%2fs13063-018-2582-y&partnerID=40&md5=6a130930d1a62ea726effc5e221a994c	Background: Latino men who have sex with men (MSM) experienced a 13% increase in HIV diagnoses from 2010 to 2014, more than any other racial/ethnic subgroup of MSM in the United States. If current HIV diagnoses rates persist, about one in four Latino MSM in the United States will be diagnosed with HIV during their lifetime. Although some efficacious HIV prevention interventions for Latino MSM exist, none have focused on couples. This paper describes the protocol of a randomized controlled trial (RCT) to test the preliminary efficacy of a couple-based HIV prevention intervention that is culturally tailored for Latino men and their same-sex partners. Methods: The RCT will determine the preliminary efficacy of Connecting Latinos en Pareja (CLP) to increase the proportion of anal sex acts that are HIV protected (i.e., anal sex acts in which condoms, pre-exposure prophylaxis (PrEP), treatment as prevention (TasP), or a combination thereof, are used to reduce risk of HIV transmission). CLP builds upon previous couple-based interventions with white and black MSM by incorporating biomedical prevention techniques, such as PrEP and TasP, implementing a framework responsive to the couple's serostatus, and addressing the socio-cultural factors that influence HIV risk among Latino MSM. We also include input from community stakeholders, members of the target population, and a community advisory board as part of intervention development. Assessments will be conducted at baseline, and 3- and 6-months post-intervention to examine the intervention effects on outcomes (HIV-protected sex acts), and factors potentially mediating or moderating intervention effects. Discussion: This paper describes an innovative RCT that incorporates multiple HIV prevention techniques for Latino MSM in couples, regardless of serostatus. The ongoing involvement of community stakeholders, members of the target population, and a community advisory board is emphasized, and plans for widespread dissemination and application of findings into practice are discussed. © 2018 The Author(s). Article	2018	Marukutira, Tafireyi; Stoové, Mark; Lockman, Shahin; Mills, Lisa A; Gaolathe, Tendani; Lebelonyane, Refeletswe; Jarvis, Joseph N; Kelly, Sherrie L; Wilson, David P; Luchters, Stanley; Crowe, Suzanne M; Hellard, Margaret	A tale of two countries: progress towards UNAIDS 90-90-90 targets in Botswana and Australia.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25090	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5838412	UNAIDS 90-90-90 targets and Fast-Track commitments are presented as precursors to ending the AIDS epidemic by 2030, through effecting a 90% reduction in new HIV infections and AIDS-related deaths from 2010 levels (HIV epidemic control). Botswana, a low to middle-income country with the third-highest HIV prevalence, and Australia, a low-prevalence high-income country with an epidemic concentrated among men who have sex with men (MSM), have made significant strides towards achieving the UNAIDS 90-90-90 targets. These two countries provide lessons for different epidemic settings. This paper discusses the lessons that can be drawn from Botswana and Australia with respect to their success in HIV testing, treatment, viral suppression and other HIV prevention strategies for HIV epidemic control. Botswana and Australia are on target to achieving the 90-90-90 targets for HIV epidemic control, made possible by comprehensive HIV testing and treatment programmes in the two countries. As of 2015, 70% of all people assumed to be living with HIV had viral suppression in Botswana and Australia. However, HIV incidence remains above one per cent in the general population in Botswana and in MSM in Australia. The two countries have demonstrated that rapid HIV testing that is accessible and targeted at key and vulnerable populations is required in order to continue identifying new HIV infections. All citizens living with HIV in both countries are eligible for antiretroviral therapy (ART) and viral load monitoring through government-funded programmes. Notwithstanding their success in reducing HIV transmission to date, programmes in both countries must continue to be supported at current levels to maintain epidemic suppression. Scaled HIV testing, linkage to care, universal ART, monitoring patients on treatment over and above strengthened HIV prevention strategies (e.g. male circumcision and pre-exposure prophylaxis) will all continue to require funding. The progress that Botswana and Australia have made towards meeting the 90-90-90 targets is commendable. However, in order to reduce HIV incidence significantly towards 2030, there is a need for sustained HIV testing, linkage to care and high treatment coverage. Botswana and Australia provide useful lessons for developing countries with generalized epidemics and high-income countries with concentrated epidemics. Article	2018	Masyuko S.; Mukui I.; Njathi O.; Kimani M.; Oluoch P.; Wamicwe J.; Mutegi J.; Njogo S.; Anyona M.; Muchiri P.; Maikweki L.; Musyoki H.; Bahati P.; Kyongo J.; Marwa T.; Irungu E.; Kiragu M.; Kioko U.; Ogando J.; Were D.; Bartilol K.; Sirengo M.; Mugo N.; Baeten J.M.; Cherutich P.	Pre-exposure prophylaxis rollout in a national public sector program: The Kenyan case study	Sexual Health	-	-	-	-	14485028	10.1071/SH18090	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056386737&doi=10.1071%2fSH18090&partnerID=40&md5=d51b4cd8c71ca01aaba577b3370a5364	Background: While advances have been made in HIV prevention and treatment, new HIV infections continue to occur. The introduction of pre-exposure prophylaxis (PrEP) as an additional HIV prevention option for those at high risk of HIV may change the landscape of the HIV epidemic, especially in sub-Saharan Africa, which bears the greatest HIV burden. Methods: This paper details Kenya's experience of PrEP rollout as a national public sector program. The process of a national rollout of PrEP guidance, partnerships, challenges, lessons learnt and progress related to national scale up of PrEP in Kenya, as of 2018, is described. National rollout of PrEP was strongly lead by the government, and work was executed through a multidisciplinary, multi-organisation dedicated team. This required reviewing available evidence, providing guidance to health providers, integration into existing logistic and health information systems, robust communication and community engagement. Mapping of the response showed that subnational levels had existing infrastructure but required targeted resources to catalyse PrEP provision. Rollout scenarios were developed and adopted, with prioritisation of 19 counties focusing on high incidence area and high potential PrEP users to maximise impact and minimise costs. Results: PrEP is now offered in over 900 facilities countrywide. There are currently over 14 000 PrEP users 1 year after launching PrEP.Conclusions: Kenya becomes the first African country to rollout PrEP as a national program, in the public sector. This case study will provide guidance for low- and middle-income countries planning the rollout of PrEP in response to both generalised and concentrated epidemics. © 2018 CSIRO. Article	2018	Matthews, Lynn T.; Beyeza-Kashesya, Jolly; Cooke, Ian; Davies, Natasha; Heffron, Renee; Kaida, Angela; Kinuthia, John; Mmeje, Okeoma; Semprini, Augusto E.; Weber, Shannon	Consensus statement: Supporting Safer Conception and Pregnancy For Men And Women Living with and Affected by HIV.	AIDS and Behavior	-	-	-	-	1573-3254 1090-7165	10.1007/s10461-017-1777-7	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5683943/	Safer conception interventions reduce HIV incidence while supporting the reproductive goals of people living with or affected by HIV. We developed a consensus statement to address demand, summarize science, identify information gaps, outline research and policy priorities, and advocate for safer conception services. This statement emerged from a process incorporating consultation from meetings, literature, and key stakeholders. Three co-authors developed an outline which was discussed and modified with co-authors, working group members, and additional clinical, policy, and community experts in safer conception, HIV, and fertility. Co-authors and working group members developed and approved the final manuscript. Consensus across themes of demand, safer conception strategies, and implementation were identified. There is demand for safer conception services. Access is limited by stigma towards PLWH having children and limits to provider knowledge. Efficacy, effectiveness, safety, and acceptability data support a range of safer conception strategies including ART, PrEP, limiting condomless sex to peak fertility, home insemination, male circumcision, STI treatment, couples-based HIV testing, semen processing, and fertility care. Lack of guidelines and training limit implementation. Key outstanding questions within each theme are identified. Consumer demand, scientific data, and global goals to reduce HIV incidence support safer conception service implementation. We recommend that providers offer services to HIV-affected men and women, and program administrators integrate safer conception care into HIV and reproductive health programs. Answers to outstanding questions will refine services but should not hinder steps to empower people to adopt safer conception strategies to meet reproductive goals. Article	2018	Mayer K.H.; Chan P.A.; Patel R.R.; Flash C.A.; Krakower D.S.	Evolving Models and Ongoing Challenges for HIV Preexposure Prophylaxis Implementation in the United States	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001579	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044480706&doi=10.1097%2fQAI.0000000000001579&partnerID=40&md5=db12799267835e828d57bc24fd103b6d	Background: The use of preexposure prophylaxis (PrEP) for HIV prevention was approved by the Food and Drug Administration in 2012, but delivery to at-risk persons has lagged. This critical review analyzes the current state of PrEP implementation in the United States, by reviewing barriers and innovative solutions to enhance PrEP access and uptake. Setting: Clinical care settings, public health programs, and community-based organizations (CBOs). Methods: Critical review of recent peer-reviewed literature. Results: More than 100 papers were reviewed. PrEP is currently provided in diverse settings. Care models include sexually transmitted disease clinics, community health centers, CBOs, pharmacies, and private primary care providers (PCPs). Sexually transmitted disease clinics have staff trained in sexual health counseling and are linked to public health programs (eg, partner notification services), whereas PCPs and community health centers may be less comfortable counseling and feel time-constrained in managing PrEP. However, PCPs may be ideal PrEP providers, given their long-term relationships with patients, integrating PrEP into routine care. Collaborations with CBOs can expand PrEP care through adherence support and insurance navigation. Pharmacies can deliver PrEP, given their experience with medication dispensing and counseling and may be more accessible for some patients, but to address other health concerns, liaisons with PCPs may be needed. Conclusions: PrEP implementation in the United States is moving forward with the development of diverse models of delivery. Optimal scale-up will require learning about the best features of each model and providing choices to consumers that enhance engagement and uptake. Copyright © 2017 Wolters Kluwer Health, Inc. Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25208	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6287093	INTRODUCTION: In sub-Saharan Africa, HIV prevalence remains high, especially among key populations. In such situations, combination prevention including clinical, behavioural, structural and biological components, as well as adequate treatment are important. We conducted a demonstration project at the Dispensaire IST, a clinic dedicated to female sex workers (FSWs) in Cotonou, on early antiretroviral therapy (E-ART, or immediate "test-and-treat") and pre-exposure prophylaxis (PrEP). We present key indicators such as uptake, retention and adherence. METHODS: In this prospective observational study, we recruited FSWs from October 4th 2014 to December 31st 2015 and followed them until December 31st 2016. FSWs were provided with daily tenofovir disoproxil fumarate/emtricitabine (Truvada®) for PrEP or received a first-line antiretroviral regimen as per Benin guidelines. We used generalized estimating equations to assess trends in adherence and sexual behaviour. RESULTS: Among FSWs in the catchment area, HIV testing coverage within the study framework was 95.5% (422/442). At baseline, HIV prevalence was 26.3% (111/422). Among eligible FSWs, 95.5% (105/110) were recruited for E-ART and 88.3% (256/290) for PrEP. Overall retention at the end of the study was 59.0% (62/105) for E-ART and 47.3% (121/256) for PrEP. Mean (±SD) duration of follow-up was 13.4 (±7.9) months for E-ART and 11.8 (±7.9) months for PrEP. Self-reported adherence was over 90% among most E-ART participants. For PrEP, adherence was lower and the proportion with 100% adherence decreased over time from 78.4% to 56.7% (p-trend < 0.0001). During the 250.1 person-years of follow-up among PrEP initiators, two seroconversions occurred (incidence 0.8/100 person-years (95% confidence interval: 0.3 to 1.9/100 person-years)). The two seroconverters had stopped using PrEP for at least six months before being found HIV-infected. In both groups, there was no evidence of reduced condom use. CONCLUSIONS: This study provides data on key indicators for the integration of E-ART and PrEP into the HIV prevention combination package already offered to FSWs in Benin. PrEP may be more useful as an individual intervention for adherent FSWs rather than a specific public health intervention. E-ART was a more successful intervention in terms of retention and adherence and is now offered to all key populations in Benin. STUDY REGISTRATION: ClinicalTrials.gov NCT02237. Article	2018	McColl, Eliza R.; Kojovic, Dea; Piquette-Miller, Micheline	Battling the HIV/AIDS Epidemic: Triumphs and Barriers.	Clinical Pharmacology and Therapeutics	-	-	-	-	1532-6535 0009-9236	10.1002/cpt.1202	https://pubmed.ncbi.nlm.nih.gov/30412658/	Worldwide, over 77 million people have been infected by human immunodeficiency virus (HIV) but its cure remains elusive. Once considered a fatal disease, advances in antiretroviral therapy (ART) have dramatically increased the life expectancy of infected persons. Much progress has been made in the development and utilization of combination ART and preventative pre-exposure prophylaxis products, however, numerous obstacles prevent eradication. Clinical pharmacologists along with world health organizations continue to play a key role in identifying and implementing strategies to combat this disease. Cheryl Bañez; Heitgerd, Janet; Stallworth, JoAna; Ferro, Benny; Santana, Alberto; German, Emilio J.; Harris, Norma	A programmatic approach to address increasing HIV diagnoses among Hispanic/Latino MSM, 2010-2014.	Preventive Medicine	-	-	-	-	1096-0260 0091-7435	10.1016/j.ypmed.2018.06.007	https://pubmed.ncbi.nlm.nih.gov/29908762/	From 2010 to 2015, young (13-24 years) Hispanic/Latino gay, bisexual and other men who have sex with men (MSM) experienced the largest increase (18%) in numbers of HIV diagnoses among all racial/ethnic groups. In 2016, the Centers for Disease Control and Prevention (CDC) assembled a team of scientists and public health analysts to develop a programmatic approach for addressing the increasing HIV diagnosis among Hispanic/Latino MSM. The team used a data driven review process, i.e., comprehensive review of surveillance, epidemiologic, and programmatic data, to explore key questions from the literature on factors associated with HIV diagnoses among Hispanic/Latino MSM and to inform the approach. This paper describes key findings from the review and discusses the approach. The approach includes the following activities: increase awareness and support testing by expanding existing campaigns targeting Hispanic/Latino MSM to jurisdictions where diagnoses are increasing; strengthen existing efforts that support treatment as prevention and increase engagement in care and viral suppression among Hispanic/Latino MSM living with HIV and promote prevention, e.g., PrEP uptake and condom use, among Hispanic/Latino MSM who are at high-risk for HIV infection. Article	2018	McCumber, Micah; Cain, Demetria; LeGrand, Sara; Mayer, Kenneth H.; Murphy, Debra A.; Psioda, Matthew A.; Seña, Arlene C.; Starks, Tyrel J.; Hudgens, Michael	Adolescent Medicine Trials Network for HIV/AIDS Interventions Data Harmonization: Rationale and Development of Guidelines.	JMIR Research Protocols	-	-	-	-	1929-0748	10.2196/11207	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6320398/	BACKGROUND: The Adolescent Medicine Trials Network for HIV/AIDS Interventions (ATN) research program aims to defeat the rising HIV epidemic among adolescents and young adults in the United States. OBJECTIVE: This study aims to optimize cross-study analyses and comparisons of standardized measures (variables) collected in the ATN. METHODS: Guidelines were developed for harmonizing measures to be collected across ATN studies. RESULTS: Eight domains were identified for harmonization-Demographics and Socioeconomic Characteristics, Sexual Behavior and Risk, Substance Use and Abuse, HIV-Positive Cascade, HIV-Negative Cascade, Mental Health, Social Support and Isolation, and Pre-exposure Prophylaxis Cascade. CONCLUSIONS: The collection of selected key measures in a uniform manner across studies facilitates the characterization of participant populations, comparisons between studies, and pooled analysis of data from multiple studies. Article	2018	McKinnon, Lyle R; Liebenberg, Lenine J; Yende-Zuma, Nonhlanhla; Archary, Derseree; Ngcapu, Sinaye; Sivro, Aida; Nagelkerke, Nico; Garcia Lerma, Jose Gerardo; Kashuba, Angela D; Masson, Lindi; Mansoor, Leila E; Karim, Quarraisha Abdool; Karim, Salim S Abdool; Passmore, Jo-Ann S	Genital inflammation undermines the effectiveness of tenofovir gel in preventing HIV acquisition in women.	Nature Medicine	-	-	-	-	1546-170X	10.1038/nm.4506	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5893390	Several clinical trials have demonstrated that antiretroviral (ARV) drugs taken as pre-exposure prophylaxis (PrEP) can prevent HIV infection, with the magnitude of protection ranging from -49 to 86% (refs.). Although these divergent outcomes are thought to be due primarily to differences in product adherence, biological factors likely contribute. Despite selective recruitment of higher-risk participants for prevention trials, HIV risk is heterogeneous even within higher-risk groups. To determine whether this heterogeneity could influence patient outcomes following PrEP, we undertook a post hoc prospective analysis of results from the CAPRISA 004 trial for 1% tenofovir gel (n = 774 patients), one of the first trials to demonstrate protection against HIV infection. Concentrations of nine proinflammatory cytokines were measured in cervicovaginal lavages at >2,000 visits, and a graduated cytokine score was used to define genital inflammation. In women without genital inflammation, tenofovir was 57% protective against HIV (95% confidence interval (CI): 7-80%) but was 3% protective (95% CI: -104-54%) if genital inflammation was present. Among women who highly adhered to the gel, tenofovir protection was 75% (95% CI: 25-92%) in women without inflammation compared to -10% (95% CI: -184-57%) in women with inflammation. Immunological predictors of HIV risk may modify the effectiveness of tools for HIV prevention; reducing genital inflammation in women may augment HIV prevention efforts. Article	2018	McNulty, Moira C.; Schneider, John A.	Care continuum entry interventions: seek and test strategies to engage persons most impacted by HIV within the United States.	AIDS	-	-	-	-	1473-5571 0269-9370	10.1097/QAD.0000000000001733	https://pubmed.ncbi.nlm.nih.gov/29381558/	: The current review re-conceptualizes seek and test strategies, particularly given the changing importance of HIV testing as care continuum entry for persons irrespective of their HIV status. Care continuum entry advances previous seek and test strategies for client engagement with two next-generation functions: use of testing to engage (or re-engage) HIV negative clients in preexposure prophylaxis (PrEP) care; and testing individuals who may already be known positives for care continuum re-entry. We review existing seek and test strategies for most impacted community members with a goal of optimizing care continuum entry as we move towards HIV transmission elimination. These strategies are context, sub-group, community and epidemic-specific. This review is timely, given the initiation of routine PrEP care, which shifts and broadens our conceptualization of care continuum entry triggered by the HIV testing event. In addition, as the epidemic becomes more concentrated, focusing on re-engagement of HIV-infected persons becomes increasingly important given that transmission events involve both those acutely and newly infected as well as the large numbers who may not be virally suppressed. We start with examination of routine testing in healthcare settings, emphasizing its potential role in re-engagement for persons out of care. Subsequently, we describe risk-based testing to identify key populations. We then review network-based approaches and their impact on the epidemic. We close with future directions for individual and combination care continuum entry strategies most relevant to elimination of HIV transmission in the United States. Article	2018	McPherson T.D.; Sobieszczyk M.E.; Markowitz M.	Cabotegravir in the treatment and prevention of Human Immunodeficiency Virus-1	Expert Opinion on Investigational Drugs	-	-	-	-	13543784	10.1080/13543784.2018.1460357	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85045152921&doi=10.1080%2f13543784.2018.1460357&partnerID=40&md5=34afd0b553cfeee49761ef4ae151f011	Introduction: Human Immunodeficiency Virus (HIV) is a chronic infection that depletes the immune system of essential components causing those infected to be at risk for multiple life-threatening infections. Worldwide, millions live with this infection, the vast majority attributable to HIV-1. Transmission persists with hundreds of thousands of new infections reported yearly. Implementation of combination antiretroviral therapy (cART) has been effective in improving outcomes and decreasing transmission. Newer co-formulated agents have provided simpler medication regimens, fewer side effects, and, in some cases, a higher barrier to the emergence of medication resistance. Areas covered: Here, we review trials of cabotegravir (CAB) as treatment of HIV-1 infection and its potential use as pre-exposure prophylaxis (PrEP) in high risk individuals, including issues around oral lead in and potential resistance emergence. Expert opinion: CAB is efficacious when used in combination therapy orally or given intramuscularly every 4 to 8 weeks. Its availability in a long-acting injectable formulation (CAB-LA) makes it a valuable, novel drug to treat HIV-1 infection when combined with long-acting injectable rilpivirine (RPV-LA). Moreover, pre-clinical and early Phase 2a studies support its testing as monotherapy as PrEP. Studies are underway comparing the efficacy of every 8 week CAB-LA to tenofovir disoproxil fumarate/emtricitabine (TDF/FTC). © 2018 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Mehrotra, Megha L; K Rivet Amico; McMahan, Vanessa; Glidden, David V; Defechereux, Patricia; Guanira, Juan V; Grant, Robert M	The Role of Social Relationships in PrEP Uptake and Use Among Transgender Women and Men Who Have Sex with Men	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2151-0	https://www.proquest.com/scholarly-journals/role-social-relationships-prep-uptake-use-among/docview/2037853672/se-2?accountid=8113	Qualitative studies suggest that social relationships play an important role in HIV pre-exposure prophylaxis (PrEP) use, but there have been few quantitative assessments of the role of social relationships in PrEP uptake or adherence. We examined the association between disclosure of study participation or LGBT identity and PrEP use in the 1603 HIV-negative participants enrolled in the iPrEx OLE study. We also evaluated the association between LGBT social group involvement and PrEP use. Study participation disclosure to parents and LGBT identity disclosure to anyone in a participant's social network were associated with greater PrEP uptake. Study participation disclosure to partners was associated with higher probability of having protective PrEP drug concentrations compared risk difference 0.15 95% CI (0.01, 0.30). For each additional type of LGBT organization a participant was involved in, the probability of PrEP uptake and having protective drug concentrations increased by 0.04 95% CI (0.03, 0.06) and 0.04 (95% CI (0.02, 0.07) respectively. Overall, social context was associated with PrEP use in iPrEx OLE, and should be taken into consideration when designing future PrEP implementation programs. Article	2018	Meunier, Étienne; Siegel, Karolynn	Sexual Risk Behaviors and Perceptions of Men Who Go to Gay Sex Parties in New York City: Comparisons Between Three HIV Groups.	Journal of Sex Research	-	-	-	-	1559-8519	10.1080/00224499.2017.1393042	https://dx.doi.org/10.1080/00224499.2017.1393042	Men who have sex with men (MSM) who attend group-sex events often engage in risky sexual behaviors that contribute to the high human immunodeficiency virus (HIV) incidence among this population. We conducted an online survey with 211 New York City MSM who attended sex parties in the prior year and asked them to describe their behaviors and perceptions of risk. We compared responses from HIV-positive-undetectable men (n = 36), HIV-negative men on pre-exposure prophylaxis (PrEP; n = 62), and HIV-negative men never on PrEP (n = 113). In bivariate analyses, undetectable and on-PrEP men had been to more sex parties in the prior six months, had more anal sex partners there, and had higher rates of sexually transmitted infection (STI) diagnoses than men never on PrEP. Although less than the other groups, 43% of the presumably HIV-negative men never on PrEP reported condomless anal sex at a party in the prior six months. About half of participants agreed that, at sex parties, they made assumptions about others' HIV status, that they sometimes took more risks than intended, and that the atmosphere of these events was conducive to risk taking. Most disagreed that there was discussion of HIV status at sex parties. Implications for sexual health interventions are discussed. Article	2018	Meyers K.; Rodriguez K.; Brill A.L.; Wu Y.; La Mar M.; Dunbar D.; Koblin B.; Margolis D.; Sobieszczyk M.E.; Van Tieu H.; Frank I.; Markowitz M.; Golub S.A.	Lessons for Patient Education Around Long-Acting Injectable PrEP: Findings from a Mixed-Method Study of Phase II Trial Participants	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-017-1871-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85025813052&doi=10.1007%2fs10461-017-1871-x&partnerID=40&md5=3a027443d905f477cfc25987f15cd590	This study aimed to identify patients' physical and psychosocial experiences of an investigational long-acting injectable PrEP product to aid in the development of patient and provider education materials. Twenty-eight participants of a Phase 2 safety, tolerability, and acceptability study of long-acting integrase inhibitor cabotegravir (CAB-LA) were interviewed on their physical and psychosocial experiences of the injections. Five themes emerged through a framework analysis on these interview transcripts: (1) injection-related pain is highly variable across individuals; (2) pain is more impactful after the injections than during; (3) patient anxiety is critical, but does not determine the experience of injections and decreases over time; (4) intimacy and awkwardness of gluteal injections impacts patients' experiences; (5) patient education and care strategies can mitigate the above factors. These findings can inform further sociobehavioral research within Phase 3 efficacy trials of CAB-LA, as well as patient education and provider guidance for future injectable PrEP products. © 2017, Springer Science+Business Media, LLC. Article	2018	Meyers K.; Wu Y.; Qian H.; Sandfort T.; Huang X.; Xu J.; Zhang J.; Xia W.; Glidden D.; Wu H.; Shang H.	Interest in Long-Acting Injectable PrEP in a Cohort of Men Who have Sex with Men in China	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-017-1845-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85023742514&doi=10.1007%2fs10461-017-1845-z&partnerID=40&md5=db8d9c4e76bcb968357980018f03a4e6	Long-acting injectable (LAI) formulations of antiretrovirals (ARVs) as pre-exposure prophylaxis (PrEP) could be an attractive alternative for men who have sex with men (MSM) who are interested in ARV-based biomedical prevention but will not use a daily pill. This study investigated interest in LAI-PrEP in a cohort of MSM in China and characterized how MSM willing to use only injectable PrEP differed from MSM who would use PrEP regardless of modality or not at all. Demographic, behavioral, and risk perception measures were collected and associations investigated. A licensed LAI-PrEP agent would increase the proportion interested in PrEP by 24.5% over oral PrEP alone. Combining interest in oral and injectable PrEP, 78.5% of the sample could be covered if reported interest in PrEP translated into actual uptake. Partnership factors differentiated those who would be willing to use only LAI-PrEP versus any PrEP modality, while higher self-perception of risk was associated with interest in LAI-PrEP versus no PrEP. The addition of a second PrEP modality could yield increased population coverage of PrEP. Social and behavioral research should be undertaken in parallel with clinical development of injectable PrEP agents to identify characteristics of those who are not interested in oral PrEP but would take advantage of ARV-based prevention with the introduction of an injectable product. © 2017, Springer Science+Business Media, LLC. Article	2018	Meyers, Kathrine; Wu, Yumeng; Brill, Atrina; Sandfort, Theodorus; × Sarit A Golub	To switch or not to switch: Intentions to switch to injectable PrEP among gay and bisexual men with at least twelve months oral PrEP experience	PLOS One	-	-	-	-	NA	10.1371/journal.pone.0200296	https://www.proquest.com/scholarly-journals/switch-not-intentions-injectable-prep-among-gay/docview/2072258968/se-2?accountid=8113	Background Phase III trials of long-acting injectable (LAI) PrEP, currently underway, have great potential for expanding the menu of HIV prevention options. Imagining a future in which multiple PrEP modalities are available to potential users of biomedical HIV prevention, we investigated which factors might help direct a patient-physician shared-decision making process to optimize the choice of biomedical HIV prevention method. Methods Participants (n = 105; ages 19–63; 46.7% men of color) were former participants in a PrEP demonstration project and had taken daily oral PrEP for ≥ 12 months. Participants were given information about LAI PrEP and asked whether they would be interested in switching from oral to LAI PrEP. Participants were also asked about specific pros/cons of LAI PrEP, PrEP attitudes and experiences, and personality factors. Results Two-thirds (66.7%) of current oral PrEP users would switch to LAI PrEP. Intention to switch was associated with product-level and psychosocial factors. Attitudes towards logistical factors (i.e. getting to regular clinic visits for recurring shots) featured more prominently than factors related to the physical experience of PrEP modality (i.e., concerns about injection pain) as motivators for switching. In a multivariate regression model, psychosocial factors including the emotional burden of daily pill taking, deriving a sense of responsibility from PrEP use, and self-identifying as an early adopter, were the strongest predictors of switching. Conclusions These data underscore the importance of attending not only to product-level factors, but also to the logistical and psychological experience of prevention methods for users. Findings have significant implications for the development of patient education materials and patient-provider shared decision aids. Article	2018	Mimiaga M.J.; Pantalone D.W.; Biello K.B.; Glynn T.R.; Santostefano C.M.; Olson J.; Pardee D.J.; Hughto J.M.W.; Garcia Valles J.; Carrico A.W.; Mayer K.H.; Safren S.A.	A randomized controlled efficacy trial of behavioral activation for concurrent stimulant use and sexual risk for HIV acquisition among MSM: Project IMPACT study protocol	BMC Public Health	-	-	-	-	14712458	10.1186/s12889-018-5856-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050734726&doi=10.1186%2fs12889-018-5856-0&partnerID=40&md5=9bf8fbf2bccf86b39b7762232cab4a1d	Background: In the United States, problematic stimulant use is a prevalent and difficult to treat problem among men who have sex with men (MSM), as well as a major driver of HIV transmission through the large number of sexual partners and concomitant condomless anal sex (CAS). Evidence-based behavioral studies that address problematic stimulant use in MSM at risk for HIV infection are also lacking. In this paper, we describe the design of a behavioral intervention trial to reduce sexual risk behavior and stimulant use in HIV-uninfected MSM. Methods: This study, funded by the National Institute on Drug Abuse (NIDA), is a randomized controlled trial (RCT) testing an integrated HIV risk reduction and behavioral activation counseling intervention (IMPACT) for HIV-uninfected, stimulant using MSM in Boston, MA, and Miami, FL. Participants are randomized (2:2:1) to either (1) the IMPACT intervention; (2) a relaxation condition, an active therapy time- and intensity-matched control; or (3) a standard of care risk reduction counseling comparison. At enrollment, all participants receive an HIV test and pre- and post-test counseling. The primary outcome is the difference in the rate of change in the number of self-reported condomless anal sex acts without the protection of consistent Pre-Exposure Prophylaxis (PrEP) use, as well as reductions in stimulant use during the prior 4-months. Major assessments are conducted at baseline, 4-, 8-, and 12-month follow-up visits. Discussion: Effective and sustainable behavioral interventions are sorely needed to reduce HIV acquisition in stimulant using MSM at risk for HIV infection. In this study, we will evaluate the evidence of efficacy of the IMPACT intervention to reduce HIV acquisition in HIV-uninfected, stimulant-using MSM. If found effective, the intervention tested here holds promise for being readily integrated into real-world clinical settings. © 2018 The Author(s). Article	2018	Mitchell J.T.; Legrand S.; Hightow-Weidman L.B.; McKellar M.S.; Kashuba A.D.M.; Cottrell M.; McLaurin T.; Satapathy G.; McClernon F.J.	Smartphone-based contingency management intervention to improve pre-exposure prophylaxis adherence: pilot trial	JMIR mHealth and uHealth	-	-	-	-	22915222	10.2196/10456	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060375072&doi=10.2196%2f10456&partnerID=40&md5=beefa16b135d7c9277891b3b1ea20c6f	Background: Pre-exposure prophylaxis (PrEP) provides a strong preventative benefit to individuals at risk for HIV. While PrEP adherence is highly correlated with its efficacy, adherence rates are variable both across and within persons. Objective: The objective of this study was to develop and pilot-test a smartphone-based intervention, known as mSMART, that targets PrEP adherence. mSMART provides contingency management in the form of monetary incentives for daily PrEP adherence based on a real-time adherence assessment using a camera-based medication event-monitoring tool as well as medication reminders, PrEP education, individualized behavioral strategies to address PrEP adherence barriers, and medication adherence feedback. Methods: This was a 4-week open-label, phase I trial in a community sample of young men who have sex with men already on PrEP (N=10). Results: Although adherence composite scores corresponding to PrEP biomarkers indicated that 90% (9/10) of the sample already had an acceptable baseline adherence in the protective range, by the end of the 4-week period, the scores improved for 30% (3/10) of the sample—adherence did not worsen for any participants. Participants reported mean PrEP adherence rates of 91% via daily entries in mSMART. At the end of the 4-week period, participants indicated acceptable ratings of satisfaction, usability, and willingness to recommend mSMART to others. There were no technical difficulties associated with smartphone compatibility, user misunderstandings about mSMART features that interfered with daily use, or study attrition. Conclusions: This study is the first to apply contingency management to PrEP adherence. Findings indicated that mSMART is feasible and acceptable. Such an adherence intervention administered via a user-friendly smartphone app can allow for widespread dissemination. Future efficacy trials are needed. © John T Mitchell, Sara LeGrand, Lisa B Hightow-Weidman, Mehri S. Article	2018	Mitchell K.M.; DImitrov D.; Hughes J.P.; Xia F.; Donnell D.; Amico K.R.; Bokoch K.; Chitwarakorn A.; Bekker L.-G.; Holtz T.H.; Mannheimer S.; Grant R.M.; Boily M.-C.	In what circumstances could nondaily preexposure prophylaxis for HIV substantially reduce program costs?	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000001766	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044207625&doi=10.1097%2fQAD.0000000000001766&partnerID=40&md5=43322652074ba8794ed75a52dc106472	Objectives: To review the main factors influencing the costs of nondaily oral preexposure prophylaxis (PrEP) with tenofovir (±emtricitabine). To estimate the cost reductions possible with nondaily PrEP compared with daily PrEP for different populations (MSM and heterosexual populations). Design: Systematic review and data triangulation. Methods: We estimated the required number of tablets/person/week for dosing regimens used in the HPTN 067/ADAPT (daily/time-driven/event-driven) and IPERGAY (on-demand) trials for different patterns of sexual intercourse. Using trial data, and behavioural and cost data obtained through systematic literature reviews, we estimated cost savings resulting from tablet reductions for nondaily versus daily oral PrEP, assuming 100% adherence. Results: Among different populations being prioritized for PrEP, the median reported number of days of sexual activity varied between 0 and 2 days/week (0-1.5 days/week for MSM, 1-2 days/week for heterosexual populations). With 100% adherence and two or fewer sex-days/week, HPTN 067/ADAPT nondaily regimens reduced the number of tablets/week by more than 40% compared with daily PrEP. PrEP program costs were reduced the most in settings with high drug costs, for example, by 66-69% with event-driven PrEP for French/US populations reporting on average one sex-day/week. Conclusion: Nondaily oral PrEP could lower costs substantially (>50%) compared with daily PrEP, particularly in high-income countries. Adherence and efficacy data are needed to determine cost-effectiveness. Copyright © 2018 The Author(s). Article	2018	Mitsch, Andrew; Singh, Sonia; Li, Jianmin; Balaji, Alexandra; Linley, Laurie; Selik, Richard	Age-Associated Trends in Diagnosis and Prevalence of Infection with HIV Among Men Who Have Sex with Men - United States, 2008-2016.	MMWR Recommendations and Reports	-	-	-	-	1545-861X 0149-2195	10.15585/mmwr.mm6737a2	https://pubmed.ncbi.nlm.nih.gov/30235184/	In 2016, two thirds of diagnosed human immunodeficiency virus (HIV) infections in the United States were attributed to male-to-male sexual contact (1). The risk for sexual acquisition and transmission of HIV changes through the lifespan (2); to better guide prevention efforts for gay, bisexual, and other men who have sex with men (MSM*), CDC analyzed National HIV Surveillance System(†) (NHSS) data for MSM aged ≥13 years by age group (13-29, 30-49, and ≥50 years) in 50 states and the District of Columbia (DC). During 2008-2016, the annual number of diagnoses of HIV infection increased 3% per year among MSM aged 13-29 years, decreased 4% per year among those aged 30-49 years and was stable for MSM aged ≥50 years. The number of HIV diagnoses among MSM aged 13-29 years was four times that of MSM aged ≥50 years. During 2008-2015, the number of MSM aged ≥50 years living with diagnosed HIV infection (prevalence of HIV infection) increased an average of 11% per year and at year-end 2015 was three times that of MSM aged 13-29 years. Racial/ethnic disparities in HIV infection persisted, particularly among younger black/African American MSM who accounted for 49% of all diagnoses among MSM aged 13-29 years during 2008-2016. To avert the most infections and improve health outcomes (3), sexually active MSM at risk for HIV infection should be tested at least once a year, and, if positive, linked to and retained in HIV medical care to achieve viral suppression (4). Those testing negative should be provided HIV prevention services, including preexposure prophylaxis (PrEP) (5). Article	2018	Mmbaga, Elia J; Moen, Kåre; Leyna, Germana H; Mpembeni, Rose; Leshabari, Melkizedeck T	HIV Prevalence and Associated Risk Factors Among Men Who Have Sex With Men in Dar es Salaam, Tanzania.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000001593	https://dx.doi.org/10.1097/QAI.0000000000001593	INTRODUCTION: Limited studies and differential risk behaviors among men who have sex with men (MSM) in Africa calls for population-specific studies. We present results from the largest integrated biobehavioral survey among MSM in Africa to inform programming. METHODS: This was a cross-sectional study using respondent-driven sampling to recruit MSM aged 18 and above. Data on sociodemographic characteristics and HIV-related risks were collected and all participants were tested for HIV, herpes simplex virus type-2 (HSV-2), hepatitis-B virus (HBV), and syphilis RESULTS:: A total of 753 MSM with a mean age of 26.5 years participated in the study and 646 (85.7%) provided blood for biological testing. The prevalence of HIV was 22.3%, HSV-2 40.9%, syphilis 1.1%, and HBV 3.25%. Significant risk factors for HIV were age above 25, having no children adjusted odds ratio (aOR), 2.4, 95% confidence interval (CI): 1.4 to 4.2, low HIV-risk perception (aOR, 2.6, 95% CI: 1.2 to 5.3), receptive position (aOR, 8.7, 95% CI: 1.2 to 5.3), and not using water-based lubricants (aOR, 2.6, 95% CI: 1.0 to 4.5) during the last anal sex. Also associated with HIV infection was, having sexual relationships with women (aOR, 8.0, 95% CI: 4.1 to 15.6), engaging in group sex (aOR, 3.8, 95% CI: 1.6 to 8.4), HSV-2 seropositivity (aOR, 4.1, 95% CI: 2.6 to 6.5), and history of genital ulcers (aOR, 4.1, 95% CI: 1.1 to 7.2). CONCLUSIONS: HIV infection and HSV-2 were highly prevalent among MSM. Low perceived HIV risk, practice of risk behaviors, and infection with HSV-2 were significant predictors of HIV infection. Behavioral interventions, HSV-2 suppressive therapies, and pre-exposure prophylaxis are highly needed. Article	2018	Molina, Jean-Michel; Charreau, Isabelle; Chidiac, Christian; Pialoux, Gilles; Cua, Eric; Delaugerre, Constance; Capitant, Catherine; Rojas-Castro, Daniela; Fonsart, Julien; Bercot, Béatrice; Bébéar, Cécile; Cotte, Laurent; Robineau, Olivier; Raffi, François; Charbonneau, Pierre; Aslan, Alexandre; Chas, Julie; Niedbalski, Laurence; Spire, Bruno; Sagaon-Teyssier, Luis; Carette, Diane; Mestre, Soizic Le; Doré, Veronique; Meyer, Laurence	Post-exposure prophylaxis with doxycycline to prevent sexually transmitted infections in men who have sex with men: an open-label randomised substudy of the ANRS IPERGAY trial.	The Lancet Infectious Diseases	-	-	-	-	1474-4457	10.1016/S1473-3099(17)30725-9	https://dx.doi.org/10.1016/S1473-3099(17)30725-9	BACKGROUND: Increased rates of sexually transmitted infections (STIs) have been reported among men who have sex with men. We aimed to assess whether post-exposure prophylaxis (PEP) with doxycycline could reduce the incidence of STIs. METHODS: All participants attending their scheduled visit in the open-label extension of the ANRS IPERGAY trial in France (men aged 18 years or older having condomless sex with men and using pre-exposure prophylaxis for HIV with tenofovir disoproxil fumarate plus emtricitabine) were eligible for inclusion in this open-label randomised study. Participants were randomly assigned (1:1) at a central site to take a single oral dose of 200 mg doxycycline PEP within 24 h after sex or no prophylaxis. The primary endpoint was the occurrence of a first STI (gonorrhoea, chlamydia, or syphilis) during the 10-month follow-up. The cumulative probability of occurrence of the primary endpoint was estimated in each group with the Kaplan-Meier method and compared with the log-rank test. The primary efficacy analysis was done on the intention-to-treat population, comprising all randomised participants. All participants received risk-reduction counselling and condoms, and were tested regularly for HIV. This trial is registered with ClinicalTrials.gov number, NCT01473472. FINDINGS: Between July 20, 2015, and Jan 21, 2016, we randomly assigned 232 participants (n=116 in the doxycycline PEP group and n=116 in the no-PEP group) who were followed up for a median of 8·7 months (IQR 7·8-9·7). Participants in the PEP group used a median of 680 mg doxycycline per month (IQR 280-1450). 73 participants presented with a new STI during follow-up, 28 in the PEP group (9-month probability 22%, 95% CI 15-32) and 45 in the no-PEP group (42%, 33-53; log-rank test p=0·007). The occurrence of a first STI in participants taking PEP was lower than in those not taking PEP (hazard ratio HR 0·53; 95% CI 0·33-0·85; p=0·008). Similar results were observed for the occurrence of a first episode of chlamydia (HR 0·30; 95% CI 0·13-0·70; p=0·006) and of syphilis (0·27; 0·07-0·98; p=0·047); for a first episode of gonorrhoea the results did not differ significantly (HR 0·83; 0·47-1·47; p=0·52). No HIV seroconversion was observed, and 72 (71%) of all 102 STIs were asymptomatic. Rates of serious adverse events were similar in the two study groups. Gastrointestinal adverse events were reported in 62 (53%) participants in the PEP group and 47 (41%) in the no-PEP group (p=0·05). INTERPRETATION: Doxycycline PEP reduced the occurrence of a first episode of bacterial STI in high-risk men who have sex with men. Article	2018	Montjane, K; Dlamini, S; Dandara, C	Truvada (emtricitabine/tenofovir) pre-exposure prophylaxis roll-out among South African university students: Lots of positives, but let us keep an eye on possible surprises.	South African Medical Journal (SAMJ)	-	-	-	-	0256-9574	10.7196/SAMJ.2017.v108i2.13035	https://dx.doi.org/10.7196/SAMJ.2017.v108i2.13035	Antiretroviral therapy (ART) has fundamentally altered the natural history of HIV/AIDS, sharply reducing HIV-related morbidity and prolonging longevity. However, there seems to be a resurgence in HIV infection rates in some parts of the world that has prompted consideration of pre-exposure prophylaxis (pre-EP) and vaccination. Despite their good viral suppression profiles, most drugs used as part of ART also have unwanted adverse drug reactions/effects (ADRs). In this article we acknowledge the utility of pre-EP in combating HIV transmission, but we also highlight the need to prepare for management of other unexpected outcomes such as ADRs and viral resistance, to ensure the success of the programme. Article	2018	Moore, David J.; Jain, Sonia; Dubé, Michael P.; Daar, Eric S.; Sun, Xiaoying; Young, Jason; Corado, Katya; Ellorin, Eric; Milam, Joel; Collins, Deborah; Blumenthal, Jill; Best, Brookie M.; Anderson, Peter; Haubrich, Richard; Morris, Sheldon R.	Randomized Controlled Trial of Daily Text Messages to Support Adherence to Preexposure Prophylaxis in Individuals at Risk for Human Immunodeficiency Virus: The TAPIR Study.	Clinical Infectious Diseases	-	-	-	-	1537-6591 1058-4838	10.1093/cid/cix1055	https://pubmed.ncbi.nlm.nih.gov/29228144/	BACKGROUND: Adherence is critical for efficacy of tenofovir disoproxil fumarate/emtricitabine (FTC) as preexposure prophylaxis (PrEP). METHODS: Between February 2013 and February 2016, 398 men who have sex with men and transgender women were randomized 1:1 to receive individualized texting for adherence building (iTAB) or standard care (SoC) for 48 weeks. The primary endpoint was dried blood spot (DBS) tenofovir diphosphate (TFV-DP) concentrations at both week 12 and the last on-drug visit of >719 fmol/punch (ie, adequate adherence). Secondary outcomes included DBS TFV-DP concentrations of >1246 fmol/punch (ie, near-perfect adherence) and plasma FTC >350 ng/mL (consistent with dosing within the past 24 hours). RESULTS: Concentrations >719 fmol/punch of TFV-DP were found in 88.6% of participants at week 12 and 82.5% at week 48. For the primary endpoint, the study arms did not differ (72.0% in iTAB and 69.2% in SoC; P > .05). For the secondary composite endpoint of >1246 fmol/punch the iTAB arm was superior to SoC (33.5% vs 24.8%; P = .06), reaching statistical significance when adjusting for age (odds ratio, 1.56 95% confidence interval, 1.00-2.42; P < .05). At week 48, iTAB was superior to SoC for near-perfect adherence (51.0% vs 37.4%; P = .02). At week 12, iTAB was superior to SoC for dosing in past 24 hours by plasma FTC (47.5% vs 33.3%; P = .007), but not at weeks 24, 36, and 48 (all P > .05). CONCLUSIONS: Automated text messaging is a low-burden tool that improves durability of near-perfect PrEP adherence. CLINICAL TRIALS REGISTRATION: NCT01761643. Article	2018	Morgan E.; Ryan D.T.; Newcomb M.E.; Mustanski B.	High Rate of Discontinuation May Diminish PrEP Coverage Among Young Men Who Have Sex with Men	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2125-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046418721&doi=10.1007%2fs10461-018-2125-2&partnerID=40&md5=d940ca0915fae1a3c3a97e7d44bc652a	Understanding pre-exposure prophylaxis (PrEP) discontinuation is key to maximizing its effectiveness at the individual and population levels. Data came from the RADAR cohort study of MSM aged 16–29 years, 2015–2017. Participants included those who reported past 6-month PrEP use and discontinued its use by the interview date. Of the 197 participants who had used PrEP in the past 6 months, 65 discontinued use. Primary reasons for PrEP discontinuation included trouble getting to doctor's appointments (14, 21.5%) and issues related to insurance coverage or loss (13, 20.0%). Few (21%) who discontinued spoke to their doctor first, which has important implications for future long acting formulations. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Morgan, Ethan; Moran, Kevin; Ryan, Daniel T; Mustanski, Brian; Newcomb, Michael E	Threefold Increase in PrEP Uptake Over Time with High Adherence Among Young Men Who Have Sex With Men in Chicago.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-018-2122-5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6204095	The goal of this work is to better understand utilization and uptake of pre-exposure prophylaxis (PrEP) among young men who have sex with men (YMSM) and transgender women (TGW). We assessed trends and correlates of PrEP use and adherence across three time points of longitudinal data collection among 885 YMSM and TGW (aged 16-29) from the RADAR cohort in Chicago, 2015-2017. Past 6-month PrEP use increased across three visits: from 6.6 to 17.5%. In multivariable models, past 6-month PrEP use was significantly associated with participation in condomless sex, having more sexual partners, and older age. At least three-quarters of current PrEP users reported being ≥ 90% adherent to PrEP medication across all visits. Past 6-month PrEP use increased over time with those who participated in high-risk HIV behaviors also those most likely to have taken PrEP. As PrEP uptake continues to rise, more research will be needed to understand predictors of PrEP usage, as well as patterns of sexual behavior change following uptake. Article	2018	Morgan, Jeffrey; Ferlatte, Olivier; Salway, Travis; Wilton, James; Hull, Mark	Awareness of, interest in, and willingness to pay for HIV pre-exposure prophylaxis among Canadian gay, bisexual, and other men who have sex with men	Canadian Journal of Public Health	-	-	-	-	00084263	10.17269/s41997-018-0090-1	https://www.proquest.com/scholarly-journals/awareness-interest-willingness-pay-hiv-pre/docview/2255492272/se-2?accountid=8113	ObjectivesPre-exposure prophylaxis (PrEP) is a highly effective, HIV prevention strategy increasingly being accessed by gay, bisexual, and other men who have sex with men (GBMSM). GBMSM face structural and individual-level barriers accessing PrEP, including awareness and cost. This paper assesses socio-demographic factors associated with awareness, interest, and willingness to pay for PrEP in a sample of Canadian GBMSM.MethodsData were derived from the 2015 Sex Now survey, a cross-sectional, online survey of GBMSM. Respondents were recruited through social media, sex-seeking "apps," and by word of mouth. We used univariable and multivariable logistic regression models to estimate associations between socio-demographic factors and three primary outcomes.ResultsOur sample consisted of 7176 HIV-negative Canadian GBMSM. Of respondents, 54.7% were aware of PrEP, 47.4% were interested in PrEP, and 27.9% of PrEP-interested respondents reported they would pay for PrEP out-of-pocket. Awareness and interest varied between provinces, while GBMSM outside urban areas were less likely to be PrEP aware. Bisexual-identified men, and men over 50, were less likely to be aware and interested in PrEP in multivariable models. Only annual income and educational attainment were associated with willingness to pay for PrEP.ConclusionThis study identifies important disparities in awareness, interest, and willingness to pay for PrEP. Future interventions and educational efforts should target non-gay-identified and older GBMSM, as well as GBMSM outside urban areas. PrEP implementation may risk further perpetuating existing health inequities based on socio-economic status if PrEP continues to be accessed primarily through private insurance or paid for out-of-pocket.Resumo alternativo:ObjectifLa prophylaxie préexposition (PrEP) est une stratégie de prévention du VIH très efficace, de plus en plus utilisée par les hommes gais et bisexuels et les hommes ayant des relations sexuelles avec d'autres hommes (GBHARSAH). Par contre, les GBHARSAH sont confrontés à des obstacles structurels et individuels face à l'accès à la PrEP, y compris la connaissance de la PrEP et les coûts. Cet article évalue les facteurs sociodémographiques associés à la connaissance, l'intérêt et la volonté de payer pour la PrEP dans un échantillon de GBHARSAH canadiens.MéthodeLes données proviennent de l'enquête Sexe au présent 2015, un sondage en ligne de GBHARSAH. Les répondants ont été recrutés par le biais des médias sociaux, des applications de rencontre et du bouche-à-oreille. Nous avons utilisé des modèles de régression logistique univariée et multivariée pour mesurer les associations entre les facteurs sociodémographiques et les trois principales variables de résultats.RésultatsNotre échantillon comprenait 7176 GBHARSAH canadiens séronégatifs. En tout, 54,7% des répondants étaient au courant de la PrEP, 47,4% des répondants étaient intéressés par la PrEP, et 27,9% des répondants intéressés par la PrEP ont indiqué qu'ils seraient prêts à payer pour la PrEP. La connaissance et l'intérêt envers la PrEP variaient d'une province à l'autre, tandis que les GBHARSAH en dehors des zones urbaines étaient moins susceptibles de connaître la PrEP. Les hommes bisexuels et les hommes de plus de 50 ans étaient moins susceptibles de connaître et d'être intéressés par la PrEP dans les modèles multivariés. Seul le revenu annuel et le niveau de scolarité étaient associés à la volonté de payer pour la PrEP.ConclusionCette étude a identifié des disparités importantes dans la connaissance, l'intérêt et la volonté de payer pour la PrEP. Les interventions et les efforts d'éducation devraient cibler les GBHARSAH qui ne s'identifient pas comme gai, les GBHARSAH plus âgés, ainsi que les GBHARSAH en dehors des zones urbaines. De plus, la mise en œuvre de la PrEP risque de perpétuer davantage les inégalités existantes en fonction du statut socioéconomique si la PrEP continue d'être accessible principalement par le biais d'une assurance privée ou si les GBHARSAH doivent payer pour celle-ci. Article	2018	Mosley, Terrance; Khaketla, Moliehi; Armstrong, Heather L; Cui, Zishan; Sereda, Paul; Lachowsky, Nathan J; Hull, Mark W; Olarewaju, Gbolahan; Jollimore, Jody; Joshua, Edward; Montaner, Julio S G; Hogg, Robert S; Roth, Eric A; Moore, David M	Trends in Awareness and Use of HIV PrEP Among Gay, Bisexual, and Other Men who have Sex with Men in Vancouver, Canada 2012–2016	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2026-4	https://www.proquest.com/scholarly-journals/trends-awareness-use-hiv-prep-among-gay-bisexual/docview/1993165086/se-2?accountid=8113	Gay, bisexual, and other men who have sex with men (gbMSM) are at the highest risk for HIV infection in British Columbia (BC). Pre-exposure prophylaxis (PrEP) has been recently licensed but is currently not publicly funded in BC. Using respondent-driven sampling, we recruited a cohort of gbMSM to complete a computer-assisted self-interview with follow-up every 6 months. Stratified by HIV status, we examined trends in awareness of PrEP from 11/2012 to 02/2016 and factors associated with PrEP awareness. 732 participants responded to the PrEP awareness question. Awareness of PrEP among HIV-negative men increased from 18 to 80% (p < 0.0001 for trend); among HIV-positive men, awareness increased from 36 to 77% (p < 0.0001). PrEP awareness was associated with factors related to HIV risk including sero-adaptive strategies and sexual sensation seeking. Eight HIV-negative men reported using PrEP. Low PrEP uptake highlights that PrEP access should be expanded for at-risk gbMSM in BC.Resumo alternativo:Los hombres que tienen relaciones sexuales con hombres (HSH) están en mayor riesgo de contraer la infección por el VIH en Columbia Británica (BC). La profilaxis previa a la exposición (PrEP) fue recientemente licenciada en Canadá pero actualmente no está financiada públicamente en BC. Usando el muestreo conducido por el encuestado, hemos reclutado una cohorte de HSH para completar una auto-entrevista asistida por ordenador con seguimiento cada seis meses. Estratificado por el estatus de VIH, examinamos tendencias en el conocimiento de la PrEP de julio de 2012 a febrero de 2016 y los factores asociados con la conciencia de la PrEP. 732 participantes respondieron a la pregunta de sensibilización sobre la PrEP. La proporción de hombres seronegativos que conocían la PrEP aumentó de 18% a 80% (p < 0,0001 para la tendencia); entre los hombres VIH positivos, la conciencia aumentó del 36% al 77% (p < 0,0001). 8 hombres VIH-negativos informaron usar PrEP. La conciencia de PrEP se asoció con factores relacionados con el riesgo de VIH, incluyendo estrategias sero-adaptativas y búsqueda de sensaciones. La baja captación de PrEP destaca que el acceso a la PrEP debería ampliarse para los HSH en riesgo en BC. Article	2018	Mugwanya K.K.; Irungu E.; Bukusi E.; Mugo N.R.; Odoyo J.; Wamoni E.; Ngure K.; Morton J.F.; Peebles K.; Masyuko S.; Barnabee G.; Donnell D.; Barnabas R.; Haberer J.; O'Malley G.; Baeten J.M.	Scale up of PrEP integrated in public health HIV care clinics: A protocol for a stepped-wedge cluster-randomized rollout in Kenya	Implementation Science	-	-	-	-	17485908	10.1186/s13012-018-0809-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052943896&doi=10.1186%2fs13012-018-0809-7&partnerID=40&md5=e98f7970b094438aad2f8c0b4e3f2a05	Background: Antiretroviral therapy (ART) for HIV-infected persons and pre-exposure prophylaxis (PrEP) for uninfected persons are extraordinarily effective strategies for HIV prevention. In Africa, the region which shoulders the highest HIV burden, HIV care is principally delivered through public health HIV care clinics, offering an existing platform to incorporate PrEP delivery and maximize ART and PrEP synergies. However, successfully bringing this integrated approach to scale requires an implementation science evaluation in public health settings. Methods: The Partners Scale Up Project is a prospective, pragmatic implementation evaluation, designed as a stepped-wedge, cluster-randomized trial, operating at 24 clinics in Kenya. In collaboration with the Kenya Ministry of Health, we are catalyzing scaled implementation of PrEP delivery integrated in HIV care clinics. The intervention package includes staff training, clinic streamlined access to PrEP commodity from the Kenya Medical Supply Authority, and ongoing intensive technical assistance to rigorously assess how PrEP delivery is implemented. PrEP service delivery including retention efforts are conducted by the clinic staff with no additional resources from the project. Guided by the RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) framework and Consolidated Framework for Implementation Science Research, project progress and learning are documented through ongoing monitoring and process evaluations, including chart abstraction and individual and key informant interviews, to evaluate pragmatic rollout and understand barriers and facilitators for successful PrEP delivery in this setting. In this staged rollout design, each step provides data for both pre-implementation (baseline) and implementation periods, and we will compare time points across steps in the baseline versus implementation periods. Discussion: Cost-effective delivery models are urgently needed to maximize the public health impact of PrEP and ART. The Partners Scale Up Project will set the stage for full-scale PrEP implementation fully run and owned by the Kenya Ministry of Health. The work combines nationally sponsored PrEP delivery with technical support and implementation science from academic partners, defining a new but sustainable paradigm for public health collaboration. Article	2018	Mugwanya, Kenneth K.; Baeten, Jared M.; Wyatt, Christina; Mugo, Nelly R.; Celum, Connie L.; Ronald, Allan; Kiarie, John; Katabira, Elly; Heffron, Renee	Frequency of Monitoring Kidney Function in HIV-Uninfected Persons Using Daily Oral Tenofovir Disoproxil Fumarate Pre-exposure Prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000001575	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5762271/	BACKGROUND: Wide-scale implementation of oral tenofovir-based pre-exposure prophylaxis (PrEP) for HIV prevention is now policy in many settings. However, the optimal frequency for monitoring kidney function remains uncertain. We investigated the impact of 6-monthly compared with 3-monthly creatinine clearance (CrCl) monitoring on the identification of moderate kidney dysfunction, defined as CrCl <60 mL/min. METHODS: Data were from 2 prospective daily oral PrEP studies in Kenya and Uganda: the Partners PrEP Study, a randomized safety, and efficacy trial of PrEP that conducted 3-monthly CrCl monitoring (n = 4404) and the Partners Demonstration Project (n = 954), an open-label delivery study of PrEP that used 6-monthly monitoring. CrCl ≥60 mL/min was required for enrollment in both studies. Abnormal results were followed with confirmatory testing within approximately 1 week. Follow-up was for up to 24 months. RESULTS: Of 5358 participants included in the analysis, 87% were younger than 45 years, a third were female, and 21% had a baseline CrCl between 60 and 90 mL/min. Confirmed CrCl <60 mL/min events were rare, occurring in 52 individuals (<1%) in 24 months. The 12-month cumulative proportion of persons with CrCl <60 mL/min was 0.2% with 3-monthly screening and 0.5% with 6-monthly screening. Older age (>45 years), lower weight (<55 kg), elevated blood pressure (>140 mm Hg), and baseline CrCl between 60 and 90 mL/min were independently associated with CrCl decline <60 mL/min during follow-up. CONCLUSIONS: In these 2 PrEP studies, with generally young participants, the occurrence and pattern of clinically relevant decline in CrCl were not qualitatively different based on 3- or 6-monthly CrCl monitoring schedule. These data suggest that for most persons receiving PrEP for up to 24 months, less frequent CrCl monitoring would be safe and reduce required expenditures for repeat confirmatory testing. Article	2018	Mullens A.B.; Kelly J.; Debattista J.; Phillips T.M.; Gu Z.; Siggins F.	Exploring HIV risks, testing and prevention among sub-Saharan African community members in Australia	International Journal for Equity in Health	-	-	-	-	14759276	10.1186/s12939-018-0772-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047551729&doi=10.1186%2fs12939-018-0772-6&partnerID=40&md5=4335d91df97b66942eb3b5da19704117	Background: Significant health disparities persist regarding new and late Human Immunodeficiency Virus (HIV) diagnoses among sub-Saharan African (SSA) communities in Australia. Personal/cultural beliefs and practices influence HIV (risk, prevention, testing) within Australia and during visits to home countries. Method: A community forum was conducted involving 23 male and female adult African community workers, members and leaders, and health workers; facilitated by cultural workers and an experienced clinician/researcher. The forum comprised small/large group discussions regarding HIV risk/prevention (responses transcribed verbatim; utilising thematic analysis). Results: Stigma, denial, social norms, tradition and culture permeated perceptions/beliefs regarding HIV testing, prevention and transmission among African Australians, particularly regarding return travel to home countries. Conclusions: International travel as a risk factor for HIV acquisition requires further examination, as does the role of the doctor in HIV testing and Pre-exposure Prophylaxis (PrEP). Further assessment of PrEP as an appropriate/feasible intervention is needed, with careful attention regarding negative community perceptions and potential impacts. © 2018 The Author(s). Article	2018	Mullins, Tanya L Kowalczyk; Lehmann, Corinne E	Oral Pre-Exposure Prophylaxis (PrEP) for HIV Prevention in Adolescents and Young Adults.	Current Pediatric Reports	-	-	-	2167-4841	10.1007/s40124-018-0163-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6192052	PURPOSE OF REVIEW: To review the literature about oral pre-exposure prophylaxis (PrEP) for HIV prevention, with specific focus on adolescents. RECENT FINDINGS: Use of PrEP reduces new HIV infections among men who have sex with men, heterosexuals, and people who inject drugs. One combination antiretroviral medication is approved for PrEP in the U.S. for adults. Limited data suggest that PrEP is safe for use in youth, although declines in adherence to PrEP over time suggest the need for adherence interventions specifically targeting youth. Safety concerns related to PrEP include potential negative impacts on bone density and renal function, as well as potential increases in riskier sexual behaviors. The U.S. Public Health Service has published guidelines for PrEP use in adults. SUMMARY: Current data suggest that PrEP use is safe in adolescents; however, further research is needed on the potential impact of long-term PrEP use on bone density and kidney function. Article	2018	Mullins, TLK; Idoine, CR; Zimet, GD; Kahn, JA	PRIMARY CARE PHYSICIAN ATTITUDES TOWARD INCORPORATING TOPICAL MICROBICIDES AND ORAL PRE-EXPOSURE PROPHYLAXIS (PREP) INTO PRACTICE FOR HIV PREVENTION IN YOUTH	Journal of Adolescent Health	-	-	-	1054-139X	10.1016/j.jadohealth.2017.11.041	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6478546/	Purpose: Understanding the attitudes of physicians toward the use of pre-exposure prophylaxis (PrEP) for human immunodeficiency virus (HIV) prevention among youth is critical to improving access to PrEP. We examined PrEP-related attitudes among physicians who provide primary care to 13–21 year-old adolescents.Methods: Individual, in-depth, semi-structured interviews were conducted with 38 physicians from adolescent medicine, family practice, internal medicine/medicine-pediatrics, obstetrics/gynecology, and pediatrics who care for any adolescents under 18 years-old. Interviews assessed familiarity with PrEP, perceived benefits and barriers to providing PrEP to adolescents, facilitating factors for prescribing PrEP, and likelihood of recommending and prescribing PrEP to adolescents. Results: Mean age was 44.6 years (SD10.9). Fourteen physicians (37%) reported being somewhat or very familiar with PrEP. Perceived benefits of prescribing PrEP included decreased acquisition/rates of HIV, improved provision of sexual health services, and improved patient awareness of HIV risk. Barriers to PrEP were reported at the patient (e.g., lack of acceptability to patients), provider (e.g., concerns about patient adherence, safety/side effects, parents as a barrier to PrEP use), and systems (e.g., high cost) levels. Facilitating factors for prescribing PrEP included low cost/coverage by insurance, physician education about PrEP, patient educational materials, and clinical guidelines for PrEP use in youth. A higher proportion of physicians reported being highly or somewhat likely to recommend (N=16, 42%) than prescribe PrEP (N=13, 34%). Conclusions: In this study of primary care physician attitudes toward PrEP prescribing for adolescents, physicians identified numerous barriers to providing PrEP. Addressing these barriers may increase adolescents' access to PrEP. Article	2018	Murray M.I.; Markowitz M.; Frank I.; Grant R.M.; Mayer K.H.; Hudson K.J.; Stancil B.S.; Ford S.L.; Patel P.; Rinehart A.R.; Spreen W.R.; Margolis D.A.	Satisfaction and acceptability of cabotegravir long-acting injectable suspension for prevention of HIV: Patient perspectives from the ECLAIR trial	HIV Clinical Trials	-	-	-	15284336	10.1080/15284336.2018.1511346	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057315216&doi=10.1080%2f15284336.2018.1511346&partnerID=40&md5=27cd1d69cfc988d2e1d852a3cf653d65	Background: Cabotegravir (GSK1265744) is an integrase strand transfer inhibitor in development as a long-acting (LA) intramuscular injectable suspension for HIV-1 pre-exposure prophylaxis (PrEP). Objective: We report participant outcomes from the phase IIa ECLAIR study related to tolerability, acceptability, and satisfaction of cabotegravir LA. Methods: The ECLAIR study (ClinicalTrials.gov identifier, NCT02076178) was a randomized, placebo-controlled study in healthy men not at high risk of acquiring HIV-1. Participants were randomized (5:1) to once-daily oral cabotegravir 30 mg or placebo tablets for 4 weeks, followed by gluteal intramuscular injections of cabotegravir LA 800 mg or saline placebo every 12 weeks. The primary objective was to evaluate the safety of cabotegravir LA over three injection cycles (to Week 41). Secondary objectives assessed the tolerability, satisfaction, and acceptability of cabotegravir LA. Results: Among 115 participants who received injections in the cabotegravir (n = 94) and placebo (n = 21) groups, 93% (n = 87) and 95% (n = 20) completed the injection phase, respectively. Injection intolerability led to withdrawal in 4 participants (4%) receiving cabotegravir LA. The most frequently reported Grade ≥2 adverse event was injection-site pain. Most participants (74% n = 67) receiving consecutive injections favored cabotegravir LA vs oral cabotegravir. Most participants were satisfied with cabotegravir LA (75% n = 64), were willing to continue (79% n = 68), and would recommend (87% n = 75) the therapy. Conclusions: While Grade ≥2 injection-site pain was common, most participants reported overall satisfaction with and preference for cabotegravir LA, with few discontinuations due to injection intolerance. These findings support investigation of cabotegravir LA as an alternative to daily oral PrEP regimens. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	cabotegravir; injectable; patient-reported outcomes; pre-exposure prophylaxis; Satisfaction	English	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Clinical
Article	2018	Musara, Petina; Montgomery, Elizabeth T; Mgodi, Nyaradzo M; Woeber, Kubashni; Akello, Carolyne A; Hartmann, Miriam; Cheng, Helen; Levy, Lisa; Katz, Ariana; Grossman, Cynthia I; Chirenje, Z Mike; van der Straten, Ariane; Mensch, Barbara	How Presentation of Drug Detection Results Changed Reports of Product Adherence in South Africa, Uganda and Zimbabwe.	AIDS and behavior	-	-	-	1090-7165	https://doi.org/10.1007/s10461-017-1685-x	https://escholarship.org/uc/item/20d2q541	Accurate estimates of study product use are critical to understanding and addressing adherence challenges in HIV prevention trials. The VOICE trial exposed a significant gap between self-reported adherence and drug detection. The VOICE-D qualitative study was designed to better understand non-adherence during VOICE, and was conducted in 2 stages: before (stage 1) and after (stage 2) drug detection results were provided to participants. Transcripts from 44 women who participated in both stages were analysed to understand the effect of presenting drug detection data on narratives of product use. Thirty-six women reported high adherence in stage 1, yet admitted non-use in stage 2, three reported high adherence in both stages (contrary to their drug detection results) and five had consistent responses across both stages and drug results. Presenting objective measures of use may facilitate more accurate product use reporting and should be evaluated in future prevention trials. Article	2018	Musinguzi, Nicholas; Muwonge, Timothy; Ngure, Kenneth; Katabira, Elly; Mugo, Nelly; Burns, Bridget Frances O'Rourke; Baeten, Jared M; Heffron, Renee; Haberer, Jessica E	Comparison of short messaging service self-reported adherence with other adherence measures in a demonstration project of HIV preexposure prophylaxis in Kenya and Uganda.	AIDS	-	-	-	1473-5571	10.1097/QAD.0000000000001955	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6755137	OBJECTIVE: Short messaging service (SMS) can collect adherence data on a frequent basis and is relatively anonymous, and therefore could potentially reduce recall and social desirability biases prevalent in other self-reported measures. METHODS: We compared SMS self-reported adherence with three self-reported adherence questions (rating of ability to adhere, frequency of doses taken, percentage of doses taken) and two objective adherence measures electronic adherence monitoring (EAM) and plasma tenofovir levels using data from HIV-uninfected members of serodiscordant couples enrolled in a preexposure prophylaxis demonstration project in Kenya and Uganda. RESULTS: Of 373 enrolled participants, 256 (69%) were male and median age at enrolment was 29 years (26, 35). Fifty-two percent were from Kenya and median education at enrolment was 10 years (7,12). Overall, median adherence was 90, 75, 85, 94 and 79%, respectively, for self-report by SMS, rating, frequency, percentage and EAM adherence. Spearman's correlation coefficient between SMS and interviewer-administered self-reported measures was 0.18 for rating and frequency, 0.22 for percentage and 0.14 for EAM (all Pâ<â0.001). The estimated difference in average adherence between SMS and self-reported rating, frequency, percentage adherence and EAM was 8.1 (Pâ<â0.001), 0.3 (Pâ=â0.81), -5.2 (Pâ<â0.001) and 9.5 (Pâ<â0.001), respectively. Area under the receiver-operating curve assessing the ability of SMS self-report to discriminate between detectable and undetectable tenofovir was 0.51. CONCLUSION: Our study found low correlation between SMS self-report and other self-reported and objective adherence measures and did not discriminate between detectable and undetectable plasma tenofovir levels. Future use of SMS self-report should explore alternative means for reducing potential biases. Article	2018	Mustanski B.; Ryan D.T.; Hayford C.; Phillips G., II; Newcomb M.E.; Smith J.D.	Geographic and Individual Associations with PrEP Stigma: Results from the RADAR Cohort of Diverse Young Men Who have Sex with Men and Transgender Women	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2159-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051144486&doi=10.1007%2fs10461-018-2159-5&partnerID=40&md5=bab9c86fe54619cfa32bbea4729dd236	Increasing the uptake of pre-exposure prophylaxis (PrEP) to prevent HIV acquisition among at-risk populations, such as young men who have sex with men (YMSM), is of vital importance to slowing the HIV epidemic. Stigma and negative injunctive norms, such as the so called "Truvada Whore" phenomenon, hamper this effort. We examined the prevalence and types of PrEP stigma and injunctive norm beliefs among YMSM and transgender women and associated individual and geospatial factors. A newly created measure of PrEP Stigma and Positive Attitudes was administered to 620 participants in an ongoing longitudinal cohort study. Results indicated lower stigma among White, compared to Black and Latino participants, and among participants not identifying as male. Prior knowledge about PrEP was associated with lower stigma and higher positive attitudes. PrEP stigma had significant geospatial clustering and hotspots were identified in neighborhoods with high HIV incidence and concentration of racial minorities, whereas coldspots were identified in areas with high HIV incidence and low LGBT stigma. These results provide important information about PrEP attitudes and how PrEP stigma differs between individuals and across communities. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Mustanski, Brian; Macapagal, Kathryn; Thomann, Matthew; Feinstein, Brian A; Newcomb, Michael E; Motley, Darnell; Fisher, Celia B	Parents' Perspectives About Adolescent Boys' Involvement in Biomedical HIV Prevention Research.	Archives of Sexual Behavior	-	-	-	1573-2800	10.1007/s10508-017-1035-0	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5837896	Research on the use of pre-exposure prophylaxis (PrEP) among adolescents at high risk for HIV is urgently needed, and parents' perspectives on these studies are essential for guiding the responsible conduct of adolescent PrEP research. We conducted interviews with 30 parents of adolescent boys (50% known/presumed heterosexual; 50% sexual minority) to understand their views of research risks and benefits and parental permission regarding their son's involvement in a hypothetical PrEP adherence trial. Parents identified several health and educational benefits of the study and expressed that waiving parental permission would overcome barriers to accessing PrEP, particularly for youth who may benefit most. Among their concerns were medication non-adherence and risk compensation. Parents provided suggestions to facilitate informed, rational, and voluntary participation decisions and protect youth's safety if parental permission was waived. These findings can inform ways to increase parental trust in PrEP research and create adequate protections for adolescent participants. Article	2018	Myers, Julie E.; Braunstein, Sarah L.; Xia, Qiang; Scanlin, Kathleen; Edelstein, Zoe; Harriman, Graham; Tsoi, Benjamin; Andaluz, Adriana; Yu, Estella; Daskalakis, Demetre	Redefining Prevention and Care: A Status-Neutral Approach to HIV.	Open Forum Infectious Diseases	-	-	-	2328-8957	10.1093/ofid/ofy097	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6016418/	Recent biomedical advances inspire hope that an end to the epidemic of HIV is in sight. Adopting new approaches and paradigms for treatment and prevention in terms of both messaging and programming is a priority to accelerate progress. Defining the key sequential steps that comprise engagement in HIV care has provided a useful framework for clinical programs and motivated quality improvement initiatives. Recently, the same approach has been applied to use of pre-exposure prophylaxis for HIV prevention. Building on the various prevention and care continua previously proposed, we present a novel schematic that incorporates both people living with HIV and people at risk, making it effectively "status-neutral" in that it proposes the same approach for engagement, regardless of one's HIV status. This multidirectional continuum begins with an HIV test and offers 2 divergent paths depending on the results; these paths end at a common final state. To illustrate how this continuum can be utilized for program planning as well as for monitoring, we provide an example using data for New York City men who have sex with men, a population with high HIV incidence and prevalence. Article	2018	Myers, Julie E; Edelstein, Zoe R; Daskalakis, Demetre C; Gandhi, Anisha D; Misra, Kavita; Rivera, Alexis V; Salcuni, Paul M; Scanlin, Kathleen; Udeagu, Chi-Chi; Braunstein, Sarah L	Preexposure Prophylaxis Monitoring in New York City: A Public Health Approach.	American Journal of Public Health	-	-	-	1541-0048	10.2105/AJPH.2018.304729	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6215383	The scale-up of preexposure prophylaxis (PrEP) represents a paradigm shift in HIV prevention that poses unique challenges for public health programs. Monitoring of PrEP implementation at the population level is a national priority, with particular significance in New York City (NYC) given the substantial HIV burden and the prominence of PrEP in state and local Ending the Epidemic program plans. We highlight the importance of local monitoring and evaluation of PrEP implementation outcomes and describe the experience at the NYC Health Department, which includes engaging communities, triangulating a variety of data sources regarding PrEP implementation, and leveraging those data to help guide programming. In NYC, we used data from national surveillance systems and incorporated PrEP-related indicators into existing local data collection systems to help illustrate gaps in PrEP awareness and use. Ultimately, ensuring that PrEP achieves the desired impact at the population level depends on identifying disparities through appropriate and accurate measurement, and addressing them through evidence-based programs. Article	2018	Needleman, Robert; Chow, Eric P F; Towns, Janet M; Cornelisse, Vincent J; Yang, Tim Z T; Chen, Marcus Y; Bradshaw, Catriona S; Fortune, Ria; Fairley, Christopher K	Access to sexual health services after the rapid roll out of the launch of pre-exposure prophylaxis for HIV in Melbourne, Australia: a retrospective cross-sectional analysis.	Sexual Health	-	-	-	1448-5028	10.1071/SH17182	https://dx.doi.org/10.1071/SH17182	Background On 26 July 2016, Victoria began a large study of HIV pre-exposure prophylaxis, called PrEPX, that involved the creation of around 2600 appointments over 3 months across multiple sites in Melbourne, Australia. At this time, the Melbourne Sexual Health Centre (MSHC) appeared to have a larger demand on its services. The aim of the present study was to determine whether this apparent increase in demand was substantially different from other demand fluctuations. METHODS: Patients presenting to the MSHC from 2014 to 2016 were reviewed. Demographic characteristics, sexual risks and sexually transmitted infection diagnoses were extracted from the clinical database. RESULTS: There were 115522 walk-in presentations for care and a rise in presentations in the week following the launch of the PrEPX study, but at least six similar peaks occurred that year. The peak coinciding with the launch of PrEPX was only apparent for men who have sex with men. There was a substantial increase in the proportion of patients who could not be seen (i.e. triaged out), from 10% in the week before PrEPX to 22.2% in the second week after, but this was primarily due to staff absences. At the time of the PrEPX study, data were collected on the duration of symptoms for common conditions and found no significant (P>0.29) change in the average duration of symptoms compared with that seen before the PrEPX launch. CONCLUSIONS: The increase in the number of medical consultations required for the PrEPX study did not result in excessive demand for public sexual health services. Theses and Dissertations	2018	Nelson, Antoinette Gail	The development of a nano-based colorectal pre-exposure prophylaxis for HIV	-	-	Rutgers University	-	-	https://doi.org/doi:10.7282/T3ST7T8P	https://rucore.libraries.rutgers.edu/rutgers-lib/57766/	The colorectal mucosa is a highly vulnerable site for Human Immunodeficiency Virus (HIV) transmission. The epithelium of this region is comprised of a thin single-cell layer that serves as a protective barrier, to prevent foreign pathogens from entering the body. Beneath the epithelial layer, the lamina propria provides direct access to an extensive population of immune cells that are highly susceptible to HIV infection. There is also access to the lymphatic system, which serves as an outlet for HIV to enter the systemic circulation, initiating permanent infection. To prevent HIV infection, it is important to achieve, and maintain, therapeutically effective concentrations of anti-HIV drugs within mucosal tissues. The objective of the current thesis is to fabricate and assess a nanoparticle (NP) platform, for use in a colorectal PrEP, with the goal to (1) deliver antiretroviral agents directly to the colorectal mucosa to minimize dosage requirements; (2) achieve high drug loading and sustained drug release; and (3) establish prolonged, therapeutically effective, drug concentrations within mucosal tissue to minimize dosing frequency to once-a-week. Based on average epithelial cell turnover rates in the colon of rodents and humans, 2-3 days in a murine model is considered equivalent to 5-8 days in humans. The overall objective of this thesis is to design, fabricate, and evaluate a nanoparticle (NP) drug delivery system (DDS), for colorectal pre-exposure prophylaxis (mPrEP) of HIV. Within the first part of this thesis, the feasibility of a modified cell penetrating peptide (CPP) bactenecin 7 (Bac7), to transport poly(ε-caprolactone)-poly(ethylene glycol) (PCL-PEG) NPs into, and across, a colorectal epithelial barrier, was evaluated. The hypothesis is that by functionalizing NPs with Bac7, NP transport across Caco-2 colonic cells will increase in vitro. Additionally, NPs of optimal architecture (dense PEG corona and effective Bac7 ligand density) will successfully traverse the colorectal mucus mesh lining in vivo. Bac7-labeled NPs with varied ligand densities resulted in a 163.2% to 384.6% increase in NP transport across a Caco-2 epithelial cell monolayer compared with plain NPs. NPs of 1% to 5% Bac7 surface coverage showed successful translocation across colorectal mucus to associate with the epithelial layer in vivo in a rat model. In the second portion of this thesis, rilpivirine-loaded NPs were assessed for sustained drug release. The hypothesis that flash nanoprecipitation can be used to fabricate NPs with high RPV drug loading via in situ salt formation, and that NP formulations can be tuned to achieve sustained release for a minimum of 24 hours, was tested. RPV was successfully encapsulated within PCL-PEG NPs resulting in high encapsulation efficiencies (85% to 98%), and moderate to high drug loadings (10.9 % to 17.7%). Cumulative release over 24 hours was modulated to achieve between 20% and 40% extent of release. Poly(lactide)-poly(ethylene glycol) (PLA-PEG) NPs resulted in a greater extent of release…	Drug delivery systems; Antiretroviral agents	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Clinical
Article	2018	Newcomb, Michael E; Moran, Kevin; Feinstein, Brian A; Forscher, Emily; Mustanski, Brian	Pre-Exposure Prophylaxis (PrEP) Use and Condomless Anal Sex: Evidence of Risk Compensation in a Cohort of Young Men Who Have Sex with Men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001604	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5825266	BACKGROUND: Young men who have sex with men (YMSM) are disproportionately impacted by HIV. Pre-exposure prophylaxis (PrEP) is highly effective at preventing HIV acquisition. It remains unclear if PrEP use increases rates of condomless sex (ie, risk compensation), which may increase risk of infection if PrEP adherence is not optimal. This study aimed to examine whether PrEP use and PrEP adherence were associated with change in sexual risk behaviors in a large longitudinal cohort of YMSM reporting on multiple sexual partnerships over time. METHOD: Data were obtained from the first 3 visits of an ongoing cohort study of YMSM in Chicago (analytic N = 953; 14.1% HIV-positive at baseline). Participants reported up to 4 sexual partnerships at each visit, including sexual behavior, PrEP use, and PrEP adherence within partnerships. RESULTS: YMSM reported higher rates of receptive condomless anal sex (CAS) in partnerships during which they were on PrEP compared with those when they were not on PrEP. This association was consistent across both HIV-negative and HIV-positive participants reporting on partnerships with both perceived HIV-negative/unknown and HIV-positive partners. The rate of receptive CAS was higher in PrEP nonadherent partnerships compared with non-PrEP partnerships. The rate of receptive CAS was also higher in PrEP nonadherent than adherent partnerships, but this was not statistically significant. CONCLUSIONS: These analyses provide compelling data suggesting that YMSM are engaging in risk compensation when on PrEP. If rates of receptive CAS are highest among YMSM who are PrEP nonadherent, PrEP as a prevention strategy could fail to curb HIV incidence among YMSM. Article	2018	Newman, Peter A; Guta, Adrian; Lacombe-Duncan, Ashley; Tepjan, Suchon	Clinical exigencies, psychosocial realities: negotiating HIV pre-exposure prophylaxis beyond the cascade among gay, bisexual and other men who have sex with men in Canada.	Journal of the International AIDS Society	-	-	-	1758-2652	10.1002/jia2.25211	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6253066	INTRODUCTION: Notwithstanding the efficacy of oral pre-exposure prophylaxis (PrEP) in clinical trials, a number of obstacles exist to achieving population-level impact among gay, bisexual and other men who have sex with men (GBM). However, few studies have explored the subjective experiences of GBM PrEP users and non-users in the community, outside of clinical trials. The objectives of this study were to explore GBM's experiences of considering, accessing and using (or not using) PrEP, and to understand emerging sexual health, social and community issues among GBM in the PrEP era. METHODS: From October 2015 to March 2016, we purposively sampled PrEP-naïve and PrEP-experienced GBM from community organizations and health centres in Toronto, Canada. In-depth, 45- to 90-minute semi-structured interviews explored PrEP perspectives and decision-making, access, initiation, use over time, sexual practices and psychosocial considerations. Interviews were recorded, transcribed verbatim, uploaded into NVIVO, reviewed using thematic analysis and then contrasted with the PrEP cascade. RESULTS: Participants included PrEP users (n = 15) and non-users (n = 14) (mean age = 36.7 years; SD = 8.2), largely gay-identified (86.2%), cisgender male (89.7%) and white (79.3%). Themes indicate not only correspondences, but also limitations of the PrEP cascade by complicating a user/non-user binary and challenging the unilateral presupposition that HIV risk perception leads to PrEP acceptance. Findings further call into question assumptions of a linear stage progression and retention in care as a universal endpoint, instead revealing alternate trajectories of seasonal or intermittent PrEP use and, for some, an end goal of terminating PrEP. GBM's narratives also revealed potent psychological/affective experiences of untethering sex from HIV anxiety; multifaceted PrEP stigma; and challenges to sexual norms and practices that complicate existing behavioural prevention strategies and sexual and social relationships. CONCLUSIONS: An expanded PrEP cascade should consider alternate trajectories of use based on dynamic relationships and behavioural risks that may call for seasonal or intermittent use; systemic barriers in access to and sustaining PrEP; and multiple end goals including PrEP maintenance and discontinuation. Incorporating GBM's lived experiences, evolving preferences, and psychosocial and community-level challenges into PrEP implementation models, rather than a circumscribed biomedical approach, may more effectively support HIV prevention and GBM's broader sexual and psychological health. Article	2018	Nguyen V.-K.; Greenwald Z.R.; Trottier H.; Cadieux M.; Goyette A.; Beauchemin M.; Charest L.; Longpré D.; Lavoie S.; Tossa H.G.; Thomas R.	Incidence of sexually transmitted infections before and after preexposure prophylaxis for HIV	AIDS	-	-	-	2699370	10.1097/QAD.0000000000001718	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042458504&doi=10.1097%2fQAD.0000000000001718&partnerID=40&md5=139812143f12edb7dc096bbc727cb3b7	Objective: Use of preexposure prophylaxis (PrEP) for HIV raises concerns about sexually transmitted infection (STI) incidence because of decreased condom use among MSM. This study examines whether PrEP is associated with STIs in the 12 months following PrEP prescription relative to the 12 months prior to PrEP and if STI rates are higher among PrEP users relative to individuals receiving postexposure prophylaxis (PEP). Design: Retrospective cohort study including PrEP users with more than 12 months of follow-up before PrEP prescription and individuals receiving PEP from 2010 to 2015 at Clinique l'Actuel (Montréal, Canada). Methods: Incidence of chlamydia, gonorrhoea, syphilis and hepatitis C virus over 12 months was compared before and after PrEP; and for PrEP versus PEP users using Poisson models to generate incidence rate ratios (IRRs) with 95% confidence intervals (CIs) and adjusted IRRs (aIRRs) controlling for frequency of STI-screening visits. Models comparing PrEP and PEP users were further adjusted for age and education. Results: One hundred and nine PrEP and 86 PEP users were included. Increased rates of STIs were observed in the 12 months after PrEP relative to the 12 months prior (IRR: 1.72, CI: 1.22-2.41; aIRR: 1.39, CI 0.98-1.96). PrEP users were also at higher STI risk relative to PEP users (IRR: 2.18, CI: 1.46-3.24; aIRR: 1.76, CI: 1.14-2.71). Conclusion: Increased rates of STIs among individuals after initiation of PrEP may suggest greater risk behaviours during the first year on PrEP. Further studies are needed to measure long-Term trends in STI acquisition following PrEP initiation. Copyright © 2018 Wolters Kluwer Health, Inc. All rights reserved. Article	2018	Nicol M.R.; Corbino J.A.; Cottrell M.L.	Pharmacology of Antiretrovirals in the Female Genital Tract for HIV Prevention	Journal of Clinical Pharmacology	-	-	-	912700	10.1002/jcph.1270	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054167970&doi=10.1002%2fjcph.1270&partnerID=40&md5=371bd67da8495c3612b89e8de1ca38d4	Preexposure prophylaxis (PrEP) is a powerful tool that, as part of a comprehensive prevention package, has potential to significantly impact the HIV epidemic. PrEP effectiveness is believed to be dependent on the exposure and efficacy of antiretrovirals at the site of HIV transmission. Clinical trial results as well as modeling and simulation indicate the threshold of adherence required for PrEP efficacy of emtricitabine/tenofovir disoproxil fumarate may differ between sites of HIV transmission with less forgiveness for missed doses in women exposed through genital tissue compared to people exposed through colorectal tissue. This suggests a role for local and host factors to influence mucosal pharmacology. Here we review the mucosal pharmacology of antiretrovirals in the female genital tract and explore potential determinants of PrEP efficacy. Host factors such as inflammation, coinfections, hormonal status, and the vaginal microbiome will be explored as well as the role of drug-metabolizing enzymes and transporters in regulating local drug exposure. The use of preclinical and early clinical models to predict clinical effectiveness is also discussed. © 2018, The American College of Clinical Pharmacology	Antiretrovirals; Clinical Pharmacology; Female Genital Tract; Gynecology; HIV/AIDS; Infectious Diseases; PrEP; Virology; Women's Health	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2018	Nicol, Melanie R.; Brewers, Lindsey M.; Kashuba, Angela D. M.; Sykes, Craig	The role of menopause in tenofovir diphosphate and emtricitabine triphosphate concentrations in cervical tissue.	AIDS	-	-	-	1473-5571 0269-9370	10.1097/QAD.0000000000001678	https://pubmed.ncbi.nlm.nih.gov/29112071/	OBJECTIVE: Although postmenopausal (post-M) women have behavioral and biological risk factors for HIV infection, the activity of preexposure prophylaxis (PrEP) agents in older adults has not been well studied. DESIGN: We used an ex-vivo approach to compare the tissue concentrations of tenofovir (TFV) diphosphate (TFVdp) and emtricitabine (FTC) triphosphate (FTCtp) in cervical tissues from premenopausal (pre-M) and post-M women. METHOD: Cervical explants from 16 pre-M and 11 post-M women were incubated in 10-300μg/ml TFV or FTC for 24h. Explants were then snap frozen in liquid nitrogen and stored until analysis. TFVdp and FTCtp were quantified using tandem liquid chromatography-mass spectrometry. RESULTS: Active metabolite concentrations of TFVdp were more than nine-fold lower in post-M explants (P<0.05). The percentage of TFV converted to TFVdp in pre-M explants was 0.0038 below the limit of quantification (BLQ)-0.5886 compared with 0.0004 (BLQ-0.0706) in post-M explants. The majority of FTCtp concentrations were BLQ. For both TFVdp and FTCtp, there was a trend for more unquantifiable concentrations in post-M vs. pre-M (TFV: 38 vs. 21%, P=0.2; FTC: 71 vs. 52%, P=0.2). CONCLUSION: These findings could have implications in the use of nucleotide-based PrEP strategies targeted to older women. If validated in vivo, lower exposures of active nucleoside/tide metabolites could mean post-M women need higher doses of TFV-based PrEP to achieve protective efficacy. Article	2018	Nideröst, Sibylle; Gredig, Daniel; Hassler, Benedikt; Uggowitzer, Franziska; Weber, Patrick	The intention to use HIV-pre-exposure prophylaxis (PrEP) among men who have sex with men in Switzerland: testing an extended explanatory model drawing on the unified theory of acceptance and use of technology (UTAUT).	Zeitschrift für Gesundheitswissenschaften (Journal of Public Health)	-	-	-	2198-1833	10.1007/s10389-017-0869-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5948261	AIM: The aim of this study was to determine the intention to use pre-exposure prophylaxis (PrEP) when available and to identify predictors of the intention to use PrEP among men who have sex with men (MSM) living in Switzerland. The theoretical model drew on the Unified Theory of Acceptance and Use of Technology and considered additional variables related specifically to PrEP, HIV protection and the resources of MSM. SUBJECT AND METHODS: For data collection, we used an anonymous, standardized self-administered online questionnaire. In 2015, we gathered a convenience sample of 556 HIV-negative MSM living in Switzerland. We analyzed the data using descriptive and bivariate statistics and used structural equation modeling to test the hypothesized model. RESULTS: Predictors of respondents' moderate intention to use PrEP were performance expectancy, effort expectancy, perceived social influence, concerns about using PrEP, attitudes toward condom use, negative experiences of condom use and age. These variables were predicted by HIV protection-related aspects and resources. CONCLUSION: The findings provide insights into the complex dynamic underlying the intention to use PrEP. Article	2018	Noret, M; Balavoine, S; Pintado, C; Siguier, M; Brun, A; Bauer, R; Loze, B; Leplatois, A; Aslan, A; Moudachirou, K; Delaugerre, C; Rozenbaum, W; Molina, JM	Daily or on-demand oral tenofovir disoproxil fumarate/emtricitabine for HIV pre-exposure prophylaxis: experience from a hospital-based clinic in France	AIDS	-	-	-	0269-9370	10.1097/QAD.0000000000001939	https://pubmed.ncbi.nlm.nih.gov/30212403/	Background: On-demand oral tenofovir disoproxil fumarate and emtricitabine (TDF/FTC) has been approved for pre-exposure prophylaxis (PrEP) in MSM in France following the results of clinical studies, but data are limited on real-world experience. Design: A single-center, open-label, prospective cohort study that recruited people at high risk of HIV infection in Paris. Methods: Participants were enrolled in a single hospital-based outpatient clinic and were proposed to start PrEP with daily or on demand TDF/FTC. At baseline and every 3 months thereafter, patients were tested for HIV and creatinine plasma levels, and data on sexual behavior, other sexually transmitted infections (STIs), and tolerability were collected. Results: From 10 November 2015 to 30 April 2017, 1069 patients were screened and 1049 (98.1%) started PrEP. Median age was 36 years, 99.4% were MSM with a median number of partners of 10, and 793 (75.6%) opted for on demand PrEP. Over 486 personyears of follow-up, four HIV-infections were diagnosed in poorly or nonadherent patients (incidence 0.82/100 person-years). Rate of condomless sex at last intercourse increased from 53.3% at baseline to 79% at month 12 (P< 10(-4)), but increase in bacterial STI rates was modest (14.6% at baseline vs. 19.2% at month 12; P< 10(-4)). Most adverse events were gastrointestinal and did not lead to PrEP discontinuation. Conclusions: Most PrEP users were high-risk MSM and opted for on-demand PrEP. PrEP use was associated with a low HIV incidence and a high rate of condomless sex with a modest increase in bacterial STIs. Copyright (C) 2018 Wolters Kluwer Health, Inc. All rights reserved. Article	2018	Nsuami M.U.; Witbooi P.J.	A model of HIV/AIDS population dynamics including ARV treatment and pre-exposure prophylaxis	Advances in Difference Equations	-	-	-	16871839	10.1186/s13662-017-1458-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042066263&doi=10.1186%2fs13662-017-1458-x&partnerID=40&md5=7d44b8b7954d546b2833f8a4ca4cc1a1	Antiretroviral treatment (ART) and oral pre-exposure prophylaxis (PrEP) have recently been used efficiently in management of HIV infection. Pre-exposure prophylaxis consists in the use of an antiretroviral medication to prevent the acquisition of HIV infection by uninfected individuals. We propose a new model for the transmission of HIV/AIDS including ART and PrEP. Our model can be used to test the effects of ART and of the uptake of PrEP in a given population, as we demonstrate through simulations. The model can also be used to estimate future projections of HIV prevalence. We prove global stability of the disease-free equilibrium. We also prove global stability of the endemic equilibrium for the most general case of the model, i.e., which allows for PrEP individuals to default. We include insightful simulations based on recently published South-African data. © 2018, The Author(s).	basic reproduction number; HIV/AIDS model; pre-exposure prophylaxis; stability	English	Egypt	Middle East and North Africa	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Quantitative
Article	2018	Nydegger, Liesl A; Walsh, Jennifer L	Strength of Implementation Intentions to Use Condoms Among Men Who Have Sex with Men.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-018-2079-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6129435	Although pre-exposure prophylaxis (PrEP) use is increasing among men who have sex with men (MSM), condoms remain key to HIV prevention. Implementation intentions-which link a behavioral action plan with a situation or cue-may predict condom use. The Strength of Implementation Intentions Scale (SIIS), which assesses condom use implementation intentions, has not been evaluated among MSM. A structural model tested whether the SIIS mediated the relationship between condom use intentions and condomless sex acts among 266 sexually-active MSM (56% White, 26% Black, 15% Latino, Mage = 32.54). After controlling for PrEP use, HIV-status, and demographics (χ2(107) = 140.06, CFI = 0.98, TLI = 0.97, RMSEA = 0.03), the SIIS fully mediated the relationship between condom use intentions and condomless sex acts. The SIIS can serve as a fidelity check for interventions, a mediator in theoretical models, and future studies should incorporate implementation intentions into HIV prevention interventions for MSM. Article	2018	Ojikutu, Bisola O; Bogart, Laura M; Higgins-Biddle, Molly; Dale, Sannisha K; Allen, Wanda; Dominique, Tiffany; Mayer, Kenneth H	Facilitators and Barriers to Pre-Exposure Prophylaxis (PrEP) Use Among Black Individuals in the United States: Results from the National Survey on HIV in the Black Community (NSHBC).	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-018-2067-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6103919	This study explores willingness to use PrEP among Black individuals in the US. From February to April 2016, an online survey was administered to a nationally representative sample of Black individuals. 855 individuals who were HIV negative by self-report participated mean age: 33.6 (SD 9.2); 45.5% male. Among all respondents, 14.5% were aware of, and 26.0% would be willing to use PrEP. Among high-risk individuals (N = 327), 19.8% knew about and 35.1% would be willing to use PrEP. The most common reason for lack of willingness among high-risk individuals was low self-perceived risk (65.1%). In multivariate analysis, individuals reporting single marital status OR 1.8 (1.2, 2.5), p = 0.002, depressive symptoms OR 1.6 (1.2, 2.2), p = 0.0054, arrest history OR 1.7(1.2, 2.4), p = 0.0003, PrEP knowledge OR 1.5 (1.0, 2.3), p = 0.0247 and belief in HIV conspiracies OR 1.3 (1.1, 1.5), p = 0.0075 were more likely to be willing to use PrEP. Participants who saw a health care provider less frequently were less willing to use PrEP OR 0.5 (0.4, 0.8), p = 0.0044. Among a nationally representative sample of Black individuals, few high risk individuals were willing to use PrEP. Interventions to increase risk awareness, PrEP knowledge and access to care are necessary to improve PrEP uptake. Article	2018	Okoro O.; Hillman L.	HIV pre-exposure prophylaxis: Exploring the potential for expanding the role of pharmacists in public health	Journal of the American Pharmacists Association	-	-	-	15443191	10.1016/j.japh.2018.04.007	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047189888&doi=10.1016%2fj.japh.2018.04.007&partnerID=40&md5=0d4150a77c37b5cb69175330d5c328e7	Objectives: The study objectives were to a) assess knowledge and experience; b) describe perceptions and attitudes; and c) identify training needs of community-based pharmacists regarding HIV pre-exposure prophylaxis (PrEP). Design: This was a cross-sectional survey study. Setting and participants: The survey was administered online to pharmacists practicing in a community setting in the state of Minnesota. Outcome measures: Measures included knowledge of and experience with HIV PrEP, perceptions and attitudes towards pharmacists' involvement, and HIV PrEP-specific training needs for pharmacists. Results: With a survey response rate of approximately 13% (n = 347), most respondents (76.4%) agreed that HIV PrEP can be beneficial in high-risk populations. Forty-six percent of respondents were not aware of U.S. Food and Drug Administration approval of emtricitabine and tenofovir disoproxil fumarate for PrEP. Most respondents (71.1%) were "not at all familiar" with Centers for Disease Control and Prevention guidelines for PrEP. Twenty-one percent of respondents had sufficient knowledge to counsel patients on PrEP. Experience with counseling on PrEP (21.8%), having dispensed PrEP in the last 2 years (33.1%), fewer years in practice (≤10 years), location of practice site (urban or suburban), and having received HIV continuing education in the last 2 years (33.0%) were associated with more knowledge of HIV PrEP. Top concerns with counseling were knowledge about the medication and behavior modification. The most frequently indicated primary concerns with implementing PrEP initiatives were identifying appropriate candidates and patient adherence. Conclusion: As pharmacists' roles continue to expand, relevant content in pharmacy education and requisite training (including continuing education) are critical to addressing knowledge gaps and competencies that will enable pharmacists engage more effectively in public health efforts such as HIV prevention. © 2018	NA	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Oldenburg, Catherine E; Nunn, Amy S; Montgomery, Madeline; Almonte, Alexi; Mena, Leandro; Patel, Rupa R; Mayer, Kenneth H; Chan, Philip A	Behavioral Changes Following Uptake of HIV Pre-exposure Prophylaxis Among Men Who Have Sex with Men in a Clinical Setting	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-017-1701-1	https://www.proquest.com/scholarly-journals/behavioral-changes-following-uptake-hiv-pre/docview/2020258237/se-2?accountid=8113	We describe changes in sexual behaviors among men who have sex with men (MSM) following initiation of pre-exposure prophylaxis (PrEP) in a clinic-based sample of MSM initiating PrEP in Providence, Rhode Island. Data were collected at baseline, 3, and 6 months following PrEP initiation including total number of anal sex partners and condom use. A longitudinal mixed effects model assessed changes in number of partners and condom use over time, adjusting for age, race, and education. There was no statistically significant difference in total number of partners over time. There was a significant increase in number of condomless anal sex partners at the 6-month visit compared to baseline (mean change +1.31 partners, 95% confidence interval 0.09–2.53, P = 0.035). As condomless anal sex may increase following PrEP uptake, adherence counseling and efforts to retain patients in PrEP care, especially during periods of non-condom use, are important as PrEP is more widely implemented. Article	2018	O'Leary, Ann	Women and HIV in the Twenty-First Century: How Can We Reach the UN 2030 Goal?	AIDS Education and Prevention	-	-	-	1943-2755 0899-9546	10.1521/aeap.2018.30.3.213	https://pubmed.ncbi.nlm.nih.gov/29969306/	Women have always been part of the HIV/AIDS epidemic. As with other populations affected by HIV, for many years the only prevention strategy available was behavior change. Behavioral interventions for women were developed and evaluated, with some success. Because women did not control the use of male condoms, efficacious interventions needed to build skills for partner negotiation. Woman-controlled technologies such as the female condom and vaginal spermicide were unable to solve the problem of male control of the condom and enable the development of safe methods for women to protect themselves. The modern era of HIV prevention has produced biomedical solutions based on highly active retroviral chemoprophylaxis, which can be hidden from the male partner and thus eliminate his possible negative reactions. Pre-exposure prophylaxis holds promise for HIV prevention among women. This article reviews the literature on HIV prevention for women, including both successes and challenges. Implementation of a Test, Treat, and Prevent HIV program among men who have sex with men and transgender women in Thailand, 2015-2016	PLOS One	-	-	-	19326203	10.1371/journal.pone.0201171	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050699648&doi=10.1371%2fjournal.pone.0201171&partnerID=40&md5=1d7d6416eda8821940e6588d908dd136	Introduction Antiretroviral therapy reduces the risk of serious illness among people living with HIV and can prevent HIV transmission. We implemented a Test, Treat, and Prevent HIV Program among men who have sex with men (MSM) and transgender women at five hospitals in four provinces of Thailand to increase HIV testing, help those who test positive start antiretroviral therapy, and increase access to pre-exposure prophylaxis (PrEP). Methods We implemented rapid HIV testing and trained staff on immediate antiretroviral initiation at the five hospitals and offered PrEP at two hospitals. We recruited MSM and transgender women who walked-in to clinics and used a peer-driven intervention to expand recruitment. We used logistic regression to determine factors associated with prevalent HIV infection and the decision to start antiretroviral therapy and PrEP. Results During 2015 and 2016, 1880 people enrolled. Participants recruited by peers were younger (p<0.0001), less likely to be HIV-infected (p<0.0001), and those infected had higher CD4 counts (p = 0.04) than participants who walked-in to the clinics. Overall, 16% were HIV-positive: 18% of MSM and 9% of transgender women; 86% started antiretroviral therapy and 46% of eligible participants started PrEP. A higher proportion of participants at hospitals with one-stop HIV services started antiretroviral therapy than other hospitals. Participants who started PrEP were more likely to report sex with an HIV-infected partner (p = 0.002), receptive anal intercourse (p = 0.02), and receiving PrEP information from a hospital (p<0.0001). Conclusions We implemented a Test, Treat, and Prevent HIV Program offering rapid HIV testing and immediate access to antiretroviral therapy and PrEP. Peer-driven recruitment reached people at high risk of HIV and people early in HIV illness, providing an opportunity to promote HIV prevention services including PrEP and early antiretroviral therapy. Sites with one-stop HIV services had a higher uptake of antiretroviral therapy and PrEP. Article	2018	Ortblad K.F.; Chanda M.M.; Musoke D.K.; Ngabirano T.; Mwale M.; Nakitende A.; Chongo S.; Kamungoma N.; Kanchele C.; Bärnighausen T.; Oldenburg C.E.	Acceptability of HIV self-testing to support pre-exposure prophylaxis among female sex workers in Uganda and Zambia: Results from two randomized controlled trials	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-018-3415-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054449872&doi=10.1186%2fs12879-018-3415-z&partnerID=40&md5=e87f5530c9dec72905e65eaf1ad1092d	Background: HIV pre-exposure prophylaxis (PrEP) is highly effective for prevention of HIV acquisition, but requires HIV testing at regular intervals. Female sex workers (FSWs) are a priority population for HIV prevention interventions in many settings, but face barriers to accessing healthcare. Here, we assessed the acceptability of HIV self-testing for regular HIV testing during PrEP implementation among FSWs participating in a randomized controlled trial of HIV self-testing delivery models. Methods: We used data from two HIV self-testing randomized controlled trials with identical protocols in Zambia and in Uganda. From September-October 2016, participants were randomized in groups to: (1) direct delivery of an HIV self-test, (2) delivery of a coupon, exchangeable for an HIV self-test at nearby health clinics, or (3) standard HIV testing services. Participants completed assessments at baseline and 4 weeks. Participants reporting their last HIV test was negative were asked about their interest in various PrEP modalities and their HIV testing preferences. We used mixed effects logistic regression models to measure differences in outcomes across randomization arms at four weeks. Results: At 4 weeks, 633 participants in Zambia and 749 participants in Uganda reported testing negative at their last HIV test. The majority of participants in both studies were "very interested" in daily oral PrEP (91% Zambia; 66% Uganda) and preferred HIV self-testing to standard testing services while on PrEP (87% Zambia; 82% Uganda). Participants in the HIV self-testing intervention arms more often reported preference for HIV self-testing compared to standard testing services to support PrEP in both Zambia (P = 0.002) and Uganda (P < 0.001). Conclusion: PrEP implementation programs for FSW could consider inclusion of HIV self-testing to reduce the clinic-based HIV testing burden. Trial registration: ClinicalTrials.gov NCT02827240 and NCT02846402. © 2018 The Author(s). Article	2018	Palk L.; Gerstoft J.; Obel N.; Blower S.	A modeling study of the Danish HIV epidemic in men who have sex with men: travel, pre-exposure prophylaxis and elimination	Scientific Reports	-	-	-	20452322	10.1038/s41598-018-33570-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055616413&doi=10.1038%2fs41598-018-33570-0&partnerID=40&md5=8ba651bf3050adaa7237a5253b7a0727	UNAIDS has identified the Danish HIV epidemic in men who have sex with men (MSM) as a priority for elimination. Incidence is close to the elimination threshold of one new infection per year per 1,000 individuals. However, surveillance data show that HIV strains are being imported into Denmark, mainly due to travel. We use a transmission model to predict (from 2018 to 2030) the impact of pre-exposure prophylaxis (PrEP) on incidence. Our model reflects the current epidemic and diagnosis rates in the Danish MSM community. We conduct a sensitivity analysis based on 20,000 simulations, and assume that PrEP coverage could range from zero to 50% and diagnosis rates increase up to three-fold. We predict that incidence will fall below the elimination threshold, even without the introduction of PrEP, reaching 0.87 (median, 95% Confidence Interval: 0.65–1.23) new infections per 1,000 MSM by 2030. PrEP could reduce incidence to well below the threshold, if it results in a significant increase in diagnosis rates and reduces the number of infections occurring abroad. The Danish Medicine Agency and Danish Health Authority have recommended introducing PrEP. Our study provides strong support for this recommendation, and shows the importance of Danish MSM using PrEP when abroad. © 2018, The Author(s). Article	2018	Paparini S.; Nutland W.; Rhodes T.; Nguyen V.-K.; Anderson J.	DIY HIV prevention: Formative qualitative research with men who have sex with men who source PrEP outside of clinical trials	PLOS One	-	-	-	19326203	10.1371/journal.pone.0202830	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052066458&doi=10.1371%2fjournal.pone.0202830&partnerID=40&md5=885d3ca76fb5166dd74a8935f3454054	Pre-exposure prophylaxis (PrEP) with antiretroviral medication is an effective, evidence-based option for HIV prevention. In England, issues of cost-effectiveness and of responsibility for commissioning prevention services have so far led National Health Service (NHS) England to decide not to commission PrEP. Given the significant lag between the awareness of PrEP efficacy and the opportunity to obtain PrEP through traditional health care routes, many gay and other men who have sex with men (MSM) have turned to 'DIY PrEP', purchasing generic formulations of PrEP for themselves on the internet or via other alternative routes. However, there is very little research on DIY PrEP practices and no qualitative study with DIY PrEP users in the UK. A formative qualitative study was conducted in 2017 to inform the development of an intervention (PrEP Club) to support DIY PrEP users and improve the safety and experience of this prevention strategy. Focus groups were held with 20 MSM who are based in London and are obtaining PrEP through means other than clinical trials, to explore their accounts of sourcing and using PrEP and the experiential meanings of these. In this article, we report findings from this first, formative study and present the different practices involved in finding out about PrEP, buying it and ascertaining legitimacy of sellers and products. We reflect on the uncertainties participants described related to actually using PrEP, including deciding on drug dosing and monitoring their health. Finally, we present the results of the discussions participants had about the kind of support they had received, the help they would have liked, and their views on proposed interventions to support DIY PrEP users, such as PrEP Club. © 2018 Paparini et al. Article	2018	Parisi D.; Warren B.; Leung S.J.; Akkaya-Hocagil T.; Qin Q.; Hahn L.; Stevens L.	A Multicomponent Approach to Evaluating a Pre-exposure Prophylaxis (PrEP) Implementation Program in Five Agencies in New York	Journal of the Association of Nurses in AIDS Care	-	-	-	-	10532390	10.1016/j.jana.2017.06.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021705003&doi=10.1016%2Fj.jana.2017.06.006&partnerID=40&md5=7c1d20c77079c6da42342f6b9b79924f	Research has shown that pre-exposure prophylaxis (PrEP) is effective for preventing HIV infection. We developed the Targeted PrEP Implementation Program (TPIP), an 18-month project that involved five statewide agencies, to assess the extent to which PrEP could be implemented in "real world" clinical settings. The target population was men who have sex with men at high risk for HIV infection. Data were collected from a variety of sources. Implementing PrEP statewide required facilitating provider capacity, developing resources, and identifying/addressing potential barriers. TPIP focused on three key questions: (a) Can providers identify and retain appropriate candidates for PrEP? (b) Can PrEP participants adhere to daily medication? (c) Can PrEP be delivered as part of a comprehensive/integrated plan? There were 171 participating clients, most of whom successfully incorporated PrEP into their daily routines. After addressing initial barriers, we found that PrEP could be routinely delivered as part of a comprehensive prevention plan. © 2017 Association of Nurses in AIDS Care	HIV prevention; men who have sex with men (MSM); pre-exposure prophylaxis (PrEP)	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
