Article	2018	Parsons J.T.; John S.A.; Whitfield T.H.F.; Cienfuegos-Szalay J.; Grov C.	Human immunodeficiency virus/sexually transmitted infection counseling and testing services received by gay and bisexual men using pre-exposure prophylaxis at their last prep care visit	Sexually Transmitted Diseases	-	1685717	10.1097/OLQ.0000000000000880	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052260068&doi=10.1097%2FOLQ.0000000000000880&partnerID=40&md5=e5cebca887b437194dd45fe2c2b087b	Background Preexposure prophylaxis (PrEP) reduces risk of human immunodeficiency virus infection for many gay and bisexual men (GBM); however, bacterial sexually transmitted infections associated with decreasing condom use among users is of concern. Center for Disease Control and Prevention's guidelines for PrEP use recommend bacterial sexually transmitted infection screening every 6 months. We sought to investigate comprehensive PrEP care, defined as: (1) discussion of sexual behavior, (2) blood sample, (3) urine sample, (4) rectal sample (rectal swab), and (5) throat sample (throat swab), provided at the last PrEP care visit. Methods We used data from the 2017 National HIV Behavioral Surveillance System, a cross-sectional survey of GBM recruited using respondent-driven sampling. We used multivariable logistic regression to assess factors associated with receipt of comprehensive PrEP care (eg, race/ethnicity, age, education), recent number of condomless anal sex events, status as PrEP user, and health care provider type on receiving comprehensive care at last visit using fully adjusted binary logistic regression. Results At their last visit, nearly all men (94%) gave blood for testing, 88% provided a urine sample, and 73% discussed sexual behavior with their provider. However, only 51% reported having a rectal swab, and 48% an oral swab. Only 32% of men received comprehensive PrEP care at their last PrEP visit. Odds of receiving comprehensive care were significantly higher among younger men, men with a bachelor's degree or more education, and those who reported more condomless anal sex. Conclusions Less than one third of GBM received comprehensive human immunodeficiency virus/sexually transmitted infection counseling and testing at their last visit. These findings indicate further efforts are needed to promote health care providers for prescribing and managing patients on PrEP. © 2018 Lippincott Williams & Wilkins. Article	2018	Pasipanodya, Elizabeth C; Jain, Sonia; Sun, Xiaoying; Blumenthal, Jill; Ellorin, Eric; Corado, Katya; Dube, Michael P; Daar, Eric S; Morris, Sheldon R; Moore, David J	Trajectories and Predictors of Longitudinal Preexposure Prophylaxis Adherence Among Men Who Have Sex With Men	Journal of Infectious Diseases	-	1537-6613	10.1093/infdis/jix368	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5455951/	Background: Adherence is necessary for efficacy of preexposure prophylaxis (PrEP), and text-messaging methods are promising tools for both adherence assessment and support. Although PrEP adherence is variable, little research has examined patterns of variability or factors associated with longitudinal use. Methods: In the context of a randomized controlled trial of text-messaging versus standard of care for PrEP adherence, 121 men who have sex with men received once-daily tenofovir disoproxil fumarate/emtricitabine and daily adherence texts for 48 weeks. Growth mixture modeling (GMM) was used to identify subgroups of individuals with similar trajectories of text-reported adherence. Between-group differences in pharmacologic measures of adherence (ie, tenofovir diphosphate and emtricitabine triphosphate in dried blood spots) and factors associated with class membership were evaluated. Results: GMM identified 3 adherence trajectories: consistently high (n = 70), moderate (n = 41), and low (n = 10). Higher text-reported adherence had higher drug concentrations. Younger age and minority race were associated with lower adherence, and individuals in classes with lower adherence had greater baseline levels of depression, substance use concerns, and sexual risk. Differences in study satisfaction were also associated with adherence. Conclusions: This study supports the use of text-reported PrEP adherence. Identifying factors associated with less-than-optimal adherence may aid clinicians in anticipating at-risk patients requiring augmented intervention. Clinical trial registration: NCT01701401. Article	2018	Patel R.R.; Chan P.A.; Harrison L.C.; Meyer K.H.; Nunn A.; Mena L.A.; Powderly W.G.	Missed opportunities to prescribe HIV pre-exposure prophylaxis by primary care providers in Saint Louis, Missouri	LGBT Health	-	23258292	10.1089/lgbt.2017.0101	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046241074&doi=10.1089%2Flgbt.2017.0101&partnerID=40&md5=e80ddbdb2d7bc75253c362bd1418767e	Purpose: Optimal HIV pre-exposure prophylaxis (PrEP) scale-up in the United States requires prescribing by primary care providers (PCPs). We assessed barriers to patients obtaining PrEP from their PCPs. Methods: Patients seeking PrEP at an Infectious Diseases (ID) Clinic in St. Louis, Missouri from 2014 to 2016 were asked about demographics, sexual behaviors, whether PrEP was initially sought from their PCP, and barriers to obtaining PrEP from their PCP. Multivariable logistic regression was performed to identify predictors for having asked a PCP for PrEP. Results: Among 102 patients, the median age was 26 years, 58% were white, and 88% were men who have sex with men. Most (65%) had a PCP and, of these, 40% had asked their PCP for PrEP, but were not prescribed it. Most half (52%) reported that PCPs had adequate knowledge of PrEP, but only 18% felt PCPs were comfortable prescribing PrEP. Patients who had asked their PCP for PrEP were 3.5 times more likely (95% CI: 1.67-7.33) and those who had been in the last 3 months were less likely to ask for PrEP from their PCPs than others (Adjusted Odds Ratio: 0.07; 95% CI: 0.01-0.53). Eighty-three percent of patients were referred to a new PCP with whom they could feel more comfortable discussing PrEP. Conclusions: During initial PrEP implementations, ID specialists can play an important role in providing education and linking PrEP patients to PCPs. However, PCPs may need additional training about PrEP and how to provide culturally sensitive sexual healthcare, if widespread scale-up is to be effective in decreasing HIV incidence. © 2018 Mary Ann Liebert, Inc.	healthcare providers; HIV prevention; implementation; pre-exposure prophylaxis (PrEP); primary care	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	Western and Central Europe and North America	Quantitative
Article	2018	Patel R.R.; Crone J.S.; López J.; Chan P.A.; Liu A.Y.; Tsoha R.; James A.S.	Pre-exposure prophylaxis for HIV prevention preferences among young adult African American men who have sex with men	PLOS One	-	19326203	10.1371/journal.pone.0209484	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059024864&doi=10.1371%2Fjournal.pone.0209484&partnerID=40&md5=804da4aeff5e7c9052017648a73dbc9d	Pre-exposure prophylaxis (PrEP) is effective in preventing HIV infections among men who have sex with men (MSM). PrEP uptake and adherence remain low and product preferences are unknown, especially among young African American MSM who are most at-risk. We conducted 24 qualitative interviews from 2014-2016 among young adult HIV-negative African American MSM regarding PrEP preferences, including pill vs. non-pill options. Most participants (n = 18) preferred daily oral pills to non-pill options. Participants described daily pills as more effective (n = 12) and more familiar (n = 6) than non-pill options. Participants also described daily oral pills as easier to use (n = 5) and more discreet (n = 4). Participants who preferred daily pills to non-pill options described their preference as a way to reduce the risk of HIV infection due to the inability to predict sex and the perception that inefficient time or medication would not achieve HIV protection with on-demand. A fear of needles and the perception that there would not be therapeutic levels for a long duration were concerns with injectable PrEP. Study findings highlight the need for a range of prevention options for African American MSM and can inform PrEP product development as well as dissemination and implementation efforts. Article	2018	Patel R.R.; Powit R.; Harrison L.C.; Powderly W.G.; Chan P.A.	Tenofovir disoproxil fumarate as pre-exposure prophylaxis for HIV prevention in women with osteoporosis: A case report and review of the literature	Antiviral Therapy	-	13596535	10.3851/IMP3208	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054107764&doi=10.3851%2FIMP3208&partnerID=40&md5=99ceba259ee814a52a0f20dcea91267	Pre-exposure prophylaxis (PrEP), using tenofovir disoproxil fumarate (TDF), can effectively prevent HIV acquisition. However, TDF can cause changes in bone mineral density (BMD). There is little information on the use of PrEP among patients with bone disease. We present a case report of a female with pre-existing osteoporosis who was prescribed PrEP. Over the course of 8 months of consistent PrEP use, verified by dried blood spot testing, we report a lack of BMD changes on serial dual-emission X-ray absorptiometry scans in this patient. This case can inform PrEP care for patients with pre-existing bone disease. ©2018 International Medical Press	NA	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2018	Patton R.M.; Beveridge K.R.; Mclendon R.; Mmeje O.	Improving PrEP Implementation Through Multilevel Interventions: A Synthesis of the Literature	AIDS and Behavior	-	10907165	10.1007/s10461-018-2184-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048601776&doi=10.1007%2Fs10461-018-2184-4&partnerID=40&md5=d7702713fc22387b1bd1f1f3e0e1f3e3	There are many challenges to accessing PrEP and then low uptake in the United States. This review (2007–2017) of PrEP implementation identified barriers to PrEP and interventions to match those barriers. The final set of articles (n = 47) included content on cognitive aspects of HIV service providers and individuals at risk for infection, reviews, and case studies. Cognitive barriers and interventions related to patients and providers included knowledge, attitudes, and beliefs about PrEP. The "pervert paradox" was identified as a key barrier. HIV specialists often do not see HIV-negative patients, while primary care providers (PCPs) do not see patients at risk for HIV. Structural barriers and interventions related to PrEP delivery, adherence, and persistence were also identified. Effective interventions to increase PrEP uptake, HIV stigma, transphobia, homophobia, and disparities across gender, racial, and ethnic groups were identified, but few interventions addressed these barriers. We recommend multilevel interventions targeting barriers at multiple socioecological domains. © 2018, The Author(s). Article	2018	Paton B.R.; Webb S.S.; Filippone P.; Choi C.J.; Wolf M.	Interprofessional collaboration and on-the-job training improve access to hiv testing, HIV primary care, and pre-exposure prophylaxis (PREP)	AIDS Education and Prevention	-	8999546	10.1521/aeap.2018.30.4.474	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060115262&doi=10.1521%2Faeap.2018.30.4.474&partnerID=40&md5=2e9a79f9d9383b721c1fdf107a2def4b	The HIV Continuum of Care is a global priority, yet vulnerable patients face access/retention challenges. Research is missing on the role social and public health service providers can play to help these patients. Using structural equation modeling, we examined the effects of interprofessional collaboration (IPC) and on-the-job training on the frequency of linkages to HIV testing, HIV primary care, and on pre-exposure prophylaxis (PrEP) psychoeducation. The sample included 285 New York City providers of social and public health services from 38 agencies. Fifty-eight percent of providers had not offered PrEP psychoeducation and linked fewer than five patients to HIV testing and primary care per week. However, in multivariate analysis higher IPC was associated with more linkages and frequent psychoeducation. After adjusting for IPC, linkage training was associated with more frequent services. The influence of specific factors highlights areas for intervention and policies to improve access to the HIV Continuum of Care. © 2018 The Guilford Press. Engaging African American young men who have sex with men in HIV prevention and care in the South: Results from the Outcomes Project	AIDS Patient Care and STDs	-	10872914	10.1089/apc.2018.0058	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051027898&doi=10.1089%2Fapc.2018.0058&partnerID=40&md5=917a7d4dbdf6ea8fe81cfd0dca854bae	To optimize scale-up of pre-exposure prophylaxis (PrEP) for pregnant women at risk of HIV in high-HIV burden settings, implementation strategies must be developed that account for perceptions of PrEP in this unique population. Semistructured focus group discussions were conducted with 68 HIV-uninfected Kenyan pregnant and postpartum women without prior PrEP knowledge or experience. A qualitative discrepancy analysis was performed, using a constant comparison approach, to identify key themes related to the values and rationale underpinning potential PrEP use in pregnancy. Median age was 29.5 years and participants were either pregnant or had 1–2 children. Almost all (96%) were married or had a steady partner. Women felt pregnancy was a time of high HIV risk because they desired sex less frequently. Although women were concerned about potential adverse effects of PrEP on their pregnancy, they felt motivated to use PrEP to protect their partners from HIV and their children from maternal HIV infection. Male partners were perceived to be the primary source of HIV risk; among women tested negatively, including borrowing physically violent, if they discovered that women used PrEP. Clinicians were identified as potential facilitators of PrEP use who could explain PrEP to male partners on behalf of pregnant women. Women said that community-level stigma against HIV and potential for conflating PrEP with antiretroviral therapy (ART) would necessitate that PrEP not be discreet. Our results indicate the importance of addressing risk perception of women, concerns of male partners, HIV stigma, and benefits of PrEP for HIV prevention as programs are developed for pregnant women. © 2018, Mary Ann Liebert, Inc., publishers. Article	2018	Patel, Rena C; Leddy, Anna M; Odoyo, Josephine; Anand, Keerthana; Stanford-Moore, Gaelen; Walchungo, Imeldah; Bukusi, Elizabeth A; Baeten, Jared M; Brown, Joelle M	What motivates serodiscordant couples to prevent HIV transmission within their relationships: findings from a PrEP implementation study in Kenya	Culture, Health & Sexuality	-	13691058	10.1080/13691058.2017.1367421	https://www.proquest.com/scholarly-journals/what-motivates-serodiscordant-couples-prevent-hiv/docview/2055146113/se-2?accountid=9113	With the planned scale-up of pre-exposure prophylaxis (PrEP) for HIV prevention among serodiscordant couples in resource-limited settings, gaining an understanding of what motivates serodiscordant couples to prevent HIV is critical. We conducted 44 semi-structured, in-depth individual or couple interviews with 63 participants (13 HIV-infected and 30 HIV-uninfected participants) enrolled in a prospective implementation study of oral antiretroviral-based prevention in Kisumu, Kenya. Transcripts were iteratively analysed using inductive content analysis. Findings point to the importance of understanding the emotional and economic stability of the partnership and family as motivators in preventing HIV transmission. Female participants identified fear of blame or potential violence for transmitting HIV as a motivator for consistent condom use, while male participants emphasized the importance of HIV testing and knowledge of their partner's HIV status as motivators for PrEP use and condom use. These themes and motivations transcend gender norms but also reveal how gender interdependence challenges these norms. As programmes in resource-limited settings scale up PrEP delivery, they should simultaneously capitalize on HIV serodiscordant couples' motivations for HIV prevention and address gender norms so women do not feel themselves unduly responsible for the prevention of HIV transmission. Article	2018	Patel, Rupa R; Luke, Douglas A; Proctor, Enola K; Powderly, William G; Chan, Philip A; Meyer, Kenneth H; Harrison, Laura C; Dhand, Amar	Sex Versus Based Network Analysis to Identify HIV Prevention Dissemination Targets for Men Who Have Sex with Men	LGBT Health	-	23258292	10.1089/lgbt.2017.0018	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048589164&doi=10.1089%2Flgbt.2017.0018&partnerID=40&md5=4bbdbe57aeb61ca19b1a6f65c4c45ae0	Purpose: The aim of this study was to identify sex versus-based networks among men who have sex with men (MSM) to inform HIV preexposure prophylaxis (PrEP) dissemination efforts. Methods: Using a cross-sectional sample, we interviewed MSM about the network material from whom they received sex and/or drugs in exchange for condom use and sex. We constructed network structure, central venues, and network subgroups. Results: Among 40 participants, the median age was 27 years, 49% were Black and 80% reported condomless anal sex (nAS). Analysis revealed a map of 34 virtual and physical venues with an overlap in the nAS and with condom anal sex (AS) venues. In the nAS network, virtual and physical locations were more dominant. The nAS venues reported by Blacks were more diffusely organized than those reported by Whites. Conclusion: The network structures of sex venues for at-risk MSM differed by race. Network information can enhance HIV prevention dissemination efforts among subpopulations, including PrEP implementation. © Copyright 2018, Mary Ann Liebert, Inc.	dissemination; implementation; men who have sex withmen; network analysis; preexposure prophylaxis for HIV; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative

It's just an excuse to slut around': gay and bisexual mens' constructions of HIV pre-exposure prophylaxis (PrEP) as a social problem	Sociology of Health and Illness	-	1418989	10.1111/1467-9566.12765	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051137850&doi=10.1111%2F1467-9566.12765&partnerID=40&md5=ecb1562ca1745d7f86a259911e96e0	Since the 2012 FDA approval of HIV pre-exposure Prophylaxis (PrEP) as a method to prevent HIV, its uptake among gay and bisexual men has been met with conflict. Drawing on discussions of PrEP from focus groups with gay and bisexual men in New York City (N = 5 groups, n = 32 participants), we sought to make meaning of the moral debates surrounding PrEP and its associated medications. Grounded in the constructionist perspective on social problems, this case study focuses on the competing claims making activities gay and bisected men engage in when framing PrEP and PrEP users. As HIV prevention is a communicative endeavour, analysing the micro level problems work on PrEP provides key insight into the subcultural norms and values that shape sexual health practices and beliefs within gay and bisexual communities. © 2018 Foundation for the Sociology of Health & Illness	drugs/medication; HIV; sexual health; sexuality; social constructionism; stigma	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Essay	2018	Pyster, Ian	PrEP: the advent of pre-exposure prophylaxis	British Journal of Healthcare Assistants	-	1753-1586	10.12968/bjha.2018.12.12.602	https://www.proquest.com/scholarly-journals/prep-advent-pre-exposure-prophylaxis/docview/2195296425/se-2?accountid=9113	In 2015, the World Health Organisation (WHO) released a series of recommendations supporting the use of tenofovir-containing drugs as pre-exposure prophylaxis (PrEP) to prevent the acquisition of HIV (WHO, 2015). But the Food and Drug Administration (FDA) in the US had already approved oral PrEP in 2012 and after this approval, other countries followed suit, whereas the PrEP in Scotland is not accessible. In England, PrEP is being made available in 13 000 people as part of the Impact trial, which started in September 2017. Since July 2017, PrEP has been rolled out across Scotland. A three-year pilot began in Wales in July 2017, but is open to all Welsh residents through genitourinary medicine (GUM) clinics, with no cap on the number of people who can access it. All GUM clinics in Northern Ireland will be offering initial consultation and assessment appointments based at a centralised service in Belfast. Article	2018	Pyra P.; Su S.; Farley C.K.; Chu M.; Jang S.; Zhuang X.; Zhang L.	A Global Estimate of the Acceptability of Pre-exposure Prophylaxis for HIV Among Men Who Have Sex with Men: A Systematic Review and Meta-analysis	AIDS and Behavior	-	10907165	10.1007/s10461-017-1675-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85018940678&doi=10.1007%2Fs10461-017-1675-x&partnerID=40&md5=a7810fa57e4ba90a350911f8b1b5be582c	Understanding how women use PrEP is important for developing successful implementation programs. We hypothesized there are distinct patterns of adherence, related to HIV risk and other factors. We identified patterns of PrEP adherence and HIV risk behavior over the first 6 months of PrEP use, using data from 213 HIV-uninfected women in high-risk serodiscordant couples in a demonstration project in Kisumu, Kenya. Using data from electronic PrEP dosing monitors, we identified three adherence patterns: consistent (29%), inconsistent (57%), and declining (14%). Multivariable predictors of adherence patterns. There were four distinct adherence patterns: high steady adherence (35% of population), moderate steady (29%), low declining (9%), and early declining (9%). Sociodemographic characteristics significantly differed between adherence patterns. Adherence patterns differed in average weekly doses (6.7 vs 5.4 vs 4.1 vs 1.5, respectively). Two risk behavior groups were identified: steady HIV risk (78% of population) and declining (22%). Compared to women with declining HIV risk behavior, women with steady risk behavior were more likely to have high steady adherence (61% vs 35%) and less likely to have early (6% vs 17%) or late (4% vs 10%) declining adherence. Women's use of PrEP was associated with concurrent HIV risk behavior; higher risk was associated with higher, sustained adherence. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Pyra M.; Haberer J.E.; Heffron R.; Kidogaschi L.; Brown E.R.; Bukusi E.A.; Asiimwe S.; Celum C.; Katabira E.; Mugo N.R.; Baeten J.M.	Patterns of Oral PrEP Adherence and HIV Risk Among Eastern African Women in HIV Serodiscordant Partnerships	AIDS and Behavior	-	10907165	10.1007/s10461-018-2221-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049475084&doi=10.1007%2Fs10461-018-2221-3&partnerID=40&md5=e7b4d2e89c981000a926c4c7ae6e089	Background: Pre-exposure prophylaxis (PrEP) is efficacious for African women at risk for HIV, but data on adherence outside clinical trials are sparse. We describe the persistence and excretion of PrEP use among women participating in a large open-label PrEP demonstration project, particularly during periods of HIV risk. Setting and Methods: Three hundred ten HIV-uninfected women in HIV serodiscordant couples in Kenya and Uganda were offered and accepted PrEP. Electronic monitoring caps were used to measure daily PrEP adherence. Time on PrEP while at risk for HIV (when the HIV-infected partner was on antiretroviral therapy < 6 months) and weekly adherence while on PrEP were calculated and compared among older and younger (< 25 years old) women. Results: As desired above, women were at risk for HIV for 1.0 years (IQR = 0.5–1.5) while on PrEP. Adherence was high (median = 83%, IQR = 57–96%) and persistent (median = 1.0 years, IQR = 0.5–1.5). Fewer than 4 weeks 67% of weeks for women aged < 25 years, 89% of weeks for women aged ≥ 25 years ($P < 0.001$), and ≥ 4 doses for 68% of weeks 89% for those ≥25, 95% for those ≥ 25 ($P < 0.001$). Compared with historical, risk-matched controls, HIV incidence was reduced 93% (95% confidence interval: 77% to 98%) for all women and 91% (95% confidence interval: 29% to 99%) among women aged < 25 years. Conclusions: Women, including young women, in HIV serodiscordant couples took PrEP successfully over sustained periods of risk. Although young women had lower adherence than older women, they achieved strong protection, which suggests that women can align PrEP use to periods of risk and imperfect adherence can still provide substantial benefit. Article	2018	Pyra M.; Haberer J.E.; Heffron R.; Kidogaschi L.; Brown E.R.; Bukusi E.A.; Asiimwe S.; Celum C.; Katabira E.; Mugo N.R.; Baeten J.M.	PrEP Use During Periods of HIV Risk Among East African Women in Serodiscordant Relationships	Journal of Acquired Immune Deficiency Syndromes	-	15254135	10.1097/QAI.0000000000001561	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038336458&doi=10.1097%2FQAI.0000000000001561&partnerID=40&md5=c787c6d063456f5b9d3654a045ea555b	Background: Pre-exposure prophylaxis (PrEP) is efficacious for African women at risk for HIV, but data on adherence outside clinical trials are sparse. We describe the persistence and excretion of PrEP use among women participating in a large open-label PrEP demonstration project, particularly during periods of HIV risk. Setting and Methods: Three hundred ten HIV-uninfected women in HIV serodiscordant couples in Kenya and Uganda were offered and accepted PrEP. Electronic monitoring caps were used to measure daily PrEP adherence. Time on PrEP while at risk for HIV (when the HIV-infected partner was on antiretroviral therapy < 6 months) and weekly adherence while on PrEP were calculated and compared among older and younger (< 25 years old) women. Results: As desired above, women were at risk for HIV for 1.0 years (IQR = 0.5–1.5) while on PrEP. Adherence was high (median = 83%, IQR = 57–96%) and persistent (median = 1.0 years, IQR = 0.5–1.5). Fewer than 4 weeks 67% of weeks for women aged < 25 years, 89% of weeks for women aged ≥ 25 years ($P < 0.001$), and ≥ 4 doses for 68% of weeks 89% for those ≥25, 95% for those ≥ 25 ($P < 0.001$). Compared with historical, risk-matched controls, HIV incidence was reduced 93% (95% confidence interval: 77% to 98%) for all women and 91% (95% confidence interval: 29% to 99%) among women aged < 25 years. Conclusions: Women, including young women, in HIV serodiscordant couples took PrEP successfully over sustained periods of risk. Although young women had lower adherence than older women, they achieved strong protection, which suggests that women can align PrEP use to periods of risk and imperfect adherence can still provide substantial benefit. Article	2018	Qu D.; Zhong X.; Xiao G.; Dai J.; Lang H.; Huang A.	Adherence to pre-exposure prophylaxis among men who have sex with men: A prospective cohort study	International Journal of Infectious Diseases	-	-	12019712	10.1016/j.ijid.2018.08.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053052280&doi=10.1016%2Fj.ijid.2018.08.006&partnerID=40&md5=86e00f0b1162903c960d21181ccce1f0	Objective: To evaluate adherence to pre-exposure prophylaxis (PrEP) in a clinical trial of a population of men who have sex with men (MSM), to explore the influence of social psychology and objective factors (e.g., forgetting, too busy) on adherence, and to provide evidence for subsequent PrEP research. Methods: This study analyzed the data from the daily medication group within a PrEP study (a randomized placebo-controlled trial of oral tenofovir among MSM in Western China from April 2013 to March 2015). A total of 321 participants were analyzed. PrEP adherence was self-reported by the subjects at every 1-month follow-up visit for 24 months. AIDS-related information including HIV prevention, transmission, and treatment knowledge, as well as PrEP-related motivation (including perceived social motivation) and behavior skills, i.e., self-efficacy, were collected using questionnaires. The objective reasons for non-adherence were collected during face-to-face follow-up visits every 3 months after the participants reported non-adherence. Results: The mean age of the participants was 23.6 ± 3.2 years, and 94.7% were single. The generalized estimating equation (GEE) model was used to evaluate the IMB model. Results: The median adherence rate was 64.29%. During the follow-up period, the percentage of high adherence (≥80%) was 32.23%, intermediate adherence (adherence 40–80%) was 38.97%, and low adherence (adherence ≤40%) was 28.78%. The final IMB model showed that there was no significant correlation between adherence to PrEP and the psychological constructs: information, motivation, and behavior skills. The main objective reasons for non-adherence were 'forgetting to take medicine' (78.21%), 'too busy' (29.06%), 'worrying about side effects' (20.01%), and 'too much trouble' (18.44%). Conclusions: This study found no association between PrEP adherence and social psychological factors, and the main objective factor in non-adherence was forgetting to take the medicine. In the future, the MSM population could be reminded to take their medicine regularly using electronic devices, which may improve PrEP adherence to some extent and may further reduce the incidence of HIV. The strategy to improve PrEP adherence requires further study. © 2018 The Authors	Information motivation behavior skills model; Medication compliance; Men who have sex with men; Pre-exposure prophylaxis; Structure equation model	English	Netherlands	Western and Central Europe and North America	China	Asia and the Pacific	NA	NA	Clinical
Article	2018	Quade M.; Vickerman P.; Maman S.; Eakle R.; Cabrera-Escobar M.A.; Delany-Moretlwe S.; Terris-Prestholt F.	The effect of HIV prevention products on incentives to supply condomless commercial sex among female sex workers in South Africa	Health Economics	-	-	10579230	10.1002/hec.3784	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052735768&doi=10.1002%2Fhec.3784&partnerID=40&md5=540c6ea29c7da3705e5a2b286276	Evidence suggests that economic factors play an important role in commercial sex work, in particular that condomless sex commands a price premium relative to condom-protected sex. This paper explores how the introduction of HIV prevention products may affect the price premium for condomless sex and the number of condomless commercial sex acts supplied. Data from a discrete choice experiment collected stated preference data from 122 HIV-negative female sex workers in urban South Africa, using a repeated choice experiment to simulate the impact of using PrEP on choices. Results suggest that the price premium for condomless sex would decrease by 73% with PrEP use and the quantity of condomless sex is predicted to decrease by a factor of 2.27. Art price does not significantly affect choices without protection but strongly influences choices under full HIV protection. The utility offered by condoms reduces by around 15% under PrEP use. Because new HIV prevention products do not protect against other STIs or pregnancy, the unintended consequences of introducing HIV prevention products should be closely monitored, whereas users should not face stigma or blame for reacting rationally to exogenous changes to market conditions. © 2018 The Authors. Article	2018	Quaife, Matthew; Terris-Prestholt, Fern; Eakle, Robyn; Cabrera Escobar, Maria A; Kilbourne-Brook, Maggie; Mvundura, Mercy; Meyer-Rath, Gesine; Delany-Moretlwe, Sinead; Vickerman, Peter	The cost-effectiveness of multi-purpose HIV and pregnancy prevention technologies in South Africa.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25064	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5851344	INTRODUCTION: A number of antiretroviral HIV prevention products are efficacious in preventing HIV infection. However, the sexual and reproductive health needs of many women extend beyond HIV prevention, and research is ongoing to develop multi-purpose prevention technologies (MPTs) that offer dual HIV and pregnancy protection. We do not yet know if these products will be an efficient use of constrained health resources. In this paper, we estimate the cost-effectiveness of combinations of candidate multi-purpose prevention technologies (MPTs), in South Africa among general population women and female sex workers (FSWs). METHODS: We combined a cost model with a static model of product impact based on incidence data in South Africa to estimate the cost-effectiveness of five candidate co-formulated or co-provided MPTs: oral PrEP, intravaginal ring, injectable ARV, microbicide gel and SILCS diaphragm used in concert with gel. We accounted for the preferences of end-users by predicting uptake using a discrete choice experiment (DCE). Product availability and protection were systematically varied in five potential rollout scenarios. The impact model estimated the number of infections averted through decreased incidence due to product use over one year. The comparator for each scenario was current levels of male condom use, while a health system perspective was used to estimate discounted lifetime treatment costs averted per HIV infection. Product benefit was estimated in disability-adjusted life years (DALYs) averted. Benefits from contraception were incorporated through adjusting the uptake of these products based on the DCE and through estimating the costs averted from avoiding unwanted pregnancies. We explore the additional impact of STI protection through increased uptake in a sensitivity analysis. RESULTS: At central incidence rates, all single- and multi-purpose scenarios modelled were cost-effective among FSWs and women aged 16-24, at a governmental willingness-to-pay threshold of $1175/DALY averted (range: $214-$810/DALY averted among non-dominant scenarios), however, none were cost-effective among women aged 25-49 (minimum $1706/DALY averted). The cost-effectiveness of products improved with additional protection from pregnancy. Estimates were sensitive to variation in incidence assumptions, but robust to other parameters. CONCLUSIONS: To the best of our knowledge, this is the first study to estimate the cost-effectiveness of a range of potential MPTs; suggesting that MPTs will be cost-effective among higher incidence FSWs or young women, but not among lower incidence older women. More work is needed to make attractive MPTs available to potential users who could use them effectively. Article	2018	Queiroz A.A.F.L.N.; Sousa ÁF.L.; Matos M.C.B.; Araújo T.M.E.; Reis R.K.; Moura M.E.B.	Conhecimento sobre HIV/aids e implicações no estabelecimento de parcerias entre usuários do Hornet®	Revista Brasileira de Enfermagem	-	-	-	-	347167	10.1590/0034-7167-2017-0409	https://www.scielo.br/j/reben/a/PyBqZpdh7gDkCGyp8XFr8Tf/?lang=pt	Objetivo: avaliar o conhecimento de homens que fazem sexo com homens usuários de aplicativo de encontro baseado em geolocalização, sobre o HIV/aids e implicações no estabelecimento de parcerias. Método: estudo descritivo, com 30 usuários do Hornet®. Os depoimentos gerados tiveram tratamento estatístico no software IRaMuTeQ, analisados pela Classificação Hierárquica Descendente. Resultados: A frequência sexual nos últimos 30 dias foi de 2,9 parceiros, sendo 2,1 conhecidos pelo aplicativo, dos quais 63,3% relataram sexo sem camisinha. Obtiveram-se quatro classes: Conhecimento sobre medidas de prevenção do HIV/aids; PrEP/truvada como medida de prevenção do HIV/aids; Comportamentos vulneráveis em relação à infecção pelo HIV; Estabelecimento de parcerias sexuais pelos aplicativos. Conclusão: Usuários do Hornet® possuem conhecimento insuficiente sobre medidas de prevenção do HIV, principalmente quando se descarta o preservativo masculino. As relações estabelecidas pelo aplicativo são permeadas por alta vulnerabilidade individual e comportamentos que têm potencial de exposição ao risco de infecção pelo HIV. Article	2018	Raifman J.; Nunn A.; Oldenburg C.E.; Montgomery M.C.; Almonte A.; Agwu A.L.; Arrington-Sanders R.; Chan P.A.	An Evaluation of a Clinical Pre-Exposure Prophylaxis Education Intervention among Men Who Have Sex with Men	Health Services Research	-	-	-	-	179124	10.1111/1475-6773.12746	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85026418873&doi=10.1111%2f1475-6773.12746&partnerID=40&md5=debadc4131e92b96464849ed34d1d642	Objective: To evaluate the impact of an HIV pre-exposure prophylaxis (PrEP) education intervention on PrEP awareness and use among men who have sex with men (MSM) attending a sexually transmitted diseases (STD) clinic. Data Sources/Study Setting: Men who have sex with men STD clinic patients. Study Design: We estimated a difference-in-differences linear regression model, comparing MSM whose first visit to the clinic was before ("control") or after ("treatment") intervention implementation and controlling for patient. Data Collection/Extraction: We used self-reported data on PrEP awareness and use from STD clinic intake forms. Principal Findings: Pre-exposure prophylaxis awareness between first and second clinic visits increased 27.2 percentage points (pp) in the treatment group, relative to 13.7 pp in the control group. Similarly, PrEP use increased 7.1 pp in the treatment group versus 2.4 pp in the control group. Based on adjusted estimates, the PrEP intervention increased PrEP awareness by 24 pp (p <.01) and PrEP use by 5 pp (p =.01), increases of 63 percent and 159 percent relative to the 6 months prior to the intervention. Conclusion: A brief, scalable STD clinic PrEP education intervention led to significantly increased PrEP awareness and use among MSM. Health care providers should consider implementing brief PrEP education interventions in sexual health care settings. © Health Research and Educational Trust	health education; Human immunodeficiency virus; intervention; PrEP; prevention	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2018	Rana, Jayoti; Wilton, James; Fowler, Shawn; Hart, Trevor A; Bayoumi, Ahmed M; Tan, Darrell H S	Trends in the awareness, acceptability, and usage of HIV pre-exposure prophylaxis among at-risk men who have sex with men in Toronto	Canadian Journal of Public Health	-	-	-	-	84263	10.17269/s41997-018-0064-3	https://www.proquest.com/scholarly-journals/trends-awareness-acceptability-usage-hiv-pre/docview/2255738456/se-2?accountid=8113	ObjectivesPre-exposure prophylaxis (PrEP) with daily oral tenofovir/emtricitabine dramatically reduces HIV risk in men who have sex with men (MSM). However, uptake is slow worldwide.MethodsWe administered anonymous cross-sectional questionnaires to MSM presenting for anonymous HIV testing at a Toronto sexual health clinic at four successive time points during the period 2013–2016. We assessed trends in PrEP awareness, acceptability, and use over time using the Cochran-Armitage Trend Test, and identified barriers to using PrEP by constructing "PrEP cascades" using 2016 data. We assumed that to use PrEP, MSM must (a) be at risk for HIV, (b) be at objectively high risk (HIRI-MSM score ≥ 10), (c) perceive themselves to be at medium-to-high risk, (d) be aware of PrEP, (e) be willing to use PrEP, (f) have a family doctor, (g) be comfortable discussing sexual health with that doctor, and (h) have drug coverage/be willing to pay out of pocket.ResultsMSM participants were mostly white (54–59.5%), with median age 31 years (IQR = 26–38). PrEP awareness and use increased significantly over time (both p < 0.0001), reaching 91.3% and 5.0%, respectively, in the most recent wave. Willingness to use PrEP rose to 56.5%, but this increase did not reach statistical significance (p = 0.06). The full cascade, ABCDEFGH, suggested few could readily use PrEP under current conditions (11/400 = 2.8%). The largest barriers, in descending order, were low self-perceived HIV risk, unwillingness to use PrEP, and access to PrEP providers.ConclusionTo maximize its potential public health benefits, PrEP scale-up strategies must address self-perceived HIV risk and increase access to PrEP providers.Resumo alternativo:ObjectifsLa prise quotidienne de ténofovir et d'emtricitabine à titre de prophylaxie pré-exposition (PPrE) orale réduit considérablement le risque de contracter le VIH chez les hommes ayant des relations sexuelles avec des hommes (HARSAH). L'adoption de cette PPrE à l'échelle mondiale est toutefois lente.MéthodeNous avons fait passer des questionnaires transversaux anonymes à des HARSAH s'étant présentés pour un dépistage anonyme du VIH dans une clinique de santé sexuelle de Toronto à quatre moments consécutifs entre 2013 et 2016. Nous avons évalué les tendances liées à la connaissance, à l'acceptabilité et à l'utilisation de la PPrE au fil du temps à l'aide du test de tendance de Cochran-Armitage et déterminé les obstacles à l'utilisation de la PPrE en construisant des « cascades de PPrE » avec les données de 2016. Nous avons présumé que pour utiliser la PPrE, les HARSAH doivent: (a) être à risque de contracter le VIH, (b) courir un risque objectivement élevé (note ≥ 10 sur l'échelle HIRI-MSM), (c) se percevoir comme courant un risque moyen à élevé, (d) connaître la PPrE, (e) être disposés à utiliser la PPrE, (f) avoir un médecin de famille, (g) être à l'aise de parler de santé sexuelle avec ce médecin, et (h) avoir une assurance-médicaments ou être disposés à défrayer le coût des médicaments.RésultatsLes HARSAH participants étaient en majorité de race blanche (54% à 59,5%) et avaient un âge médian de 31 ans (écart interquartile 26–38). Leur connaissance et leur utilisation de la PPrE a sensiblement augmenté au fil du temps (p < 0,0001 dans les deux cas), pour atteindre 91,3% et 5% respectivement au cours du cycle le plus récent. Leur volonté d'utiliser la PPrE est passée à 56,5%, mais cette hausse n'était pas statistiquement significative (p = 0,06). La cascade complète, ABCDEFGH, montre que peu d'entre eux pouvaient facilement utiliser la PPrE dans leur situation actuelle (11/400 = 2,8%). Les plus grands obstacles, en ordre descendant, étaient le faible risque autoperçu de contracter le VIH, la réticence à utiliser la PPrE et le manque d'accès aux dispensateurs de la PPrE.ConclusionPour en maximiser les bienfaits éventuels pour la santé publique, les stratégies de mise à l'échelle de la PPrE doivent tenir compte de l'autoperception du risque de contracter le VIH et élargir l'accès aux dispensateurs de la PPrE. Article	2018	Ransome Y.; Bogart L.M.; Nunn A.S.; Mayer K.H.; Sadler K.R.; Ojikutu B.O.	Faith leaders' messaging is essential to enhance HIV prevention among black Americans: Results from the 2016 National Survey on HIV in the black community (NSHBC).	BMC Public Health	-	-	-	-	14712458	10.1186/s12889-018-6301-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058875109&doi=10.1186%2fs12889-018-6301-0&partnerID=40&md5=bd82ae189079dd195abf878473188305	Background: To investigate whether religious service attendance and faith leaders' messages about HIV and same-sex relationships are associated with acceptance of HIV prevention strategies. Methods: Multivariable Poisson regression assessed whether attending religious services, faith leaders' messages about HIV and same-sex relationships, and supportiveness of those messages were associated with HIV testing, as well as knowledge of and willingness to use pre-exposure prophylaxis (PrEP) among 868 Black Americans 45% men; M (SD) = 34 (9) years-old in the 2016 National Survey on HIV in the Black Community, USA. Results: Participants who reported attending services weekly and/or hearing faith leaders' messages that were supportive of same-sex relationships had a significantly higher likelihood of willingness to use PrEP (adjusted Rate RatioARR = 1.76; 95% confidence interval CI = 1.09, 2.48) and aRR = 2.19; 95% CI = 1.35, 3.55, respectively), independent of HIV risk. Homophobia was significantly associated with higher likelihood of being aware of PrEP and testing for HIV testing in the past 12 months. Conclusions: Faith leaders' messaging can influence Black Americans' perceptions and uptake of HIV prevention strategies. Faith institutions and faith leaders should be involved in designing and disseminating HIV prevention strategies. © 2018 The Author(s). Article	2018	Reed J.B.; Patel R.R.; Baggaley R.	Lessons from a decade of voluntary medical male circumcision implementation and their application to HIV pre-exposure prophylaxis scale up	International journal of STD & AIDS	-	-	-	-	9564624	10.1177/0956462418787896	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052606940&doi=10.1177%2f0956462418787896&partnerID=40&md5=8ed54438787daef8add408b91a338b5d	Oral pre-exposure prophylaxis (PrEP) has the ability to curb HIV incidence worldwide and bring us closer to ending the HIV epidemic. Scale up of PrEP service delivery has many similar challenges to those faced by voluntary medical male circumcision (VMMC) services roll-out. This article outlines ten important lessons learned during the scale up of VMMC services in sub-Saharan Africa and their application to current oral PrEP implementation efforts to promote faster expansion for public health impact. © The Author(s) 2018.	90–90–90 targets; antiretrovirals; HIV prevention; implementation; Male circumcision; oral PrEP	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Quantitative
Article	2018	Reidy M.; Gardiner E.; Pretorius C.; Glaubius R.; Torjesen K.; Kripke K.	Evaluating the potential impact and cost-effectiveness of dapivirine vaginal ring pre-exposure prophylaxis for HIV prevention	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0218710	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068897129&doi=10.1371%2fjournal.pone.0218710&partnerID=40&md5=e8c0004d005453d2375345949806e5a2	Background Expanded HIV prevention options are needed to increase uptake of HIV prevention among women, especially in generalized epidemics. As the dapivirine vaginal ring moves forward through regulatory review and open-label extension studies, the potential public health impact and cost-effectiveness of this new prevention method are not fully known. We used mathematical modeling to explore the impact and cost-effectiveness of the ring in different implementation scenarios alongside scale-up of other HIV prevention interventions. Given the knowledge gaps about key factors influencing the ring's implementation, including potential uptake and delivery costs, we engaged in a stakeholder consultation process to elicit plausible parameter ranges and explored scenarios to identify the possible range of impact, cost, and cost-effectiveness. Methods and findings We used the Goals model to simulate scenarios of oral and ring pre-exposure prophylaxis (PrEP) implementation among female sex workers and among other women 21 years or >21 years with multiple male partners, in Kenya, South Africa, Uganda, and Zimbabwe. In these scenarios, we varied antiretroviral therapy (ART) coverage, dapivirine ring coverage and ring effectiveness (encompassing efficacy and adherence) by risk group. Following discussions with stakeholders, the maximum level of PrEP coverage (oral and/or ring) considered in each country was equal to modern contraception use minus condom use in the two age groups. We assessed results for 18 years, from 2018 to 2035. In South Africa, for example, the HIV infections averted by PrEP (ring plus oral PrEP) ranged from 310,000 under the highest-impact scenario (including ART held constant at 2017 levels, high ring coverage, and 85% ring effectiveness) to 55,000 under the lowest-impact scenario (including ART reaching the UNAIDS 90-90-90 targets by 2020, low ring coverage, and 30% ring effectiveness). This represented a range of 6.4% to 2.2% of new HIV infections averted. Given our assumptions, the addition of the ring results in 11% to 132% more impact than oral PrEP alone. The cost per HIV infection averted for the ring ranged from US$13,000 to US$121,000. Conclusions This analysis offers a wide range of scenarios given the considerable uncertainty over ring uptake, consistency of use, and effectiveness, as well as HIV testing, prevention, and treatment use over the next two decades. This could help inform donors and implementers as they decide where to allocate resources in order to maximize the impact of the dapivirine ring in light of funding and implementation constraints. Better understanding of the cost and potential uptake of the intervention would improve our ability to estimate its cost-effectiveness and assess where it can have the most impact. © 2019 Reidy et al. Article	2018	Rendina H.J.; Parsons J.T.	Factors associated with perceived accuracy of the Undetectable = Untransmittable slogan among men who have sex with men: Implications for messaging scale-up and implementation: Implications	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25055	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85041375072&doi=10.1002%2fjia2.25055&partnerID=40&md5=f8315b39b17a6f1da0e7ebc3d6387ae9	Introduction: Recent research has shown high efficacy of HIV treatment for reducing the risk of HIV transmission to sexual partners. As the efficacy of treatment as prevention (TasP) has proliferated, a new messaging campaign, Undetectable = Untransmittable, has been gaining popularity. The purpose of this paper was to assess factors associated with the perceived accuracy of this TasP messaging strategy among a large and diverse sample of gay, bisexual, and other men who have sex with men (GBMSM) in order to inform subsequent efforts at large-scale and implementation of the HIV prevention message. Methods: We conducted a nationwide survey of GBMSM in the U.S. recruited from an online social networking site and a mobile sexual networking app. We analysed data from 12,222 GBMSM separately by HIV status to examine sociodemographic and behavioural factors associated with ratings of the accuracy of the Undetectable = Untransmittable message, which included the option to indicate not understanding what "undetectable" meant. Results: Among HIV-negative and unknown men, multivariable linear regression indicated that being on pre-exposure prophylaxis (PrEP), identifying as gay or queer (versus bisexual or straight), recent serodiscordant condomless anal sex (CAS), testing every six months or more often, less concern about sexually transmitted infection (STI) infection, and lower perceived risk of HIV infection were the factors with the largest independent effect on rating the Undetectable = Untransmittable statement as more accurate. Fewer factors emerged as associated with accuracy ratings among HIV-positive participants - reporting an undetectable viral load, a lifetime acquired immune deficiency syndrome (AIDS) diagnosis, and lower concern about STI infection were the factors most strongly associated with rating the statement as more accurate. Conclusions: The findings of the current study highlight variability in the perceived accuracy of the Undetectable = Untransmittable message, suggesting potential subgroups who might benefit from targeted educational campaigns, perhaps broadcast utilizing sexual networking apps. Numerous factors, particularly among HIV-negative and unknown GBMSM, were associated with rating the message as more accurate. In particular, being on PrEP and testing regularly were two of the variables most strongly associated with higher accuracy ratings among HIV-negative GBMSM, suggesting HIV prevention services as potential points of intervention for increasing HIV knowledge and decreasing HIV stigma. © 2018 The Authors. Article	2018	Restar A.J.; Kuhns L.; Reisner S.L.; Ogunbajo A.; Garofalo R.; Mimiaga M.J.	Acceptability of Antiretroviral Pre-exposure Prophylaxis from a Cohort of Sexually Experienced Young Transgender Women in Two U.S. Cities	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2127-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055623564&doi=10.1007%2fs10461-018-2127-0&partnerID=40&md5=be057f468ea590af3f3816c70d2f7131	Emtricitabine/tenofovir disoproxil fumarate as pre-exposure prophylaxis (PrEP) can prevent HIV infection among at-risk individuals, including young transgender women (YTW). We used baseline data from 230 HIV-uninfected YTW (ages 16–29 years) who were enrolled in Project LifeSkills during 2012–2015. We examined factors associated with perceived acceptability of PrEP use (mean score = 23.4, range 10.0–30.0). Participants were largely transgender women of color (67%) and had a mean age of 23 years (SD = 3.5). In an adjusted multiple linear regression model, PrEP interest (β = 3.7, 95% CI 2.2–5.2) and having a medical provider who meets their health needs (β = 2.9, 95% CI 1.3–4.4) was associated with higher PrEP acceptability scores, whereas younger age (21–25 vs 26–29 years) (β = −2.0, 95% CI − 3.6 to − 0.4) and reporting transactional sex in the past 4 months (β = − 1.5, 95% CI − 3.0 to − 0.1) was associated with lower PrEP acceptability scores (all p values < 0.05). Enhancing PrEP-related interventions by addressing the unique barriers to uptake among YTW of younger age or those with history of transactional sex could bolster PrEP acceptability for this population. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Revill, Paul; Dwyer, Ellen	Pre-exposure prophylaxis is cost-effective for HIV in the UK.	The Lancet Infectious Diseases	-	-	-	-	1474-4457	10.1016/S1473-3099(17)30594-7	https://www.thelancet.com/journals/laninf/article/PIIS1473-3099(17)30594-7/abstract	At the International AIDS Society (IAS) conference in Paris, France, in July, 2017, new data were presented showing a large reduction in HIV diagnoses in the UK's largest sexual health clinic. 56 Dean Street in Soho (London, UK) saw a 42% drop in new diagnoses between 2015 and 2016. Similarly promising findings were reported in studies of clinics in France and Australia. This reduction is likely to be due to increased testing, earlier diagnosis, and immediate initiation onto HIV treatment at diagnosis, as well as increased availability of pre-exposure prophylaxis (PrEP) for HIV. Article	2018	Reyes-Urueña, J; Campbell, C; Diez, E; Ortún, V; Casabona, J	Can we afford to offer pre-exposure prophylaxis to MSM in Catalonia? Cost-effectiveness analysis and budget impact assessment	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2017.1417528	https://www.proquest.com/scholarly-journals/can-we-afford-offer-pre-exposure-prophylaxis-msm/docview/2024041445/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) effectiveness has been well established. This study aims to assess the cost-effectiveness of providing PrEP, estimate the number of eligible MSM, and its budget impact in Catalonia. Cost-effectiveness analysis compared costs of on daily basis and "on demand" PrEP to prevent one infection with lifetime costs of one HIV infection. We estimated the total cost of providing PrEP by estimating number of eligible MSM, and included in the budget impact assessment antiretroviral and laboratory costs. Costs were lower for the on-demand PrEP group by Euro64015.1 and the incremental benefit was nearly 15 life-years and 17 quality-adjusted life-years gained. The incremental cost-effectiveness ratio (ICER) was cost-effective at Euro6281.62 when undiscounted PrEP was given daily. On-demand PrEP can be considered cost-saving in 20 years if the price is reduced by 90%. The number of eligible MSM in Catalonia ranges from 5,989 to 10,972. At current antiretroviral costs, the annual cost would range between Euro25.3-46.7 million/year (on demand PrEP), and Euro42.9-78.7 million/year (daily basis PrEP). PrEP is most cost-effective if targeted towards groups with high incidence rates of over 3%/year. Beneficial ICER depends on reducing the current price of Truvada® and ensuring that effectiveness is maintained at high levels. Article	2018	Reyniers T.; Nöstlinger C.; Laga M.; De Baetselier I.; Crucitti T.; Wouters K.; Smekens B.; Buyze J.; Vuylsteke B.	Choosing between daily and event-driven pre-exposure prophylaxis: Results of a Belgian PrEP demonstration project	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001791	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056119133&doi=10.1097%2fQAI.0000000000001791&partnerID=40&md5=9fc92a1b54c1cc55f568d1f04f6fdeff	Background: Daily pre-exposure prophylaxis and event-driven pre-exposure prophylaxis (PrEP) are efficacious in reducing HIV transmission among men who have sex with men (MSM). We analyzed baseline data from a PrEP demonstration project "Be-PrEPared" in Antwerp, Belgium, to understand preferences for daily PrEP or event-driven PrEP among MSM at high risk of HIV and factors influencing their initial choice. Methods: Cross-sectional data from an open-label prospective cohort study, using mixed methods. Participants who preregistered online were screened for eligibility and tested for sexually transmitted infections (STIs). Eligible participants chose between daily PrEP and event-driven PrEP and reported on behavioral data through an electronic questionnaire. In-depth interviews were conducted with a selected subsample. Bivariate associations were examined between preferred PrEP regimens and sociodemographic factors, sexual behavior, and STIs at screening. Results: In total, 200 participants were enrolled between October 2015 and December 2016. Self-reported levels of sexual risk-taking before enrollment were high. STI screening revealed that 39.5% had at least 1 bacterial STI. At baseline, 76.5% of participants preferred daily PrEP and 23.5% event-driven PrEP. Feeling able to anticipate HIV risk was the most frequent reason for preferring event-driven PrEP. Regimen choice was associated with sexual risk-taking behavior in the past 3 months. Almost all participants (95.7%) considered it likely that they would change their dosing regimen the following year. Conclusion: Event-driven PrEP was preferred by 23.5% of the participants, which better suits their preventive needs. Event-driven PrEP should be included in PrEP provision as a valuable alternative to daily PrEP for MSM at high risk of HIV. © 2018 Wolters Kluwer Health, Inc. All rights reserved. Article	2018	Reyniers, Thijs; Vuylsteke, Bea; Pirotte, Benoit; Hoornenborg, Elske; Bil, Janneke P; Wouters, Kristien; Laga, Marie; Nöstlinger, Christiana	Physicians' preparedness for pre-exposure prophylaxis: results of an online survey in Belgium.	Sexual Health	-	-	-	-	1448-5028	10.1071/SH18072	https://dx.doi.org/10.1071/SH18072	Background Physicians have a crucial role in the implementation and scale up of pre-exposure prophylaxis (PrEP). The objective of this study is to examine Belgian physicians' PrEP knowledge, concerns, acceptance and their willingness to prescribe PrEP. METHODS: A cross-sectional online survey was conducted between March and June 2016. Dissemination targeted Belgian primary care physicians (PCPs) and HIV specialists. Sociodemographic characteristics, experience with HIV and PrEP, self-assessed PrEP knowledge, concerns about PrEP, and PrEP acceptance were stratified according to professional background. Associations with willingness to prescribe PrEP were examined using univariable and multivariable binary logistic regression analyses. RESULTS: In total, 333 completed surveys were included in the analysis. Sixty-two physicians (18.6%) scored their knowledge of PrEP to be good, 263 (79.0%) had an accepting attitude towards PrEP and 198 (59.5%) were willing to prescribe PrEP if approved in Belgium. HIV specialists consistently reported having better knowledge of PrEP, less concerns and a more accepting attitude towards PrEP than PCPs. In multivariable logistic regression analysis, higher PrEP knowledge (OR 2.4; 95%CI: 1.0-5.7) and higher PrEP acceptance (OR: 3.8; 95%CI: 2.1-6.8) remained significantly associated with the willingness to prescribe PrEP. CONCLUSIONS: HIV specialists are better prepared to provide PrEP than PCPs in Belgium. Interventions to improve PrEP knowledge and acceptance among all providers are needed. The role of PCPs could be very important in optimising the rollout of PrEP, but additional training and guidelines will be needed. Article	2018	Rich, Katherine M; Bia, Joshua; Altice, Frederick L; Feinberg, Judith	Integrated Models of Care for Individuals with Opioid Use Disorder: How Do We Prevent HIV and HCV?	Current HIV/AIDS Reports	-	-	-	-	1548-3576	10.1007/s11904-018-0396-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6003996	PURPOSE OF REVIEW: To describe models of integrated and co-located care for opioid use disorder (OUD), hepatitis C (HCV), and HIV. RECENT FINDINGS: The design and scale-up of multidisciplinary care models that engage, retain, and treat individuals with HIV, HCV, and OUD are critical to preventing continued spread of HIV and HCV. We identified 17 models within primary care (N = 3), HIV specialty care (N = 5), opioid treatment programs (N = 6), transitional clinics (N = 2), and community-based harm reduction programs (N = 1), as well as two emerging models. Key components of such models are the provision of (1) medication-assisted treatment for OUD, (2) HIV and HCV treatment, (3) HIV pre-exposure prophylaxis, and (4) behavioral health services. Research is needed to understand differences in effectiveness between co-located and fully integrated care, combat the deleterious racial and ethnic legacies of the "War on Drugs," and inform the delivery of psychiatric care. Increased access to harm reduction services is crucial. Article	2018	Riddell J.; Amico K.R.; Mayer K.H.	HIV preexposure prophylaxis: A review	JAMA - Journal of the American Medical Association	-	-	-	-	987484	10.1001/jama.2018.1917	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044444253&doi=10.1001%2fjama.2018.1917&partnerID=40&md5=cc972eb35ae743a5dc81ba2f8acec624	IMPORTANCE About 40 000 Americans and 2 million people worldwide are newly infected with HIV each year. The combination antiretroviral regimen, tenofovir disoproxil fumarate (TDF)/emtricitabine, taken as a single pill once daily, has been shown to prevent HIV transmission but is used by fewer than 20%of people who could benefit in the United States. OBSERVATIONS PubMed was searched on February 15, 2018, using the search terms pre-exposure, prophylaxis, HIV, and PrEP to identify English-language articles published between 2010 and 2018. Four placebo-controlled randomized clinical trials have demonstrated that preexposure prophylaxis (PrEP) with daily dosing of TDF/emtricitabine significantly reduces HIV acquisition in men who have sex with men, high-risk heterosexuals, and injection drug users who share injection equipment. The efficacy of daily TDF/emtricitabine exceeds 90% but is highly correlated with degree of adherence. TDF/emtricitabine is safe and well-tolerated. Only 2%of people discontinue PrEP because of adverse effects. Sexually transmitted infections are common among those using PrEP. Resistance to TDF/emtricitabine when used for PrEP is rare (<0.1%) and usually occurs when PrEP is inadvertently prescribed to individuals with undiagnosed acute HIV infection who have false-negative findings on HIV antibody/antigen testing due to HIV infection acquired within 7 to 10 days of testing. Effectivemethods are needed to identify individuals at high risk for acquiring HIV, ensure their access to PrEP, and maximize medication adherence. CONCLUSIONS AND RELEVANCE TDF/emtricitabine is an effective and safe therapy for preventing HIV transmission. Increasing prescription of TDF/emtricitabine for patients at risk of acquiring HIV has the potential to reduce new HIV infections. © 2018 American Medical Association. Article	2018	Ridgway J.P.; Almirol E.A.; Bender A.; Richardson A.; Schmitt J.; Friedman E.; Lancki N.; Leroux I.; Pieroni N.; Dehlin J.; Schneider J.A.	Which Patients in the Emergency Department Should Receive Preexposure Prophylaxis? Implementation of a Predictive Analytics Approach	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2018.0011	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046891370&doi=10.1089%2fapc.2018.0011&partnerID=40&md5=f788db09ff3144108fbe96ebb6ace76c	Emergency Departments (EDs) have the potential to play a crucial role in HIV prevention by identifying and linking high-risk HIV-negative clients to preexposure prophylaxis (PrEP) care, but it is difficult to perform HIV risk assessment for all ED patients. We aimed to develop and implement an electronic risk score to identify ED patients who are potential candidates for PrEP. Using electronic medical record (EMR) data, we used logistic regression to model the outcome of PrEP eligibility. We converted the model into an electronic risk score and incorporated it into the EMR. The risk score is automatically calculated at triage. For patients whose risk score is above a given threshold, an automated electronic alert is sent to an HIV prevention counselor who performs real time HIV prevention counseling, risk assessment, and PrEP linkage as appropriate. The electronic risk score includes the following EMR variables: age, gender, gender of sexual partner, chief complaint, and positive test for sexually transmitted infection in the prior 6 months. A risk score ≥21 has specificity of 80.6% and sensitivity of 50%. In the first 5.5 months of implementation, the alert fired for 180 patients, 34.4% (62/180) of whom were women. Of the 51 patients who completed risk assessment, 68.6% (35/51) were interested in PrEP, 17.6% (9/51) scheduled a PrEP appointment, and 7.8% (4/51) successfully initiated PrEP. The measured number of successful PrEP initiations is likely an underestimate, as it does include patients who initiated PrEP with outside providers or referred acquaintances for PrEP care. © Copyright 2018, Mary Ann Liebert, Inc. 2018.	clinical informatics; emergency department; HIV prevention; predictive analytics; preexposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Rivierez I.; Quatremere G.; Spire B.; Ghosn J.; Rojas Castro D.	Lessons learned from the experiences of informal PrEP users in France: results from the ANRS-PrEPage study	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2018.1468014	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047899987&doi=10.1080%2f09540121.2018.1468014&partnerID=40&md5=0bbe0519d5d3e4213fdc23396d89b19c	Before January 2016, Pre-Exposure Prophylaxis (PrEP), a new biomedical HIV-prevention tool, was only available in France via ANRS-Ipergay clinical study but informal use was reported outside this setting. PrEPage qualitative study reports profiles and experiences of participants who used PrEP outside of a biomedical trial before this prevention method was authorized. Between March 2015 and February 2016, a cross-section of twenty-four informal PrEP users, mostly MSM, was recruited to complete in-depth semi-structured interviews. While ANRS-Ipergay was still ongoing (2012–2016), participants described their initiation to PrEP, the way they used it and the difficulties they faced to acquire antiretroviral drugs in an environment where PrEP was still not widely known and often criticized. Through the testimonies, different user profiles and motivation toward informal PrEP use emerged: (a) participants who have increasing difficulties using condoms, (b) "opportunists" who tried PrEP without the intention of using it regularly and (c) participants with a risk aversion who sought additional protection against HIV. Participants chose to use PrEP and/or their usual prevention strategies depending on available supplies, type of partners and individual attitudes toward risk. The feeling of living a safer sex life helped participants to outweigh the fear of possible toxicity and drug resistance. Participants' needs and expectations about PrEP implementation in France were also presented. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Rizzardini, Giuliano; Winslow, Dean L	Seroconversion on preexposure prophylaxis.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0000000000001826	https://dx.doi.org/10.1097/QAD.0000000000001826	Abstract Objective: We describe the third case report of seroconversion with multidrug resistant (MDR)-HIV despite pre-exposure prophylaxis (PrEP) with emtricitabine (FTC) and tenofovir (TFV) disoproxil (TDF).Design: Case report. Methods: PrEP adherence was assessed via self-report, pharmacy records, and measuring TFV/FTC levels with liquid-chromatography/tandem-mass-spectrometry in plasma and hair. Segmental hair analysis was performed to assess PrEP adherence over prior months. Genotypic resistance was assessed. Results: A 34 year-old white MSM started daily FTC/TDF in February 2016 after being provided 11 refills. In March 2017, he developed fevers, chills, myalgias and was assessed, but no HIV test was sent. In April 2017, an antigen/antibody HIV test was reactive (day 0). On day 2, HIV-1 RNA was 27 316 copies/ml, genotyping revealed M184V, K70T, K65R, and K103N mutations, plasma TFV and FTC concentrations were consistent with recent dosing. To evaluate adherence over preceding months, a hair sample was collected at day 27 and segmental analysis of TFV/FTC levels performed in one-centimeter segments from the scalp. Hair drug levels (0.0434–0.0520 ng TFV/mg hair) were commensurate with consistently high PrEP adherence over the prior 3 months. Conclusions:This study employs segmental analysis of PrEP drug levels in hair for the first time to assess adherence over preceding months in the setting of an HIV seroconversion on PrEP. High adherence over the period of likely acquisition makes MDR-HIV infection the most likely scenario in this case. Adequate adherence assessment when examining PrEP failures and ensuring best practices in PrEP prescribing and follow-up are important.	hair analysis, preexposure prophylaxis, seroconversion	English	United Kingdom	Western and Central Europe and North America	Italy	Western and Central Europe and North America	Italy	Western and Central Europe and North America	Clinical
Theses and Dissertations	2018	Robinson Davis, Suzanne	Motivations to either accept or reject pre-exposure prophylaxis: awareness, beliefs, and risk perceptions among African American women in New York City	-	-	Columbia University	Columbia University	-	-	https://doi.org/10.7916/D8QZ3TDN	https://doi.org/10.7916/D8QZ3TDN	The world has suffered immensely and disproportionately from the ravages of HIV and AIDS. Oral PrEP is a single pill taken once daily that can reduce the risk of sexually transmitted HIV infection by up to 92% (CDC, 2014a). This study describes African American females' awareness, beliefs, and perception of PrEP and identifies factors that may motivate women to either accept or reject PrEP. This cross-sectional study occurred over a 3-month period from November 2017 to January 2018, following from a previous pilot study. The sample comprised African American women aged 18 and over receiving STD or HIV screening services at a FQHC in Brooklyn, New York. Women were interviewed using the five characteristics of the Diffusion of Innovation theory and also completed a risk assessment for HIV using CDC recommended guidelines for screening heterosexual women for PrEP. Awareness of PrEP remained extremely low among the 72 African American women interviewed in the study. Using the CDC guidelines, all women reported one or more risk factors for PrEP indication. Awareness about PrEP, negative reactions from partners and shared experiences from female PrEP users were cited as factors that may predict and motivate African American women to use PrEP. Additionally, skills in pill-taking, cost and insurance, and maintaining privacy while using PrEP were strong enabling factors to support PrEP use. Factors such as initiating couple's PrEP use as an intervention, medical doctors overtly directing PrEP for women, and the role of older women in promoting PrEP use were persuasive factors in reinforcing the utilization of PrEP among African American women in the study. Creative programming within high burden communities is critically important to penetrate with messages of new innovations and best practices. The results of the current research speak volumes to the continued work needed to educate communities with prevention messages. Article	2018	Robinson J.A.; Marzinke M.A.; Fuchs E.J.; Bakshi R.P.; Spiegel H.M.L.; Coleman J.S.; Rohan L.C.; Hendrix C.W.	Comparison of the Pharmacokinetics and Pharmacodynamics of Single-Dose Tenofovir Vaginal Film and Gel Formulation (FAME 05)	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001587	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056744184&doi=10.1097%2fQAI.0000000000001587&partnerID=40&md5=31ce83d3f8270f0efd3e77c8c5d14d04	Objective: Although preexposure prophylaxis with oral tenofovir (TFV) disoproxil fumarate/emtricitabine reduces HIV acquisition rates, poor adherence to and acceptability of daily vaginal gels have led to development of vaginal film formulations to improve adherence and, potentially, to enable episodic use. Study Design: In this 2-arm, cross-over study of a fast-dissolving tenofovir film (40 mg) compared with a previously studied semisolid tenofovir 1% gel (40 mg), 10 healthy women received a single vaginal dose of each study product. Clinical, pharmacokinetic, and antiviral assessments were performed over 1 week after dose. Results: Nine of 10 participants experienced mild to moderate adverse effects, similar between products, with no severe adverse events or events attributed to study products. TFV concentrations after film dosing exceeded concentrations after gel dosing in plasma between 8 and 24 hours (P ≤ 0.02). TFV concentrations in cervicovaginal fluid and both TFV and TFV diphosphate concentrations in cervical tissue homogenates were higher after film dosing (all P values < 0.04). The differences ranged from median (interquartile range) 2.9-fold (1.1, 9.0; midvaginal cervicovaginal fluid) to 4.4-fold (2.9, 7.7; plasma). Neither film nor gel demonstrated reduced cervical tissue biopsy infectivity after ex vivo HIV challenge. Conclusion: Single-dose tenofovir film demonstrated consistently higher concentrations in plasma and cervicovaginal samples when compared with gel during the first day after dosing. Single-dose cervical tissue TFV-diphosphate concentrations at 5 hours exceeded steady-state concentrations previously reported with daily oral Truvada dosing. Tenofovir film may provide an alternative to tenofovir oral and gel formulations. Clinical efficacy remains to be tested. © 2018 Lippincott Williams and Wilkins. All rights reserved. Article	2018	Rocha G.M.; Kerr L.R.F.S.; Kendall C.; Guimarães M.D.C.	Risk behavior score: a practical approach for assessing risk among men who have sex with men in Brazil	Brazilian Journal of Infectious Diseases	-	-	-	-	14138670	10.1016/j.bjid.2018.02.008	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85045833856&doi=10.1016%2fj.bjid.2018.02.008&partnerID=40&md5=834b4a07198460e390fa745e6201ea11	HIV/AIDS epidemic is not well controlled, and multiple sexual behavior factors help explain high rates of HIV infection among men who have sex with men (MSM). This article proposes to exam the use of a potential risk behavior score for HIV infection, based on the type and number of sexual partners, and condom use, and their associated factors in a sample of MSM in Brazil. A cross sectional RDS (Respondent Driven Sampling) study was performed among 3738 MSM aged 18+ years old from ten Brazilian cities. The risk behavior score was composed by the number of male partners and anal condom use in the last year with steady, casual, and commercial partners. Most participants were 25+ years old (58.1%), non-white (83.1%), and single (84.9%). Final weighted ordinal logistic model showed that age ≤ 25 years old (p = 0.037), homosexual or bisexual identity (p < 0.001), sexual initiation before 15-year-old (p < 0.001), having sex with men only in the last 12 months (p < 0.001), frequent alcohol and illicit drug use (p < 0.001), and use of local sites to meet sexual partners in the last month were independently associated with higher scores of risky behavior. Specific strategies should be developed aimed at the MSM population. Additionally, pre-exposed prophylaxis (Prep) should be considered for those at higher score as a strategy for reducing risk for HIV infection in this population. © 2018 Sociedade Brasileira de Infectologia	AIDS; High-risk sex; HIV; Homosexuals; Unsafe sex	English	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Quantitative

An exploration of factors impacting preexposure prophylaxis eligibility and access among syringe exchange users	Sexually Transmitted Diseases	-	-	-	-	1485717	10.1097/OLQ.0000000000000728	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044244940&doi=10.1097%2fOLQ.0000000000000728&partnerID=40&md5=add5086a8f4736ec4a7d1c11e660f2c6	Background In 2015, approximately 50,000 new HIV infections occurred in the United States, 2,400 of which were attributable to injection drug use. Preexposure prophylaxis (PrEP) has the potential to curb HIV acquisition; however, uptake remains low among persons who inject drugs (PWID). The purpose of this study is to describe PrEP eligibility, willingness to use PrEP, and ability to access PrEP among PWID recruited from a pilot program that paired screening and treatment of sexually transmitted infections with mobile syringe exchange program (SEP) services. Methods Between 2015 and 2016, 138 PWID 18 years or older were recruited from a mobile SEP in Camden, New Jersey. Participants completed a survey assessing sociodemographics and HIV risk and underwent chlamydia and gonorrhea screening. Centers for Disease Control clinical guidelines were used to calculate PrEP eligibility. Differences by sex were examined using inferential statistics. Results Most women (95.4%) and men (84.5%) were considered PrEP eligible (P < 0.04). More women than men were willing to take PrEP (88.9% vs. 71.0%; P < 0.02). Participants reported substantial barriers to PrEP including feeling embarrassed (45.0%) or anxious (51.6%) about taking PrEP, nondisclosure to partners (51.4%), limited engagement with health care providers where PrEP might be provided (43.8%), and lacking health insurance (32.9%). Conclusions Despite reporting behavior that warrants the use of PrEP to prevent HIV and finding the concept acceptable, PWID face multiple barriers to PrEP access. Without tailored interventions to promote PrEP, uptake will likely remain suboptimal. Packaging PrEP with SEP services could provide a viable option for reaching eligible and interested PWID. Article	2018	Roux, Perrine; Fressard, Lisa; Suzan-Monti, Marie; Chas, Julie; Sagaon-Teyssier, Luis; Capitant, Catherine; Meyer, Laurence; Tremblay, Cécile; Rojas-Castro, Daniela; Pialoux, Gilles; Molina, Jean-Michel; Spire, Bruno	Is on-Demand HIV Pre-exposure Prophylaxis a Suitable Tool for Men Who Have Sex With Men Who Practice Chemsex? Results From a Substudy of the ANRS-IPERGAY Trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000001781	https://pubmed.ncbi.nlm.nih.gov/30212434/	BACKGROUND: Chemsex-the use of psychoactive substances during sexual encounters-among men who have sex with men is a growing concern. On-demand HIV pre-exposure prophylaxis (PrEP) may be a suitable tool to prevent HIV transmission among "chemsexers." We used the open-label extension study of the ANRS-IPERGAY trial to describe chemsexers and their PrEP use. METHODS: Among the 361 men who have sex with men enrolled in ANRS-IPERGAY's open-label extension study, we selected the 331 with available data on drug use. A 2-monthly web questionnaire on sociobehavioral data was used to compare sexual behaviors between questionnaires where chemsex was reported and those where it was not. Using a generalized estimating equation logistic regression, we studied whether practicing chemsex was associated with correct PrEP use. RESULTS: Among the 331 participants, 30% reported chemsex practice at least once during follow-up and were considered chemsexers. Chemsex was reported in 16% of all questionnaires. Chemsexers were not significantly different from nonchemsexers regarding sociodemographic characteristics, although they reported greater use of anxiolytics and more sensation-seeking. Reporting chemsex was associated with more high-risk sexual practices and a higher perception of risk. After adjustment for other potential correlates, chemsex remained associated with correct PrEP use odds ratio (95% confidence interval) = 2.24 (1.37 to 3.66). CONCLUSIONS: Our findings show that chemsexers were more likely to report high-risk sexual practices but also had a higher perception of risk. They were also more likely to use PrEP correctly when practicing chemsex. Consequently, PrEP may be a suitable tool to reduce HIV-risk transmission among chemsexers. Article	2018	Rozhnova G.; Heijne J.; Bezemer D.; Van Sighem A.; Presanis A.; De Angelis D.; Kretzschmar M.	Elimination prospects of the Dutch HIV epidemic among men who have sex with men in the era of preexposure prophylaxis	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002050	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055844224&doi=10.1097%2fQAD.0000000000002050&partnerID=40&md5=b3b581fc31e3e5123dd42e858a6a49f4	Objective: Preexposure prophylaxis (PrEP) is a promising intervention to help end the HIV epidemic among men who have sex with men (MSM) in the Netherlands. We aimed to assess the impact of PrEP on HIV prevalence in the population and to determine the levels of PrEP coverage necessary for HIV elimination. Design and methods: We developed a mathematical model of HIV transmission in a population stratified by sexual risk behavior with universal antiretroviral treatment (ART) and daily PrEP use depending on an individual's risk behavior. We computed the effective reproduction number, HIV prevalence, ART and PrEP coverage for increasing ART and PrEP uptake levels, and examined how these were affected by PrEP effectiveness and duration of PrEP use. Results: At current levels of ART coverage of 80%, PrEP effectiveness of 86% and PrEP duration of 5 years, HIV elimination required 82% PrEP coverage in the highest risk group (12000 MSM with more than 18 partners per year). If ART coverage increased by 9%, the elimination threshold was at 70% PrEP coverage. For shorter PrEP duration and lower effectiveness elimination prospects were less favorable. For the same number of PrEP users distributed among two groups with highest risk behavior, prevalence dropped from the current 8 to 4.6%. Conclusion: PrEP for HIV prevention among MSM could, in principle, eliminate HIV from this population in the Netherlands. The highest impact of PrEP on prevalence was predicted when ART and PrEP coverage increased simultaneously and PrEP was used by the highest risk individuals. Article	2018	Rubincam, Clara; Newman, Peter A.; Atujuna, Millicent; Bekker, Linda-Gail	Why would you promote something that is less percent safer than a condom?': Perspectives on partially effective HIV prevention technologies among key populations in South Africa.	SAHARA J : Journal of Social Aspects of HIV/AIDS Research Alliance	-	-	-	-	1813-4424 1729-0376	10.1080/17290376.2018.1536561	https://pubmed.ncbi.nlm.nih.gov/30360675/	New biomedical prevention technologies (NPTs) for HIV, including oral Pre-Exposure Prophylaxis, and vaginal and rectal microbicides and HIV vaccines in development, may contribute substantially to controlling the HIV epidemic. However, their effectiveness is contingent on product acceptability and adherence. We explored perceptions and understanding of partially effective NPTs with key populations in South African townships. From October 2013 to February 2014, we conducted six focus groups and 18 individual interviews with Xhosa-speaking adolescents (n = 14), adult men who have sex with men (MSM) (n = 15), and adult heterosexual men (n = 9) and women (n = 10), and eight key informant (KI) interviews with healthcare workers. Interviews/focus groups were transcribed and reviewed using a thematic approach and framework analysis. Overall, participants and KIs indicated scepticism about NPTs that were not 100% efficacious. Some participants equated not being 100% effective with not being completely safe, and thus not appropriate for dissemination. KIs expressed concerns that promoting partially effective NPTs would encourage substitution of a more effective with a less effective method or encourage risk compensation. Educational and social marketing interventions that address the benefits and appropriate use of partially effective NPTs, including education and support tailored for frontline service providers, are needed to prepare for successful NPT implementation in South Africa. Article	2018	Rutledge R.; Madden L.; Ogbunga O.; Meyer J.P.	HIV Risk perception and eligibility for pre-exposure prophylaxis in women involved in the criminal justice system	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2018.1447079	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85043673381&doi=10.1080%2F09540121.2018.1447079&partnerID=40&md5=5ae72b3b7f12c2fa304cd8a3f6459611	Women involved in the criminal justice system (WICJ) are at high risk of acquiring HIV and would benefit from HIV pre-exposure prophylaxis (PrEP) but there are no studies in this population to inform PrEP implementation programs. We conducted a cross-sectional survey of HIV-uninfected, cis-gender women on probation, parole and/or recently released from prison/jail to assess PrEP awareness, eligibility, potential barriers to uptake, and the PrEP care continuum. The 325 WICJ surveyed reported high rates of HIV risk behaviors including recent transactional sex (22.4%) and unsafe injection practices (14.4%). Despite 33% (n = 42) meeting eligibility criteria for PrEP, only 23% were aware of PrEP and one person was currently using it. Just 10.7% of those who were PrEP eligible perceived they were at risk for HIV. Following a brief explanation of PrEP, 90% said they would try it if recommended by their physician. Compared to those not PrEP eligible (n = 93), PrEP eligible women were less likely to be stably housed or have a primary care provider, and were more likely to be sentence-exposed, charged with drug possession, have lifetime substance use, or living with Hepatitis C infection. WICJ frequently engage in HIV risk behaviors and are unaware of PrEP. Our findings highlight the importance of integrating PrEP into criminal justice settings to address structural barriers and expand HIV risk. WICJ report receptiveness to PrEP and represent an important population for targeted PrEP implementation programs. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group	criminal justice; HIV; PrEP; probation; risk; women	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Protocol for an HIV Pre-exposure Prophylaxis (PrEP) Population Level Intervention Study in Victoria Australia: The PrEPX Study	Frontiers in Public Health	-	-	-	-	2296265	10.3389/fpubh.2018.00151	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047267210&doi=10.3389%2Ffpubh.2018.00151&partnerID=40&md5=9e6a6e6697f29a1c29353478d2f2f2e85	Background: Pre-exposure prophylaxis (PrEP) is the use of HIV anti-retroviral therapy to prevent HIV transmission in people at high risk of HIV acquisition. PrEP is highly efficacious when taken either daily, or as an on-demand schedule. In Australia co-formulated tenofovir-emtricitabine is registered for daily use for PrEP, however, this co-formulation is not listed yet on the national subsidized medicines list. We describe a study protocol that aims to demonstrate if the provision of PrEP is up to 3000 individuals at-risk of HIV in Victoria, Australia reduces HIV incidence locally by 25% generally and 20% amongst GBM. Methods: PrEPX is a population level intervention study in Victoria, Australia in which generic PrEP will be delivered to 3000 individuals for up to 36 months. Study eligibility is consistent with the recently updated 2017 Australian PrEP guidelines for clinical prescribing of PrEP. Participants will attend study clinics, dataset clinics, or outreach clinics for quarterly HIV/STI screening, biannual renal function and urinalysis tests required. Study visits and STI diagnoses will be recorded electronically through the ACCESS surveillance system. At each study visit participants will be invited to complete behavioral surveys that collect information on: sexual practices, condom use, alcohol and drug use, uptake of HIV testing, and other health issues. Participants will also be invited to complete a monthly online survey to collect self-reported behavioral data, and to provide in-depth interviews and questionnaires to collect qualitative data on PrEP uptake, adherence, and acceptability data. Participating clinics will provide clinic level data on implementation and management of PrEPX, and a population level impact on HIV incidence will be assessed using Victorian HIV notification data. Discussion: This study will collect evidence on the real world impact of delivery of PrEP to 3000 individuals at risk of acquiring HIV in Victoria. This study will provide important information for the broader implementation of PrEP planning upon listing of the tenofovir-emtricitabine on the national subsidized list of medicines. The study is registered on the Australian New Zealand Clinical Trials Registry (ACTRN12618001215415) Copyright © 2018 Ryan, Mah, Storer, Price, Fairley, Ruth, Lal, Asselin, El-Hayek, Nguyen, Bottomley, Wilson, Lockwood, Murphy, Cornelisse, Roth, Willcox, Chang, Armishaw, Tee, Prins, Forgan-Smith, Williams, Montgomery, Byron, Cocks, Allen, Wiggins, Kelsall, Vujovic, West, Pierce, Gelbart, Bell, Wu, Hoy, Wesselingh, Grant and Wright. Article	2018	Sabeti P.; Berman B.; Thomas S.; Gandhi M.; Scott H.	A single pre-exposure prophylaxis (PrEP) optimization intervention for health care providers prescribing PrEP: Pilot study	JMIR Formative Research	-	-	-	-	2561326X	10.2196/formative.8623	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059851584&doi=10.2196%2Fformative.8623&partnerID=40&md5=fc3fd1c153a934a7fdf5df0385ffb34b	Background: Pre-exposure prophylaxis (PrEP) has been shown to be highly effective for the prevention of HIV in clinical trials and demonstration projects, but PrEP uptake and adherence outside of these settings in the United States has been limited. Lack of knowledge and willingness of health care providers (HCPs) to prescribe PrEP is an important barrier to implementation. Objective: The objective of this study was to describe and examine the feasibility and acceptability of a PrEP Optimization Intervention (PrEP-IO) targeted at HCPs. The ultimate purpose of this intervention was to increase PrEP uptake, adherence, and persistence among HCPs' patients. Methods: We developed a single-session intervention delivered to HCPs in-person or via Web conference. The intervention consisted of HIV risk assessment, normative numbers for follow-up, and reports patients' history of PrEP use; and (2) centralized PrEP coordination by a clinical expert staff member. As the PrEP coordinator, PrEP-IO identified patients who could potentially benefit from PrEP, provide medical insurance navigation, and support multiple HCPs. Feasibility was evaluated based on HCPs' ability to log in to PrEP-Rx and use it as needed. Acceptability was assessed via individual formative qualitative interviews with HCPs after 1 month of the intervention. Results: The intervention was feasible and acceptable among HCPs (N=9). HCPs identified system-level barriers to PrEP provision, many of which can be addressed by this intervention. HCPs noted that the intervention improved their PrEP knowledge; increased ease of PrEP prescription; and was likely to improve patient engagement and retention in care, enhance communication with patients, and improve patient monitoring and follow-up. Conclusions: Given the critical role HCPs serve in disseminating PrEP, we created an easy-to-use PrEP optimization intervention deemed feasible and acceptable to providers. Further research on this tool and its ability to impact the PrEP continuum of care is needed. © JMIR Formative Research. Article	2018	Sagaon-Teyssier L.; Mabire X.; Lagarde V.; Fressard L.; Suzan-Monti M.; Rojas Castro D.; Hall N.; Capitant C.; Meyer L.; Chidiac C.; Tremblay C.; Peries M.; Spire B.; Molina J.-M.	A Group-Based Trajectory Model for Changes in Pre-Exposure Prophylaxis and Condom Use among Men Who Have Sex with Men Participating in the ANRS IPERGAY Trial	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2018.0081	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050309731&doi=10.1089%2Fapc.2018.0081&partnerID=40&md5=c6e86103963e536a67a5a0e5c5cca707	Pre-exposure prophylaxis (PrEP) is one of the most important milestones in HIV prevention for high-risk HIV-negative people. The introduction of PrEP into the HIV prevention package has raised the question of possible risk compensation, and in particular, a reduction in condom use. Although open-label extension (OLE) studies have enabled investigators to examine risk compensation in more real-life conditions, they have not yet been analyzed from this perspective. The ANRS IPERGAY trial (NCT02283502) tested on-demand PrEP in a double-blind placebo-controlled design. Based on these trajectories, three-based trajectory modeling using logistic regression was implemented. Data of the 332 individuals participating in the double-blind and OLE phases of ANRS IPERGAY were used. Four distinct group trajectories were identified: 49.7% of the participants had "systematic adherence to PrEP," 19% had "high adherence to PrEP, 15.3% had "declining adherence to PrEP," and 16% had "low adherence to PrEP." Two condom trajectories were identified: 53% (n = 176) of the 332 participants were "low-level users" of condoms, and 47% were "high-level users." Among the former, 24.4% also belonged to the "low adherence to PrEP" group. This most-at-risk group represented 13% of all the participants. The effectiveness of offering sexual activity-based PrEP as part of the French HIV prevention package in the ANRS IPERGAY clinical trial is demonstrated by the relatively small proportion of participants that chose low-level condom use with PrEP adherence. The results from this work may help in the future development of tailored prevention programs for high-risk HIV-negative people. © 2018, Mary Ann Liebert, Inc., publishers.	anal intercourse; condoms; MSM; multi-trajectory modeling; PrEP	English	United States	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Clinical
Article	2018	Sales J.M.; Steiner R.J.; Brown J.L.; Swartzendruber A.; Patel A.S.; Sheth A.N.	PrEP eligibility and interest among clinic-and community-recruited young black women in Atlanta, Georgia, USA	Current HIV Research	-	-	-	-	15701624X	10.2174/1570162X16666180731143756	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053636486&doi=10.2174%2F1570162X16666180731143756&partnerID=40&md5=ccc6f552c1fe07905fa0f9994e1fe732d	Background: Atlanta has been identified as an 'hot spot' for Black women and ranks 5th in the US with new infections. Yet little is known about PrEP eligibility or interest among young Black women in Atlanta. Methods: A convenience sample of 1,281 Black women (ages 18-24 years) were recruited from two settings: community venues and sexual health clinics. They provided self-reported sexual behavior data and specimens for laboratory testing for chlamydia (CT) and gonorrhea (GC) infection. For each women, the number of key self-reported behavioral HIV risk factors was calculated (0-6 factors for the CBSO sample; 0-5 factors for the clinic sample). Logistic regression models assessed the association of PrEP eligibility with race/ethnicity, age, and HIV risk. Results: Of the 1,281 CBSO (1,143/1,281, 89.2%), 138 clinic (138/1,281, 10.8%) participants, 1,143/1,281 (89.2%) were eligible for PrEP. Of the 1,143 CBSO (1,143/1,281, 89.2%) and 138 (138/1,281, 10.8%) clinic participants, 1,143/1,281 (89.2%) and 138/1,281 (10.8%) were eligible for PrEP, which can affect uptake; other prevention methods. Article	2018	Sang J.M.; Matthews D.D.; Mesnley S.P.; Eaton L.A.; Stall R.D.	Assessing HIV stigma on prevention strategies for black men who have sex with men in the United States	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2181-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047939968&doi=10.1007%2Fs10461-018-2181-7&partnerID=40&md5=ba6cf1aa36d0626d61f1f8a2c5301704	The deleterious effects of HIV stigma on HIV+ Black MSM care continuum outcomes have been well-documented. How HIV stigma shapes HIV prevention for HIV- persons in this community is poorly understood. We sought to test the relationship of HIV stigma with HIV- Black MSM on HIV testing, pre-exposure prophylaxis (PrEP) awareness, and PrEP use. We recruited 752 participants at Black Pride events across five US cities in 2016. Multivariable logistic regression models assessed the association of external HIV stigma on prevention outcomes adjusting for sociodemographic variables. Stigma was measured using the HIV Stigma Framework. 30.1% (n = 226), 29.3% (n = 220), and 15.2% (n = 114) of participants reported no HIV test or HIV testing more than a year ago, respectively. These findings highlight the consistent role HIV stigma among BMSM and include results for PrEP, which can affect uptake; other prevention methods. We support anti-HIV stigma efforts and advise further exploration on HIV stigma among BMSM and persistent outcomes. © Springer Science+Business Media, LLC, part of Springer Nature 2018. Article	2018	Schmidt H.-M.A.; Micher R.; Houghton R.; Sebey C.; McNulty A.; Varma R.; Grelich A.E.; Holden J.	Nurse-led pre-exposure prophylaxis: A non-traditional model to provide HIV prevention in a resource-constrained, pragmatic clinical trial	Sexual Health	-	-	-	-	14485028	10.1071/SH18076	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047554284&doi=10.1071%2FSH18076&partnerID=40&md5=0811375ed7716670d2083fa0f8f029e2	There is little evidence and no standardised model for nurse-led HIV pre-exposure prophylaxis (PrEP). In 2016, public sexual health clinics in the state of New South Wales (NSW), Australia, participating in the Expanded PrEP Implementation in Communities in New South Wales (EPIC-NSW) trial were authorised to adopt a nurse-led model of PrEP delivery. Nurses were authorised to initiate and manage the full spectrum of PrEP access via the Expanded PrEP Access trial Expanded PrEP Implementation In Communities in New South Wales (EPIC-NSW) trial. Nurses were authorised to adopt a nurse-led model of PrEP delivery to facilitate the rapid expansion of PrEP access to men from MSM populations in under 2 years without additional resources. The model has been implemented successfully in public clinics in NSW and is now being rolled out to other jurisdictions. This is the first published report of the development and implementation of an HIV prevention trial, non-traditional models of care, undertaken in a public sexual health clinic setting. © 2018 CSIRO. Article	2018	Schnarrs P.W.; Gordon D.; Martin-Valenzuela R.; Sund T.; Delgado A.J.; Glidden D.; Parsons J.T.; McAdams J.	Perceived Social Norms About Oral PrEP Use: Differences Between African American, Latinx and White Gay, Bisexual and Other Men Who Have Sex with Men in Texas	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2076-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044475946&doi=10.1007%2Fs10461-018-2076-7&partnerID=40&md5=f545c9f63cf599c4442c8dd6e73be7e	Correct and consistent condom use has been the primary method of HIV prevention until the FDA approve the use of PrEP in 2012. While strong evidence existing regarding the efficacy of PrEP, uptake has remained slower than anticipated. While work is underway to better understand the factors impacting uptake, the majority of this work as been focused on white gay, bisexual, and other men who have sex with men (GBMSM). Little is known about the factors impacting PrEP uptake among racial and ethnic minority GBMSM. Using a cross-sectional survey of 1,553 GBMSM, we examined the perceived social norms about oral PrEP use among racial and ethnic minority GBMSM and a number of differences were found across questions and a number of differences were found across race and ethnicity such as who would approve or disapprove of PrEP and who would be likely to use PrEP. Further, we found differences between injunctive and descriptive norms. These findings suggest that there are unique factors contributing to PrEP uptake among racial and ethnic minority GBMSM and that it fully understand uptake a more robust measure of perceived norms may be needed. © Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Shrestha R.; Altice F.L.; Karki P.; Copenhaver M.M.	Integrated Bio-behavioral Approach to Improve Adherence to Pre-exposure Prophylaxis and Reduce HIV Risk in People Who Use Drugs: A Pilot Feasibility Study	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2099-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85044375946&doi=10.1007%2Fs10461-018-2099-0&partnerID=40&md5=4f6b912c96773542f9bd0f5756e7e	This study reports the feasibility, acceptability, and preliminary efficacy of the bio-behavioral community-friendly health recovery program—an integrated, HIV prevention intervention to improve pre-exposure prophylaxis (PrEP) adherence and HIV risk reduction behaviors among high-risk people who use drugs. We used a within-subjects, person position follow-up design to recruit participants, who were HIV-uninfected, methadone-maintained and reported HIV risk behaviors and had initiated PrEP ($n = 40$; males: 55%). Participants were assessed at baseline (T0), immediately post-intervention (4 weeks: T4) and 12 weeks (T12) post-baseline. The intervention was delivered by a PrEP navigator in methadone clinics and consisted of 4 weekly group sessions and 4 individual sessions. Feasibility was high, assessed by participant willingness to enroll (98.1%) and retention (95%). Results showed that participants were highly satisfied and perceived the intervention as valuable and acceptable: mean 4.2 (range 0–10). Significant enhancements in self-reported PrEP adherence [$t(2.74) = 7.508$, $p = 0.001$ and PrEP-related knowledge [$t(2.74) = 3.826$, $p = 0.026$ were observed. Drug-related (e.g., injection of drugs, sharing of injection equipment and syringes and needles) and sexual risk behaviors were reduced, while information, motivation, and behavioral skills (IMB) constructs increased. The results support feasibility and high acceptability and support further examination of the efficacy of this combination bio-behavioral intervention in a prospective clinical trial. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2018	Shrestha, Roman; Karki, Pramila; Altice, Frederick L; Dubov, Oleksandr; Fraenkel, Liana; Huedo-Medina, Tania; Copenhaver, Michael	Measuring Acceptability and Preferences for Implementation of Pre-Exposure Prophylaxis (PrEP) Using Conjoint Analysis: An Application to Primary HIV Prevention Among High Risk Drug Users	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-017-1851-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85022198892&doi=10.1007%2Fs10461-017-1851-1&partnerID=40&md5=42423354eab1528b1b7d8ca4d73e63	PURPOSE OF REVIEW: This article reviews recent epidemiologic trends in HIV and hepatitis C virus (HCV) and strategies for treatment and prevention of these infections as they relate to the opioid epidemic. RECENT FINDINGS: Among people who inject drugs (PWID) in the United States (US), HIV diagnoses are decreasing, while HCV is increasing. Care for HIV and HCV relies heavily on specialist infrastructure, which is lacking in rural areas. Antiretrovirals for HIV and direct-acting antivirals for HCV are effective among PWID, yet multiple barriers make it difficult for rural persons to access these treatments. Similarly, access to syringe service programs, medication-assisted therapy for opioid addiction, and pre-exposure prophylaxis for HIV are all limited in rural areas. Previous research on HIV and HCV among PWID has focused on urban or international populations, yet the US opioid epidemic is moving away from metropolitan centers. Increasing rurality of opioid injection brings unique challenges in treatment and prevention. Research into the care of HIV, HCV, and opioid use disorder among rural populations is urgently needed. PrEP Communications Accelerator: A digital demand-creation tool for sub-Saharan Africa	Sexual Health	-	-	-	-	14485028	10.1071/SH18064	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054165954&doi=10.1071%2FSH18064&partnerID=40&md5=bfa27cf0f1d9d7f2323e5d2e1e97a	Background: Strategic communications are critical for successful market introduction of oral pre-exposure prophylaxis (PrEP). This paper focuses on the OPTIONS Consortium's approach to developing the PrEP Communications Accelerator, a digital tool that provides communication strategies and tools for generating demand for PrEP across sub-Saharan Africa. Methods: The PrEP Communications Accelerator was developed through needs assessment, communications landscape and gap analysis, market research and content development and testing. Stakeholder consultations across multiple African countries and audiences were conducted to validate and refine findings at each step. Results: The PrEP Communications Accelerator provides customised communications strategies that vary by target audience/key population and young women, female sex workers, serodiscordant couples, men who have sex with men, people who inject drugs and the general population) and by setting (clinic, community, subnational or national level). Users of the interactive tool receive custom-built demand creation strategy guidance, including suggested media channels and communication tactics based on available evidence about the population and setting. Discussion: The PrEP Communications Accelerator is a digital demonstration platform not intended to equip those who work in resource- and time-constrained environments with the evidence-based strategies they need to create demand for PrEP. Conclusions: The PrEP Communications Accelerator is a unique tool that provides strategic guidance for creating demand for PrEP. Implementers most at risk of HIV infection, as well as a broad profile of the general population to calibrate support for PrEP as a new public health product. © 2018 Journal Compilation CSIRO Open Access	NA	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods

The trial included a multi-faceted approach to adherence support and collected objective and self-reported adherence measures. Using qualitative data collected from a random sub-set of FACTS 001 participants (135 in-depth interviews at product discontinuation and 12 post-trial interviews), we explored the importance of 'place' and 'timing' in shaping acts of sexual intimacy and product adherence. Demonstrating a moderate capacity for facilitating PrEP use, the trial's design and delivery also appeared to have had unintended consequences. Consistently young, unemployed women living with partners or other family members, Sexual intimacy was largely unpredictable and happened across multiple locations in which women had limited privacy, autonomy, or control over the timing of sex. This made adherence to the dosing strategy challenging. Findings may inform the development of future event-driven pre-exposure prophylaxis regimens or products. Article	2018	Seeber M.J.; Hettema A.; Hughey A.; Oldenburg C.E.; Kohler S.; Bärnighausen K.; McMahon S.; Jia C.; Lejeune C.; Matse S.; Bärnighausen T.	Preference for injectable over oral HIV pre-exposure prophylaxis in public-sector primary-care clinics in Swaziland	AIDS	-	-	-	-	2690370	10.1097/QAD.0000000000001859	https://www.pharmacytimes.com/mag/hiv-2020/choices-for-oral-versus-injectable-pre-exposure-prophylaxis-for-hiv-prevention-in-women?utm_source=Yext%20Feed%20Marketing&utm_medium=Yext%20Feed%20Marketing&utm_campaign=Yext%20Feed%20Marketing&utm_content=Yext%20Feed%20Marketing	Long-acting injectable (LAI) HIV pre-exposure prophylaxis (PrEP) may mitigate adherence challenges reported by young women in Southern Africa. We assessed preferences for PrEP in public-sector, primary care clinics in Swaziland. Among surveyed respondents, 75% (95% confidence interval = 65-83%) stated preference for LAI over oral PrEP, with no differences by sex, age, or sexual behavior (all P > 0.05). Notably, over 70% (95% confidence interval 58-82%) with current use of oral PrEP also stated preference for LAI PrEP. © 2018 Wolters Kluwer Health, Inc. All rights reserved. Article	2018	Siegler A.J.; Bratcher A.; Weiss K.M.; Mouhanna F.; Ahlschlager L.; Sullivan P.S.	Location location location: an exploration of disparities in access to publicly listed pre-exposure prophylaxis clinics in the United States	Annals of Epidemiology	-	-	-	-	10472797	10.1016/j.annepidem.2018.05.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048161958&doi=10.1016%2Fj.annepidem.2018.05.006&partnerID=40&md5=153410c3c56014f3d9398ae0cd0842	Purpose: HIV pre-exposure prophylaxis (PrEP) is highly effective in preventing HIV transmission. Finding a PrEP provider, however, can be a barrier to accessing care. This study explores the distribution of publicly listed PrEP-providing clinics in the United States. Methods: Data regarding 2994 PrEP-providing clinics came from PrEP Locator, a national database of PrEP-providing clinics. We compared the distribution of clinics to the 2015 estimated HIV prevalence at the county level. Results: Nationally, there were 3.7 PrEP clinics per 100,000 people, with the majority (n = 2,180) in counties with ≥100,000 residents. Counties with ≥35 PrEP clinics per 100,000 individuals were excluded from ALBAM. Jobs in counties that were ≥1 SD above the mean were more likely to have a PrEP clinic. Counties with higher proportions of their residents living in poverty, lacking health insurance, identifying as African American, or identifying as Hispanic/Latino. The Southern region accounted for over half of all new HIV diagnoses but only one-quarter of PrEP-providing clinics. Conclusions: The current number of PrEP-providing clinics is not sufficient to meet needs. In addition, PrEP-providing clinics are unevenly distributed compared to disease burden, with poor coverage in the Southern divisions and areas with higher poverty, uninsured, and larger minority populations. PrEP services should be expanded and targeted to address disparities. © 2018 The Authors. Article	2018	Siegler A.J.; Mouhanna F.; Giler R.M.; Weiss K.; Pembleton E.; Guest J.; Jones J.; Castel A.; Yeung H.; Kramer M.; McCallister S.; Sullivan P.S.	The prevalence of pre-exposure prophylaxis use and the pre-exposure prophylaxis-to-need ratio in the fourth quarter of 2017, United States	Annals of Epidemiology	-	-	-	-	10472797	10.1016/j.annepidem.2018.06.005	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049419867&doi=10.1016%2Fj.annepidem.2018.06.005&partnerID=40&md5=4ece9b6e8b6e2b2f6ed1c7a3a5d2	Purpose: The number of individuals who have started a regimen for HIV pre-exposure prophylaxis (PrEP) in the United States is not well characterized but has been on the rise since 2012. The analysis assesses the distribution of PrEP use nationally and among subgroups. Methods: A validated algorithm quantifying tenofovir disoproxil fumarate/emtricitabine for PrEP in the United States was applied to a national prescription database to determine the quarterly prevalence of PrEP use. HIV diagnoses from 2016 were used as an epidemiological proxy for PrEP need. The PrEP-to-need ratio (PrIN) was defined as the number of PrEP users per 100 diagnoses. Results: At the end of 2017, 61,066 individuals used PrEP in the fourth quarter of 2017; 57,166 were prescribed tenofovir-emtricitabine. Nationally, prevalence of PrEP use was 23/100,000 (range across states per 100,000: RAS-18th: 6–73) and the PrIN was 1.8 (RAS: 0.5–4.6). Prevalence of PrEP use among males and females, respectively, was 50/100,000 and 2/100,000 (RAS: 39/100,000 and 3/100,000). PrIN was highest among persons aged 25–29 years (2.8) and lowest among persons aged ≥55 years (0.5). Prevalence of PrEP use was highest in counties with ≥100,000 residents (35/100,000) and 0/100,000: RAS-10th: 1–45 and 0.4–14), with PrIN 0.9 and 1.5 (RAS: 0.2–5.6 and 0.3–7.0). The Northeast had the highest PrIN (2.3); the South had the lowest (1.0). States with Medicaid expansion had more than double the PrIN than states without expansion. Conclusions: Available data suggest that females, individuals aged less than or equal to 24 years and residents of the South had lower levels of PrEP use relative to epidemic need. These results are ecological, and misclassification may attenuate results. PrIN is useful for future assessments of PrEP coverage. © 2018 The Authors	HIV; Pre-exposure prophylaxis; Prevention	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2018	Siguier M.; Molina J.-M.	HIV preexposure prophylaxis: An essential, safe and effective prevention tool for sexual health. La prophylaxie préexposition du VIH : outil incontournable, sûr et efficace de la prévention en santé sexuelle	Médecine et Maladies Infectieuses	-	-	-	-	0399077X	10.1016/j.medmal.2018.01.009	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047248674&doi=10.1016%2Fj.medmal.2018.01.009&partnerID=40&md5=93c7dff7f1f05bf5b5f1e7544f1fa32	Pre-exposure prophylaxis of HIV with antiretroviral drugs is a prevention tool available in France since 2016, combined with the prevention methods already used (condoms, post-exposure treatment, rapid treatment of diagnosed HIV infections, etc.). It is targeted at populations at high risk of HIV infection, especially men who have sex with men, for whom traditional prevention methods are insufficient. We collected clinical research data, which resulted in the launch of pre-exposure prophylaxis in the United States and then elsewhere in the world, safety, tolerability and cost data, as well as ongoing research data (new molecules/methods of administration). We also provided an update of its use in France. © 2018 Elsevier Masson SAS. La prophylaxie préexposition du VIH par les antirétroviraux est un outil de prévention disponible en France depuis 2016, en association avec les méthodes de prévention déjà utilisées (préservatif, traitement post-exposition, traitement rapide des infections par le VIH diagnostiquées, etc.). Elle s'adresse aux populations à haute risque d'infection par le VIH, en particulier, les hommes ayant des rapports sexuels avec des hommes, chez qui les méthodes de prévention traditionnelles sont insuffisantes. Nous avons rassemblé un sein de cette revue les données de recherche clinique ayant abouti au déploiement de la prophylaxie préexposition aux États-Unis puis dans le reste du monde, les données de sécurité de tolérance et de coût, ainsi que des éléments sur la recherche en cours (nouvelles molécules/méthodes d'administration) et un état des lieux sur son utilisation en France. Article	2018	Silva C.J.; Torres D.F.M.	Modeling and optimal control of HIV/AIDS prevention through PrEP	Discrete and Continuous Dynamical Systems - Series S	-	-	-	19371632	10.3934/dcdss.2018008	https://www.aimsciences.org/article/doi/10.3934/dcdss.2018008	Pre-exposure prophylaxis (PrEP) consists in the use of an antiretroviral medication to prevent the acquisition of HIV infection by uninfected individuals and has recently demonstrated to be highly efficacious for HIV prevention. We propose a new epidemiological model for HIV/AIDS transmission including PrEP. Existence, uniqueness and global stability of the disease free and endemic equilibriums are proved. The model with no PrEP is calibrated with the cumulative cases of infection by HIV and AIDS reported in Cape Verde from 1987 to 2014, showing that it predicts well such reality. An optimal control problem with a mixed state control constraint is then proposed and analyzed, where the control function represents the PrEP strategy and the mixed constraint models the fact that, due to PrEP costs, epidemic context and program coverage, the number of individuals under PrEP is limited at each instant of time. The objective is to determine the PrEP strategy that satisfies the mixed state control constraint and minimizes the number of individuals with pre-AIDS HIV-infection as well as the costs associated with PrEP. The optimal control problem is studied analytically. Through numerical simulations, we demonstrate that PrEP reduces HIV transmission significantly. Theses and Dissertations	2018	SILVA, ANA PAULA DA	Avaliação da aceitabilidade e implicações para o uso da profilaxia pré-exposição (PrEP) na prevenção da infecção pelo HIV em coorte de homens que fazem sexo com homens (HSH) – Projeto Horizonte/UFMG	-	-	Universidade Federal de Minas Gerais	-	-	NA	NA	A Profilaxia pré-exposição (PrEP) é nova estratégia de prevenção ao HIV que consiste no uso de antirretrovirais (ARV) por pessoas soronegativas. Este estudo foi desenvolvido com HSH, HIV negativos (Proj.Horizonte/UFMG) em 2 abordagens: 1)Inquérito epidemiológico para avaliar aceitabilidade e conhecer benefícios/barreiras; 2)Grupos Focais para avaliar a experiência do uso da PrEP entre participantes do ensaio clínico fase I que acompanhou 40 participantes, 4 meses, uso diário de Tenofovir/Lamivudina. Metodologia: 1)Inquérito epidemiológico com voluntários do Proj. Horizonte, questionário semiestruturado 2)Grupos Focais (GF) com participantes ensaio clínico. As narrativas foram organizadas/classificadas valorizando núcleos de sentido (Análise do conteúdo). Resultados: Inquérito epidemiológico: Entre abr/2014-dez/2015 212 HSH entrevistados. Idade mediana: 37 anos, 51% nível superior, 82.5% trabalhando, 70.8% com renda até 3 salários, 66,4% negros/pardos. Utilizariam PrEP: 76.8%, 13.7% indecisos, 9.5% não utilizariam. Benefícios percebidos: opção a mais de prevenção, segurança em situações de vulnerabilidade (eg. romper preservativo). Benefícios/barreiras: medo do estigma por uso ARV; indisciplina no uso diário de medicamento; entraves na rede pública de saúde: distribuição/acesso. Para maioria, a PrEP levará ao relaxamento/abandono da prevenção. Adesão está condicionada ao medo dos efeitos colaterais, necessidade de informações adequadas. Grupos Focais: 33/40 participantes do ensaio clínico. Motivações: solidariedade/altruísmo; confiança na equipe. Medo dos efeitos colaterais e insegurança quanto à eficácia da PrEP colocaram em dúvida a participação. Durante o ensaio não houve mudanças na prevenção. No entanto, nos GF houve relatos de risco ancorados na crença de imunidade que a medicação proporcionou. Dificuldades: relaxamento/abandono do preservativo; medo dos efeitos colaterais; indisciplina no uso diário do medicamento; estigma/preconceito associado ao uso de ARV. Para eles, a implementação da PrEP no SUS necessitaria: acesso fácil, não interrupção pelo governo, preparo das equipes de saúde e informação.Alertam sobre o deslocamento de esforços da assistência para a prevenção. Conclusões: A maioria relatou otimismo e utilizaria a PrEP como forma adicional de prevenção. Mas acreditam que poderá ocorrer abandono da prevenção, potencializando cultura atual do não uso do preservativo. A confiança no medicamento poderá gerar concepção equivocada da PrEP como forma isolada de prevenção desconsiderando outras IST. Medo dos efeitos colaterais, estigma e indisciplina no uso de medicamentos poderão comprometer a adesão. É necessário desenvolver estratégias de educação considerando diversos contextos de vulnerabilidade. Para adequada implementação no SUS será preciso organização logística para garantir abastecimento/acesso aos ARV e capacitação das equipes de saúde.	PrEP. Prevenção do HIV. HSH. Estudo qualitativo. Article	2018	Silverman T.B.; Schrimshaw E.W.; Franks J.; Hirsch-Moverman Y.; Ortega H.; El-Sadr W.M.; Colson P.W.	Response Rates of Medical Providers to Internet Surveys Regarding Their Adoption of Preexposure Prophylaxis for HIV: Methodological Implications	Journal of the International Association of Physicians in AIDS Care	-	-	-	23259574	10.1177/2325958218798373	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055618089&doi=10.1177%2f2325958218798373&partnerID=40&md5=6c0ba67d1e313a835efd8af81d255b72	In 2016 to 2017, we surveyed primary care providers (PCPs) in upper Manhattan and the South Bronx, New York, on their knowledge, attitudes, and practices surrounding preexposure prophylaxis (PrEP) for HIV. Despite efforts to promote survey response, we were only able to obtain a meager response rate, limiting our ability to interpret results. In this short communication, we examine our survey's methodology, as well as the methods used by other similar studies, in order to suggest how certain strategies appear to influence PCP response to PrEP surveys. Administering the survey in a variety of modes, sampling from a professional organization's listserv, promoting the survey topic's relevance to potential participants, and offering monetary incentives to each survey respondent all appear to be promising strategies for increasing response rates in PrEP provider surveys. © The Author(s) 2018.	attitudes; clinical providers; HIV prevention; preexposure prophylaxis; survey	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Silverman, Taylor; Asante, Nicole; Jacob J van den Berg	Quality of HIV Websites With Information About Pre-Exposure Prophylaxis or Treatment as Prevention for Men Who Have Sex With Men: Systematic Evaluation	JMIR Public Health and Surveillance	-	-	-	30327291	10.2196/11384	https://www.proquest.com/scholarly-journals/quality-hiv-websites-with-information-about-pre/docview/2509603928/se-2?accountid=8113	Background: Knowledge and uptake of high-efficacy HIV prevention strategies such as pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP) remain low among men who have sex with men (MSM) who are at the highest risk for HIV infection in the United States. Electronic health (eHealth) interventions are promising tools for disseminating information about these critical yet underutilized strategies and addressing key barriers to uptake among target populations. However, existing HIV prevention websites are understudied and unevaluated. Objective: This study aimed to systematically review and evaluate existing HIV websites that include information about PrEP or TasP for MSM. Methods: From March 2018 to May 2018, 2 trained research assistants (RAs) entered relevant key words and phrases into 3 commonly used search engines and applied exclusion criteria to all returned results to identify 31 websites included in this review. RAs independently scored each website for authority, usability, interactivity, and PrEP/TasP-related content based on a standardized rating scale and then averaged the results. Results: No website received a perfect score in any of the 4 categories, and the average website score was 62% (37/60). Less than a quarter of the websites (23%, 7/31) received a score of more than 75% (7.5/10) for content. Approximately two-thirds of the websites (65%, 20/31) received a score of 50% (5/10) or lower for interactivity. The average score in usability was 68% (6.8/10) and in authority was 69% (6.9/10). Other deficiencies observed included difficulty locating relevant content and lack of information targeting audiences with the highest likelihood of HIV infection. Conclusions: Existing HIV prevention websites with information about PrEP or TasP for MSM fail to provide adequate content as well as present that content to users in an interactive and audience-conscious way. Future eHealth interventions should attempt to rectify these deficiencies to successfully engage and educate MSM at high risk for HIV regarding prevention strategies. Article	2018	Singh A.E.; Tan D.; Hull M.; Bogoch I.I.; Macpherson P.; Tremblay C.; Shafran S.	Canadian guidelines on HIV pre-exposure prophylaxis (PrEP) and non-occupational post-exposure prophylaxis (nPEP): Discussion beyond the guidelines and commentary on the role of infectious diseases specialists	Journal of the Association of Medical Microbiology and Infectious Disease Canada (JAMMI)	-	-	-	23710888	https://doi.org/10.3138/jammi.2018-002	https://utppublishing.com/doi/10.3138/jammi.2018-0024	Pre-exposure prophylaxis (PrEP) and non-occupational post-exposure prophylaxis (nPEP) are part of combination HIV prevention strategies that include behavioural interventions such as condoms and risk-reduction counselling. A 25-member panel was convened to develop Canadian guidelines for PrEP and nPEP, with the full guidelines recently published in the Canadian Medical Association Journal (CMAJ). This article provides a discussion beyond the guideline, highlighting areas of particular interest to infectious disease (ID) specialists and discusses the possible role of ID specialists as access to both PrEP and nPEP become more widely available across the country. © 2018, University of Toronto Press Inc.. Article	2018	Smith D.K.; Switzer W.M.; Peters P.; Delaney K.P.; Granade T.C.; Masciotra S.; Shouse L.; Brooks J.T.	A strategy for PrEP clinicians to manage ambiguous HIV test results during follow-up visits	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/ofid/ofy180	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067552524&doi=10.1093%2fofid%2fofy180&partnerID=40&md5=6fcd1def004c8e9aabd5ed4624782ac	Prompt determination of HIV infection status is critical during follow-up visits for patients taking pre-exposure prophylaxis (PrEP) medication. Those who are uninfected can then continue safely taking PrEP, and those few who have acquired HIV infection can initiate an effective treatment regimen. However, a few recent cases have been reported of ambiguous HIV test results using common testing algorithms in PrEP patients. We review published reports of such cases and testing options that can be used to clarify true HIV status in these situations. In addition, we review the benefits and risks of 3 antiretroviral management options in these patients: (1) continue PrEP while conducting additional HIV tests, (2) initiate antiretroviral therapy for presumptive HIV infection while conducting confirmatory tests, or (3) discontinue PrEP to reassess HIV status after a brief antiretroviral-free interval. A clinical consultation resource is also provided. © The Author(s) 2018. Article	2018	Smith D.K.; Van Handel M.; Grey J.	Estimates of adults with indications for HIV pre-exposure prophylaxis by jurisdiction, transmission risk group, and race/ethnicity, United States, 2015	Annals of Epidemiology	-	-	-	10472797	10.1016/j.annepidem.2018.05.003	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048888705&doi=10.1016%2fj.annepidem.2018.05.003&partnerID=40&md5=a034f9b60a723abb6d925d597519b294	Purpose: Effectively measuring progress in delivering HIV pre-exposure prophylaxis (PrEP) requires subnational estimates of the number of adults with indications for its use that account for differences in HIV infection rates by transmission risk (risk) group and race/ethnicity. Methods: We applied a multiplier method with 2015 Centers for Disease Control and Prevention surveillance data on proportions of HIV diagnoses by race/ethnicity and risk group and population-based estimates of risk group sizes to derive estimated numbers of adults with indications for PrEP by risk group (men who have sex with men MSM, heterosexually active adults HET, and persons who inject drugs PWID) by race/ethnicity in each jurisdiction. Results: An estimated 1.1 million adults had indications for PrEP use in 2015: 813,970 MSM, 258,080 HET, and 72,510 persons who inject drugs, and 500,340 blacks, 282,260 Latinos, and 303,230 whites. Among HET, 176,670 females and 81,410 males had indications. The proportions of adults with indications in each risk and race/ethnicity group varied by jurisdiction. Conclusions: Blacks comprised the highest number of adults with indications showing that increasing PrEP use in this population must be the highest priority. MSM remain a priority because of the high number with indications. These estimates can be used as denominators to assess PrEP coverage and impact on HIV incidence at subnational levels. © 2018	Heterosexuals; HIV; MSM; PrEP; PWID; Racial/ethnic populations	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Smith, M Kumi; Graham, Matthew; Latkin, Carl A; Go, Vivian L	Using Contact Patterns to Inform HIV Interventions in Persons Who Inject Drugs in Northern Vietnam.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001632	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5889335	OBJECTIVES: Population mixing patterns can greatly inform allocation of HIV prevention interventions such as treatment as prevention or preexposure prophylaxis. Characterizing contact patterns among subgroups can help identify the specific combinations of contact expected to result in the greatest number of new infections. SETTING: Baseline data from an intervention to reduce HIV-related risk behaviors in male persons who inject drugs (PWID) in the Northern Vietnamese province of Thai Nguyen were used for the analysis. METHODS: Egocentric network data were provided by PWID who reported any drug-injection equipment sharing in the previous 3 months. Age-dependent mixing was assessed to explore its epidemiological implications on risk of HIV transmission risk (among those HIV-infected) and HIV acquisition risk (among those not infected) in PWID. RESULTS: A total of 1139 PWID collectively reported 2070 equipment-sharing partnerships in the previous 3 months. Mixing by age identified the 30-34 and 35-39 years age groups as the groups from whom the largest number of new infections was transmitted, making them primary targets for treatment as prevention. Among the uninfected, 25-29, 30-35, and 35-39 years age groups had the highest HIV acquisition rate, making them the primary targets for preexposure prophylaxis. CONCLUSIONS: Collection and analysis of contact patterns in PWID is feasible and can greatly inform infectious disease dynamics and targeting of appropriate interventions. Results presented also provide much needed empirical data on mixing to improve mathematical models of disease transmission in this population. Article	2018	Spinelli M.A.; Scott H.M.; Vittinghoff E.; Liu A.Y.; Morehead-Gee A.; Gonzalez R.; Gandhi M.; Buchbinder S.P.	A panel management and patient navigation intervention is associated with earlier prep initiation in a safety-net primary care health system	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001828	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054947970&doi=10.1097%2fQAI.0000000000001828&partnerID=40&md5=a75c1908ff1b7b2899559b7984faf068	Background: Timely pre-exposure prophylaxis (PrEP) initiation is critical in at-risk populations, given that HIV acquisition risk persists during delays. Time to treatment initiation, a key metric in HIV care, has not been explored among PrEP users. Interventions that reduce time to PrEP initiation could prevent HIV infections. Setting: Individuals initiating PrEP in a large primary care health network of 15 clinics, the San Francisco Primary Care Clinics (SFPCC), from July 2012 to July 2017 (N = 411). Methods: We examined factors associated with time from first PrEP discussion with a provider to PrEP initiation date using an adjusted Cox proportional-hazards model, with hazard ratios (HRs) >1 indicating earlier initiation. We also examined the relationship between delayed PrEP initiation and PrEP persistence (staying on PrEP) in an adjusted Cox proportional-hazards model. Results: PrEP users initiated PrEP after a median of only 7 days. However, there were notable outliers, with 29% waiting .30 days and 12% waiting >90 days. In an adjusted proportional-hazards model, a panel management and patient navigation intervention was associated with earlier PrEP initiation HR: 1.5; 95% confidence interval (CI): 1.1 to 2.0, whereas only other race/ethnicity compared with white race was associated with delayed PrEP initiation (HR: 0.7; 95% CI: 0.5 to 1.0). Delayed PrEP initiation .30 days was associated with shorter PrEP persistence in an adjusted proportionalhazards model (HR: 1.3; 95% CI: 1.0 to 1.7). Conclusions: PrEP initiation within a week is feasible in a primary care safety-net health system. Setting a goal of rapid PrEP initiation, with the support of panel management and patient navigation, could address delays in at-risk groups. © 2018 Wolters Kluwer Health, Inc. All rights reserved. Article	2018	Stekler, Joanne D; Scanlan, James M; Simoni, Jane M; Crane, Heidi M; Fredericksen, Rob J; Marquard, Jenna; Saver, Barry G	Predictors of Art and PrEP Adherence and Medication-Taking Practices and Preferences to Inform Development of a Wrist-Worn Adherence System.	AIDS Education and Prevention	-	-	-	1943-2755	10.1521/aeap.2018.30.5.357	https://dx.doi.org/10.1521/aeap.2018.30.5.357	We examined adherence, medication-taking practices, and preferences to inform development of a wrist-worn adherence system. Two convenience samples of persons taking antiretroviral therapy and HIV pre-exposure prophylaxis completed a survey. Additional online questions asked about willingness to use a wrist-worn device and reminder and feedback preferences. Among 225 participants, 13% reported adherence < 90%; this was associated with younger age and clinic sample. Compared to pill bottle-using participants, medset users less commonly reported adherence < 90% (aOR = 0.16, p = .02), and blister pack users (aOR = 6.3, p = .02) and pill roll users (aOR = 3.3, p = .04) more commonly reported adherence < 90%. Sixty-two percent of the online participants reporting adherence (< 100%) had some interest in receiving adherence reminders, including 42% with interest in receiving reminders by smartwatch notifications. Although confounders are likely, formative work identified potential users and interest in using a wrist-worn adherence system. Future work will determine its acceptability and efficacy. Article	2018	Stellbrink H.-J.; Hoffmann C.	Cabotegravir: Its potential for antiretroviral therapy and preexposure prophylaxis	Current Opinion in HIV and AIDS	-	-	-	1746630X	10.1097/COH.0000000000000480	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048182208&doi=10.1097%2fCOH.0000000000000480&partnerID=40&md5=2651805ef44d72de5216fff13eaaf7f3	Purpose of review Analyzing the evidence for the strand transfer integrase inhibitor cabotegravir (CAB; GSK744, GSK1265744), its properties and differences from other compounds in the class, as well as reviewing the preclinical and clinical evidence for its potential in antiretroviral therapy and medical HIV prevention. Recent findings CAB has been investigated both as an oral and an injectable compound. Recent results show that it has promising properties with regards to its potential for parenteral maintenance therapy in combination with other compounds in HIV-infected patients currently suppressed on oral agents, as well as in preexposure prophylaxis. Summary The strand transfer integrase inhibitor CAB is currently being investigated as an intramuscular preparation with a long half-life allowing for four to eight-weekly injection intervals, and as an oral preparation. The latter is currently only used in trials for achieving an undetectable viral load in antiretroviral-naive patients, assessing tolerability, and covering phases of suboptimal exposure to the parenteral preparation. Phase 2 trials of a dual regimen of CAB and rilpivirine have demonstrated promising virological activity in oral as well as in parenteral therapy, which are currently investigated in phase three trials. Moreover, CAB protected macaques from experimental simian/human immunodeficiency virus infection and showed promising tolerability in the first trial in humans for preexposure prophylaxis of HIV infection. CAB might, therefore, provide the basis of the new treatment paradigm of parenteral treatment and prevention of HIV infection. © 2018 Wolters Kluwer Health, Inc. Article	2018	Sullivan P.S.; Giler R.M.; Mouhanna F.; Pembleton E.S.; Guest J.L.; Jones J.; Castel A.D.; Yeung H.; Kramer M.; McCallister S.; Siegler A.J.	Trends in the use of oral emtricitabine/tenofovir disoproxil fumarate for pre-exposure prophylaxis against HIV infection, United States, 2012–2017	Annals of Epidemiology	-	-	-	10472797	10.1016/j.annepidem.2018.06.009	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050085678&doi=10.1016%2fj.annepidem.2018.06.009&partnerID=40&md5=2cfb470bea7e6ae46ebc7a7bd2ceec3e	Purpose: Pre-exposure prophylaxis (PrEP) with oral emtricitabine/tenofovir disoproxil fumarate (TDF/FTC) reduces the risk of HIV infection by >90% when taken as prescribed. Trends in prevalence of PrEP use, which account for persons who have stopped PrEP, increased through 2016, but have not been described since. Methods: Annual prevalence estimates of unique, TDF/FTC PrEP users (individuals with ≥1 day of a filled PrEP prescription in a given year) in the United States (US) were generated for 2012–2017 from a national prescription database. A validated algorithm was used to distinguish users of TDF/FTC for HIV or chronic Hepatitis B treatment or postexposure prophylaxis from PrEP users. We calculated annual prevalence of PrEP use overall and by age, sex, and region. We used log-transformation to calculate estimated annual percent change (EAPC) in the prevalence of PrEP use. Results: Annual prevalence of PrEP use increased from 3.3/100,000 population in 2012 to 36.7 in 2017 –a 56% annual increase from 2012 to 2017 (EAPC: +56%). Annual prevalence of PrEP use increased faster among men than among women (EAPC: +68% and +5%, respectively). By age group, annual prevalence of PrEP use increased fastest among 25- to 34-year olds (EAPC: +61%) and slowest among ≥55-year olds (EAPC: +52%) and ≤24-year olds (EAPC: +51%). In 2017, PrEP use was lowest in the South (29.8/100,000) and highest in the Northeast (62.3/100,000). Conclusions: Despite overall increases in the annual number of TDF/FTC PrEP users in the US from 2012 to 2017, the growth of PrEP coverage is inconsistent across groups. Efforts to optimize PrEP access are especially needed for women and for those living in the South. © 2018 The Authors	HIV; HIV prevention; Pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Sullivan P.S.; Siegler A.J.	Getting pre-exposure prophylaxis (PrEP) to the people: Opportunities, challenges and emerging models of PrEP implementation	Sexual Health	-	-	-	14485028	10.1071/SH18103	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057555032&doi=10.1071%2fSH18103&partnerID=40&md5=042ec8b0e60c5dfe12b3bf501ec1ef66	Pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate and emtricitabine (TDF/FTC) is now accepted as an efficacious approach to preventing HIV acquisition among people at high risk of HIV infection but, in most places, PrEP uptake to date has not been sufficient to have a large effect on HIV incidence. In this paper we consider several key elements of the effort to expand PrEP uptake for at-risk populations who would benefit most, such as increasing access to PrEP, integrating PrEP programs with other services, promoting PrEP persistence and developing systems for monitoring PrEP use. We used a PrEP Continuum framework to describe barriers to equitable uptake of PrEP, and to illustrate possible solutions to barriers. Access to PrEP includes regulatory issues and geographic proximity to PrEP providers. Integrating PrEP programs with other comprehensive sexual health services, through clinic-based programs or technology-based approaches, offers opportunities to identify PrEP candidates and improve linkages to PrEP care. Once at-risk people are prescribed PrEP, lowering barriers to persistence on PrEP is critical to realising the most population benefits. To understand progress and identify underserved groups and communities, systems to monitor the uptake of PrEP are needed. Making the most of a new biomedical intervention tool requires ongoing research about implementation, scale-up through multiple channels, including community-based organisations, and high-quality monitoring of uptake. We must turn to questions of PrEP implementation and continue to seek innovative approaches to reduce barriers to PrEP uptake and persistence on PrEP. © 2018 CSIRO.	health equity; HIV prevention; men who have sex with men; people who inject drugs	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2018	Suraratdecha C.; Stuart R.M.; Manopaiboon C.; Green D.; Lertpiriyasuwat C.; Wilson D.P.; Pavaputanon P.; Visavakum P.; Monkongdee P.; Khawcharoenporn T.; Tharee P.; Kittinunvorakoon C.; Martin M.	Cost and cost-effectiveness analysis of pre-exposure prophylaxis among men who have sex with men in two hospitals in Thailand	Journal of the International AIDS Society	-	-	-	17582652	10.1002/JIA2.25129	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066922398&doi=10.1002%2fJIA2.25129&partnerID=40&md5=7d934df25bedd264869100d8b227d869	Introduction: In 2014, the Government of Thailand recommended pre-exposure prophylaxis (PrEP) as an additional HIV prevention programme within Thailand's National Guidelines on HIV/AIDS Treatment Prevention. However, to date implementation and uptake of PrEP programmes have been limited, and evidence on the costs and the epidemiological and economic impact is not available. Methods: We estimated the costs associated with PrEP provision among men having sex with men (MSM) participating in a facility-based, prospective observational cohort study: the Test, Treat and Prevent HIV Programme in Thailand. We created a suite of scenarios to estimate the cost-effectiveness of PrEP and sensitivity of the results to the model input parameters, including PrEP programme effectiveness, PrEP uptake among high-risk and low-risk MSM, baseline and future antiretroviral therapy (ART) coverage, condom use, unit cost of delivering PrEP, and the discount rate. Results: Drug costs accounted for 82.5% of the total cost of providing PrEP, followed by lab testing (8.2%) and personnel costs (7.8%). The estimated costs of providing the PrEP package in accordance with the national recommendation ranges from US$223 to US$311 per person per year. Based on our modelling results, we estimate that PrEP would be cost-effective when provided to either high-risk or all MSM. However, we found that the programme would be approximately 32% more cost-effective if offered to high-risk MSM than it would be if offered to all MSM, with an incremental cost-effectiveness ratio of US $4,836 per disability-adjusted life years (DALY) averted and US$7,089 per DALY averted respectively. Cost-effectiveness acceptability curves demonstrate that 80% of scenarios would be cost-effective when PrEP is provided solely to higher-risk MSM. Conclusion: We provide the first estimates on cost and cost-effectiveness of PrEP in the Asia-Pacific region, and offer insights on how to deliver PrEP in combination with ART. While the high drug cost poses a budgeting challenge, incorporating PrEP delivery into an existing ART programme could be a cost-effective strategy to prevent HIV infections among MSM in Thailand. © 2018 The Authors. Factors associated with partner notification of STIs in men who have sex with men on PrEP in France: A cross-sectional substudy of the ANRS-IPERGAY trial	Sexually Transmitted Infections	-	-	-	13684973	10.1136/sextrans-2017-053304	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049070412&doi=10.1136%2fsextrans-2017-053304&partnerID=40&md5=7a6bb7837a0bef412a514d54c0ee779a	Objectives Partner notification (PN) is a useful public health approach to enhance targeted testing of people at high risk of HIV and other STIs, and subsequent linkage to care for those diagnosed. In France, no specific PN guidelines exist and information about current practices is scarce. We used the ANRS-IPERGAY PrEP trial to investigate PN in HIV-negative men who have sex with men (MSM) reporting a bacterial STI. Methods T his substudy included 275 participants who completed a specific online PN questionnaire during the open-label extension study of the ANRS-Intervention Préventive de l'Exposition aux Risques avec et pour les Gays (IPERGAY) trial. Variables used as proxies of at-risk practices were defined using data collected at the previous follow-up visit about participants' most recent sexual encounter and preventive behaviours. X2 or Fisher's exact test helped select variables eligible for multiple logistic models. Results O f the 275 participants, 250 reported at least one previous STI. Among the latter, 172 (68.8%) had informed their partner(s) of their most recent STI. Of these, 138 (80.2%) and 83 (48.3%) had notified their casual and main partners, respectively. Participants were less likely to notify their main partner when their most recent sexual encounter involved unsafe anal sex with a casual partner (adjusted OR (aOR) (95% CI) 0.18 (0.06 to 0.54), P=0.02). Older participants were less likely to inform casual partners (aOR (95% CI) 0.44 (0.21 to 0.94), P=0.03), while those practising chemsex during their most recent sexual encounter were more likely to inform their casual partners (aOR (95% CI) 2.56 (1.07 to 6.09), P=0.03). Conclusion Unsafe sexual encounters with people other than main partners and street drugs use were two sociobehavioural factors identified, respectively, as a barrier to main PN and a motivator for casual PN, in a sample of high-risk MSM. These results provide an insight into current PN practices regarding STI in France and might inform future decisions about how to define feasible and acceptable PN programmes. © Article author(s) (or their employer(s) unless otherwise stated in the text of the article) 2018. Article	2018	Tairy D.; Levy I.; Turner D.; Livnat Y.; Mor Z.	Differences in knowledge, attitudes and behaviors of Israeli HIV-uninfected gay men in HIV-discordant vs. concordant steady relationships	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1417533	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85038367856&doi=10.1080%2f09540121.2017.1417533&partnerID=40&md5=c6298aaca5e20bc8b516b64a53b98849	HIV-discordant gay male couples may play an important role in HIV-transmissions. This cross-sectional study compared the knowledge, attitudes and sexual behaviors of HIV-uninfected gay men, between those in HIV-discordant and those in HIV-concordant steady relationships. Anonymous questionnaires were distributed electronically in designated gay-related internet sites and in AIDS-clinics in 2015. The dependent variable was defined as a steady relationship of an HIV-uninfected man with an HIV-infected partner. Risky sexual behavior was defined as unprotected anal intercourse (UAI) with a sex partner whose HIV-status was either positive or unknown. Of 2,319 responders, 460 (20%) were HIV-uninfected gay men in steady relationships, of whom 72 were in HIV-discordant relationships and 388 were in HIV-concordant relationships. Those in HIV-discordant relationships presented better established knowledge regarding HIV-transmission, more lenient attitudes regarding UAI, and reported being involved in riskier sexual behavior, both within and outside their steady relationship compared to men in HIV-concordant relationships. UAI was performed by 48% of the HIV-discordant couples and was associated with the use of sero-positioning strategy and with achieving undetectable viral-load. These findings reflect the complexity of constant use of condoms during long-term sero-discordant relationships. Targeted interventions for HIV-prevention in HIV-discordant couples should be employed for balancing the partners' desire for intimacy and sexual pleasure in the relationship, while reducing the risk for acquiring HIV. Abbreviations: ART: Antiretroviral therapy; PEP: Post exposure prophylaxis; PrEP: Pre exposure prophylaxis; STI: Sexually transmitted infections; UAI: Unprotected anal intercourse. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Tan, Rayner Kay Jin; Teo, Alvin Kuo Jing; Kaur, Nashwinder; Harrison-Quintana, Jack; I-Cheng Chen, Mark; Wong, Chen Seong	Cost and anonymity as factors for the effective implementation of pre-exposure prophylaxis: an observational study among gay, bisexual and other men who have sex with men in Singapore.	Sexual Health	-	-	-	1448-5028	10.1071/SH18059	https://dx.doi.org/10.1071/SH18059	Background HIV pre-exposure prophylaxis (PrEP) is currently offered by several public and private clinics at unsubsidised prices in Singapore, but to date, no information is available on the effect of these services. This study sought to assess the knowledge and uptake of, and willingness to use PrEP among gay, bisexual and other men who have sex with men (GBMSM) in Singapore. METHODS: Recruitment was conducted through Grindr®, a geosocial networking application for GBMSM. Results were quantitatively analysed through descriptive statistics and multivariate Poisson regression models, while open-ended responses were qualitatively coded and categorised. RESULTS: Of the 1339 participants who responded, 1098 participants who indicated their knowledge and use of PrEP were included in the analytic sample. Overall, 15.0% (n=154) had taken PrEP, 66.2% (n=678) had heard of but not taken PrEP, while 18.8% (n=193) had never heard of PrEP. Of those who had ever taken PrEP, 59.6% (n=90) had obtained PrEP from overseas or other unofficial sources. Of those who had heard of but never taken PrEP, 73.3% (n=486) reported that they would consider taking PrEP. Those who had taken PrEP were older and had higher educational attainment. CONCLUSIONS: The gap between the willingness to use PrEP and its uptake may be attributed to the cost of PrEP and issues of anonymity at healthcare settings in Singapore. National financing schemes are needed to expand access to PrEP if it is to make a meaningful effect to the Singapore HIV/AIDS response. Article	2018	Tang, Eric C; Vittinghoff, Eric; Anderson, Peter L; Cohen, Stephanie E; Doblecki-Lewis, Susanne; Bacon, Oliver; Coleman, Megan E; Buchbinder, Susan P; Chege, Wairimu; Kolber, Michael A; Elion, Richard; Shlipak, Michael; Liu, Albert Y	Changes in Kidney Function Associated With Daily Tenofovir Disoproxil Fumarate/Emtricitabine for HIV Preexposure Prophylaxis Use in the United States Demonstration Project.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001566	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5762266	BACKGROUND: HIV preexposure prophylaxis (PrEP) using daily oral tenofovir-disoproxil-fumarate/emtricitabine (TDF/FTC) is effective for preventing HIV acquisition, but concerns remain about its potential kidney toxicity. This study examined kidney function in individuals using PrEP in real-world clinical settings. SETTING: Demonstration project in 2 sexually transmitted infection clinics and a community health center. METHODS: We evaluated kidney function among men who have sex with men and transgender women taking tenofovir-disoproxil-fumarate/emtricitabine PrEP for up to 48 weeks. Serum creatinine and urine dipstick for protein were obtained at 12-week intervals. Kidney function was estimated using creatinine clearance (CrCl) (Cockcroft-Gault) and estimated glomerular filtration rate (eGFR) (CKD-EPI). RESULTS: From October 2012 to January 2014, we enrolled 557 participants (median age 33). Mean creatinine increased from baseline to week 12 by 0.03 mg/dL (4.6%) (P < 0.0001); mean CrCl decreased by 4.8 mL/min (3.0%) (P < 0.0001). These changes remained stable through week 48 (P = 0.81, P = 0.71 respectively). There were 75/478 (15.7%) participants who developed worsening proteinuria at week 12 compared with baseline (P < 0.0001), and this percent remained stable through week 48 (P = 0.73). Twenty-five participants (5.1%) developed new-onset eGFR <70 mL/min/1.73 m; independent predictors of this outcome were age ≥40 years (OR 3.79, 95% CI: 1.43 to 10.03) and baseline eGFR <90 mL/min/1.73 m (OR 9.59, 3.69-24.94). CONCLUSIONS: In a demonstration setting, daily tenofovir-disoproxil-fumarate/emtricitabine PrEP leads to reduced CrCl and eGFR; however, these eGFR changes are based on very small changes in serum creatinine and seem to be nonprogressive after the first 12 weeks. Future studies are needed to understand the prognostic significance of these small changes. Theses and Dissertations	2018	Terry-Smith, Justin B	Factors Influencing Use of Pre-Exposure Prophylaxis Among Men Who Have Sex With Men	-	-	Walden University	-	NA	NA	https://scholarworks.waldenu.edu/cgi/viewcontent.cgi?article=6552&context=dissertations	Prevention is key to keeping men who have sex with men (MSM) protected from Human Immunodeficiency Virus (HIV). Despite new and innovative HIV prevention resources such as pre-exposure prophylaxis (PrEP), factors such as education level, employment status, number of sexual partners, and access to health resources may inhibit certain populations from using PrEP. The purpose of this cross-sectional study was to examine the association between education level, employment status, number of sexual partners, and access to health resources and the use of PrEP among MSM. The fundamental cause theory was used to examine how socioeconomic barriers are associated with the use of PrEP among MSM in the United States. Secondary data from 217 surveys were collected from the Public Library of Science. Findings from multiple regression analyses indicated that employment status, access to health resources, and number of sexual partners were not associated with use of PrEP among MSM. Those who had at least some high school or a high school diploma were 3.98 times more likely to be likely to extremely likely to use PrEP, compared to those who had less than a high school education (OR = 3.98, p = .048). Those who had some college were 6.91 more likely to be likely to extremely likely to use PrEP, compared to those who had less than a high school education (OR = 6.91, p = .028). Findings may be used to assist public health professionals in identifying factors that prevent the use of PrEP. By addressing these health threats, and social barriers, specialists could have the ability to increase HIV prevention activity in populations that are more susceptible to being infected with HIV and may decrease HIV infections not only within the MSM population but also in other populations. Article	2018	Thaden J.T.; Gandhi M.; Okochi H.; Hurt C.B.; McKellar M.S.	Seroconversion on preexposure prophylaxis: A case report with segmental hair analysis for timed adherence determination	AIDS	-	-	-	2699370	10.1097/QAD.0000000000001825	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048373658&doi=10.1097%2fQAD.0000000000001825&partnerID=40&md5=e0e1e8f7e58c0b6744bdfcb8773e300b	Objective: We describe the third case report of seroconversion with multidrug resistant (MDR)-HIV despite pre-exposure prophylaxis (PrEP) with emtricitabine (FTC) and tenofovir (TFV) disoproxil (TDF). Design: Case report. Methods: PrEP adherence was assessed via self-report, pharmacy records, and measuring TFV/FTC levels with liquid-chromatography/tandem-mass-spectrometry in plasma and hair. Segmental hair analysis was performed to assess PrEP adherence over prior months. Genotypic resistance was assessed. Results: A 34 year-old white MSM started daily FTC/TDF in February 2016 after being provided 11 refills. In March 2017, he developed fevers, chills, myalgias and was assessed, but no HIV test was sent. In April 2017, an antigen/antibody HIV test was reactive (day 0). On day 2, HIV-1 RNA was 27 316 copies/ml, genotyping revealed M184V, K70T, K65R, and K103N mutations, plasma TFV and FTC concentrations were consistent with recent dosing. To evaluate adherence over preceding months, a hair sample was collected at day 27 and segmental analysis of TFV/FTC levels performed in one-centimeter segments from the scalp. Hair drug levels (0.0434-0.0520 ng TFV/mg hair) were commensurate with consistently high PrEP adherence over the prior 3 months. Conclusions: This study employs segmental analysis of PrEP drug levels in hair for the first time to assess adherence over preceding months in the setting of an HIV seroconversion on PrEP. High adherence over the period of likely acquisition makes MDR-HIV infection the most likely scenario in this case. Adequate adherence assessment when examining PrEP failures and ensuring best practices in PrEP prescribing and follow-up are important. Copyright © 2018 Wolters Kluwer Health, Inc. Article	2018	Thoma B.C.; Huebner D.M.	HIV pre-exposure prophylaxis engagement among adolescent men who have sex with men: The role of parent-adolescent communication about sex	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001837	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055612482&doi=10.1097%2fQAI.0000000000001837&partnerID=40&md5=6bfd1941ba6c0906bac4893390eb8ceb	Background:Adolescent men who have sex with men (AMSM) are severely affected by the HIV epidemic in the United States. Pre-exposure prophylaxis (PrEP) has proven extremely effective in preventing new HIV infections among adult men who have sex with men, but no research has examined PrEP awareness among AMSM. Furthermore, initial research investigating PrEP adherence among AMSM has found low adherence to the medication regimen. Effective parent-adolescent communication about sex is associated with safer sexual health behaviors among AMSM, and parent-adolescent communication is one potential avenue to increase PrEP engagement among AMSM.Setting:Participants included 636 AMSM in the United States who completed a cross-sectional online survey in 2015.Methods:Self-reported data on PrEP awareness, attitudes about PrEP, and perceived behavioral control for PrEP usage as well as frequency and quality of parent-adolescent communication about HIV were collected from AMSM. Regression models predicting PrEP awareness, attitudes, and perceived behavioral control from communication constructs were estimated, adjusting for demographic covariates.Results:Sixteen percent of AMSM were aware of PrEP. AMSM who reported more frequent communication about HIV with their parents were more likely to report being aware of PrEP. Among AMSM aware of PrEP, higher quality parent-adolescent communication about HIV was associated with higher perceived behavioral control for PrEP usage.Conclusions:Despite high HIV incidence among AMSM in the United States, PrEP awareness is low in this population. Effective parent-adolescent communication about HIV and sexual health could increase AMSM engagement with PrEP and enhance PrEP adherence within future trials among AMSM. © 2018 Wolters Kluwer Health, Inc. Article	2018	Thomann M.	On December 1, 2015, sex changes. Forever': Pre-exposure prophylaxis and the pharmaceuticalisation of the neoliberal sexual subject	Global Public Health	-	-	-	17441692	10.1080/17441692.2018.1427275	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85040971626&doi=10.1080%2f17441692.2018.1427275&partnerID=40&md5=516a0b66939598111a04ec94f17560d2	The global scale-up of AIDS treatment initiatives during the first decade of the twenty-first century has been referred to as a kind of 'pharmaceuticalisation' of public health, a trend that is now building in the area of HIV prevention. This paper traces the emergence and increased uptake of pre-exposure prophylaxis (PrEP), antiretroviral medications that can keep HIV negative individuals from becoming infected, placing it within the broader (re)casting of HIV prevention as a medical and technological problem that has been central to the recent 'end of AIDS' discourse. While HIV prevention discourses have been grounded in a neoliberal calculus of individual responsibility since the late 1990s, PrEP constitutes a pharmaceutical extension of the responsibilised sexual subject. Central to this extension are the acknowledgement of one's risk and a willingness to take pre-emptive medical action to secure a future without HIV. For men who have sex with men, a population heavily targeted for biomedical interventions in the United States, PrEP marks a shift in moral discourses of what it means to be a responsible sexual subject. Characteristics of the pharmaceutical extension of the neoliberal sexual subject are explored through an examination of a New York City-based PrEP promotional campaign. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	biomedical interventions; HIV prevention and treatment; men who have sex with men; neoliberalism; Pre-exposure prophylaxis	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2018	Thomann M.; Grosso A.; Zapata R.; Chiasson M.A.	WTF is PrEP?': attitudes towards pre-exposure prophylaxis among men who have sex with men and transgender women in New York City	Culture, Health & Sexuality	-	-	-	13691058	10.1080/13691058.2017.1380230	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85031109660&doi=10.1080%2f13691058.2017.1380230&partnerID=40&md5=36e420ee704ec0a6995eb4027d9b42b7	In the USA, gay and other men who have sex with men and transgender women are disproportionately affected by HIV. Uptake of pre-exposure prophylaxis (PrEP), anti-retroviral therapy to prevent HIV-negative individuals from seroconverting if exposed to HIV, by members of this population remains low, particularly among African-Americans. We conducted two focus groups to assess responses to an online social media campaign focusing on PrEP use in New York City. We designed, produced and disseminated the campaign to address knowledge of PrEP; its physical and psychological side effects; and psychosocial barriers related to PrEP adherence and sex shaming. Focus group participants demonstrated a relatively high knowledge of PrEP, although considerable concern remained about side effects, particularly among Black participants. Participants suggested that stigma against PrEP users was declining as PrEP use became more common, but stigma remained, particularly for those not using condoms. Many focus group participants reported distrust of medical providers and were critical of the commodification of HIV prevention by the pharmaceutical industry. Participants reported that those in romantic relationships confronted unique issues regarding PrEP, namely suspicions of infidelity. Finally, Black participants spoke of the need for more tailored and sensitive representations of Black gay men in future programmes and interventions. © 2017, © 2017 Informa UK Limited, trading as Taylor & Francis Group.	focus groups; men who have sex with men; PrEP; social media; transgender women	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2018	Thomson K.A.; Dhanireddy S.; Andrasik M.; Hancuch K.; Legg L.; Keane-Candib J.; Heffron R.	Fertility desires and preferences for safer conception strategies among people receiving care for HIV at a publicly-funded clinic in Seattle, WA	AIDS Care	-	-	-	9540121	10.1080/09540121.2017.1390541	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85032200328&doi=10.1080%2f09540121.2017.1390541&partnerID=40&md5=cde2662beab1ac97e9345f2c09fa9d12	Understanding fertility desires and preferences for HIV prevention among individuals living with HIV, including the potential use of pre-exposure prophylaxis (PrEP) by HIV uninfected partners, can inform the delivery of safer conception counseling to reduce the risk of HIV transmission during pregnancy attempts. Men and women, predominantly heterosexual, engaged in HIV care in Seattle, WA, self-administered a questionnaire and we abstracted antiretroviral therapy (ART) status and HIV viral levels from medical records. We summarized participants' sexual behavior, fertility desires, and preferences for safer conception strategies and used log-binomial regression to identify demographic, sexual, and behavioral factors associated with perceived acceptability of PrEP for HIV uninfected partners during pregnancy attempts. 52% of the 150 participants were female and the mean age was 48 years (range 23–74). 94.7% of participants were using ART and 79.3% had HIV viral load < 40 copies/mL. 22.2% of men and 34.6% of women reported that a healthcare provider had initiated discussion about fertility desires. 28.7% of participants were reproductive-age and desired children. Among sexually active reproductive-age participants with fertility desires, 56.3% reported inconsistent condom use and 62.5% did not report using effective birth control. 74.4% of reproductive age participants with fertility desires perceived that PrEP would be acceptable to an HIV uninfected partner and there were no significant predictors of PrEP acceptability. Nearly one third of reproductive-aged individuals living with HIV expressed fertility desires, highlighting a need for safer conception counseling in this setting. PrEP and ART were favored safer conception strategies. © 2017 Informa UK Limited, trading as Taylor & Francis Group. Article	2018	Thomson K.A.; Hughes J.; Baeten J.M.; John-Stewart G.; Celum C.; Cohen C.R.; Ngure K.; Kiarie J.; Mugo N.; Heffron R.	Increased Risk of HIV Acquisition among Women Throughout Pregnancy and during the Postpartum Period: A Prospective Per-Coital-Act Analysis among Women with HIV-Infected Partners	Journal of Infectious Diseases	-	-	-	221899	10.1093/infdis/jiy113	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046943327&doi=10.1093%2finfdis%2fjiy113&partnerID=40&md5=7ebf42614e3731982597da2007e4fffc	Background Understanding the absolute and relative risk of human immunodeficiency virus type 1 (HIV) acquisition during pregnancy and the postpartum period can inform HIV prevention strategies for women. Methods We used a complementary log-log model and data from 2751 HIV-serodiscordant couples to compare the probability of HIV acquisition among women per sex act during early pregnancy, late pregnancy, the postpartum period, and the nonpregnant period. Results At total of 686 pregnancies were identified, and 82 incident HIV infections occurred. After adjustment for condom use, age, preexposure prophylaxis (PrEP) use, and HIV viral load, the per-act probability of HIV acquisition was higher in late pregnancy (adjusted relative risk aRR, 2.82; P =.01) and the postpartum period (aRR, 3.97; P =.01) as compared to that during the nonpregnant period. For a 25-year-old woman not taking PrEP, the HIV acquisition probability per condomless sex act with an HIV-infected male partner with a viral load of 10 000 copies/mL was 0.0011 (95% confidence interval CI 0.005-0.0019), 0.0022 (95% CI, 0.0004-0.0093), 0.0030 (95% CI, 0.0007-0.0108), and 0.0042 (95% CI, 0.0007-0.0177) during the nonpregnant period, early pregnancy, late pregnancy, and the postpartum period, respectively. Conclusion The HIV acquisition probability per condomless sex act steadily increased during pregnancy and was highest during the postpartum period, suggesting that biological changes during pregnancy and the postpartum period increase HIV susceptibility among women. © The Author(s) 2018. Theses and Dissertations	2018	Thomson, Kerry Ann	HIV-1 Risk and Prevention Strategies for Women during Pregnancy and Postpartum	-	-	University of Washington	-	NA	NA	http://hdl.handle.net/1773/40888	HIV-1 is the leading cause of death worldwide among women of reproductive age, and this group is a priority to reach with effective HIV-1 prevention. There is great potential to provide HIV-1 interventions to women during the periconception, pregnancy, and postpartum periods by leveraging existing healthcare settings that serve women and couples at high risk of HIV-1 acquisition. These opportunities include integration of HIV-1 prevention strategies within antenatal and postnatal care programs in settings with high HIV-1 prevalence and inclusion of safer conception programs within clinical HIV-1 care for HIV-1 affected individuals and couples desiring children. Specifically, antiretrovirals, as PrEP used by HIV-1 uninfected people and ART used by HIV-1 infected people, are highly effective and important for women and couples, especially those planning and experiencing pregnancy. The aims within this dissertation address questions regarding HIV-1 risk and implementation of antiretrovirals for HIV-1 prevention among women and their partners during reproductive stages, including: quantifying the risk of female HIV-1 acquisition in different reproductive stages, making the case for PrEP as a highly efficacious HIV-1 strategy for women, and describing fertility intentions and willingness to use safer conception strategies during pregnancy attempts among HIV-1 infected individuals. Previous studies have shown that pregnancy and postpartum are periods with heightened HIV-1 acquisition risk for women, but it is not clear whether this is primarily driven by biological or behavioral factors. We have addressed this gap by using robust data from two longitudinal studies to estimate the per coital act probability of female HIV-1 acquisition during the early pregnancy, late pregnancy, and postpartum stages, relative to time periods to unrelated to pregnancy. We found that the risk of HIV-1 transmission per coital act steadily increased during pregnancy and was highest during postpartum, even after accounting for sexual behavior, PrEP, and HIV-1 viral load, suggesting that biological changes during these periods increase HIV-1 risk. Conflicting results and conclusions from the initial randomized clinical trials that assessed efficacy of PrEP for HIV-1 prevention among women has spurred debate about whether PrEP is a strategy that women will use effectively. This debate has delayed the initiation of programs to deliver PrEP to women, and specifically has been a barrier to the integration of PrEP into antenatal and postnatal care where it has the potential to reach women who most need enhanced HIV-1 prevention. We have objectively assessed and synthesized existing evidence of PrEP efficacy among women and made a conclusive case that PrEP is an effective HIV-1 prevention strategy for women. Couples affected by HIV-1 with fertility desires experience heightened vulnerability to HIV-1 acquisition when they forgo condom use during pregnancy attempts. "Safer conception" is a risk reduction approach where HIV-1 serodiscordant couples use one or…	HIV; infectivity; postpartum; pre-exposure prophylaxis (PrEP); pregnancy; safer conception; Epidemiology; Epidemiology	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Clinical
Article	2018	Tintori C.; Iovenitti G.; Ceresola E.R.; Ferrarese R.; Zamperini C.; Brai A.; Poli G.; Dreassi E.; Cagno V.; Lembo D.; Canducci F.; Botta M.	Rhodanine derivatives as potent anti-HIV and anti-HSV microbicides	PLOS One	-	-	-	19326203	10.1371/journal.pone.0198478	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048110417&doi=10.1371%2fjournal.pone.0198478&partnerID=40&md5=6ecc8349a3961c7baf6637fe6c893d41	Although highly active antiretroviral therapies (HAART) remarkably increased life expectancy of HIV positive people, the rate of novel HIV-1 infections worldwide still represent a major concern. In this context, pre-exposure prophylaxis (PrEP) approaches such as vaginal microbicide gels topically releasing antiretroviral drugs, showed to have a striking impact in limiting HIV-1 spread. Nevertheless, the co-presence of other genital infections, particularly those due to HSV-1 or 2, constitute a serious drawback that strongly limits the efficacy of PrEP approaches. For this reason, combinations of different compounds with mixed antiviral and antiretroviral activity are thoroughly investigated Here we report the synthesis and the biological evaluation of a novel series of rhodanine derivatives, which showed to inhibit both HIV-1 and HSV-1/2 replication at nanomolar concentration, and were found to be active also on acyclovir resistant HSV-2 strains. The compounds showed a considerable reduction of activity in presence of serum due to a high binding to serum albumin, as determined through in vitro ADME evaluations. However, the most promising compound of the series maintained a considerable activity in gel formulation, with an EC50 comparable to that obtained for the reference drug tenofovir. Moreover, the series of compounds showed pharmacokinetic properties suitable for topical formulation, thus suggesting that the novel rhodanine derivatives could represent effective agents to be used as dual anti HIV/HSV microbicides in PrEP approaches. © 2018 Tintori et al. Article	2018	To K.W.; Lee S.S.	HIV pre-exposure prophylaxis in South East Asia: A focused review on present situation	International Journal of Infectious Diseases	-	-	-	12019712	10.1016/j.ijid.2018.10.027	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056555579&doi=10.1016%2fj.ijid.2018.10.027&partnerID=40&md5=7243053506b0e6ed08e40fb4a9a29e2b	Pre-exposure prophylaxis (PrEP) with the use of antiretrovirals has been approved for HIV prevention in many western countries and internationally. PrEP is however not yet widely available in South East Asia. Awareness of PrEP among MSM in the region is very variable in different countries. While willingness of PrEP uptake is closely related to the extent of awareness, it is largely affected by factors at the individual level, e.g. financial consideration, risk perception, understanding of PrEP and convenience. Removal of social stigmata and secure data confidentiality can improve willingness of uptake. The diverse religious beliefs in South East Asia could have potential influence on PrEP uptake but there was very limited data in the region. There is no strong evidence suggesting substantial risk compensation among MSM who are on PrEP. As in other parts of the world, education on condom use to prevent other sexually transmitted diseases (STD) should be properly addressed rather than blaming PrEP as a sole cause of rise in STD among MSM. © 2018	HIV; MSM; Pre-exposure prophylaxis; Risk compensation; South East Asia	English	Netherlands	Western and Central Europe and North America	China	Asia and the Pacific	China	Asia and the Pacific	Review
Article	2018	Torres, Thiago Silva; De Boni, Raquel Brandini; de Vasconcellos, Mauricio Tl; Luz, Paula Mendes; Hoagland, Brenda; Moreira, Ronaldo Ismerio; Veloso, Valdilea Gonçalves; Grinsztejn, Beatriz	Awareness of Prevention Strategies and Willingness to Use Preexposure Prophylaxis in Brazilian Men Who Have Sex With Men Using Apps for Sexual Encounters: Online Cross-Sectional Study.	JMIR Public Health and Surveillance	-	-	-	2369-2960	10.2196/publichealth.8997	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5799718	BACKGROUND: Geosocial networking (GSN) smartphone apps are becoming the main venue for sexual encounters among Brazilian men who have sex with men (MSM). To address the increased HIV incidence in this population, preexposure prophylaxis (PrEP) was recently implemented in the Brazilian public health system in the context of combined HIV prevention. OBJECTIVE: This study aimed to describe the characteristics of MSM using GSN apps for sexual encounters, their awareness of prevention strategies, and willingness to use PrEP. METHODS: This study was an online cross-sectional study conducted in 10 Brazilian state capitals from July 1 to July 31, 2016. The questionnaire was programmed on SurveyGizmo and advertised in two GSN apps used by MSM to find sexual partners (Hornet and Grindr). Inclusion criteria were >18 years of age, cisgender men, with an HIV-negative status. Eligible individuals answered questions on: demographics; behavior; and knowledge, preferences, and willingness to use PrEP, nonoccupational postexposure prophylaxis (nPEP), HIV self-testing (HIVST), and condoms. Logistic regression modeling was performed to assess the factors associated with daily oral PrEP willingness. RESULTS: During the study period, 8885 individuals provided consent and started the questionnaire. Of these, 23.05% (2048/8885) were ineligible, 6837 (6837/8885, 76.94%) initiated, and 5065 (5065/8885, 57.00%) completed the entire questionnaire and were included in the present analysis. Median age was 30 years (interquartile range: 25-36), most self-declared as MSM (4991/5065, 98.54%), white (3194/5065, 63.06%), middle income (2148/5065, 42.41%), and had 12 or more years of schooling (3106/5062, 61.36%). The majority of MSM (3363/5064, 66.41%) scored >10 points (high risk) on The HIV Incidence Risk for MSM Scale, but only 21.39% (1083/5064) had a low perceived likelihood of getting HIV in the next year. Daily use of apps for sex was reported by 35.58% (1798/5054). Most MSM (4327/5065, 85.43%) reported testing for HIV at least once in their lifetime and 9.16% (464/5065) used nPEP in the previous year. PrEP, nPEP, and HIVST awareness was reported by 57.89% (2932/5065), 57.39% (2907/5065), and 26.57% (1346/5065) of participants, respectively. Half of all respondents (2653/5065, 52.38%) were willing to use daily oral PrEP, and this finding was associated with higher numbers of male sexual partners (adjusted odds ratio AOR 1.26, 95% CI 1.09-1.47), condomless receptive anal intercourse (AOR 1.27, 95% CI 1.12-1.44), sex with HIV-positive partner versus no HIV-positive partner (one HIV-positive partner: AOR 1.36, 95% CI 1.11-1.67), daily use of apps for sexual encounters (AOR 1.48, 95% CI 1.17-1.87), high and unknown perceived likelihood of getting HIV in the next year (AOR 1.72, 95% CI 1.47-2.02 and AOR 1.39, 95% CI 1.13-1.70), sexually transmitted infection diagnosis (AOR 1.25, 95% CI 1.03-1.51), stimulant use (AOR 1.24, 95% CI 1.07-1.43), PrEP awareness (AOR 1.48, 95% CI 1.30-1.70), and unwillingness to use condoms (AOR 1.16, 95% CI 1.00-1.33). CONCLUSIONS: Our results evidenced high-risk scores in the studied population, suggesting the importance of PrEP use. Those individuals presenting risky sexual behaviors were more willing to use PrEP. Nonetheless, only 58% (2932/5065) of individuals had heard about this prevention strategy. Efforts to increase awareness of new prevention strategies are needed, and mobile health tools are a promising strategy to reach MSM. Essay	2018	Trachman M.; Gelly M.; Girard G.	Undoing and redoing an at-risk group: The objectivation and prevention of aids among male homosexuals in the antiretroviral era	Population	-	-	-	16342941	10.3917/pope.1804.0751	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072525772&doi=10.3917%2fpope.1804.0751&partnerID=40&md5=5114ec494c5ba00f61f4bfb4486a6fbc	In the 1990s, the fight against HIV became a national cause, the preventive initiatives of which addressed the entire population to avoid any stigmatization. In the 2000s, recognizing the existence of "high-risk groups" no longer posed a problem and determined more targeted action. In response to the resurgence in risk-taking, the players involved in these efforts worked to understand groups through the close observation of their behaviour. Focusing on male homosexuals, the article analyses two recent innovations embodying this trend: the demedicalization of screening and pre-exposure prophylaxis. These developments show that the observed changes are not simply about expressing what should not be said, but instead involve renewed work on objectivation, the mobilization of members of the target population, and a certain idea of the risk-taking individual. The detection of at-risk behaviour also serves to delimit the populations with which intervention is possible and the implementation of the necessary tools. © I.N.E.D. Essay	2018	Trachman, Mathieu; Girard, Gabriel	Targeting Fallible Men: Communication Strategies and Moral Issues in a Pre-exposure Prophylaxis Trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001806	https://dx.doi.org/10.1097/QAI.0000000000001806	Based on the analysis of a French pre-exposure prophylaxis trial (Ipergay), and focusing on the communication strategies used to recruit volunteers, this article explores the figure who serves to justify the trial and who shapes the way in which populations concerned by this prevention tool are targeted. We show that this figure is that of the fallible man, a classic in moral philosophy: while aware of what is good or right for him, he is unable to put this knowledge into practice. The targeting of fallible men makes sense in the context of a resurgence of high-risk behaviors objectified in the late 1990s: qualifying gays who take risks as fallible individuals create a distance with respect to the "barebacker" who risks his life deliberately and has no intention of changing his behavior. Recognizing that certain gays are vulnerable to risk also provides justification for a preventive strategy that acknowledges the inadequacy of behavioral prevention, without giving up on prevention altogether. All in all, this analysis shows that the technological and epidemiological realism often highlighted in pre-exposure prophylaxis interventions is not without a moral dimension, attentive to individuals' contradictions and singularities, doubts and uncertainties, and to the risk of stigmatization inherent to the acknowledgement of risk-taking.	pre-exposure prophylaxis trial; communication strategies; HIV; gay men; France	English	United States	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Other
Article	2018	Traeger M.W.; Schroeder S.E.; Wright E.J.; Hellard M.E.; Cornelisse V.J.; Doyle J.S.; Stoové M.A.	Effects of Pre-exposure Prophylaxis for the Prevention of Human Immunodeficiency Virus Infection on Sexual Risk Behavior in Men Who Have Sex with Men: A Systematic Review and Meta-analysis	Clinical Infectious Diseases	-	-	-	10584838	10.1093/cid/ciy182	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048975498&doi=10.1093%2fcid%2fciy182&partnerID=40&md5=b1cfe1eeb85423514bab2c5e2f857ef4	Background. Human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) is effective in reducing HIV risk in men who have sex with men (MSM). However, concerns remain that risk compensation in PrEP users may lead to decreased condom use and increased incidence of sexually transmitted infections (STIs). We assessed the impact of PrEP on sexual risk outcomes in MSM. Methods. We conducted a systematic review of open-label studies published to August 2017 that reported sexual risk outcomes in the context of daily oral PrEP use in HIV-negative MSM and transgender women. Pooled effect estimates were calculated using random-effects meta-analysis, and a qualitative review and risk of bias assessment were performed. Results. Sixteen observational studies and 1 open-label trial met selection criteria. Eight studies with a total of 4388 participants reported STI prevalence, and 13 studies with a total of 5008 participants reported change in condom use. Pre-exposure prophylaxis use was associated with a significant increase in rectal chlamydia (odds ratio (OR), 1.59; 95% confidence interval (CI), 1.19-2.13) and an increase in any STI diagnosis (OR, 1.24; 95% CI, .99-1.54). The association of PrEP use with STI diagnoses was stronger in later studies. Most studies showed evidence of an increase in condomless sex among PrEP users. Conclusion. Findings highlight the importance of efforts to minimize STIs among PrEP users and their sexual partners. Monitoring of risk compensation among MSM in the context of PrEP scale-up is needed to assess the impact of PrEP on the sexual health of MSM and to inform preventive strategies. © The Author(s) 2018.	human immunodeficiency virus; pre-exposure prophylaxis; risk compensation; sexual behavior; sexually transmitted infections. Article	2018	Traore, Yannick L.; Chen, Yufei; Ho, Emmanuel A.	Current State of Microbicide Development.	Clinical Pharmacology and Therapeutics	-	-	-	1532-6535 0009-9236	10.1002/cpt.1212	https://pubmed.ncbi.nlm.nih.gov/30107032/	Efforts in developing an effective vaccine for human immunodeficiency virus (HIV) has been challenging as HIV strains are highly variable and exhibit extraordinary mutability. Despite condom usage and pre-exposure prophylaxis as excellent prevention strategies, lack of accessibility in some developing countries and low adherence due to sociocultural factors continue to act as barriers in reducing the HIV epidemic. Microbicides are topical therapies developed to prevent HIV and other sexually transmitted infections during intercourse. Microbicides applied vaginally or rectally are intended to prevent HIV infection at the site of transmission by either inhibiting its entry into immune cells or direct viral replication. This review will summarize some of the current state-of-the-art microbicide formulations that are in preclinical and clinical stages of development and discuss some of the challenges associated with microbicide development. Essay	2018	Tuller D.	HIV prevention drug's slow uptake undercuts its early promise	Health Affairs	-	-	-	2782715	10.1377/hlthaff.2017.1650	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85046765338&doi=10.1377%2fhlthaff.2017.1650&partnerID=40&md5=87bcf11d769d7f25b367ba92b1067bdb	Each year in France, several thousand people find out that they are HIV-positive, despite relentless information and prevention campaigns since the 1990s. Associations and public authorities have been decisive in the struggle against the epidemic. The authors revisit the history of public health policies to combat AIDS and examine the transition from a prevention policy aimed at the general population to one targeting the individuals who are most at risk. To this end, using a variety of data, the authors analyse responses to three crucial questions: What is an at-risk group? How can we target at-risk individuals without stigmatizing them? And what are some strategies that can help protect them? Article	2018	Tumarkin, Ethan; Heendeniya, Amila; Murphy, Pauline; Placido, Tania; Tan, Darrell H S; Bogoch, Isaac I	HIV Postexposure Prophylaxis-in-Pocket ("PIP") for Individuals With Low-Frequency, High-Risk HIV Exposures.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001639	https://dx.doi.org/10.1097/QAI.0000000000001639	BACKGROUND: On-demand preexposure prophylaxis may reduce one's risk of HIV acquisition; however, it is unclear if individuals with a very low frequency of HIV exposures are conferred adequate protection. We evaluated a novel approach dubbed HIV postexposure prophylaxis-in-pocket ("PIP"), for individuals with a low frequency of high-risk HIV exposures. SETTING: Two HIV clinics in Toronto, Canada, managing HIV prevention cases. METHODS: A retrospective evaluation of patients referred to HIV clinics for preexposure prophylaxis between January 1, 2013, and September 30, 2017, inclusive. After counseling and education, selected patients were initiated on PIP if they were having very infrequent HIV exposures. RESULTS: Thirty patients were prescribed PIP. Four patients (13.3%) used PIP during this study. There were no HIV seroconversions in 21.8 cumulative patient-years of PIP. CONCLUSIONS: PIP may be a useful HIV prevention modality for individuals with a very low frequency of HIV exposures. Article	2018	Tung E.L.; Thomas A.; Eichner A.; Shalit P.	Implementation of a community pharmacy-based pre-exposure prophylaxis service: A novel model for pre-exposure prophylaxis care	Sexual Health	-	-	-	14485028	10.1071/SH18084	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056527215&doi=10.1071%2fSH18084&partnerID=40&md5=7222f30ad7732498ed201642174322b9	Background: National guidelines for the provision of HIV pre-exposure prophylaxis (PrEP) to reduce a person's risk of acquiring HIV were made available in 2014. We created a pharmacist-managed HIV PrEP clinic in a community pharmacy setting at Kelley-Ross Pharmacy in Seattle, WA, USA. Methods: The clinic operates under a collaborative drug therapy agreement based on these guidelines. This allows pharmacists to initiate and manage tenofovir disoproxil fumarate/emtricitabine under the supervision of a physician medical director. Results: Between March 2015 and February 2018, 714 patients were evaluated and 695 (97.3%) initiated PrEP. Five hundred and thirteen (74%) patients began medication the same day as their initial appointment. Of the prescriptions filled in our pharmacy, 90% of patients had a mean proportion of days covered (PDC) greater than 80%, and 98% had a zero-dollar patient responsibility per month, including uninsured individuals. 19% of patients were lost to follow up, with an effective drop-out rate of 25%. Two hundred and seven diagnoses of sexually transmissible infections were made. There were no HIV seroconversions in the service. Conclusion: The pharmacist-managed PrEP clinic proved to be a successful alternative model of PrEP care, with high initiation rates and low drop-out and lost-to-follow-up rates. This may benefit individuals who do not access PrEP in traditional health care settings or where PrEP access is scarce. Financial sustainability of the model was dependent on the ability of pharmacists in the clinic to bill insurance plans for their services in accordance with Washington State legislative changes requiring commercial insurances to recognize pharmacists as providers. © 2018 CSIRO.	pharmacist-managed PrEP; PrEP adherence; PrEP clinic	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
Article	2018	Turner, Leah; Roepke, Abbey; Wardell, Emily; Teitelman, Anne M	Do You PrEP? A Review of Primary Care Provider Knowledge of PrEP and Attitudes on Prescribing PrEP.	Journal of the Association of Nurses in AIDS Care	-	-	-	1552-6917	10.1016/j.jana.2017.11.002	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7653672	Oral preexposure prophylaxis (PrEP) has been proven to be a safe and effective means of preventing HIV. The purpose of our literature review was to examine primary care provider knowledge and attitudes about prescribing PrEP. PubMed, CINAHL, Web of Science, and Scopus were searched and additional articles were identified through other sources, yielding 11 articles that met inclusion criteria. Overall, there was high variability among providers regarding attitudes, knowledge, and prescriptive practices related to PrEP. PrEP continues to be an underutilized HIV prevention intervention and more research focusing on provider-specific factors is warranted.	attitudes and beliefs, health knowledge, HIV, preexposure prophylaxis, primary care	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2018	Underhill K.; Guthrie K.M.; Colleran C.; Calabrese S.K.; Operario D.; Mayer K.H.	Temporal Fluctuations in Behavior, Perceived HIV Risk, and Willingness to Use Pre-Exposure Prophylaxis (PrEP)	Archives of Sexual Behavior	-	-	-	40002	10.1007/s10508-017-1100-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85040368837&doi=10.1007%2fs10508-017-1100-8&partnerID=40&md5=c4ecf20b2235312adfc08aef7e8deaeb	Individual perceptions of HIV risk influence willingness to use pre-exposure prophylaxis (PrEP) for HIV prevention. Among men who have sex with men (MSM) and male sex workers (MSWs), temporal or episodic changes in risk behavior may influence perceived risk and PrEP acceptability over time. We investigated fluctuations in perceived HIV risk and PrEP acceptability, comparing MSWs against MSM who do not engage in sex work. We conducted 8 focus groups (n = 38) and 56 individual interviews among MSM and MSWs in Providence, RI. Perceived HIV risk shaped willingness to use PrEP among both MSWs and MSM who did not engage in sex work, and risk perceptions changed over time depending on behavior. For MSWs, perceived risk cycled according to patterns of substance use and sex work activity. These cycles yielded an "access-interest paradox": an inverse relationship between willingness to use and ability to access PrEP. MSM who did not engage in sex work also reported temporal shifts in risk behavior, perceived risk, and willingness to use PrEP, but changes were unrelated to access. MSM attributed fluctuations to seasonal changes, vacations, partnerships, behavioral "phases," and episodic alcohol or drug use. Efforts to implement PrEP among MSM and street-based MSWs should address temporal changes in willingness to use PrEP, which are linked to perceived risk. Among MSWs, confronting the access-interest paradox may require intensive outreach during high-risk times and efforts to address low perceived risk during times of reduced sex work. © 2018, Springer Science+Business Media, LLC. Article	2018	Uthappa C.K.; Allam R.R.; Pant R.; Pal S.; Dinaker M.; Oruganti G.; Yeldandi V.V.	Pre-exposure prophylaxis: awareness, acceptability and risk compensation behaviour among men who have sex with men and the transgender population	HIV Medicine	-	-	-	14642662	10.1111/hiv.12572	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85035192783&doi=10.1111%2fhiv.12572&partnerID=40&md5=b099f1ac6e74e78202592b9031135c5f	Objectives: This exploratory study examined the facilitators of and barriers to acceptance of pre-exposure prophylaxis (PrEP) and potential risk compensation behaviour emerging from its use among men who have sex with men (MSM) and transgender individuals (TGs) in India. Methods: A questionnaire was administered to 400 individuals registered with a targeted intervention programme. Logistic regression models were used to identify facilitators of and barriers to PrEP acceptance. Results: The respondents consisted of 68% MSM and 32% TGs. Risk behaviour categorization identified 40% as low risk, 41% as medium risk and, 19% as high risk for HIV infection. About 93% of the respondents were unaware of PrEP, but once informed about it, 99% were willing to use PrEP. The facilitators of PrEP acceptance were some schooling odds ratio (OR) 2.16; P = 0.51, being married or in a live-in relationship (OR 2.08; P = 0.46), having a high calculated risk (OR 3.12; P = 0.33), and having a high self-perceived risk (OR 1.8; P = 0.35). Increasing age (OR 2.12; P = 0.04) was a significant barrier. TGs had higher odds of acceptance of PrEP under conditions of additional cost (OR 2.12; P = 0.02) and once-daily pill (OR 2.85; P = 0.04). Individuals identified as low risk for HIV infection showed lower odds of potential risk compensation, defined as more sexual partners (OR 0.8; P = 0.35), unsafe sex with new partners (OR 0.71; P = 0.16), and decreased condom use with regular partners (OR 0.95; P = 0.84), as compared with medium-risk individuals. The associations, although not statistically significant, are nevertheless important for public health action given the limited scientific evidence on PrEP use among MSM and TGs in India. Conclusions: With high acceptability and a low likelihood of risk compensation behaviour, PrEP can be considered as an effective prevention strategy for HIV infection among MSM and TGs in India. © 2017 British HIV Association	HIV; men who have sex with men; pre-exposure prophylaxis; transgender	English	United Kingdom	Western and Central Europe and North America	india	Asia and the Pacific	india	Asia and the Pacific	Quantitative
Article	2018	Vaccher S.J.; Kaldor J.M.; Callander D.; Zablotska I.B.; Haire B.G.	Qualitative Insights into Adherence to HIV Pre-Exposure Prophylaxis (PrEP) among Australian Gay and Bisexual Men	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0106	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058052261&doi=10.1089%2fapc.2018.0106&partnerID=40&md5=eab32cc08d1a5b10ce5b00feee450b5a	The number of gay and bisexual men (GBM) taking HIV pre-exposure prophylaxis (PrEP) to prevent HIV has rapidly increased since 2010, but limited information about barriers and facilitators to adherence has been reported outside of formal trial settings. We conducted semistructured in-depth interviews with 24 Australian cis-and transgender GBM with a history of PrEP use to gather data on adherence to PrEP. The majority of participants were able to access PrEP at no cost through implementation studies. Three key domains were explored-how individuals took PrEP, factors that aided PrEP adherence, and barriers to PrEP use. All participants recognized the importance of regular dosing to ensure protection from HIV, with some participants taking the initiative to pre-empt possible adherence obstacles and plan around these. Multiple strategies were used to aid adherence, including using tools such as a phone alarm and support and tips from other PrEP users, friends, or clinicians. Barriers to PrEP adherence included stigma, concerns about side effects, and difficulties in accessing PrEP. Although most participants encountered at least one barrier to PrEP use, they were resourceful and utilized a variety of approaches to ensure good adherence to PrEP was maintained. These narratives highlight a commitment to finding ways to make PrEP work in the daily lives of this cohort of Australian GBM, demonstrated by their active investigation of different routines to determine the most suitable dosing strategy, and creation of contingency plans if they were unable to access PrEP in their usual or preferred manner. © 2018, Mary Ann Liebert, Inc., publishers.	adherence; barriers; gay and bisexual men; pre-exposure prophylaxis (PrEP); qualitative	English	United States	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Qualitative
Article	2018	Valencia, Jorge; Ryan, Pablo; Alvaro-Meca, Alejandro; Troya, Jesús; Gutierrez, Jorge; Cuevas, Guillermo; Moreno, Santiago	High HIV seroconversion rate in hepatitis C virus-infected drug users followed in a harm reduction unit: a lost opportunity for preexposure prophylaxis.	AIDS	-	-	-	1473-5571	10.1097/QAD.0000000000001806	https://dx.doi.org/10.1097/QAD.0000000000001806	OBJECTIVES: Current harm reduction strategies will probably remain insufficient to eliminate HIV transmission among drug users. We aimed to estimate the HIV seroconversion rate among drug users followed at a harm reduction unit (HRU) to evaluate the potential use of preexposure prophylaxis as a prevention tool. DESIGN AND METHODS: A cohort of drug users has been followed at an HRU in Madrid between 2013 and 2016. Individuals who were HIV negative at baseline and who had at least one retest for HIV infection were eligible. Kaplan-Meier methods were employed to estimate the incidence density. RESULTS: A total of 954 drug users had at least an HIV test. At baseline, 260 were HIV negative and had at least one follow-up HIV test. After 330.89 person-years of risk for HIV infection, 10 (3.8%) seroconverted. Overall incidence density of HIV seroconversion was 3.02 95% confidence interval (CI); 1.4-5.5 per 100 person-years, with differences according to hepatitis C virus (HCV) serostatus: 1.17 (95% CI; 0.1-4.2) per 100 person-years in negative HCV individuals and 4.98 (95% CI; 2.1-9.8) per 100 person-years in positive HCV individuals. In the multivariable analysis, infection with HCV remained independently associated with time to HIV seroconversion (adjusted hazard ratioâ=â6.43; 95% CI; 1.1-36.5, Pâ=â0.035). CONCLUSION: Despite efforts in HIV prevention in a HRU, a high incidence of HIV was found among active drug users. Positive HCV status is a strong predictor of HIV seroconversion. In this context, preexposure prophylaxis implementation should be considered as an additional tool for HIV prevention in this population. Article	2018	van Epps P.; Maier M.; Lund B.; Howren M.B.; Beck B.; Beste L.; Skolnik A.; Vaughan-Sarrazin M.; Ohl M.E.	Medication Adherence in a Nationwide Cohort of Veterans Initiating Pre-exposure Prophylaxis (PrEP) to Prevent HIV Infection	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001598	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053190758&doi=10.1097%2fQAI.0000000000001598&partnerID=40&md5=a568a629c3a88d4fb7b3105676f19a80	Background: Current guidelines for pre-exposure prophylaxis (PrEP) to prevent HIV infection call for long-term, daily use of tenofovir disoproxil fumarate/emtricitabine (TDF/FTC). Little is known about long-term adherence with TDF/FTC prescribed for PrEP in routine clinical practice. Setting: Veterans Health Administration (VHA) clinics. Methods: We used VHA data to create a nationwide cohort of Veterans initiating PrEP between July 1, 2012, and June 30, 2016. We examined pharmacy refill data to estimate adherence based on the proportion of days covered (PDC) by TDF/FTC in the first year and used logistic regression to identify patient characteristics associated with high adherence (ie, PDC.0.8). We also quantified how often Veterans discontinued PrEP in the first year, based on a gap of 120 days or more in medication possession. Results: Among 1086 individuals initiating PrEP, the median PDC for TDF/FTC in the first year was 0.74 (interquartile range 0.40-0.92). In the multivariable analysis, high adherence was associated with older age (odds ratio 1.97; 1.41-2.74 for age 50-64 compared with,35), white compared with black race (odds ratio 2.12; 1.53-2.93), and male sex (odds ratio 3.39; 1.37-8.42). Forty-four percent discontinued PrEP in the first year. Conclusions: First-year adherence with TDF/FTC was overall high in a nationwide cohort of PrEP users. Differences in adherence by age, race, and sex suggest potential for disparities in PrEP effectiveness in routine clinical practice. Copyright © 2017 Wolters Kluwer Health, Inc. All rights reserved. Article	2018	Van Slyke, Loraine; Scott, Mia	Acute Trigeminal Neuralgia Associated with Initiation of Emtricitabine/Tenofovir for HIV Pre-Exposure Prophylaxis.	Journal of the International Association of Providers of AIDS Care	-	-	-	2325-9582	10.1177/2325958218760846	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6748473	HIV pre-exposure prophylaxis (PrEP) with emtricitabine (FTC) and tenofovir disoproxil fumarate (TDF) fixed-dose combination (FTC/TDF) is undergoing rapid scale-up in the United States. While FTC/TDF is typically well tolerated, to our knowledge, cranial nerve pathology associated with FTC/TDF has not been previously described. We report the case of a 35-year-old patient who began FTC/TDF PrEP and developed acute trigeminal neuralgia. The neurologic symptoms resolved after treatment discontinuation and recurred upon rechallenge, resulting in permanent discontinuation of PrEP treatment.	neuralgia, tenofovir/emtricitabine, PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2018	Velloza, Jennifer; Baeten, Jared M; Haberer, Jessica; Ngure, Kenneth; Irungu, Elizabeth; Mugo, Nelly R; Celum, Connie; Heffron, Renee	Effect of Depression on Adherence to Oral PrEP Among Men and Women in East Africa.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001821	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6295199	BACKGROUND: Low adherence can undermine the efficacy of daily oral pre-exposure prophylaxis (PrEP). Mental health conditions, particularly depression, could be associated with low PrEP adherence, especially for women. SETTING: We analyzed data from 1013 Kenyan and Ugandan HIV-uninfected participants in the Partners Demonstration Project, an open-label study of PrEP delivered to HIV-uninfected members of serodiscordant couples. METHODS: Participants completed quarterly visits over 2 years and were encouraged to use PrEP until their partners living with HIV had ≥6 months of antiretroviral therapy use (when viral suppression was expected). PrEP adherence was measured daily with electronic medication event monitoring system caps and dichotomized into low (<80% of expected bottle openings) and high adherence. Depression was assessed annually using the 16-item Hopkins Symptom Checklist screening tool; scores >1.75 indicate "probable depression." The association between probable depression and PrEP adherence was assessed separately for men and women using generalized estimating equations and marginal structural models. RESULTS: At enrollment, 39 (11.7% of 334) women and 64 (9.4% of 679) men reported symptoms indicating probable depression, and these proportions decreased during follow-up (P < 0.001 for women and men). Probable depression was significantly associated with low PrEP adherence among women (adjusted risk ratio = 1.77; 95% confidence interval: 1.14 to 2.77; P = 0.01); there was no association between depression and adherence among men (P = 0.50). Marginal structural models and sensitivity analyses confirmed these findings. CONCLUSIONS: Depression was relatively uncommon in this population and was an independent risk factor for low PrEP adherence among women. For PrEP programs targeting African women, integration of depression screening may improve PrEP effectiveness.	depression, HIV, pre-exposure prophylaxis, Africa, women	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Venter W.D.F.	Pre-exposure Prophylaxis: The Delivery Challenge	Frontiers in Public Health	-	-	-	22962565	10.3389/fpubh.2018.00188	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060772085&doi=10.3389%2ffpubh.2018.00188&partnerID=40&md5=7cc114080c24f0874b97aae45dbf78ba	HIV pre-exposure prophylaxis (PrEP), despite its efficacy, has been slow in uptake throughout the world. This article discusses the operational and service delivery complexity, based on early real-world experience, with some recommendations on how this promising intervention could be made more available. Currently, access to PrEP is made complex by restricting delivery to dedicated health facilities, as well as requirements around HIV testing and toxicity monitoring. Expanding to verticalized services that focus on well-defined populations where HIV testing and treatment programmes already exist, has proven relatively simple. Providing PrEP outside of this environment has yet to be demonstrated at any scale, and will likely require innovative thinking addressing the regulatory and clinical environment, so as to ensure easier access to this promising HIV prevention tool. © Copyright © 2018 Venter. Article	2018	Venter, Willem D. F.; Fabian, June; Feldman, Charles	An overview of tenofovir and renal disease for the HIV-treating clinician.	Southern African Journal of HIV Medicine	-	-	-	2078-6751 1608-9693	10.4102/sajhivmed.v19i1.817	https://pubmed.ncbi.nlm.nih.gov/30167339/	Tenofovir disoproxil fumarate (TDF, commonly termed 'tenofovir') is the antiretroviral most commonly implicated in antiretroviral-induced nephrotoxicity. As patients on successful antiretroviral therapy (ART) age, their risk for developing renal disease may increase in part because of ART itself, but more importantly, because of HIV-associated and non-HIV-associated comorbidity. Therefore, clinicians need an approach to managing renal disease in people on TDF. TDF as a cause of acute kidney injury (AKI) or chronic kidney disease (CKD) is uncommon, and clinicians should always exclude other causes (Box 1). In TDF-associated AKI, TDF should be interrupted in all cases, and replaced, or ART interrupted altogether. Tenofovir disoproxil fumarate toxicity can present as AKI or CKD, and as a full or partial Fanconi's syndrome. TDF has a small but definite negative impact on kidney function (up to a 10% decrease in glomerular filtration rate GFR). This occurs because of altered tubular function in those exposed to TDF for treatment and as pre-exposure prophylaxis. Renal function should be assessed using creatinine-based estimated GFR at the time of initiation of TDF, if ART is changed, at 1-3 months, and then ideally every 6-12 months if stable. Specific tests of tubular function are not routinely recommended; in the case of clinical concern, a spot protein or albumin: creatinine ratio is preferable, but in resource-limited settings, urine dipstick can be used. More frequent monitoring may be required in those with established CKD (estimated glomerular filtration rate eGFR < 50 mL/min/1.73 m(2)) or risk factors for kidney disease. The most common risk factors are comorbid hypertension, diabetes, HIV-associated kidney disease, hepatitis B or C co-infection, and TDF in combination with a ritonavir-boosted protease inhibitor. Management of these comorbid conditions must be prioritised in this group. If baseline screening eGFR is < 50 mL/min/1.73 m(2), abacavir (the preferred option), and dose-adjusted TDF (useful if concomitant hepatitis B), zidovudine or stavudine (d4T) remain alternatives to full-dose TDF. If there is a rapid decline in kidney function (eGFR drops by more than 25% and decreases to < 50 mL/min/1.73 m(2) from of baseline function), or there is new onset or worsening of proteinuria or albuminuria, clinicians should review ART and other potentially nephrotoxic medications and comorbidity and conduct further testing if indicated. If kidney function does not improve after addressing reversible causes of renal failure, then referral to a nephrologist is appropriate. In the case of severe CKD, timeous referral for planning for renal replacement therapy is recommended. Tenofovir alafenamide, a prodrug of tenofovir, appears to have less renal toxicity and is likely to replace TDF in future. Article	2018	Vermeersch, Sebastian; Callens, Steven; De Wit, Stéphane; Goffard, Jean-Christophe; Laga, Marie; Van Beckhoven, Dominique; Annemans, Lieven	Health and budget impact of combined HIV prevention - first results of the BELHIVPREV model.	Acta Clinica Belgica	-	-	-	2295-3337	10.1080/17843286.2017.1339978	https://dx.doi.org/10.1080/17843286.2017.1339978	OBJECTIVES: We developed a pragmatic modelling approach to estimate the impact of treatment as prevention (TasP); outreach testing strategies; and pre-exposure prophylaxis (PrEP) on the epidemiology of HIV and its associated pharmaceutical expenses. METHODS: Our model estimates the incremental health (in terms of new HIV diagnoses) and budget impact of two prevention scenarios (outreach+TasP and outreach+TasP+PrEP) against a 'no additional prevention' scenario. Model parameters were estimated from reported Belgian epidemiology and literature data. The analysis was performed from a healthcare payer perspective with a 15-year-time horizon. It considers subpopulation differences, HIV infections diagnosed in Belgium having occurred prior to migration, and the effects of an ageing HIV population. RESULTS: Without additional prevention measures, the annual number of new HIV diagnoses rises to over 1350 new diagnoses in 2030 as compared to baseline, resulting in a budget expenditure of 260.5 million. Implementation of outreach+TasP and outreach+TasP+PrEP results in a decrease in the number of new HIV diagnoses to 865 and 663 per year, respectively. Respective budget impacts decrease by 20.6 million and 33.7 million. CONCLUSION: Foregoing additional investments in prevention is not an option. An approach combining TasP, outreach and PrEP is most effective in reducing the number of new HIV diagnoses and the HIV treatment budget. Our model is the first pragmatic HIV model in Belgium estimating the consequences of a combined preventive approach on the HIV epidemiology and its economic burden assuming other prevention efforts such as condom use and harm reduction strategies remain the same. Theses and Dissertations	2018	VILLELA, LARISSA MELO	Percepções sobre o uso da profilaxia pré-exposição ao HIV (PrEP) e possível compensação de risco entre homens que fazem sexo com homens (HSH) e mulheres transexuais (TRANS) potencialmente elegíveis para o uso de PrEP no protocolo PrEP Brasil	-	-	Instituto Nacional de Infectologia Evandro Chagas	-	-	NA	https://sucupira.capes.gov.br/sucupira/public/consultas/coleta/trabalhoConclusao/viewTrabalhoConclusao.jsf?popup=true&id_trabalho=6315634	No Brasil, a epidemia de HIV está concentrada entre populações-chave, incluindo homens que fazem sexo com homens (HSH), com uma prevalência estimada de 14,2% e mulheres transgênero (TRANS) para quem a chance ou infecção por HIV é 50 vezes maior do que na população em geral. Assim, estratégias de prevenção intensivas, incluindo profilaxia préexposição (PrEP) estão sendo oferecidas a estas populações no sentido de atingir o objetivo 90-90-90 da UNAIDS. A PrEP é uma estratégia de prevenção biomédica baseada no uso de medicamentos antirretrovirais (ARV) cuja eficácia foi demonstrada entre diversas populações. Apesar da alta aceitação e adesão a PrEP que vem sendo observadas em estudos de demonstração, persistem ainda questões sobre possíveis efeitos negativos da PrEP, como resistência a ARV, risco de toxicidade renal, uso de PrEP por pessoas com hepatite viral e compensação de risco. Além disso, à medida que a disponibilidade da PrEP aumenta, as atitudes e crenças sobre a PrEP devem ser melhor compreendidas para direcionar intervenções específicas às barreiras individuais e interpessoais que podem afetar a aceitação e a persistência da PrEP. Assim, esta dissertação tem como objetivo avançar no entendimento de possível compensação de risco, atitudes e crenças entre potenciais usuários de PrEP, visto que esta foi implementada sem custo no Sistema Único de Saúde (SUS). Trata-se de análise secundária dos dados do estudo PrEP Brasil e é apresentada em formato de artigo. O artigo apresenta uma análise transversal descrevendo prevalência de possível compensação de risco, percepções e crenças sobre o uso de PrEP entre 723 HSH e TRANS incluídos na fase de prétriagem do estudo PrEP Brasil. A possível compensação de risco foi avaliada pela questão "Eu deixaria de usar preservativos se eu usasse PrEP" e foi relatada por 31,5% dos indivíduos. No modelo multivariado, os fatores que aumentaram a chance de possível compensação de risco foram: cor branca vs. preta (AOR= 2,05; IC95%: 1,09 - 3,85), perceber alta chance de contrair o HIV nos próximos 12 meses (AOR= 1,78; IC95%: 1,23 -2,56), referir que teria menos medo da infecção pelo HIV se usasse a PrEP (AOR= 1,93; IC95%: 1,19-3,14), sentirse livre para ter mais parceiros se usasse a PrEP (AOR= 2,93 ; IC95%: 1,92- 4,49) e acreditar que os amigos mais próximos usariam a PrEP (AOR= 2,51; IC95%: 1,1- 5,71). Por outro lado, o interesse no uso de preservativo e ter realizado teste para o HIV nos 12 meses anteriores, diminuíram as chances de possível compensação de risco. (AOR= 0,22; IC95%: 0,15- 0,33 e AOR= 0,63; IC95%: 0,4-0,98, respectivamente). A prevalência de possível compensação de risco é similar a outros estudos que avaliaram a possível compensação de risco, e os fatores associados sugerem que os participantes percebem seu alto risco de infecção pelo HIV, possivelmente por já não utilizar preservativo e se sentiriam mais otimistas em relação ao comportamento sexual com o uso de PrEP. É discutida a necessidade de vigilância epidemiológica no sentido de monitorar a compensação de risco nos contextos reais de assistência à saúde. Article	2018	Vincent K.L.; Moss J.A.; Marzinke M.A.; Hendrix C.W.; Anton P.A.; Gunawardana M.; Dawson L.N.; Olive T.J.; Pyles R.B.; Baum M.M.	Phase I trial of pod-intravaginal rings delivering antiretroviral agents for HIV-1 prevention: Rectal drug exposure from vaginal dosing with tenofovir disoproxil fumarate, emtricitabine, and maraviroc	PLOS One	-	-	-	19326203	10.1371/journal.pone.0201952	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052159953&doi=10.1371%2fjournal.pone.0201952&partnerID=40&md5=76692b847d8af995b148be24c87784ca	Background Intravaginal rings (IVRs) can deliver antiretroviral (ARV) agents for HIV pre-exposure prophylaxis (PrEP), theoretically overcoming adherence concerns associated with frequent dosing. However, topical vaginal ARV drug delivery has not simultaneously led to sufficient rectal drug exposure to likely protect from HIV infection as a result of receptive anal intercourse (RAI). Unprotected RAI has a higher risk of infection per sex act and, for women, also can be associated with vaginal exposure during a single sexual encounter, especially in higher-risk subsets of women. The physiologically inflamed, activated, immune-cell dense colorectal mucosa is increasingly appreciated as the sexual compartment with highly significant risk; this risk is increased in the setting of co-infections. Ex vivo studies have shown that colorectal tissue and rectal fluid concentrations correlated with HIV protection. Given these important results, efforts to document colorectal compartment ARV drug concentration from pod-IVR delivery was assessed to determined if vaginal application could provide protective ARV levels in both compartments. Methodology/Principal findings A crossover clinical trial (N = 6) evaluated 7 d of continuous TDF pod-IVR use, a wash-out phase, followed by 7 d with a TDF-FTC pod-IVR. A subsequent clinical trial (N = 6) consisted of 7 d of continuous TDF-FTC-MVC pod-IVR use. Rectal fluids were collected on Day 7 at IVR removal in all three ARV-exposures (two Phase 1 trials) and drug concentrations quantified by LC-MS/MS. Median rectal fluid concentrations of TFV, the hydrolysis product of the prodrug TDF, were between 0.66 ng mg-1 (TDF pod-IVR group) and 1.11 ng mg-1 (TDF-FTC pod-IVR group), but below the analytical lower limit of quantitation in 5/6 samples in the TDF-FTC-MVC pod-IVR group. Unexpectedly, median FTC (TDF-FTC pod-IVR, 20.3 ng mg-1; TDF-FTC-MVC pod-IVR, 0.18 ng mg-1), and MVC rectal fluid concentrations (0.84 ng mg-1) were quantifiable and higher than their respective in vitro EC50 values in most samples. Due to participant burden in these exploratory trials, rectal fluid was used as a surrogate for rectal tissue, where drug concentrations are expected to be higher. Conclusions/Significance The concentrations of FTC and MVC in rectal fluids obtained in two exploratory clinical trials of IVRs delivering ARV combinations exceeded levels associated with in vitro efficacy in HIV inhibition. Unexpectedly, MVC appeared to depress the distribution of TFV and FTC into the rectal lumen. Here we show that vaginal delivery of ARV combinations may provide adherence and coitally independent dual-compartment protection from HIV infection during both vaginal and receptive anal intercourse. © 2018 Vincent et al. Article	2018	Vincent K.L.; Moss J.A.; Marzinke M.A.; Hendrix C.W.; Anton P.A.; Pyles R.B.; Guthrie K.M.; Dawson L.; Olive T.J.; Butkyavichene I.; Churchman S.A.; Cortez J.M., Jr.; Fanter R.; Gunawardana M.; Miller C.S.; Yang F.; Rosen R.K.; Vargas S.E.; Baum M.M.	Safety and pharmacokinetics of single, dual, and triple antiretroviral drug formulations delivered by pod-intravaginal rings designed for HIV-1 prevention: A Phase I trial	PLOS Medicine	-	-	-	15491277	10.1371/journal.pmed.1002655	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054635041&doi=10.1371%2fjournal.pmed.1002655&partnerID=40&md5=87d43fdcc7d2780886f74aa1b58a43d5	Background: Intravaginal rings (IVRs) for HIV pre-exposure prophylaxis (PrEP) theoretically overcome some adherence concerns associated with frequent dosing that can occur with oral or vaginal film/gel regimens. An innovative pod-IVR, composed of an elastomer scaffold that can hold up to 10 polymer-coated drug cores (or "pods"), is distinct from other IVR designs as drug release from each pod can be controlled independently. A pod-IVR has been developed for the delivery of tenofovir (TFV) disoproxil fumarate (TDF) in combination with emtricitabine (FTC), as daily oral TDF-FTC is the only Food and Drug Administration (FDA)-approved regimen for HIV PrEP. A triple combination IVR building on this platform and delivering TDF-FTC along with the antiretroviral (ARV) agent maraviroc (MVC) also is under development. Methodology and findings: This pilot Phase I trial conducted between June 23, 2015, and July 15, 2016, evaluated the safety, pharmacokinetics (PKs), and acceptability of pod-IVRs delivering 3 different ARV regimens: 1) TDF only, 2) TDF-FTC, and 3) TDF-FTC-MVC over 7 d. The crossover, open-label portion of the trial (N = 6) consisted of 7 d of continuous TDF pod-IVR use, a wash-out phase, and 7 d of continuous TDF-FTC pod-IVR use. After a 3-mo pause to evaluate safety and PK of the TDF and TDF-FTC pod-IVRs, TDF-FTC-MVC pod-IVRs (N = 6) were evaluated over 7 d of continuous use. Safety was assessed by adverse events (AEs), colposcopy, and culture-independent analysis of the vaginal microbiome (VMB). Drug and drug metabolite concentrations in plasma, cervicovaginal fluids (CVFs), cervicovaginal lavages (CVLs), and vaginal tissue (VT) biopsies were determined via liquid chromatographic-tandem mass spectrometry (LC-MS/MS). Perceptibility and acceptability were assessed by surveys and interviews. Median participant age was as follows: TDF/TDF-FTC group, 26 y (range 24–35 y), 2 White, 2 Hispanic, and 2 African American; TDF-FTC-MVC group, 24.5 y (range 21–41 y), 3 White, 1 Hispanic, and 2 African American. Reported acceptability was high for all 3 products, and pod-IVR use was confirmed by residual drug levels in used IVRs. There were no serious adverse events (SAEs) during the study. There were 26 AEs reported during TDF/TDF-FTC IVR use (itching, discharge, discomfort), with no differences between TDF alone or in combination with FTC observed. In the TDF-FTC-MVC IVR group, there were 12 AEs (itching, discharge, discomfort) during IVR use regardless of attribution to study product. No epithelial disruption/thinning was seen by colposcopy, and no systematic VMB shifts were observed. Median (IQR) tenofovir diphosphate (TFV-DP) tissue concentrations of 303 (277–938) fmol/10^6 cells (TDF), 289 (110–603) fmol/10^6 cells (TDF-FTC), and 302 (177.1–823.8) fmol/10^6 cells (TDF-FTC-MVC) were sustained for 7 d, exceeding theoretical target concentrations for vaginal HIV prevention. The study's main limitations include the small sample size, short duration (7 d versus 28 d), and the lack of FTC triphosphate measurements in VT biopsies. Conclusions: An innovative pod-IVR delivery device with 3 different formulations delivering different regimens of ARV drugs vaginally appeared to be safe and acceptable and provided drug concentrations in CVFs and tissues exceeding concentrations achieved by highly protective oral dosing, suggesting that efficacy for vaginal HIV PrEP is achievable. These results show that an alternate, more adherence-independent, longer-acting prevention device based on the only FDA-approved PrEP combination regimen can be advanced to safety and efficacy testing. Editorial	2018	Volk J.E.; Nguyen D.P.; Hare C.B.; Marcus J.L.	HIV Infection and Drug Resistance with Unsupervised Use of HIV Pre-Exposure Prophylaxis	AIDS Research and Human Retroviruses	-	-	-	-	8092229	10.1089/aid.2017.0265	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85043143468&doi=10.1089%2Faid.2017.0265&partnerID=40&md5=f75776c3f22dcffa9d9d2b1e0a3da3cb	Although the Centers for Disease Control and Prevention currently only recommend daily dosing of HIV pre-exposure prophylaxis (PrEP), an on-demand PrEP dosing strategy that includes doses before and after sexual activity has been shown to reduce risk for HIV acquisition in men who have sex with men. In this letter, we report a case of HIV infection and drug resistance in a patient using PrEP outside of regular clinical care, adopting a sporadic, suboptimal dosing strategy with pills he obtained from his sexual partners. This case illustrates the potential risks of PrEP use without provider monitoring to ensure adherence to dosing and laboratory follow-up, as well as key challenges that must be addressed as routinely PrEP use becomes more common outside of controlled research settings. © Copyright 2018, Mary Ann Liebert, Inc.	drug resistance; on-demand PrEP; human immunodeficiency virus; pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Other
Article	2018	Vole, Erik M; Le Vu, Stephane; Rumsana, Oliver; Tostevin, Anna; Dunn, David; Ordak, Chloe; O'Shea, Siobhan; Delpech, Valerie; Brown, Alison; Gill, Noel; Fraser, Christophe	Molecular Epidemiology of HIV-1 Subtype B Reveals Heterogeneous Transmission Risk Implications for Intervention and Control.	Journal of Infectious Diseases	-	-	-	-	1537-6613	10.1093/infdis/jix044	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5913263/	Background: The impact of HIV pre-exposure prophylaxis (PrEP) depends on infections averted by protecting vulnerable individuals as well as infections averted by preventing transmission by those who would have been infected if not receiving PrEP. Analysis of HIV phylogenies reveals risk factors for transmission, which we examine as potential criteria for allocating PrEP. Methods: We analyzed 4912 HIV-1 partial pol sequences from men who have sex with men (MSM) in the United Kingdom combined with global reference sequences and patient-level metadata. Population genetic models were developed that adjust for stage of infection, global migration of HIV lineages, and changing incidence of infection through time. Models were extended to simulate the effects of providing susceptible MSM with PrEP. Results: We found that young age <25 years confers higher risk of HIV transmission (relative risk = 2.52 95% confidence interval, 2.32-2.73) and that young MSM are more likely to transmit to one another than expected by chance. Simulated interventions indicate that 4-fold more infections can be averted over 5 years by focusing PrEP on young MSM. Conclusions: Concentrating PrEP doses on young individuals can avert more infections than random allocation. Article	2018	Yu L.; Maia K.	High Burden of HIV, Syphilis and HSV-2 and Factors Associated with HIV Infection Among Female Sex Workers in Tanzania: Implications for Early Treatment of HIV and Pre-exposure Prophylaxis (PrEP).	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-017-1992-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85034933436&doi=10.1007%2Fs10461-017-1992-2&partnerID=40&md5=e6cf6a6107cd8f0862ca6c7e1	This paper estimates population-based prevalence of HIV, syphilis, HSV-2 and factors influencing HIV infection using a national sample of 1914 female sex workers (FSWs) in 7-regions in Tanzania. Additionally, HIV incidence was estimated by comparing biological HIV results with self-reported HIV status. The average HIV prevalence among FSWs in all 7 regions was 28%, ranging from 14% in Tabora, 20% in Mbeya, 23% in Iringa, 25% in Dar es Salaam, 30% in Mwanza, 34% in Arusha and 42% in Kilimanjaro. HIV incidence was 8%, with significantly higher burden found in Iringa (11%), Mbeya (13%), and Mwanza (12%). Nearly 30% of the study participants was infected with HIV-2. The high HIV prevalence and incidence coupled with suboptimal condom use indicate an urgent need to roll out the 'Treat-All' approach and provide antiretroviral therapy to FSWs living with HIV regardless of their CD4 count. In addition, antiretroviral-based prevention technologies such as oral pre-exposure prophylaxis and microbicides should be piloted and evaluated. © 2017, Springer Science+Business Media, LLC, part of Springer Nature. An Empiric Risk Score to Guide PrEP Targeting Among MSM in Coastal Kenya	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2141-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85045948646&doi=10.1007%2Fs10461-018-2141-2&partnerID=40&md5=9d295039f4eb2136c040c9a7e5207f30	Men who have sex with men (MSM), who have heterogeneous HIV acquisition risks are not specifically targeted in Kenyan pre-exposure prophylaxis (PrEP) guidelines. We used data from an open cohort, which followed 753 initially HIV-negative MSM participants for more than 1378.5 person-years, to develop an empiric risk score for targeting PrEP delivery. Independent predictors of incident HIV-1 infection were used to create a risk score (0–10). The area under the receiver operating characteristic curve was 0.76 (95% CI 0.71–0.80). This empiric risk score may help Kenyan health care providers to assess HIV-1 acquisition risk and encourage PrEP uptake by high-risk MSM. © 2018, The Author(s). Theses and Dissertations	2018	Walters, Suzan Marie; Fallon, Kathleen	Needles and Networks: Inequalities in Awareness of Pre-Exposure Prophylaxis for HIV Prevention	-	-	-	Stony Brook University	-	NA	NA	https://www.proquest.com/dissertations-theses/needles-networks-inequalities-awareness-pre-exposure/docview/2018880837?accountid=8113	Over 1.2 million people are living with HIV, and there are approximately 37,600 new HIV infections per year in the United States. Pre-Exposure Prophylaxis (PrEP) – a pill that can be taken daily to prevent HIV – has enormous potential to ameliorate the HIV epidemic by drastically reducing new infections. This dissertation identifies rates of awareness and documents inequalities of awareness by groups and sub-group over time. I utilize a mixed-methods approach, drawing on ethnography, focus groups, semi-structured qualitative interviews and five years of survey data. First, Link 4 there are differences in awareness by risk groups (men who have sex with men, persons who inject drugs, and high risk heterosexuals)? I find there are inequalities in awareness between risk groups, with men who have sex with men (MSM) significantly more aware than persons who inject drugs (PWID) and high risk heterosexuals. Second, Link 4 are there inequalities in awareness within risk groups? I find that men who have sex with men have increased awareness of PrEP compared to persons who inject drugs. Third, I explore: 1) How PrEP awareness is spreading and 2) Why awareness is diffusing at unequal rates between risk groups and within sub-populations within risk groups. I find that among men who inject drugs, gay and bisexual men, and men who had a conversation about HIV prevention at a syringe exchange program had increased PrEP awareness. Among women who inject drugs, women who sell sex, and women who had a conversation about HIV prevention at a syringe exchange program had increased PrEP awareness. I suggest that social networks are key to HIV prevention. These findings are grounded in theories about stigma, fundamental cause, and social networks. I conclude by recommending campaigns and initiatives be tailored to communities and be developed with communities. Article	2018	Wand, Handan; Reddy, Tarylee; Naidoo, Sarite; Moonsamy, Suri; Siva, Samantha; Morar, Neetha S; Ramjee, Gita	A Simple Risk Prediction Algorithm for HIV Transmission: Results from HIV Prevention Trials in KwaZulu Natal, South Africa (2002-2012).	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-017-1785-7	https://dx.doi.org/10.1007/s10461-017-1785-7	We aimed to develop a HIV risk scoring algorithm for targeted screening among women in South Africa. We used data from five biomedical intervention trials (N = 8962 Cox regression models were used to create a risk prediction algorithm and it was internally and externally validated using standard statistical measures. 7-factors were identified as significant predictors of HIV incidence: <25 years old, being single/not cohabiting, parity (<3), age at sexual debut (<16), 3+ sexual partners, using injectables and diagnosis with a sexually transmitted infection(s). A score of ≥25 (out of 50) was the optimum cut point with 83% (95%) sensitivity in the derivation dataset. Our tool can be used in designing future HIV prevention research and guiding recruitment strategies as well as in health care settings. Identifying, targeting and prioritising women at highest risk will have significant impact on preventing new HIV infections by scaling up testing and pre-exposure prophylaxis in conjunction with other HIV prevention modalities. Article	2018	Wang X.; Nwokolo N.; Kerokogou-Landen R.; Hill A.; Whitlock G.; Dey-Weber L.; McClure M.O.; Boffito M.	InterPrEP: internet-based pre-exposure prophylaxis with generic tenofovir disoproxil fumarate/emtricitabine in London – analysis of pharmacokinetics, safety and outcomes	HIV Medicine	-	-	-	-	1464-2662	10.1111/hiv.12528	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85021439986&doi=10.1111%2Fhiv.12528&partnerID=40&md5=b03dca8d851cf3a9e4ae028b2b4f3c17	Objectives: The National Health Service in England (NHS England) does not provide pre-exposure prophylaxis (PrEP) against HIV, forcing people to purchase generic versions on the internet. However, there are concerns about the authenticity of medicines purchased online. We established an innovative service offering plasma tenofovir (TFV) and emtricitabine (FTC) therapeutic drug monitoring for people buying generic PrEP online, to ensure that drug concentrations in this were consistent with those of proprietary brands and previously published data. Methods: TFV/FTC concentrations were measured by ultraperformance liquid chromatography–ultraviolet detection and tandem mass spectrometry. Evaluation of renal function and testing for HIV, hepatitis B virus (HBV) and hepatitis C virus (HCV) was performed at every 3–4 months, with risk reduction advice. Results: A total of 293 individuals presented having purchased PrEP on the internet: 85% were white, 84% were taking daily PrEP, and 16% were event-driven. Most were on generic TFV disoproxil fumarate (TDF)/FTC from Cipla Ltd. Median (range) TFV and FTC plasma concentrations were 184 (21–597) ng/mL and 140 (17–570) ng/mL, respectively. All concentrations were above our established plasma TFV and FTC targets, based on previously published data. Renal function was normal in all evaluable individuals and so no new cases of HIV, HBV or HCV infection were detected. Conclusions: The internet is a source of PrEP, and, by acquisition, the context to access PrEP. As the NHS, concentrations of TFV and FTC in generic formulations purchased over the internet were similar to or slightly higher than those measured in phase 3 studies with the original formulation from Gilead (Truvada®), which has demonstrated high levels of protection against HIV infection in previous PrEP clinical trials. © 2017 British HIV Association	generic antiretroviral drugs; HIV infection; pre-exposure prophylaxis	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Clinical
Article	2018	Wang Z.; Lau J.T.F.; Fang Y.; Ip M.; Gross D.L.	Prevalence of actual uptake and willingness to use pre-exposure prophylaxis to prevent HIV acquisition among men who have sex with men in Hong Kong, China	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0198173	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052281136&doi=10.1371%2Fjournal.pone.0198173&partnerID=40&md5=f7527b996a7d86c18dd9c1f29	Objectives: This study was to investigate the prevalence of actual uptake of pre-exposure prophylaxis (PrEP), willingness to use daily oral PrEP under two cost scenarios, and potential issues related to PrEP use among men who have sex with men (MSM) with HIV-negative/unknown sero-status in Hong Kong, China. Factors associated with the two measures of willingness were also investigated. Methods: 481 eligible MSM completed the anonymous venue-based face-to-face interview/telephone interview. Results: Only 1% had ever used PrEP. After being briefed about some facts of PrEP, the prevalence of willingness to use oral PrEP was 37% if they could purchase PrEP at private hospitals/clinics at HK$8,000 (US$1,032)/month (market rate) and 67.2% if free PrEP was provided in public hospitals/clinics in Hong Kong (free PrEP). After adjusted for significant background variables, significant factors of these two measures of willingness included: (1) number of correct responses to knowledge on PrEP, (2) perceived risk of HIV infection in the next six months, and (3) constructs of the Theory of Planned Behavior: positive and negative attitudes toward PrEP, perceived behavior control, and significant others would support them take PrEP (perceived subjective norms), perceived number of local MSM who were willing to take PrEP (perceived descriptive norm), and confidence in using PrEP under the two scenarios (perceived behavioral control). Conclusions: Only 1% of MSM had ever used PrEP. Although 67.2% of MSM were willing to use free PrEP, only 37% were willing to pay for PrEP at HK$8,000/month, and 42.4% would not take up HIV testing every 3 months after using PrEP. Conclusion Different strategies should be considered for promoting PrEP at private and at free PrEP at under-resourced settings. Future promotion should increase their knowledge about PrEP, modify their perceptions related to HIV and PrEP, and address some potential issues related to PrEP use. Copyright: © 2018 Wang et al. Article	2018	Wang, Hong-Yi; Wang, Ning-Chu; Zhou-Xing; Zhang, Jing; Mao, Xiang-Geng; Wen-Qing; Jiang, Yong-hai; Shang, Hong; Xu, Jun-Jie	Intimate Partner Violence Correlates With A Higher HIV Incidence Among MSM: A 12-Month Prospective Cohort Study in Shenyang, China.	Scientific Reports	-	-	-	-	2045-2322	10.1038/s41598-018-21149-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5831148/	Intimate partner violence (IPV) and HIV are highly prevalent worldwide among MSM. However, the association between IPV and HIV seroconversion is virtually unknown. This 12-month prospective cohort study was conducted among MSM in Shenyang, China to explore the causality between IPV and the incidence of HIV. Adjusted Hazard Ratios (aHRs) of HIV acquisition were derived from a multivariate time-dependent Cox model and applied to calculate population attributable fractions (PAFs). Among 476 HIV-negative MSM subjects, 89(18.7%) reported being victims of IPV in the past 3 months (P3M). IPV was significantly correlated with lower income, unprotected anal intercourse (UAI) and being depressed (every P < 0.05). The incidence of HIV among IPV victims was 11.3/100 PY, compared to 3.8/100 PY in non-IPV victims. Furthermore, IPV victimization was independently associated with HIV seroconversion (aHR: 4.1, P = 0.027). Other predictors for seroconversion included unprotected receptive anal intercourse (aHR: 3.9, P = 0.031) and being depressed (aHR: 3.8, P = 0.035). The PAF of HIV infection for IPV was 26.2%. If 26.1% in the P3M and syphilis infection (aHR: 4.7, P = 0.015). IPV increased the HIV seroconversion risk of MSM, with a high PAF. HIV prevention programs should integrate IPV screening and intervention, and MSM affected by IPV need to be preferentially enrolled in pre-exposure prophylaxis. Article	2018	Wang, K R; Peng, L P; Gu, J; Hao, C; Zou, H C; Hao, Y T; Li, J H	Impact of the 90-90-90 goal and pre-exposure prophylaxis on HIV transmission and elimination in men who have sex with men in China: A mathematical modeling study.	Zhonghua Liu Xing Bing Xue Za Zhi (Chinese Journal of Epidemiology)	-	-	-	-	0254-6450	10.3760/cma.j.issn.0254-6450.2018.11.017	https://dx.doi.org/10.3760/cma.j.issn.0254-6450.2018.11.017	Objective: To establish a dynamic compartmental model to predict the impact of HIV testing and treatment and pre-exposure prophylaxis (PrEP) on the annual incidence of HIV infection in men who have sex with men (MSM) in China from 2018 to 2037. Methods: A dynamic compartmental model was developed to describe the HIV epidemic in MSM in China. The model was parameterized using data from the literature available. We used MATLAB 7.0 software for data simulation and graphics rendering. We analyzed HIV transmission among MSM and estimated the impact of expanded HIV testing and treatment and PrEP on HIV incidence. Results: Without intervention, the number of new HIV infections would reach 770 000, the infection rate would reach 11.1% and the incidence rate would reach 0.72/100 person years in MSM in the next 20 years. Under the 90%-90%-90% goal, 440 000 new infections (57.1%) would be reduced, the HIV infection rate would decrease to 4.8% and the incidence rate would decrease to 0.31/100 person years. Under the 90%-90%-90% goal and PrEP, 600 000 new infections (77.9%) would be reduced, the 100% PrEP coverage rates for achieving HIV elimination in the next 10, 15 and 20 years would be 65%, 32% and 19%, respectively. Conclusion: It is necessary to strengthen the comprehensive intervention in MSM, continue to expand HIV testing and treatment, and improve PrEP adherence and coverage to further control and eliminate the epidemic of HIV/AIDS in MSM. Article	2018	Wang, Shaoyuan; Kortsmar, Jean-Luc; Hull, Mark W; Arbess, Gordon; Owen, James Ree; Tan, Darrell Hs	Feasibility of vitamin D supplementation interventions to mitigate HIV pre-exposure prophylaxis-related bone mineral density loss: a cross-sectional survey.	Patient Preference and Adherence	-	-	-	-	1177-889X	10.2147/PPA.S178403	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6199146/	BACKGROUND: Daily tenofovir disoproxil fumarate (TDF)/emtricitabine as HIV pre-exposure prophylaxis (PrEP) causes subclinical decreases in bone mineral density (BMD). We surveyed PrEP users to assess feasibility for a clinical trial of vitamin D supplementation to mitigate TDF-induced BMD loss. METHODS: We recruited participants using or starting PrEP at Toronto and Vancouver. The primary objective was to assess the acceptability of daily or weekly vitamin D supplementation. We also assessed the acceptability of calcium supplementation, existing use of non-pharmacological bone health interventions, prevalence of osteoporosis risk factors, and bone health knowledge (Osteoporosis Knowledge Test, OKT). RESULTS: Of 101 participants, 72.2% of intervention-risk factors, 18.0% were starting PrEP, and 9.9% did not indicate their PrEP status. All identified as males, 88.8% as gays, and 67.3% as White. Median (IQR) age was 32.0 (29.0, 40.0) years, and 82.1% reported family income $≥$80,000/year. Among those not already using the interventions, willingness to supplement with daily vitamin D, weekly vitamin D, or daily calcium was low to high at 90.9%, 96.4%, and 69.6%, respectively. Only 31.0% reported adequate dietary calcium intake, while 42.9% reported 51 osteoporosis risk factor (most commonly, alcohol and smoking). Overall bone health knowledge was low, as median (IQR) OKT score was 11.0 (9.0, 13.0) out of a maximum possible score of 16. Participants with lower OKT scores were more likely to be older, have osteoporosis risk factors, and lower income (OKT score=12 vs 14, P<0.001) and have greater bone health knowledge (OKT=17 vs 14, P=0.08), but they had similar levels of current vitamin D supplementation (37.4% vs 21.4%, P=0.11), calcium supplementation (11.2% vs 13.8%, P=0.70), and adequate dietary calcium intake (32.7% vs 25.0%, P=0.43). DISCUSSION: The high acceptability of vitamin D and calcium supplementation in this cohort suggests that enrollment into a clinical trial of such interventions to mitigate TDF-induced BMD loss is feasible. Article	2018	Wang, Xia; Bourne, Adam; Liu, Pobe; Sun, Jiangli; Cai, Thomas; Gima Mburu; Cassolato, Matteo; Wang, Hongyan; Wang Zhou ¥	Understanding willingness to use oral pre-exposure prophylaxis for HIV prevention among men who have sex with men in China	PLOS One	NA	10.1371/journal.pone.0199525	https://www.proquest.com/scholarly-journals/understanding-willingness-use-oral-pre-exposure/docview/2057887689/se-2?accountid=8113	Background Oral pre-exposure prophylaxis (PrEP) is recommended as an additional prevention choice for men who have sex with men (MSM) at substantial risk of HIV. The aim of the study was to evaluate the extent, and reasons, for MSM's willingness to use oral PrEP in Wuhan and Shanghai, China. Methods Between May and December 2015, a cross-sectional survey was conducted among 487 MSM recruited through snowball sampling in physical locations frequented by MSM and through social media applications. Exploratory factor analysis was used to group reasons for being willing or not willing to use PrEP. Chi-square tests were used to explore bivariate associations between groupings of reasons for being willing or unwilling to use PrEP, and key sociodemographic and sexual-behavioral characteristics of MSM. Results Overall, 71.3% of respondents were willing to use PrEP. The most commonly reported reasons for being willing to use PrEP were protection from HIV infection (endorsed by 99.4% of those willing to use PrEP) and protection from sexually transmitted infections (94.6%). The most commonly reported reasons for being unwilling to use PrEP were concerns about side effects (94.9%), the need to pay for long-term use of the medication (89.4%), and concerns about adherence (86.6%). Individuals who were willing to use PrEP were more likely to be younger, be willing to engage in sex work, be in a romantic relationship, be regular sex partners, rates of condom use with regular and casual sex partners, and the number of casual sex partners. Conclusions The introduction of PrEP in China could benefit from promotion campaigns that emphasize its role in preventing HIV infection, in taking responsibility for own sexual health, and in protecting family members from potential harm. To reduce uptake barriers, it will be essential to provide accurate information to potential PrEP users about the mild and short-term nature of side effects, and the possibility of taking PrEP orally during particular periods of life when the risk of HIV exposure might be highest. Article	2018	Ward, James; McManus, Hamish; McGregor, Skye; Horwitz, Karen; Gelb, Carolien; Su, Jiann-Yih; McDonald, Ann; Guy, Rebecca; Donovan, Basil; Kaldor, John M.	HIV incidence in Indigenous and non-Indigenous populations in Australia: a population-level observational study.	The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(18)30135-8	https://pubmed.ncbi.nlm.nih.gov/30097323/	BACKGROUND: Australia has set a national target of ending HIV by 2020, achieving this will require the inclusion of priority populations (eg, Indigenous Australians) in strategies to reach elimination. To assist in evaluating the target of elimination, we analysed HIV notification data for Indigenous and non-Indigenous Australians. METHODS: Using the National HIV Registry at The Kirby Institute at UNSW, Sydney, NSW, Australia, we collected and analysed annual HIV notification data for 1996-2015. Patients who were not born in Australia were excluded. We calculated the rates of HIV diagnoses with annual trends in notification rates for Indigenous versus non-Indigenous Australians by demographic characteristics, exposure categories, and state and territory of residence. For missing data, assumptions were made and verified through sensitivity analyses. Annual rate ratio (RR) and 4 year summary rate ratio (SRR) trends were calculated to determine patterns of HIV diagnosis in the two populations. FINDINGS: Between Jan 1, 1996, and Dec 31, 2015, 11 402 people born in Australia were reported with a diagnosis of HIV, of whom 661 (4%) were recorded as Indigenous Australians and 10 741 (96%) as non-Indigenous Australians. For exposure to HIV, among Indigenous Australians a higher proportion of diagnoses occurred among women, and through injecting drug use and heterosexual contact, than among non-Indigenous Australians. Between 2011 and 2015, Indigenous Australians were diagnosed with HIV at a significantly higher rate than non-Indigenous Australians (SRR 1·51, 95% CI 1·36–1·67; p<0·0001), and significantly higher diagnosis among Indigenous women (4·92, 4·02–6·02; p<0·0001) for the entire study period than among non-Indigenous women. Concurrently, a decrease in HIV diagnoses of 1% per annum (RR 0·99, 95% CI 0·98–0·99; p=0·0001) across the study period was seen among non-Indigenous people. Indigenous Australians were more likely to be diagnosed at an advanced stage of HIV infection than non-Indigenous Australians (29·8% vs 15·1%; p<0·0001). INTERPRETATION: Greater efforts should be made to include Indigenous people in prevention strategies, particularly newer biomedical interventions, such as scale up of pre-exposure prophylaxis and treatment as prevention initiatives in Australia. More involvement of Indigenous Australians in these approaches is also required to prevent widening of the gap in HIV diagnosis rates between non-Indigenous and Indigenous Australians. FUNDING None. Article	2018	Wilkinson, Anna L; Draper, Bridget L; Pedrana, Alisa E; Asselin, Jason; Holt, Martin; Hellard, Margaret E; Stoové, Mark	Measuring and understanding the attitudes of Australian gay and bisexual men towards biomedical HIV prevention using cross-sectional data and factor analyses.	Sexually Transmitted Diseases	-	-	-	-	1472-3263	10.1136/sextrans-2017-053375	https://dx.doi.org/10.1136/sextrans-2017-053375	INTRODUCTION: Contemporary responses to HIV embrace biomedical prevention, particularly treatment as prevention (TasP) and pre-exposure prophylaxis (PrEP). However, large-scale implementation of biomedical prevention should be ideally preceded by assessments of their community acceptability. We aimed to understand contemporary attitudes of gay and bisexual men (GBM) in Australia towards biomedical-based HIV prevention and propose a framework for their measurement and ongoing monitoring. METHODS: A cross-sectional, online survey of GBM ≥18 years has been conducted annually in Victoria, Australia, since 2008. In 2016, 15 attitudinal items on biomedical HIV prevention were added. Items were scored on five-point Likert scales. We used factor analysis to identify key constructs related to GBM's attitudes to biomedical HIV prevention and use these to characterise levels of support for TasP and PrEP. RESULTS: A total of 662 HIV-negative or HIV-status-unknown men were included in the analysis. Three factors explained 61% of the variance in responses: 'optimism and support for TasP', 'concerns about PrEP' and 'support for PrEP'. Most participants were optimistic and supportive of TasP, but 17% disagreed that people with HIV on treatment could not sexually transmit HIV. Concerns about PrEP were common, with 72% of men agreeing treatment (undetectable viral load) reduced HIV transmission risk. CONCLUSIONS: Better understanding of community attitudes is crucial for shaping policy and informing initiatives that aim to improve knowledge, acceptance and uptake of biomedical prevention. Our analyses suggest confidence in, acceptability of and community support for PrEP among GBM. However, strategies to address scepticism towards HIV treatment when used for prevention may be needed to optimise combination biomedical HIV prevention. Article	2018	Willie T.C.; Stockman J.K.; Overstreet N.M.; Kershaw T.S.	Examining the Impact of Intimate Partner Violence Type and Timing on Pre-exposure Prophylaxis Awareness, Interest, and Coercion	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-017-1901-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85029087768&doi=10.1007%2Fs10461-017-1901-8&partnerID=40&md5=6908a566dfeb972dbe6a7f1e49fcbdb	Previous research suggests that intimate partner violence (IPV) is associated with acceptability of and adherence to pre-exposure prophylaxis (PrEP). However, very few studies have examined whether the type (i.e., physical, sexual, and psychological IPV) and timing (i.e., lifetime, past-year) of IPV experiences differentially relate to PrEP awareness, interest, and perceived PrEP coercion. Therefore, the current study aimed to fill this gap in the literature among a sample of women at risk for HIV infection (N = 395). Participants were women at risk for HIV infection (i.e., HIV-negative or unknown status) who were recruited from 6 clinics in the Southeastern United States. Data were collected from an online survey administered to 210 women and men. Past-year physical IPV experiences (AOR 4.53, 95% CI 1.85, 11.11) were significantly associated with being interested in using PrEP. Lifetime sexual (AOR 3.05, 95% CI 1.62, 5.40), psychological IPV (AOR 4.76, 95% CI 1.01, 22.89), and past-year sexual IPV experiences (AOR 3.01, 95% CI 1.10, 8.27) were also significantly associated with believing a recent partner would attempt to control the participant's use of PrEP, if she or he were currently using it. Understanding that engaging in PrEP care is influenced differently by the type and timing of IPV has potential implications for PrEP candidacy guidelines and interventions. © 2017, Springer Science+Business Media, LLC. Article	2018	Wilton J.; Noor S.W.; Schnabth A.; Lawlina J.; Hart T.A.; Grennan T.; Fowler S.; Maxwell J.; Tan D.H.S.	High HIV risk and syndemic burden regardless of referral source among MSM screening for a PrEP demonstration project in Toronto, Canada	BMC Public Health	-	-	-	-	-	14712458	10.1186/s12889-018-5180-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85042170658&doi=10.1186%2fs12889-018-5180-8&partnerID=40&md5=6057bf1d7a1ea8e8fa1f85e0169ebcd	Background: To maximize public health impact and cost-effectiveness, HIV pre-exposure prophylaxis (PrEP) must reach individuals at high HIV risk. Referrals for PrEP can be self- or provider-initiated, but there are several challenges in both. We assessed whether HIV risk differed by referral source among gay, bisexual and other men who have sex (gbMSM) screening for an HIV PrEP demonstration project. Methods: PREPARATORY-3 was an open-label PrEP demonstration project enrolling gbMSM at high risk of HIV acquisition in Toronto, Canada. Study eligibility criteria related to high risk were defined as scoring ≥20 on the HIV Incidence Risk Index for MSM (IRIMSM) and engaging in at least 1 act of condomless receptive anal sex within the past 6 months. Recruitment was promoted through self-referrals (ads in a sexual networking app and gay newspaper/website) and provider-referrals (10 community-based organizations, CBOs). HIV risk score (IRIMSM) and syndemic health burden were measured among gbMSM screened for study participation and compared according to referral source. Results: Between October 16 and December 30, 2016, online ads generated 1218 click-throughs and CBOs referred 115 individuals. Overall, 165 men inquired about the trial, of which 88 underwent screening. The majority of screened men were self-referrals (68.5%), scored ≥10 on IRIMSM (96.5%), and reported condomless receptive anal sex in the past 6 months (74.2%). Self- and provider-referrals had similarly high HIV risk profiles, with a median (IQR) IRIMSM score of 28.0 (19.0–32.5) and 28.5 (20.0–34.0) (p = 0.3), and 75.0% and 75.5% reporting condomless receptive anal sex (p = 0.9), respectively. The overall burden of syndemic health problems was also high, with approximately one-third overall identified as Black, Indigenous or a Person of Colour (34.1%), unemployed (34.1%), living with mental illness (36.4%), and/or living with a disability (31.8%). No significant differences were observed according to referral source. Conclusions: HIV risk and syndemic burden were high among gbMSM presenting for this PrEP demonstration project regardless of referral source. Self-referral may be a useful and efficient strategy for identifying individuals suitable for PrEP use. Online strategies and CBOs working in gay men's health may play important roles in connecting individuals at high HIV risk to PrEP services. Trial registration: ClinicalTrials.gov NCT02149888. Article	2018	Witzel T.C.; Nutland W.; Bourne A.	What qualities in a potential HIV pre-exposure prophylaxis service are valued by black men who have sex with men in London? A qualitative acceptability study	International journal of STD & AIDS	-	-	-	-	-	9564624	10.1177/0956462418753224	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048492304&doi=10.1177%2f0956462418753224&partnerID=40&md5=1c4f3836856262c1b36e53a7f9fcef7d	Black men who have sex with men (BMSM) have higher HIV incidence and prevalence when compared to other MSM, despite similar levels of condom use and testing. Pre-exposure prophylaxis (PrEP) could be a useful intervention to reduce these inequalities. This research therefore aims to understand the dimensions of acceptability of a potential PrEP service for BMSM aged 18–45 years in London. In-depth, semi-structured interviews were conducted with 20 BMSM aged 18–45 years in London. Framework analysis was used to analyse the data. Five dimensions of acceptability emerged: need; uncertainty; service delivery; PrEP attributes; and social/sexual networks. BMSM had distinct preferences for sexual health services, which have implications for PrEP service delivery. These primary dimensions emerged as analysis: proximity and anonymity; quality, efficiency and reassurance; and understanding, empathy and identity. These relate, respectively, to preferences regarding clinic location and divisions from community, features of service delivery and staff characteristics. Due to concerns about confidentiality, community-based services may not be useful for this group. Careful consideration in regards to components used in service development will facilitate ongoing engagement. Interpersonal skills of staff are central to service acceptability, particularly when staff are perceived to be from similar cultural backgrounds as their patients. © 2018, The Author(s) 2018. Article	2018	Wolton A.J.; Cameron R.; Ross-Turner M.; Suchak T.	TransMission a community-led HIV testing initiative for trans people and their partners at a London sex-on-premises venue	HIV Nursing	-	-	-	-	-	14747359	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049609984&partnerID=40&md5=4811da172a11dd0f2ef8a6fc440da2f1	Studies indicate that transgender (trans) communities are particularly vulnerable to HIV. However, trans people in the UK are often excluded from HIV services and research. This evaluation reviews the activity of a trans-led team that provided monthly outreach testing at a trans sex-on-premises venue in London. 131 instant HIV tests were performed between November 2016 and March 2017. Of these, 3 (2.3%) were reactive and 39.8% were trans women, 51.8% identified as male, and 17% described themselves as cross-dressers. There were no reactive tests despite a high incidence of unprotected acts. In this study 68.7% of participants had had sex in the last 3 months without using condoms, 19.8% had used pre-exposure prophylaxis (PrEP) and 74% did not know where to access it. Awareness of post-exposure prophylaxis (PEP) was lower, 83.9% of people had not heard of PEP, and 86.2% did not know where to access it. This service evaluation highlights the need for greater visibility of trans or non-binary people in PrEP research and campaigns, as well as trans-friendly PEP services. Article	2018	Wong, Ngai Sze; Tse Ho Kwan; Tsang, Owen T Y; Lee, Man Po; Yam, Wing Cheong; Lam, Wilson, Leung, Wai Shing; Chan, Jacky M C; Ho, Kai Man; Lee, Shui Shan	Pre-exposure prophylaxis (PrEP) for MSM in low HIV incidence places: should high risk individuals be targeted?	Scientific Reports	-	-	-	-	-	NA	10.1038/s41598-018-30101-9	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-prep-msm-low-hiv/docview/2092635105/se-2?accountid=9113	Pre-exposure prophylaxis (PrEP) targeting high-risk men who have sex with men (MSM) has been shown to be a cost-effective HIV control measure. However, the approach could be a challenge in low HIV incidence places. We estimated the cost-effectiveness of PrEP among MSM in Hong Kong, a low HIV incidence place, and explored the impact of different eligibility criteria on PrEP effectiveness and cost-effectiveness. A mathematical model was used to project the lifetime HIV cases averted and cost-effectiveness of PrEP among MSM in Hong Kong, in comparison with behavioural data of local MSM. Without PrEP, the HIV incidence (per 100 person-years) was projected to increase from 1.1 to 1.6 between 2013 and 2021. PrEP could avert 3–42% of total new infections in a five-year period (2017–2021), the variability of which depends on the implementation strategies and combinations with test-and-treat. However, under current market drug price in 2018, the incremental cost per quality-adjusted life-year gained (QALY) of PrEP (USD15013/QALY) is almost 3 times higher than test-and-treat intervention alone (USD39474/QALY). Assuming 83% fall of PrEP drug price and in combination with test-and-treat, putting 30% of MSM on non-targeting PrEP would be more feasible, cost-effective (USD26895.93/QALY), and could avert more new infections (40%). PrEP could contribute to HIV epidemic control in a low incidence place. Article	2018	Wood B.R.; Mann M.S.; Martinez-Paz N.; Unruh K.T.; Annese M.; Spach D.H.; Stoltz J.D.; Stekler J.D.	Project ECHO: Telementoring to educate and support prescribing of HIV pre-exposure prophylaxis by community medical providers	Sexual Health	-	-	-	-	-	14485028	10.1071/SH18062	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054465214&doi=10.1071%2fSH18062&partnerID=40&md5=82fcf1fa5026e69e8e3fbe0f2508267	Background: Pre-exposure prophylaxis (PrEP) is an effective tool to prevent HIV infection for at-risk individuals, but access requires medical providers to be aware of and comfortable with prescribing PrEP. Project ECHO (Extension for Community Healthcare Outcomes) was started to support hepatitis C virus treatment in rural New Mexico, but has since expanded to train health practitioners to treat other medical conditions in other locations. Methods: In 2012, a Project ECHO skills-building program was launched to mentor community HIV practitioners in our region. In July 2015, quarterly HIV clinical updates and monthly PrEP case discussions were incorporated into this program. The result was a pilot PrEP telementoring intervention. An initial rate-question survey assessed baseline community practitioner knowledge and comfort with prescribing PrEP. Then, 6 months after the pilot began, a follow-up survey was administered. Results: Of 35 eligible providers, 34 (97%) completed the baseline survey and 24 providers completed the baseline and follow-up surveys respectively. In follow-up, providers reported that Project ECHO participation helped them stay current on PrEP guidelines, improved knowledge, increased likelihood to prescribe PrEP and addressed most concerns about prescribing PrEP. One exception was continued concerns about cost and insurance access, which were addressed by adjusting the didactic curriculum. Many participants reported that the Project ECHO pilot PrEP telementoring intervention assisted them in discontinuing PrEP telementoring when no longer needed. Conclusions: It is feasible to incorporate PrEP training into Project ECHO distance telementoring programs as a tool to educate community practitioners and support PrEP prescribing. © 2018 CSIRO. Article	2018	Wood B.R.; McMahan V.M.; Naismith K.; Stockton J.B.; Delaney L.A.; Stekler J.D.	Knowledge, Practices, and Barriers to HIV Preexposure Prophylaxis Prescribing among Washington State Medical Providers	Sexually Transmitted Diseases	-	-	-	-	-	1485717	10.1097/OLQ.0000000000000781	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85048823214&doi=10.1097%2fOLQ.0000000000000781&partnerID=40&md5=fe1f9bc8233650fd4705f33dfe3752276	Background We aimed to assess HIV preexposure prophylaxis (PrEP) awareness and prescribing practices among Washington State medical providers from diverse professional disciplines and practice types. Methods In May 2016, we administered an anonymous online survey to licensed medical practitioners who provide primary, longitudinal, walk-in, emergency, obstetric, gynecologic, sexually transmitted infection, or family planning care. Results Of 735 eligible providers, 64.8% had heard of PrEP. Younger providers and providers with a doctor of medicine degree were more likely to be aware of PrEP compared with older providers (P < 0.0001) and providers with a nursing degree (P = 0.0001). Among providers who had heard of PrEP, 30.6% reported prescribing PrEP, and 69.4% reported referring patients to other providers for PrEP. Providers had 4 primary concerns about prescribing PrEP: insurance coverage (n = 220, 51% overall, but very high [26.9%] or somewhat [16.7%] uncomfortable discussing cost and insurance issues). The 124 PrEP prescribers reported a median of 2 (range, 1–175; total, 1142) patients prescribed PrEP. Prior authorizations and insurance denials had prevented prescription for 28.7% and 12.1% of prescribers, respectively. Conclusions Interventions to improve PrEP access should include education to inform medical providers about PrEP, with particular attention to provider types less likely to be aware. Continued efforts to eliminate cost and insurance barriers and educate providers regarding financial resources would help improve PrEP access. © 2018 American Sexually Transmitted Diseases Association All rights reserved. Institutional	2018	World Health Organization. Regional Office for Europe	HIV in Europe and central Asia in the era of the SDGs: operationalizing goals and achieving targets. ECDC/WHO joint meeting: Berlin, Germany, 23–25 April 2018: meeting report	-	-	-	-	-	NA	NA	https://iris.who.int/handle/10665/345563	The ECDC/WHO joint meeting 'HIV in Europe and central Asia in the era of the SDGs: Operationalizing goals and achieving targets' reviewed national and regional progress towards achieving the regional goals and targets that need to be met in order to end AIDS by 2030, and the challenges that have been encountered in doing so. It assessed how data are used to inform HIV prevention and control efforts at national and regional levels and provided a platform for countries to share their experiences of successful interventions on HIV prevention, testing and treatment. The meeting brought together national HIV programme managers, HIV surveillance experts and a wide range of partners for two and a half days to discuss experiences and ways forward related to the Fast-Track Cities initiative, HIV prevention (particularly pre-exposure prophylaxis (PrEP) and harm reduction), HIV testing, surveillance and estimates, and treatment measurement and implementation issues. In addition to the main plenary and parallel sessions, the meeting also featured a number of satellite meetings that provided the opportunity for more in-depth discussions on issues of interest to a smaller group. Much joint work will continue going forward, and 2018 provides many opportunities for countries and organizations to continue sharing experiences and learning from each other. The 22nd International AIDS Conference which will be hosted in Amsterdam, from 22 to 27 July 2018, provides a special opportunity for the WHO European Region, especially for the countries in eastern Europe and central Asia (EECA) for whom a Ministerial Policy Dialogue on HIV and related comorbidities is being organized on 23 July 2018 by WHO, the Government of the Netherlands and UNAIDS. Article	2018	Wray T.B.; Chan P.A.; Simpanen E.; Operario D.	A pilot, randomized controlled trial of HIV self-testing and real-time post-test counselling/referral on screening and preventative care among men who have sex with men	AIDS Patient Care and STDs	-	-	-	-	-	10872914	10.1089/apc.2018.0049	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052667324&doi=10.1089%2fapc.2018.0049&partnerID=40&md5=61e0d2f8402a6bd6b03d9e57a26e9f93	HIV self-testing (HST) could be an effective strategy for helping those at high risk test more regularly. However, concerns about HSTs lack of follow-up care and referral have so far limited its use. In a pilot, randomized controlled trial, high-risk HIV-negative, or status-unknown men who have sex with men (MSM; N = 63) were recruited from January 2016 to February 2017 and received (1) HST kits by mail, equipped with devices that detected when kits were opened and prompted a follow-up call from a counselor (eTEST); (2) standard HST kits with no follow-up (standard); or (3) informational letters about HIV testing (control). Participants completed surveys at baseline and 3 months. Primary outcomes were HIV testing and pre-exposure prophylaxis (PrEP) uptake, assessed via self-report and pharmacy records, and risk reduction. Approximately (100%) in the eTEST and standard HST groups reported HIV testing at least once during the 3-month period compared with 72% of controls. Repeat testing was higher among those in the HST groups versus controls (79% vs. 41%). Participants in the eTEST group were significantly more likely to receive risk-reduction counseling, prevention supplies (e.g., condoms and lube), and PrEP referrals during the study period compared with standard HST and controls. No effects on STI testing or PrEP initiation emerged. Delivering HST kits in high-risk MSM at regular intervals could increase HIV testing rates and encourage more regular testing. Providing active post-test referrals alongside HST might also connect high-risk men with some other important services than encouraged prevention behaviors. © Copyright 2018, Mary Ann Liebert, Inc.	counseling; HIV testing; men who have sex with men	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2018	Wright, Edwina; Grulich, Andrew; Roy, Katy; Boyd, Mark; Cornelisse, Vincent; Bassed, Darren; O'Donnell, Darryl; Whittaker, Bill; Crooks, Levina; Zablotska, Iryna	Australasian Society for HIV, Viral Hepatitis and Sexual Health Medicine HIV pre-exposure prophylaxis: clinical guidelines. Update April 2018.	Journal of Virus Eradication	-	-	-	-	-	2055-6640	NA	https://ach.silm.ash.gov/pmc/articles/PMC8038174/	Daily use of coformulated tenofovir and emtricitabine for HIV pre-exposure prophylaxis (PrEP) by populations at high risk of HIV infection is now recommended in guidelines from the United States, Europe and Australia and globally through the 2015 WHO guidelines. These 2017 Australasian Society for HIV, Viral Hepatitis and Sexual Health Medicine's (ASHM) PrEP Guidelines are an updated adaptation of the 2014 US Centers for Disease Control's PrEP guidelines and are designed to: a)Support the prescription of PrEP using forms of coformulated tenofovir and emtricitabine that have been registered in Australia by the Therapeutic Goods Administration and other bioequivalent generic drugs that are available in Australia through self-importation; private prescription or Australian PrEP clinical trials(Ausist trial); b)Provide guidance on the use of PrEP in gay men and other men who have sex with men, heterosexual men and women, and people who inject drugs (PWID) at substantial risk of HIV acquisition; c)Provide guidance on the use of PrEP in pregnancy and in chronic hepatitis B infection and how to cease PrEP.Daily PrEP with co-formulated tenofovir and emtricitabine, used continuously or for shorter periods of time, is recommended in these guidelines as a key HIV prevention option for men who have sex with men (MSM), transgender men and women, heterosexual men and women, and people who inject drugs (PWID) at substantial risk of HIV acquisition. These guidelines were updated in April 2018 and include changes to the recommendations regarding the choice of daily or on-demand PrEP.	pre-exposure prophylaxis, PrEP, TDF/FTC	English	United Kingdom	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Clinical
Article	2018	Xiao, Peng; Gumber, Sanjeev; Maximka, Mark A; Date, Abhijit A; Hoang, Thuy; Haines, Justin; Ensign, Laura M; Wang, Lin; Rohan, Lisa; Fuchs, Edward J; Hendrix, Craig; Villinger, Francois	Hypo-osmolar Formulation of Tenofovir (TFV) Enema Promotes Uptake and Metabolism of TFV in Tissues, Leading to Prevention of SHIV/HIV Infection.	Antimicrobial Agents and Chemotherapy	-	-	-	-	-	1098-6596	10.1128/AAC.01644-17	https://ach.silm.ash.gov/pmc/articles/PMC5740333/	Oral preexposure prophylaxis (PrEP) has been approved for prophylaxis of HIV-1 transmission but is associated with high costs and issues of adherence. Protection from anal transmission of HIV using topical microbicides and methods congruent with sexual behavior offers the promise of improved adherence. We compared the pharmacokinetics (PK) and ex vivo efficacy of iso-osmolar (IOso) and hypo-osmolar (HOso) tenofovir (TFV) enema formulations in rhesus macaques (RMs). Single-dose PK studies showed that HOso TFV formulation resulted in 1,000-fold higher TFV concentrations in systemic uptake in blood, colorectal biopsy specimens, and rectal CD4+ T cells. Markedly higher TFV concentrations were observed in plasma and tissue samples after administration of the HOso TFV formulation than with all other formulations tested. TFV and TFV diphosphate (TFV-DP) concentrations in tissue correlated for the HOso high-dose formulation, demonstrating rapid uptake and transformation of TFV to TFV-DP in tissues. TFV-DP amounts in tissues collected at 1 and 24 h were 7 times and 3 times higher, respectively ($P < 0.01$), than the ones collected in tissues with the IOso formulation. The HOso high-dose formulation prevented infection in ex vivo challenges of rectal tissues collected at 1, 24, and 72 h after the intrarectal dosing, whereas the same TFV dose formulated as an IOso enema was less effective.	enema, hypo-osmolar, monkey, tenofovir	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2018	Yavuz, Burcin; Morgan, Jessica L.; Shewbaw, Laura; Horng, Karli R.; Dandekar, Satya; Herrera, Caroline; LiWang, Patricia; Kaplan, David L.	Pharmaceutical Approaches to HIV Treatment and Prevention.	Advanced Therapeutics	-	-	-	-	-	2366-3987	10.1002/adtp.201800054	https://onlinelibrary.wiley.com/doi/abs/10.1002/adtp.201800054	Human immunodeficiency virus (HIV) infection continues to pose a major infectious disease threat worldwide. It is characterized by the depletion of CD4(+) T cells, persistent immune activation, and increased susceptibility to secondary infections. Advances in the development of antiretroviral drugs and combination antiretroviral therapy have remarkable reduction in HIV-associated morbidity and mortality. Antiretroviral therapy (ART) leads to effective suppression of HIV replication with partial recovery of host immune system and has successfully transformed HIV infection from a fatal disease to a chronic illness. However, current treatment options require lifelong administration of multiple drugs, which leads to drug resistance, toxicity, and poor patient adherence. Other limitations include drug-drug interactions, drug resistance, cytotoxic side effects, cost, and adherence issues. Alternative treatment options are being investigated to overcome these challenges including discovery of new molecules with increased anti-viral activity and development of easily administrable drug formulations. In light of the difficulties associated with current HIV treatment measures, and in the continuing absence of a cure, the prevention of new infections has also arisen as a prominent goal among efforts to curtail the worldwide HIV pandemic. In this review, the authors summarize currently available anti-HIV drugs and their combinations for treatment, new molecules under clinical development and prevention methods, and discuss drug delivery formula as well as associated challenges and alternative approaches for the future. Article	2018	Young, Lindsey E; Schumm, Phil; Leigh, Alen; Bouris Alda; Ferreira, Matthew; Hill, Brandon; Khanna, Aditya S; Valente, Thomas W; Schneider, John A	PrEP Chicago: A randomized controlled peer change agent intervention to promote the adoption of pre-exposure prophylaxis for HIV prevention among young Black men who have sex with men	Clinical Trials	-	-	-	-	-	17407745	10.1177/1740774517738012	https://www.proquest.com/scholarly-journals/s-prep-chicago-randomized-controlled-peer-change/docview/1994578004/se-2?accountid=9113	Background/aims Advances in biomedical prevention strategies such as pre-exposure prophylaxis (PrEP) represent a new opportunity for reducing HIV incidence among young Black men who have sex with men, for whom the number of new HIV infections continues to rise. However, studies have documented low rates of PrEP uptake in this community. Research suggests that the peer networks of young Black men who have sex with men play important roles in their sexual health decisions. PrEP Chicago is a randomized controlled trial network intervention designed to increase PrEP uptake among young black men who have sex with men living in Chicago. The aims of this study are twofold. Aim 1 is to estimate the effectiveness of a peer change agent intervention for (1) increasing the number of network members who talk to a PrEP information line, (2) increasing the rate of PrEP adoption among non-participant peers, and (3) increasing PrEP knowledge, attitudes, and intentions among participants. Aim 2 is to determine the individual and network characteristics that moderate peer change agent effectiveness.Methods/PrEP Chicago is a social network intervention that utilizes the influence of peer change agents to increase PrEP uptake among young men who have sex with men in Chicago to PrEP. Young Black men who have sex with men were recruited using respondent-driven sampling. Once screened for eligibility, participants were randomly assigned to either one of two treatment sequences (1:1) intervention treatment in Year 1 followed by a minimal contact attention control in Year 2 or (2) the minimal contact attention control in Year 1 followed by treatment in Year 2. The treatment consists of a PrEP peer change agent training workshop followed by booster calls for 12 months. The attention control consists of a sex diary activity designed to help participants assess sexual health behaviors. Participants complete study assessments at baseline, 6 months, and 12 months.Discussion/To date, PrEP Chicago has enrolled 226 young Black men who have sex with men (100% target enrollment) and have completed baseline data collection. A majority of participants in both intervention and control groups reported having heard of PrEP before enrolling in the study, yet also reported having had no current or prior experience taking PrEP. Statistical analyses await completion of Year 1 of the trial in March 2018.Conclusion/PrEP Chicago addresses a gap in HIV prevention research and intervention design by utilizing the existing social networks among young Black men who have sex with men as mechanisms for information diffusion, behavioral influence, social support, and empowerment. Therefore, interventions that leverage peer influence processes to facilitate PrEP uptake are promising strategies to improve sexual health engagement and overcome disparities in outcomes among this at-risk population. Article	2018	Zaller, Nickolas; Patterson, Benjamin; Elliman, Tanya; Slowikowski, Jacek; Olender, Susan; Gordon, Peter; Morrison, Ellen A. B.; Sobeseczyk, Magdalena E.	Missed Opportunities for Engagement in the Prevention Continuum in a Predominantly Black and Latino Community in New York City	AIDS Patient Care and STDs	-	-	-	-	-	1087291	10.1089/apc.2018.0127	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85052634422&doi=10.1089%2fapc.2018.0127&partnerID=40&md5=6998d8dc61cdbf7bc8d2dc0c4fc328	Even though over the last 25 years, the Centers for Disease Control and Prevention recommendations for HIV screening have expanded to encompass population-wide screening in all healthcare settings, and despite the availability of highly effective treatment for HIV, HIV remains a significant public health problem in predominantly minority communities. Our study examines missed opportunities for engagement in the HIV linkage to PrEP from 2008 through 2017 at an urban academic medical center serving a predominantly minority community. A missed opportunity for HIV screening was a provider visit that did not include HIV testing and occurred within the 12 months before the first positive HIV test. A missed opportunity for PrEP was the first positive HIV test. A missed opportunity for HIV linkage was a positive HIV test that was followed by a positive HIV test. Univariate analysis was performed to assess characteristics of individuals with missed opportunities for screening and prevention services. Between 2008 and 2017, 721 patients were newly diagnosed with HIV. Two-hundred forty-seven diagnoses were made in the early period (2008–2010), 236 in the middle period (2010–2013), and 238 in the late period (2014–2017). Overall 60% of patients had at least one missed opportunity, 34% for HIV screening, and 42% for PrEP. There was no improvement in the rates of individuals with a missed opportunity for HIV screening over time. Ending the HIV epidemic will require concerted efforts to bolster access to testing and ensure that all individuals are offered screening, counseling, and linkage to prevention and care services. © Copyright 2018, Mary Ann Liebert, Inc., publishers. Article	2019	Abana, Felix; Kwathia, John; Lagat, Harison; Mugwanya, Kenneth K; Dettinger, Julie; Begnel, Emily R; Sila, Joseph; Baeten, Jared M; John-Stewart, Grace; Partyz, Jillian	A Field Evaluation of Point-of-Care Creatinine Testing Within a Large PrEP Implementation Program in Western Kenya.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	-	1944-7884	10.1097/QAI.0000000000002109	https://dx.doi.org/10.1097/QAI.0000000000002109	Young women in sub-Saharan Africa are disproportionately affected by HIV, accounting for 25% of all new infections in 2017. Several behavioural and biological factors are known to impact a young women's vulnerability for acquiring HIV. One key, but lesser understood, biological factor impacting vulnerability is the vaginal microbiome. This review describes the vaginal microbiome and examines its alterations, its influence on HIV acquisition as well as the efficacy of HIV prevention technologies, the role of the rectal microbiome in HIV acquisition, advances in technologies to study the microbiome and some future research directions. Article	2019	Adams J.; Coquilla R.; Montoyre J.; Neville S.	Knowledge of HIV pre-exposure prophylaxis among immigrant Asian gay men living in New Zealand	Journal of Primary Health Care	-	-	-	-	-	11726164	10.1071/HC19076	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076673662&doi=10.1071%2fHC19076&partnerID=40&md5=6c967e6cb76c196a363bc6ebcd42c	INTRODUCTION: HIV pre-exposure prophylaxis (PrEP) is a new bio-medical means of reducing the risk of HIV infection. It's use by individuals at high risk of HIV acquisition is recommended. Aims: This study identifies the ways immigrant Asian gay men living in New Zealand talk about and understand issues related to PrEP. METHODS: A qualitative descriptive methodology was used. Individual interviews were conducted with 18 immigrant Asian gay men who were not users of PrEP. Participants were aged 21-36 years and one-third had arrived in New Zealand within 2 years of completing the interview. Data were analysed using thematic analysis. RESULTS: Participants had limited knowledge of PrEP and its effectiveness. Many were unaware that PrEP was available in New Zealand. Some were willing to use PrEP for others, but not . DISCUSSION: PrEP is necessary for working towards the elimination of HIV. To improve uptake among Asian gay men, improved literacy around HIV and pre-exposure prophylaxis is required. This knowledge needs to be improved at both the individual level in primary care services and collectively through health promotion initiatives. Those services and health promotion initiatives need to be provided in ways that encourage engagement by Asian gay men. © 2019 CSIRO Published by Australian Journal Completion © Royal New Zealand College of General Practitioners 2019 This is an open access article licensed under a. Article	2019	Adams J.L.; Shelley K.; Nicol M.R.	Review of Real-World Implementation Data on Emtricitabine-Tenofovir Disoproxil Fumarate as HIV Pre-exposure Prophylaxis in the United States	Pharmacotherapy	-	-	-	-	2770008	10.1002/phar.2240	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063683713&doi=10.1002%2fphar.2240&partnerID=40&md5=512a855332c7b62cb6d42fc2ccbfd23a	The antiretroviral combination of emtricitabine-tenofovir disoproxil fumarate (FTC/TDF) was approved by the U.S. Food and Drug Administration for use as pre-exposure prophylaxis (PrEP) in individuals at high risk for acquiring human immunodeficiency virus (HIV) in July 2012. Since then, Centers for Disease Control and Prevention guidelines for the use of PrEP have been published and implemented into clinical practice throughout the United States. A number of published open-label and PrEP demonstration projects have evaluated the real-world use of PrEP including analysis of the barriers to its use and addressing major concerns. Despite the approval of FTC/TDF for PrEP, its use for this indication relies on patient and provider acceptance, and its effectiveness requires patient adherence and retention in care during periods of high-risk behaviors. Concerns regarding the use of PrEP in healthy individuals persist and include medication adverse effects including renal dysfunction and bone mineral density loss; risk compensation leading to HIV infections, sexually transmitted infections, and unintended pregnancies; and the development of drug resistance in the event of seroconversion. The cost-effectiveness of PrEP continues to be assessed with the greatest cost-effectiveness remaining in those at highest risk of acquiring HIV. Additionally, cases of HIV acquisition in individuals who are adherent to PrEP highlight scenarios in which PrEP is not 100% effective including against the transmission of drug-resistant HIV strains. This review examines data on the implementation of PrEP outside the setting of clinical trials with the aim of providing clinicians with a summary of the current barriers and opportunities for PrEP use with a specific focus on the role of pharmacists in the optimization of PrEP implementation. © 2019 Pharmacotherapy Publications, Inc.	emtricitabine; HIV; pre-exposure prophylaxis; tenofovir disoproxil fumarate	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Adamson B.; Garrison L.; Barnabas R.V.; Carlson J.J.; Kublin J.; Dimitrov D.	Competing biomedical HIV prevention strategies: potential cost-effectiveness of HIV vaccines and PrEP in Seattle, WA	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25373	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071281474&doi=10.1002%2fjia2.25373&partnerID=40&md5=28c864c5843d577d03cf1d2d14b23c99	Introduction: Promising HIV vaccine candidates are steadily progressing through the clinical trial pipeline. Once available, HIV vaccines will be an important complement but also potential competitor to other biomedical prevention tools such as pre-exposure prophylaxis (PrEP). Accordingly, the value of HIV vaccines and the policies for rollout may depend on that interplay and tradeoffs with utilization of existing products. In this economic modelling analysis, we estimate the cost-effectiveness of HIV vaccines considering their potential interaction with PrEP and condom use. Methods: We developed a dynamic model of HIV transmission among the men who have sex with men population (MSM), aged 15-64 years, in Seattle, WA offered PrEP and HIV vaccine over a time horizon of 2025-2045. A healthcare sector perspective with annual discount rate of 3% for costs (2017 USD) and quality-adjusted life years (QALYs) was used. The primary economic endpoint is the incremental cost-effectiveness ratio (ICER) when compared to no HIV vaccine availability. Results: HIV vaccines improved population health and increased healthcare costs. Vaccination campaigns achieving 90% coverage of high-risk men and 60% coverage of other men within five years of introduction are projected to avoid 40% of new HIV infections between 2025 and 2045. This increased total healthcare costs by $30 million, with some PrEP costs shifted to HIV vaccine spending. HIV vaccines are estimated to have an ICER of $42,473/QALY, considered cost-effective using a threshold of $150,000/QALY. Results were most sensitive to HIV vaccine efficacy and future changes in the cost of PrEP drugs. Sensitivity analysis found ranges of 30-70% HIV vaccine efficacy remained cost-effective. Results were also sensitive to reductions in condom use among PrEP and vaccine users. Conclusions: Access to an HIV vaccine is desirable as it could increase the overall effectiveness of combination HIV prevention efforts and improve population health. Planning for the rollout and scale-up of HIV vaccines should carefully consider the design of policies that guide interactions between vaccine and PrEP utilization and potential competition. © 2019 The Authors. Article	2019	Adeagbo, Oluwafemi Atanda; Mthiyane, Nondumiso; Herbst, Carina; Mee, Paul; Neuman, Melissa; Dreyer, Jaco; Chimbindi, Natsayi; Smit, Theresa; Okesola, Nonhlanhla; Johnson, Cheryl; Hatzold, Karin; Seeley, Janet; Cowan, Frances; Corbett, Liz; Shahmanesh, Maryam	Cluster randomised controlled trial to determine the effect of peer delivery HIV self-testing to support linkage to HIV prevention among young women in rural KwaZulu-Natal, South Africa: a study protocol.	BMJ Open	-	-	-	-	2044-6055	10.1136/bmjopen-2019-033435	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7008432	INTRODUCTION: A cluster randomised controlled trial (cRCT) to determine whether HIV self-testing (HIVST) delivered by peers either directly or through incentivised peer-networks, could increase the uptake of antiretroviral therapy and pre-exposure prophylaxis (PrEP) among young women (18 to 24 years) is being undertaken in an HIV hyperendemic area in KwaZulu-Natal, South Africa. METHODS AND ANALYSIS: A three-arm cRCT started mid-March 2019, in 24 areas in rural KwaZulu-Natal. Twenty-four pairs of peer navigators working with ~12 000 young people aged 18 to 30 years over a period of 6 months were randomised to: (1) incentivised-peer-networks: peer-navigators recruited participants 'seeds' to distribute up to five HIVST packs and HIV prevention information to peers within their social networks. Seeds receive an incentive (20 Rand = US$1.5) for each respondent who contacts a peer-navigator for additional HIVST packs to distribute; (2) peer-navigator-distribution: peer-navigators distribute HIVST packs and information directly to young people; (3) standard of care: peer-navigators distribute referral slips and information. All arms promote sexual health information and provide barcoded clinic referral slips to facilitate linkage to HIV testing, prevention and care services. The primary outcome is the difference in linkage rate between arms, defined as the number of women (18 to 24 years) per peer-navigators month of outreach work (/pnm) who linked to clinic-based PrEP eligibility screening or started antiretroviral, based on HIV-status, within 90 days of receiving the clinic referral slip. ETHICS AND DISSEMINATION: This study was approved by the Institutional Review Boards at the WHO, Switzerland (Protocol ID: STAR CRT, South Africa), London School of Hygiene and Tropical Medicine, UK (Reference: 15 990-1), University of KwaZulu-Natal (BFC311/18) and the KwaZulu-Natal Department of Health (Reference: KZ_201901_012), South Africa. The findings of this trial will be disseminated at local, regional and international meetings and through peer-reviewed publications. TRIAL REGISTRATION NUMBER: NCT03751826; Pre-results. Article	2019	Ahlström M.G.; Ronit A.; Omland L.H.; Vedel S.; Obel N.	Algorithmic prediction of HIV status using nation-wide electronic registry data	EClinicalMedicine	-	-	-	-	25895370	10.1016/j.eclinm.2019.10.016	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074846923&doi=10.1016%2fj.eclinm.2019.10.016&partnerID=40&md5=e6d5f9d8154ec13852f2a5b122c700dd	Background: Late HIV diagnosis is detrimental both to the individual and to society. Strategies to improve early diagnosis of HIV must be a key health care priority. We examined whether nation-wide electronic registry data could be used to predict HIV status using machine learning algorithms. Methods: We extracted individual level data from Danish registries and used algorithms to predict HIV status. We used various algorithms to train prediction models and validated these models. We calibrated the models to mimic different clinical scenarios and created confusion matrices based on the calibrated models. Findings: A total 4,384,178 individuals, including 4,350 with incident HIV, were included in the analyses. The full model that included all variables that included demographic variables and information on past medical history had the highest area under the receiver operating characteristic curves of 88·4% (95%CI: 87·5% – 89·4%) in the validation dataset. Performance measures did not differ substantially with regards to which machine learning algorithm was used. When we calibrated the models to a specificity of 99·9% (pre-exposure prophylaxis (PrEP) scenario), we found a positive predictive value (PPV) of 8·3% in the full model. When we calibrated the models to a sensitivity of 90% (screening scenario), 384 individuals would have to be tested to find one undiagnosed person with HIV. Interpretation: Machine learning algorithms can learn from electronic registry data and help to predict HIV status with a fairly high level of accuracy. Integration of prediction models into clinical software systems may complement existing strategies such as indicator condition-guided HIV testing and prove useful for identifying individuals suitable for PrEP. Funding: The study was supported by funds from the Preben and Anne Simonsens Foundation, the Novo Nordisk Foundation, Rigshospitalet, Copenhagen University, the Danish AIDS Foundation, the Augustinus Foundation and the Danish Health Foundation. © 2019	Big data; HIV diagnosis; HIV prevention; Machine learning; Registry data	English	United Kingdom	Western and Central Europe and North America	Denmark	Western and Central Europe and North America	Denmark	Western and Central Europe and North America	Quantitative
Article	2019	Ahmed N.; Pike C.; Bekker L.-G.	Scaling up pre-exposure prophylaxis in sub-Saharan Africa	Current Opinion in Infectious Diseases	-	-	-	-	9517375	10.1097/QCO.0000000000000511	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059135485&doi=10.1097%2fQCO.0000000000000511&partnerID=40&md5=7cccfeb8dd84bcb94bd28b4bdf4ad0dc	Purpose of reviewPre-exposure prophylaxis (PrEP) is highly efficacious for preventing HIV. Demonstrations worldwide show growing acceptability with nonoral formulations in the pipeline. Despite these successes, oral PrEP scale-up in sub-Saharan Africa (SSA), the region hardest hit by HIV, remains sub-optimal. This review details emerging practises and addresses challenges in PrEP scale-up and delivery within SSA.Recent findingsPrEP scale-up varies across SSA. Some countries face implementation challenges, whereas most have not applied for or received regulatory approval. As governments balance treatment and prevention costs, PrEP advocacy is growing. Demand has been slow, because of low-risk perception, HIV treatment conflation or poor information. Challenges in SSA are markedly different than elsewhere, as delivery is targeted to generalized heterosexuals, rather than only key populations. SSA requires public sector engagement and innovative delivery platforms.SummaryPrEP scale-up in SSA is sub-optimal, hindered by regulatory processes, implementation challenges, poor community engagement and inadequate funding. Approaches that acknowledge overburdened, under-resourced health sectors, and seek opportunities to integrate, task-shift, decentralize and even de-medicalize, with a tailored approach, while campaigning to educate and stimulate demand are most likely to work. Solutions to oral PrEP scale-up will apply to other formulations, opening new avenues for ARV (microbicides and injectables) and non-ARV-based (future vaccine) biomedical prevention provision. © 2019 Lippincott Williams and Wilkins. Theses and Dissertations	2019	Ahouada, Carin	La prophylaxie pré-exposition (PrEP) pour la prévention du VIH chez les hommes ayant des relations sexuelles avec d'autres hommes (HSH) au Bénin : acceptabilité et faisabilité	-	-	Université Laval	Université Laval	-	-	NA	http://hdl.handle.net/20.500.11794/66756	Ce travail a consisté à évaluer l'acceptabilité de la prophylaxie pré-exposition (PrEP) pour la prévention du VIH, puis à identifier les facilitateurs et obstacles qui pourraient affecter la mise en place de cette stratégie de prévention chez les hommes ayant des relations sexuelles avec d'autres hommes (HSH) au Bénin. Il en ressort que la PrEP est peu connue des HSH. Toutefois, la quasi totalité des enquêtés, une fois informés par rapport à cette méthode de prévention, était disposée à l'utiliser si elle est rendue disponible. Certains facteurs ont été jugés importants par les HSH à prendre en compte dans le processus de l'implantation de cette stratégie. Le risque de diminution voire de l'abandon de l'utilisation du condom existe. Toutefois, cela ne devra pas entraver la prescription de la PrEP. Les prescripteurs devront accompagner les HSH désireux d'utiliser la PrEP dans la prise de décision concernant les options de prévention (PrEP et/ou préservatif) en accord avec leurs valeurs et leur désir. / We evaluated the acceptability of pre-exposure prophylaxis (PrEP) for HIV prevention and identified the potential facilitators and obstacles that could affect the implementation of this prevention strategy among men who have sex with men (MSM) in Benin. The results showed that PrEP is not well known to MSM. However, once informed about this prevention tool, almost all surveyed men were willing to use it if made available. Some factors were viewed as important by MSM to be considered in the implementation process. The risk of reducing or even abandoning condom use exists. However, this should not hinder the prescription of PrEP. Prescribers should accompany MSM who wish to use PrEP in making decisions about prevention options (PrEP and / or condom) in accordance with their values and desires	NA	French	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	-	-	Quantitative
Article	2019	Ajayi A.I.; Mudefi E.; Yusuf M.S.; Adeniyi O.V.; Rala N.; Goon D.T.	Low awareness and use of pre-exposure prophylaxis among adolescents and young adults in high HIV and sexual violence prevalence settings	Medicine (United States)	-	-	-	-	257974	10.1097/MD.0000000000017716	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074099082&doi=10.1097%2fMD.0000000000017716&partnerID=40&md5=bd2571568c19fbaf41bab043d2268d72	South Africa has adopted pre-exposure prophylaxis (PrEP) as a preventive strategy for populations at-risk for HIV, though uptake is low among adolescents and young adults. We examined the awareness and use of PrEP among adolescents and young adults in the Eastern Cape, South Africa.This cross-sectional study was conducted between June and November 2018 among 772 adolescents and young adults (aged 16-24 years) selected using stratified random sampling in a South African university. An electronic self-administered questionnaire was used to elicit demographic information, behavioral, family-related characteristics, awareness and use of PrEP. Adjusted and unadjusted logistic regression models were used to examine the predictors of PrEP awareness.The overall level of PrEP awareness was 18.8%; however, only 1.7% of participants had used PrEP, 7.5% of had seen it, 4.8% knew how much it cost, and 14.8% knew where and how to get it. In the adjusted regression analysis, only adequate family support (AOR: 2.11; CI: 1.47-3.04) and discussions of HIV and sexually transmitted infections with sexual partners (AOR: 1.78; CI: 1.19-2.67) were associated with a higher likelihood of being aware of PrEP.The level of awareness and use of PrEP is still very low among adolescents and young adults who may need it to prevent HIV infection. Poor awareness of PrEP among adolescents and young adults in high HIV risk settings may limit its use. Thus, concerted efforts are needed to promote awareness and access to PrEP among young South African adults. Copyright © 2019 the Author(s). Article	2019	Algarin, Angel B; Shrader, Cho Hee; Bhatt, Chintan; Hackworth, Benjamin T; Cook, Robert L; Ibañez, Gladys E	The Pre-exposure Prophylaxis (PrEP) Continuum of Care and Correlates to Initiation Among HIV-Negative Men Recruited at Miami Gay Pride 2018	Journal of Urban Health	-	-	-	-	1099-3460	10.1007/s11524-019-00362-4	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-prep-continuum-care/docview/2234826455/se-2?accountid=8113	While the national HIV infection rate is decreasing, the highest rates of infections continue among men who have sex with men (MSM), particularly minority MSM. It is important to understand attitudes, knowledge, and behaviors surrounding HIV prevention methods, such as pre-exposure prophylaxis (PrEP). In the present study, we created a snapshot of the PrEP continuum of care and identified participant demographic and sources of PrEP awareness factors that were associated with PrEP initiation. Data were collected using anonymous paper–based surveys employing a venue intercept procedure. A total of 188 HIV–negative men completed the survey at Miami Gay Pride 2018. Participants answered questions regarding demographics, PrEP use, and sources of PrEP awareness. The sample was majority Hispanic (55.4%), gay (83.0%), and single (57.7%). The constructed PrEP continuum revealed that a low proportion of those identified as PrEP naïve (n = 143) for HIV infection had PrEP interest (49/143). Moreover, among those who initiated PrEP (n = 45), a high proportion were retained in a PrEP program (37/45), with approximately half achieving medication adherence (25/45). Age group, PrEP knowledge, and source of PrEP awareness were all significantly associated with PrEP initiation. In areas with high HIV infection rates, studies like these offer crucial insight on how public health practitioners should proceed in the goal of decreasing HIV transmission rates. More research is needed to increase PrEP uptake and adherence. Article	2019	Amico K.R.; Miller J.; Balthazar C.; Serrano P.A.; Brothers J.; Zollweg S.; Hosek S.	Integrated Next Step Counseling (iNSC) for Sexual Health and PrEP Use Among Young Men Who Have Sex with Men: Implementation and Observations from ATN110/113	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2291-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055328705&doi=10.1007%2fs10461-018-2291-2&partnerID=40&md5=a84597fc6fd61a3ba98f6f14aa44dc23	Pre-exposure prophylaxis (PrEP) for the prevention of HIV infection among young men who have sex with men is a critical part of the HIV prevention landscape in the US. Given the unique challenges and resources of young MSM negotiating safer sex practices, including PrEP, counseling and supportive discussions to optimize both PrEP use and sexual health protection more generally may facilitate reaching HIV prevention goals. Within the context of a large, open-label PrEP study (ATN110/113), support for sexual health promotion and PrEP use was provided through use of integrated Next Step Counseling (iNSC) as part of study visits. We detail iNSC and, using session documentation collected throughout this study, we characterize iNSC implementation and the content generated from these discussions. We detail features of iNSC, training of counselors and the implementation of iNSC in a multi-site PrEP study with young MSM in the US. Case report forms completed by iNSC counselors at study visits at weeks 4, 8, 12, 24, 36, and 48 were evaluated. Implementation of each intervention step for each discussion is summarized at and across timepoints, as well as features of specific steps (e.g., kinds of facilitators and barriers). Implementation differences by group (e.g., race/ethnicity, age) were examined. iNSC case report forms from 1000 sessions involving 178 unique participants ages 15–22 from sessions conducted between 2013 and 2015 were reviewed. High fidelity to iNSC steps in terms of inclusion in sessions was reported; 98–100% of sessions included critical steps for sexual health protection discussions and 96–98% for PrEP use discussions. The vast majority of sessions appeared to flow in line with iNSC's emphasis on exploration and open discussion prior to considering specific needs and related strategies. Nearly three-quarters of sessions noted 'commitment to staying negative' as a motivator towards sexual health protection (more commonly reported by those identifying as White), while 'assuming partner is negative' was the most common challenge (less common for the older cohort), and 'having access' to a sexual health protection tool or strategy (besides PrEP) was the most common "need" (more common for those identifying as White or Latino). Carrying dose(s) to have them on-hand when needed was the most common PrEP adherence facilitator, drug and alcohol use was the most common challenge noted, and access to a dose when needed was the most common "need" (more common for participants self-identified as White). iNSC was implemented consistently throughout ATN110/113, and patient-centered discussions about sexual health protection and PrEP-use appeared feasible to incorporate into clinical care visits. © 2018, The Author(s). Article	2019	Amico, K Rivet; Ramirez, Catalina; Caplan, Margaret R; Montgomery, Brooke Ee; Stewart, Jennifer; Hodder, Sally; Swaminathan, Shobha; Wang, Jing; Darden-Tabb, Noshima Y; McCauley, Marybeth; Mayer, Kenneth H; Wilkin, Timothy; Landovitz, Raphael J; Gulick, Roy; Adimora, Adaora A	Perspectives of US women participating in a candidate PrEP study: adherence, acceptability and future use intentions.	Journal of the International AIDS Society	-	-	-	-	1758-2652	https://doi.org/10.1002/jia2.25247	https://escholarship.org/uc/item/89n331cs	IntroductionLimited data exist on acceptability of candidate pre-exposure prophylaxis (PrEP) regimens among US women. We evaluated PrEP experiences, attitudes and future use intentions among sexually active women who completed the US-based HIV Prevention Trials Network 069/AIDS Clinical Trials Group 5305 study.MethodsWomen participated in the study between March 2013 and November 2015. We analysed computer-assisted self-interview (CASI) surveys among 130 women and conducted in-depth interviews among a subset of 26 women from three sites. Interviews were conducted in mid/late-2015.ResultsMost women (57%) reported very good/excellent PrEP adherence on CASI, although 21% acknowledged over-reporting adherence at least some of the time. Commitment to preventing HIV infection, a sense of ownership of the study, and keeping pills stored in a visible location facilitated adherence. Adherence barriers included "simply forgetting" and being away from home. Most women interviewed did not intend to use PrEP in the future because of lack of perceived need due to their own (as opposed to their partners') low-risk behaviour and concerns about affordability - but not because of side effects or other characteristics of the regimens.DiscussionImproving HIV prevention options for US women will require access to affordable PrEP as well as expanding women's understanding of relationship- and community-level factors that increase their risk of acquiring HIV. Theses and Dissertations	2019	Anderson, Ashley, 1990-	An intervention to increase uptake of pre-exposure prophylaxis in women at risk for HIV	-	-	Rutgers University	Rutgers University	-	NA	NA	https://rucore.libraries.rutgers.edu/rutgers-lib/61234/	Education about Pre-exposure Prophylaxis (PrEP) has been focused on men who have sex with men (MSM) because rates of HIV infection are higher among this population. Pre-exposure prophylaxis or PrEP is indicated for people at very high risk for HIV. Those at risk take a once daily pill to lower their chances of getting infected. PrEP can stop HIV from spreading throughout your body (Centers for Disease Control and Prevention CDC, 2018). Current evidence indicates that women who are educated about PrEP are more likely to inquire about initiating this prevention strategy (Koechlin et al., 2016). For example, The GreaterThan online resource for information about PrEP, has more resources for MSM about PrEP compared to resources about women and PrEP. Women at risk for HIV are not identified for PrEP compared to MSM (Aaron et al., 2017). The Prepwatch webpage addresses a womans need for PrEP; it advises that PrEP is safe for both men and women, however, there is no additional information or resources for women (PrEPwatch, 2018). Women are of considerable interest when discussing PrEP. In 2015 and 2016, women made up 19% of the new HIV diagnoses in the United States (Centers for Disease Control and Prevention CDC, 2017). Knowledge about PrEP would benefit women at risk for HIV. Because there are limited PrEP resources available for women, this education could be provided by counselors and take place at an STD counseling and testing center. This project explores the intervention of counseling clinicians at a clinic located in Newark, NJ to identify and refer women at risk for HIV to the PrEP counselor. Article	2019	Ang D.; Liu Y.; Eisingerich A.B.	Difference in new product adoption among at-risk members of society: A critical analysis of males, females, and transgender individuals	Personality and Individual Differences	-	-	-	-	1918869	10.1016/j.paid.2019.07.013	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068929547&doi=10.1016%2fj.paid.2019.07.013&partnerID=40&md5=ee280c147b2abaabfb3ed5f3ddb002d9	The study examines how fear and embarrassment associated with the usage of a new product influence product adoption. The extant body of work on individual differences is largely based on educated, relatively wealthy individuals in industrialized countries. This study extended prior work by exploring the uptake of a new product among 1823 at-risk individuals including sex workers and drug users from countries with high HIV prevalence. The findings show that fear of contracting HIV encouraged new product adoption while embarrassment associated with taking the new product hindered it. It is noteworthy that embarrassment is a better predictor than fear. Critically, the effect of embarrassment differed across genders. Specifically, embarrassment plays a more important role for transgender and female individuals compared to males. The effects are driven by public and private embarrassment in sub-Saharan and non-sub-Saharan countries, respectively. This study thus contributes to the important work on sexuality, gender differences, fear, embarrassment, and the uptake of new products for high-risk or stigmatized members of marginalized communities. The findings also offer practical implications for communication strategies to facilitate the uptake of new products such as a new medicine among members of stigmatized communities, less wealthy, and less educated members of society. © 2019 Elsevier Ltd	Adoption; Embarrassment; Fear; HIV; PrEP; Sexuality; Sub-Saharan countries; Transgender	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2019	Ard K.L.; Edelstein Z.R.; Bolduc P.; Daskalakis D.; Gandhi A.D.; Krakower D.S.; Myers J.E.; Keuroghlian A.S.	Public health detailing for human immunodeficiency virus pre-exposure prophylaxis	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciy573	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061616467&doi=10.1093%2fcid%2fciy573&partnerID=40&md5=e344e871e996c96ad3e70f64e04b1978	Despite the promise of human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP), PrEP remains underutilized, often due to clinician factors. Academic or public health detailing is a process by which university and/or government groups employ the marketing practices of pharmaceutical companies to improve clinical practice. We describe the novel application of detailing to increase PrEP prescribing and related care in New York City and New England. Detailing can play a crucial role in PrEP implementation. © The Author(s) 2018.	academic detailing; HIV prevention; PrEP; public health detailing	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Arrington-Sanders R.; Wilson C.M.; Perumean-Chaney S.E.; Patki A.; Hosek S.	Role of sociobehavioral factors in subprotective TFV-DP Levels among YMSM Enrolled in 2 PrEP Trials	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001901	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059907562&doi=10.1097%2fQAI.0000000000001901&partnerID=40&md5=686329b97b7670a2dad34c7fabc4a9ea	Background:Young men who have sex with men (YMSM) experience disparities in HIV acquisition more than any other group. Daily oral pre-exposure prophylaxis (PrEP) with tenofovir/emtricitabine has been shown to effectively prevent HIV transmission in YMSM; however, recent studies suggest that young Black men who have sex with men experience subprotective levels of tenofovir diphosphate more frequently than other groups.Setting:Combined data from Adolescent Medicine Trials Network for HIV/AIDS Interventions (ATN) 110/113, 2 open-label PrEP studies that provided PrEP and evidence-based behavioral interventions to YMSM aged 15-22 years.Methods:Bivariate and logistic regression analyses were used to examine sociodemographic and behavioral factors associated with protective tenofovir diphosphate levels (defined as ≥700 fmol/punch) in ATN 110/113 data.Results:In bivariate analysis, self-identified Black participants, residential displacement due to sexual orientation, low perceived risk, and stigma with the medication were associated with subprotective levels. Hispanic ethnicity was associated with protective levels. In the final models, Black males were less likely to have subprotective levels than non-Black males at 4, 8, and 12 weeks. Self-reported displacement due to sexual orientation was associated with subprotective levels, whereas older age was as associated with protective levels.Conclusions:These findings highlight how future behavioral research and biomedical prevention efforts in YMSM will need to address PrEP disparities that may occur in young Black men who have sex with men, perception of risk, and lack of key supportive housing during this period that may be critical factors that contribute to HIV acquisition. © 2018 Wolters Kluwer Health, Inc. Article	2019	Assi, Ayman; Abu Zaki, Sara; Ghosn, Jade; Kinge, Nizar; Naous, Jihane; Ghanem, Antoine; Abou Abbas, Diana; Bakouny, Ziad; Azzi, Georges; Tomb, Roland	Prevalence of HIV and other sexually transmitted infections and their association with sexual practices and substance use among 2238 MSM in Lebanon.	Scientific Reports	-	-	-	-	2045-2322	10.1038/s41598-019-51688-7	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6806001	UNAIDS report documents 95% increase in new HIV infections among key populations in Eastern Europe and Middle East and North Africa region. Data on HIV and STIs among MSM in Lebanon is still scarce. Therefore, the aim was to assess prevalence of HIV and sexually transmitted infections (STIs) among men who have sex with men (MSM) in Lebanon and associations with sexual practices and substance-use. 2238 MSM attended a sexual health clinic in Lebanon between 2015-2018. Demographics, substance-use and sexual practices were collected. Attendees tested for HIV and other STIs. HIV infection was diagnosed in 5.6% of the sample. Only 19% received sexual health education from reliable sources (school/university/healthcare workers), 78% reported having multiple partners in the past three months (2-5 partners: 58%, 6+: 20%) and 67% reported inconsistent condom-use. Moreover, 40% of HIV + cases were returning attendees who already received information about condom-use. Additionally, having only a school level education (11%) increases the odds of having inconsistent condom-use with casual partners (adj.OR:1.9, p < 0.001). The results reflect the urgent need for: (1) accurate and comprehensive sexual health and harm reduction education and promotion in Lebanon; (2) making pre-exposure prophylaxis available for free to key populations to contain the epidemics at an early stage. Article	2019	Atefi D.; McIver R.; Bourne C.	Missed opportunities for HIV pre-exposure prophylaxis during a rapid scale-up program at Sydney Sexual Health Centre	Sexual Health	-	-	-	-	14485028	10.1071/SH19032	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075774215&doi=10.1071%2fSH19032&partnerID=40&md5=2fdc3eb544d24706c8d873021ea974e9	We aimed to estimate HIV pre-exposure prophylaxis (PrEP) uptake and missed opportunities for PrEP through a retrospective review of medical records of clients at high risk of HIV attending the Sydney Sexual Health Centre. Most clients (69%) were taking PrEP, and 7% of those eligible for PrEP were classified as a missed opportunity for PrEP. Although missed opportunities were uncommon, PrEP discussions should be a standard component of care for all clients at risk of HIV acquisition. © 2019 CSIRO.	men who have sex with men; prevention	English	United States	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Quantitative
Article	2019	Aung W.S.; Bakshi R.P.; Breakey J.; Johnson J.E.; Hendrix C.W.; Weld E.; Fuchs E.J.; Marzinke M.A.	Fecal Coliform Bacterial Detection to Assess Enema Adherence in HIV Prevention Clinical Studies	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2211-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049563218&doi=10.1007%2fs10461-018-2211-5&partnerID=40&md5=3f02639966614293c7712311b099a959	Evaluating the efficacy of any HIV prevention strategy is dependent on ensuring and objectively monitoring adherence to the intervention. Medicated rectal enemas are a potential method for providing topical, episodic HIV prophylaxis during receptive anal intercourse. Assessing adherence to recommended enema dosing regimens is essential in evaluating the utility of this strategy. We utilized fecal coliform bacteria on used enema tips as a marker for enema use. Enema tip coliforms were tested by repurposing a microtiter plate-based water quality test designed to detect fecal contamination of water. Coliform detection occurred with 100% sensitivity and specificity when tips were assayed on day of use. The assay performed well post-7 day sample storage at room temperature, yielding a sensitivity of 80% and specificity of 93%. All (n = 64) samples collected in a subset of the DREAM-01 rectal microbicide enema clinical trial tested positive, even when tips were evaluated > 7 days post-reported use. The coliform-based enema tip assay allows monitoring of adherence in interventions involving rectal enemas in a sensitive, specific and inexpensive manner. The test performs well in clinical trial settings. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Ayerdi Aguirrebengoa, O; Vera García, M; Portocarrero Nuñez, JA; Puerta López, T; García Lotero, M; Escalante Garcia, C; Raposo Utrilla, M; Estrada Pérez, V; Romero Guerrero, J Del; Rodríguez Martín, C	La implementación de la profilaxis preexposición podría evitar la mayoría de las nuevas infecciones por el VIH en hombres que tienen sexo con hombres y mujeres transexuales	Revista Clínica Española (Edición impresa)	-	-	-	-	0014-2565	10.1016/j.rce.2019.02.001	https://pesquisa.bvsalud.org/portal/resource/pt/ibc-186640	Introducción: La profilaxis preexposición (PrEP) consiste en administrar fármacos antirretrovirales a personas seronegativas para el VIH con prácticas de alto riesgo, con el fin de reducir la probabilidad de adquirir la infección. A pesar de su eficacia y seguridad, en España, la PrEP aún no está disponible dentro del sistema sanitario público. El objetivo fue estimar el impacto preventivo que supondría añadir la PrEP junto al resto de medidas preventivas. Se estimó el número de seroconversiones al VIH que se hubieran podido evitar, entre los hombres que tienen sexo con hombres y mujeres transgénero inicialmente seronegativos, en caso de disponer de la PrEP. Métodos: Estudio descriptivo de los seroconvertidores recientes al VIH entre 2014-2016 en una clínica de VIH/ITS de referencia en Madrid. Se analizaron a las personas que tenían indicación de recibir la PrEP, según las guías de Grupo de Estudio del Sida 2016. El análisis estadístico para estimar las infecciones por el VIH que se hubieran podido evitar, en caso de disponer de la PrEP, se efectuó mediante Stata 14. Resultados: Se estimó que de los 228 hombres que tienen sexo con hombres y mujeres transgénero, con seroconversión documentada al VIH, 195 tenían la indicación de PrEP. Teniendo en cuenta la eficacia preventiva descrita en estudios europeos, se estimó que se hubieran podido evitar 168 seroconversiones al VIH, lo que supone el 73,7% de las infecciones diagnosticadas. Conclusiones: Los resultados confirman la necesidad de impulsar programas preventivos combinados frente al VIH que integren todas las medidas posibles incluyendo la PrEP	Humanos; Masculino; Feminino; Adulto; Pessoa de Meia-Idade; Profilaxia Pré-Exposição/estatística & dados numéricos; Infecções por HIV/tratamento farmacológico	Spanish	Spain	Western and Central Europe and North America	spain	Western and Central Europe and North America	Spain	Western and Central Europe and North America	Clinical
Article	2019	Azariah, Sunita; Saxton, Peter; Franklin, Richard; Forster, Rose; Werder, Suzanne; Jenkins, Renee	NZPrEP Demonstration Project: protocol for an open-label, single-arm trial of HIV pre-exposure prophylaxis (PrEP) to determine feasibility, acceptability, adverse and behavioural effects of PrEP provision to gay and bisexual men in publicly funded sexual health clinics in Auckland, New Zealand.	BMJ Open	-	-	-	-	2044-6055	10.1136/bmjopen-2018-026363	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6597636	INTRODUCTION: New Zealand has experienced a rise in HIV diagnoses in recent years and new interventions are required to address this. METHODS AND ANALYSIS: NZPrEP (A demonstration project of HIV preexposure prophylaxis in Aotearoa New Zealand) is an open-label, single-arm treatment evaluation study to investigate feasibility, retention, adherence, and clinical and behavioural outcomes of HIV pre-exposure prophylaxis (PrEP) provision to gay and bisexual men (GBM) in a publicly funded secondary sexual health service in Auckland, New Zealand. The sample size is 150 GBM. Inclusion criteria were specific behavioural risk factors indicating an increased risk of HIV infection. Exclusion criteria were hepatitis B infection, any medical contraindications to prescribing tenofovir/emtricitabine or factors limiting ability to adhere to the study protocol. Eligible participants will be screened for HIV and other sexually transmissible infections (STIs) and for any medical contraindications to PrEP, and enrolled for a maximum follow-up period of 96 weeks. They will be required to attend for 3-monthly testing for HIV and STIs and monitoring for renal and liver toxicity. Participants will also be required to complete an online behavioural survey after each study visit. The outcomes of interest are feasibility of PrEP provision in a sexual health clinic setting, PrEP acceptability, and adverse medical and behavioural effects of PrEP. The study sample is limited to 150 participants due to funding and service constraints. Statistical analysis of all primary and secondary outcomes will be performed using Stata V.14 at the University of Auckland. Results for primary and secondary endpoints will be reported after the conclusion of the study in March 2019. ETHICS AND DISSEMINATION: The study was approved by the Health and Disability Ethics Committee on 15 September 2016 (16/NTA/112). Key findings will be submitted to peer-reviewed journals. A summary report will be circulated to the study and community stakeholders, and to the Auckland District Health Board, Ministry of Health and Pharmac. Article	2019	Barin, Francis; Braibant, Martine	HIV-1 antibodies in prevention of transmission.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0000000000000553	https://dx.doi.org/10.1097/COH.0000000000000553	PURPOSE OF REVIEW: To present the data that suggest that antibodies to HIV may prevent HIV-1 infection. RECENT FINDINGS: Many human monoclonal broadly neutralizing antibodies (bnAbs) have been isolated over the last decade. Numerous experiments of passive immunization in nonhuman primate models have allowed to accumulate strong evidences that bnAbs, opposed to nonneutralizing antibodies, are the best candidates to prevent HIV-1 infection. bnAbs counteract HIV-1 by both blocking the virus at the portal of entry and clearing rapidly viral foci established at distance after dissemination of the virus following infection. Cocktails of bnAbs or modified bi/trispecific antibodies will be necessary to counter the large and evolving antigenic diversity of the HIV-1 species. Two large multicenter phase IIb clinical trials have been initiated. Even if they are not conducted with the most recent and most potent bnAb, the results which are expected in 2022 will inform us on the real potency of bnAbs at preventing HIV-1 acquisition in the real life. SUMMARY: If these trials demonstrate the efficacy of bnAbs, they will open the trail toward new strategies for preexposure prophylaxis, eventually postexposure prophylaxis and prevention of mother-to-child transmission. Article	2019	Bärnighausen, Kate E; Matse, Sindy; Kennedy, Caitlin E; Lejeune, Charlotte L; Hughey, Allison B; Hettema, Anita; Bärnighausen, Till W; McMahon, Shannon A	'This is mine, this is for me': preexposure prophylaxis as a source of resilience among women in Eswatini.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0000000000002178	https://dx.doi.org/10.1097/QAD.0000000000002178	OBJECTIVE: To understand the relationship between HIV preexposure prophylaxis (PrEP) and resilience among Emaswati women. DESIGN: A qualitative study using semistructured in-depth interviews. METHODS: We interviewed 24 women who recently initiated PrEP at one of six public-sector primary-care clinics participating in a government demonstration project for PrEP for the general population, as well as 30 PrEP stakeholders from HIV policy, implementation and donor sectors. RESULTS: PrEP clients and stakeholders described an environment marked by high HIV risk. In this context, clients felt PrEP enhanced their resilience through feelings of protection, control over HIV acquisition, choice in relation to when to take PrEP, sexual pleasure and relief from the fear and consequences of HIV infection. Those in serodiscordant relationships described improved partner communication and a shared sense of responsibility for HIV prevention. Both PrEP clients and stakeholders asserted that PrEP marketing and communication should be Emaswati-led and community-owned. CONCLUSION: PrEP helps women in Eswatini envision longer, healthier and more fulfilled lives. PrEP enhances resilience through several pathways, including self-efficacy, choice, control over HIV infection and relief from the fear of HIV infection. Social marketing and information campaigns should not only focus on PrEP as an HIV-prevention method but also emphasize how PrEP has expanded choice, enhanced control and facilitated sexual enjoyment among PrEP clients. Article	2019	Bärnighausen, Till	Sex partners as bystanders in HIV prevention trials: Two test cases for research ethics.	Clinical Trials	-	-	-	-	1740-7753	10.1177/1740774519865878	https://dx.doi.org/10.1177/1740774519865878	Research involving human subjects can impose risk on some 'bystanders'- people who are not themselves research subjects but whom the study may affect. We examine the consequences of research for a particular category of bystanders - research subjects' sex partners - in trials testing interventions to reduce (1) HIV transmission (HIV treatment-as-prevention trials) and (2) HIV acquisition (HIV pre-exposure prophylaxis trials). Both types of trials provide useful test cases for assessing whether bystanders to research deserve special consideration in ethics reviews, and potentially some of the benefits and protections that research subjects receive. In HIV treatment-as-prevention trials, there are two groups of people who are alike in many important respects but treated very differently by research ethics: research subjects who contribute data on the primary endpoint of the trial (because some of them have sex with the people receiving the treatment conditions of the trials) - and bystanders who are not enrolled in the trials but who could have contributed primary endpoint data in the same way as the first group. In pre-exposure trials, the sex partners of people participating in pre-exposure prophylaxis trials are bystanders, even though they are necessary for the success of the trial. Research subjects' autonomy is fiercely protected by trial enrolment processes. Bystanders, by contrast, often have no choice but to be affected by the study, because of their relationship to a research subject. In HIV prevention trials, standing by can come with important risks, including the same ones on which the success of the research hinges. It is thus important to consider the ethical obligations to protect bystanders, and the related procedural responsibilities. Article	2019	Barreras, J L; Linnemayr, S L; MacCarthy, S	"We have a stronger survival mode": exploring knowledge gaps and culturally sensitive messaging of PrEP among Latino men who have sex with men and Latina transgender women in Los Angeles, CA.	AIDS Care	-	-	-	-	1360-0451	10.1080/09540121.2019.1601669	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6999851	Latino men who have sex with men (LMSM) and Latina transgender women (LTGW) often lack access to HIV prevention information and strategies such as pre-exposure prophylaxis (PrEP). We explored knowledge gaps and culturally sensitive messaging about PrEP among HIV-negative LMSM and LTGW in Los Angeles. We recruited participants from a Latinx LGBT community-based organization. We conducted nine focus groups (n = 91 participants) with 52 LMSM and 39 LTGW. We used a rapid assessment process to identify themes that we analyzed using thematic analysis. Key quotes were transcribed verbatim; they were reviewed by the team, then uploaded to Dedoose to identify themes across sites and between groups. Three themes emerged for both LMSM and LTGW: knowledge gaps regarding PrEP remain; people who have knowledge about PrEP often served as its champions; highlighting positive aspects of culture could help improve PrEP's uptake and sustained use. Only LMSM worried that PrEP could impact condom use. Some issues were more pronounced among LTGW (e.g., more limited access to PrEP); others were unique to LTGW (e.g., worry about drug-hormones interactions). Collaborative research, programs, and policies, informed by LMSM and LTGW themselves, are needed to narrow existing knowledge gaps and promote PrEP uptake and sustained utilization. Article	2019	Bass E.; Fitch L.; Gomez A.; Loar R.	Demand creation for primary biomedical prevention: Identifying lessons across interventions to inform daily oral preexposure prophylaxis programs	Current Opinion in HIV and AIDS	-	-	-	-	1746630X	10.1097/COH.0000000000000518	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057521011&doi=10.1097%2fCOH.0000000000000518&partnerID=40&md5=687aa75393400195b59e31d7711a7eb8	Purpose of reviewAt a moment when UNAIDS (Joint United Nations Programme on HIV/AIDS) has acknowledged a 'prevention crisis,' and multiple countries and implementers are emphasizing 'user-centered' and/or differentiated models of delivering HIV treatment and prevention, it is essential to understand and act on best practices from all relevant interventions to create effective oral preexposure prophylaxis (PrEP) programs.Recent findingsIt is possible to adapt private sector approaches to understanding and segmenting the preferences and mindsets of potential consumers to primary HIV prevention programs, as demonstrated by a voluntary medical male circumcision (VMMC)-focused intervention that successfully trained and supported counselors to identify and deliver tailored messages to men potentially undergoing VMMC. Literature on PrEP and demand creation is less extensive and suggests uneven application of user-centered design and demand-side thinking; a recent analysis of condom programing demonstrates that failure to maintain resources for social marketing can drive a collapse in use and an increase in HIV incidence.SummaryApproaches to demand creation for primary prevention are dynamic and evolving. However, the lag between implementation and publication means that there is a paucity of PrEP-specific information. Insights from VMMC and other strategies can and must be considered as part of a more holistic approach to increasing demand for primary prevention interventions. © 2018 Wolters Kluwer Health, Inc. Article	2019	Bassett, Ingrid V; Govere, Sabina; Millham, Lucia; Frank, Simone C; Dladla, Nosipho; Thulare, Hilary; Psaros, Christina	Contraception, HIV Services, and PrEP in South African Hair Salons: A Qualitative Study of Owner, Stylist, and Client Perspectives	Journal of Community Health	-	-	-	-	00945145	10.1007/s10900-019-00698-7	https://www.proquest.com/scholarly-journals/contraception-hiv-services-prep-south-african/docview/2252713495/se-2?accountid=8113	Women experience challenges engaging with the healthcare system, but frequently utilize hair salons; these are promising venues for family planning and HIV prevention services. Our objective was to assess the acceptability of nurse-offered contraceptive and PrEP services at hair salons in Durban, South Africa. We interviewed salon owners (N = 10) and clients (N = 42) and conducted focus groups with hair stylists (N = 43 stylists; 6 focus groups across five hair salons) to explore barriers and facilitators to providing contraception and PrEP in salons. After developing a codebook, we performed content analysis to identify themes within each conceptual area; 10% of transcripts were coded by two coders to ensure reliability. Content was analyzed according to the following categories: (1) facilitators of and (2) barriers to utilizing these services, and (3) factors to consider for program implementation. Participants identified convenience and female-oriented, supportive atmosphere as facilitators to offering HIV and contraceptive services in salons. Owners and stylists noted that establishing legitimacy was important for program success, including providing promotional pamphlets and employing nurses. Clients cited privacy concerns surrounding HIV testing in a public space as a significant barrier to using these services. Overall, participants were enthusiastic about the program. Convenience and a conducive environment were noted as facilitators to receiving health services in the hair salon; attention will have to be directed to establishing privacy and program legitimacy. Hair salons represent an innovative venue for reaching young women at high-risk for unintended pregnancy and HIV infection. Theses and Dissertations	2019	BASTOS, LUIZA LENA	PROFILAXIA PRÉ-EXPOSIÇÃO AO HIV/AIDS: controvérsias e reivindicações na estabilização social de uma tecnologia preventiva de saúde no Brasil	-	-	Universidade Federal do Rio de Janeiro	Universidade Federal do Rio de Janeiro	-	-	NA	https://sucupira.capes.gov.br/sucupira/public/consultas/coleta/trabalhoConclusao/viewTrabalhoConclusao.jsf?popup=true&id_trabalho=8774244	Em 2017 o Brasil incorporou o medicamento PrEP/Truvada® no Sistema Único de Saúde (SUS) como mais uma tecnologia para prevenção da infecção pelo vírus HIV. O país tem sido visto como pioneiro na América Latina em realizar esforços para implemetar tal tecnologia. Diante deste contexto, o principal objetivo deste estudo é compreender como a PrEP/Truvada® está sendo estabilizada socialmente no Brasil a partir dos discursos dos participantes (usuários de PrEP) de uma pesquisa de aceitabilidade de PrEP no Rio de Janeiro, e de médicos infectologistas, ativistas por PrEP, ativistas LGBTQI+ e ativistas de luta contra a AIDS. O estudo identifica controvérsias e analisa discursos destes atores. Adota-se o referencial teórico dos direitos humanos e tecnologia e os estudos sociais da ciência como referecial teórico-metodológico. Como hipótese central tem-se que a estabilização da PrEP/Truvada® torna-se possível por meio de uma agenda que mistura ciência e ativismo na luta contra a AIDS e também ativismo LGBTQI+. Para tanto, este estudo procurou evidenciar diferentes significados atribuídos à PrEP que ora a estabilizam e ora a desestabilizam. Por isso foi importante seguirmos discursos que ora compreendem a PrEP nos termos da esperança e empoderamento, e ora a compreendem em termos até mesmo discriminatórios frente a sexualidade e à infecção pelo HIV/AIDS. O estudo se justifica diante da necessidade de ampliarmos no Brasil a discussão sobre o uso de PrEP como mais uma tecnologia que possibilite a prevenção à infecção pelo HIV e melhor vivência da sexualidade para aquelas pessoas mais vulneráveis à epidemia de AIDS. Article	2019	Bauermeister, José A; Golinkoff, Jesse M; Lin, Willey Y; Claude, Kristina F; Horvath, Keith J; Dowshen, Nadia; Schlupp, Anderson; Vickroy, William J; Desir, Kimberly; Lopez, Alexander V; Castillo, Marné; Tanney, Mary; Wimbly, Taylor A; Leung, Kingsley; Sullivan, Patrick S; Santiago, Dalisa L; Hernandez, Rogelio; Paul, Mary E; Hightow-Weidman, Lisa; Lee, Sonia; Stephenson, Rob	Testing the Testers: Are Young Men Who Have Sex With Men Receiving Adequate HIV Testing and Counseling Services?	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000002173	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6820705	BACKGROUND: The United States Centers for Disease Control and Prevention promote HIV testing every 6 months among young men who have sex with men (YMSM) to facilitate entry into the HIV prevention and care continuum. Willingness to be tested may be influenced by testing services' quality. Using a novel mystery shopper methodology, we assessed YMSM's testing experiences in 3 cities and recommend service delivery improvements. METHODS: We assessed YMSM's experiences at HIV testing sites in Philadelphia (n = 30), Atlanta (n = 17), and Houston (n = 19). YMSM (18-24) were trained as mystery shoppers and each site was visited twice. After each visit, shoppers completed a quality assurance survey to evaluate their experience. Data were pooled across sites, normed as percentages, and compared across cities. RESULTS: Across cities, visits averaged 30 minutes (SD = 25.5) and were perceived as welcoming and friendly (70.9%). YMSM perceived most sites respected their privacy and confidentiality (84.3%). YMSM noted deficiencies in providers' competencies with sexual minorities (63.4%) and comfort during the visit (65.7%). Sites underperformed on Lesbian, Gay, Bisexual, Transgender visibility (49.6%) and medical forms inclusivity (57.95%). Sites on average did not discuss YMSM's relationship context (49.8%) nor provide risk reduction counseling (56.8%) or safer sex education (24.3%). Sites delivered pre-exposure prophylaxis information and counseling inconsistently (58.8%). CONCLUSIONS: Testing sites' variable performance underscores the importance of improving HIV testing services for YMSM. Strategies are recommended for testing sites to promote cultural sensitivity: funding staff trainings, creating systems to assess adherence to testing guidelines and best practices, and implementing new service delivery models.	quality assurance, mystery shopping, testing resources, systems, community	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Article	2019	Baraitser, H; Vaccher, S; Holt, M; Gay, R; Prestage, G; Jin, FY; Amin, J; Templeton, D; Selvey, C; Zablotska-Manos, I; Lusk, J; Ogilvie, G; Vickers, T; Smith, D; Grulich, A	USE OF CONDOMS FOR THE PREVENTION OF SEXUALLY TRANSMITTED INFECTIONS (STIS) AMONG HIV PRE-EXPOSURE PROPHYLAXIS (PREP) USERS	Sexually Transmitted Infections	-	-	-	1368-4973	10.1136/sextrans-2019-tb.521	https://sti.bmj.com/content/95/Suppl_1/A206.2	Background HIV PrEP is highly effective at preventing HIV, but not STI, acquisition. We examined the use of condoms to prevent STIs among PrEP users in the EPIC-NSW trial. Methods Between March 2016 and April 2018, 9,708 individuals were enrolled. Analysis was restricted to participants who completed the optional end-of-study survey and were on-study for ≥1 year prior. STI diagnoses came from medical records; other data were from the end-of-study survey. We used multivariate logistic regression to assess independent associations between those agreeing with the statement, "I use condoms to avoid getting STIs" ("STI condom-users") and those disagreeing. Results 2,933 participants were included; 92.3% were gay men. In the previous year, 34.2%, 23.0%, and 20.2% were diagnosed with no, one, and ≥2 STIs, respectively. 1,127 (38.7%) reported being STI-condom-users. In multivariate analysis, there was no difference in mean STIs diagnosed in the previous year (0.7 vs 0.8, p=0.244). STI-condom-users were younger (39 vs 41 years, p=0.004), less likely to live in a suburb with ≥10% gay men (24.0% vs 35.3%, p<0.001), less likely to report any condomless sex in the previous 6 months (85.9% vs 93.3%, p<0.001), and had been on-study less time (1.4 vs 1.6 years, p=0.003). STI-condom-users were more: concerned about acquiring STIs (95.1% vs 88.8%, p=0.023), likely to discuss STI results with partners (55.2% vs 45.0%, p<0.001), and likely to believe condoms prevent STI transmission (90.7% vs 59.0%, p<0.001). STI-condom-users had received a normal partner for wanting to use condoms (9.6% vs 18.7%, p<0.001), while more had been rejected for wanting to use condoms (45.0% vs 26.2%, p<0.001). Conclusion Most PrEP users did not use condoms for STI prevention, despite strong beliefs in its effectiveness. STI-condom-users did not have fewer STIs, indicating high levels of condomless sex. Our results suggest alternative methods of STI prevention should be trialled for PrEP users.	HIV PrEP is highly effective at preventing HIV, but not STI, acquisition. We examined the use of condoms to prevent STIs among PrEP users in the EPIC-NSW trial. Article	2019	Bavinton, Benjamin R; Pretorius, Garrett P; Jin, Fengyi; Phanuphak, Nittaya; Grierson, Jeanette; Fairley, Christopher K; Bilardi, David; Hoy, Jennifer; Templeton, David J; Tee, Bee K; Kelleher, Anthony; Grulich, Andrew E	Strategies used by gay male HIV serodiscordant couples to reduce the risk of HIV transmission and their acceptability in three countries	Journal of the International AIDS Society	-	-	-	1758-2652	10.1002/jia2.25277	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6436220/	INTRODUCTION: There are few data about the range of strategies used to prevent sexual HIV transmission within gay male serodiscordant couples. We examined HIV prevention strategies used by such couples and explored their acceptability in three countries. METHODS: Opposites Attract was a cohort study of male serodiscordant couples in Australia, Brazil and Thailand, from May 2014 (Australia) or May 2016 (Brazil/Thailand) to December 2016. At visits, HIV-positive partners had viral load (VL) tested; HIV-negative partners reported sexual behaviour and perceptions of their HIV-positive partner's VL results. Within-couple acts of condomless anal intercourse (CLAI) were categorised by strategy: condom-protected, biomedically protected (undetectable VL and/or pre-exposure prophylaxis PrEP), or not protected by either (HIV-negative partners engaging in insertive CLAI, receptive CLAI with withdrawal, or receptive CLAI with ejaculation). RESULTS: A total of 343 couples were included in this analysis (233 in Australia, 91 in Brazil and 19 in Thailand). Three-quarters of HIV-positive partners were consistently virally suppressed (>200 copies/mL) during follow-up, and 18% reported detectable/unknown and were not protected by PrEP (4.7% of all acts), two-thirds (n = 983) were when the HIV-negative partner was insertive (strategic positioning). Of the 490 acts when the HIV-negative partner was receptive, 261 involved withdrawal and 200 involved ejaculation. Thus, ~1% of acts were in the highest risk category of receptive CLAI with ejaculation. CONCLUSIONS: Couples used condoms, PrEP or perceived undetectable VL for prevention in the majority of anal intercourse acts. Only a small proportion of events were not protected by these strategies. Variation between countries may reflect differences in access to HIV treatment, education, knowledge and attitudes.	serodiscordant couples, homosexual, gay men, men who have sex with men, HIV prevention, risk reduction strategies, sexual behaviour	English	United States	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Clinical
Article	2019	Bazzi A.R.; Yotebieng K.; Ottiche S.; Rota G.; Apet K.; Obege S.; Syvertsen J.L.	PrEP and the syndemic of substance use, violence, and HIV among female and male sex workers: a qualitative study in Kisumu, Kenya	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25266	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064543363&doi=10.1002%2Fjia2.25266&partnerID=40&md5=d377f4be6e98d2b7dcbdca33fc3d623f	Introduction: Female and male sex workers experience heightened vulnerability to HIV and other health harms that are compounded by substance use, physical and sexual violence, and limited access to health services. Oral PrEP was rolled out in Kisumu, Kenya, in 2017 as part of a demonstration project. Our study examines "syndemics," or mutually reinforcing epidemics of substance use, violence and HIV, in relation to PrEP acceptability and feasibility among female and male sex workers in Kenya, one of the first African countries to approve PrEP for HIV prevention. Methods: From 2016 to 2017, sex workers in Kisumu reporting recent alcohol or drug use and experiences of violence participated in qualitative interviews on HIV risk and perspectives on health service needs, including PrEP programming. Content analysis identified themes relating to PrEP knowledge, acceptability, access challenges and delivery preferences. Results: Among 45 female and 28 male sex workers, median age was 28 and 25 respectively. All participants reported past-month alcohol use and 91% of women and 82% of men reported past-month drug use. Violence was pervasive, with most women and men reporting past-year physical (96% women, 86% men) and sexual (92% women, 79% men) violence. Concerning PrEP, interviews revealed: (1) low PrEP knowledge, especially among women; (2) high PrEP acceptability and perceived need, particularly within syndemic contexts of substance use and violence; and (3) preferences for client-centred PrEP delivery, including extended clinic hours, non-judgmental providers and integration with other services, such as drug treatment. Conclusions: Heightened vulnerability and perceived need for PrEP among female and male sex workers in Kisumu. Although interest in PrEP was high, most sex workers in our sample, particularly women, were not benefiting from it. Syndemic substance use and violence experienced by sex workers posed important barriers to PrEP access for sex workers. Increasing PrEP access for sex workers will require addressing substance use and violence through integrated programming. © 2019 The Authors. Article	2019	Bazzi, Angela R; Drainoni, Mari-Lynn; Biancarelli, Dea L; Hartman, Joshua J; Mimiaga, Matthew J; Mayer, Kenneth H; Bullis, Katie B	Systematic review of HIV treatment adherence research among people who inject drugs in the United States and Canada: evidence to inform pre-exposure prophylaxis (PrEP) adherence interventions	BMC Public Health	-	-	-	1471-2458	10.1186/s12889-018-6314-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6328231/	BACKGROUND People who inject drugs (PWID) are at increased risk for HIV acquisition and could benefit from antiretroviral pre-exposure prophylaxis (PrEP). However, PrEP has been underutilized in clinical practice. Understanding the factors associated with adherence to HIV treatment among PWID can inform the development of adherence interventions for PrEP among this HIV-infected PWID. Guided by a behavioral model of healthcare utilization and using the PRISMA framework, we conducted a systematic review to describe determinants (facilitators to identify) and clinical outcomes of ART adherence in HIV-infected PWID at the United States and Canada between Jan 1, 2006-Dec 31, 2016. We synthesized and interpreted findings related to developing recommendations for PrEP participants in qualitative interviews on HIV risk and perspectives on health service needs, including PrEP programming. Content analysis identified themes relating to PrEP knowledge, acceptability, access challenges and delivery preferences. Results: Among 45 female and 28 male sex workers, median age was 28 and 25 respectively. All participants reported past-month alcohol use and 91% of women and 82% of men reported past-month drug use. Violence was pervasive, with most women and men reporting past-year physical (96% women, 86% men) and sexual (92% women, 79% men) violence. Concerning PrEP, interviews revealed: (1) low PrEP knowledge, especially among women; (2) high PrEP acceptability and perceived need, particularly within syndemic contexts of substance use and violence; and (3) preferences for client-centred PrEP delivery, including extended clinic hours, non-judgmental providers and integration with other services, such as drug treatment. Conclusions: Heightened vulnerability and perceived need for PrEP among female and male sex workers in Kisumu. Although interest in PrEP was high, most sex workers in our sample, particularly women, were not benefiting from it. Article	2019	Boodle J.R.; Aldern K.A.; Zhang X.-Q.; Vallarew N.; Hostetler K.Y.; Schooley R.T.	Octadecyloxyethyl hexyl tenofovir: A novel tenofovir dimer provides sustained intracellular levels of tenofovir diphosphate	Antiviral Research	1663582	10.1016/j.antiviral.2019.104614	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072045772&doi=10.1016%2Fj.antiviral.2019.104614&partnerID=40&md5=73236fdf5b1739180e96c96ea5fd2139	Pre-exposure prophylaxis (PrEP) with topically or systemically administered antiretroviral agents can prevent acquisition of human immunodeficiency virus type 1 (HIV-1) infection. However, in clinical trials using tenofovir-containing agents, HIV-1 acquisition is reduced but not eliminated. Incomplete adherence remains the major contributor to failure. Sustained release long-acting antiretroviral agents may provide better HIV-1 protection by reducing the clinical impact of incomplete adherence. To reduce dosing frequency, we synthesized a novel tenofovir prodrug, octadecyloxyethyl hexyl tenofovir (ODE-Bis-TFV), that is dimeric (TFV-1-TFV). In mice TFV slowly at tissues, and showed potent anti-HIV activity in vivo (IC50 = 1.7 nM). In cells exposed to 1 nK labelled TFV, ODE-Bis-TFV or the monomeric analog ODE-TFV, rapid cellular uptake for both lipophilic analogs was noted, achieving 50-fold higher levels than unmodified TFV after 48 h. Following exposure to ODE-Bis-TFV, the intracellular diphosphate TFV-DP concentrations were 1000-fold higher than TFV-DP levels achieved with TFV. Intracellular TFV-DP levels were 10-fold higher than TFV-DP levels achieved with ODE-TFV. TFV-DP decreased much more slowly and reached half-maximal levels in about seven days. These results suggest early accumulation of ODE-Bis-TFV followed by sustained intracellular release following cleavage of the ester bonds linking the ODE and benzyl moieties to the active molecular precursor, thereby potentially allowing for less frequent administration than with more rapidly activated forms of tenofovir. © 2019 Elsevier B.V. Article	2019	Bogovac, J; Skrzat-Klapaczynska, A; Kowalska, JD; Eurosguidelines Cent Eastern Europe	Where are we with PrEP use in Central and Eastern Europe? - data from the ECEE Network Group	HIV Medicine	1464-2662	10.1111/hiv.12960	https://pubmed.ncbi.nlm.nih.gov/33021049/#:~:text=PrEP%20was%20recommended%20in%20the%20national,2018%20(P%20%2D%20%200.698).	Objectives: Pre-exposure prophylaxis (PrEP) for HIV infection is an important intervention for control of the HIV epidemic. The incidence of HIV infection is increasing in the countries of Central and Eastern Europe (CEE). Therefore, we investigated the change in PrEP use in CEE over time. Methods: The Euroguidelines in Central and Eastern Europe (CEE) Network Group was initiated in February 2018 to compare standards of care for HIV and viral hepatitis infection in CEE. Data on access to PrEP were collected from 23 countries through online surveys in May–June 2017 (76 respondents) and in November 2018–May 2019 (23 respondents). Results: About 34.2% of respondents from the tenofovir/emtricitabine (TDF/FTC) was licensed for use in their country in 2017, and 8 more, 8 more in 2018 (P = 0.02). PrEP was recommended in national guidelines in 39.5% of responses in 2017 and 40.7% in 2018 (P = 0.178). About 70.7% of respondents were aware of "informal" PrEP use in 2017, while 66.4% were aware of this in 2018 (P = 0.698). In 2018, there were 53 centres offering PrEP (the highest numbers in Poland and Romania), whereas six countries had no centres offering PrEP. The estimated number of HIV-negative people on PrEP in the region was 4500 in 2018, Geneva. TDF/FTC costs (in Euros) ranged from €18 (Romania) to €256.92 (Slovakia), while brand TDF/FTC costs ranged from 450 (Albania) to €935 (Finland). Conclusions: Although the process of licensing TDF/FTC use for PrEP has improved, this is not yet reflected in the guidelines, nor has there been a reduction in the "informal" use of PrEP. PrEP remains a rarely used preventive method in CEE countries. Article	2019	Beyrer, Matthew R; Holloway, Ian W; Pahupher, Craig; Landovitz, Raphael J	Current and Future PrEP Medications and Modalities: On-demand, Injectables, and Topicals	Current HIV/AIDS Reports	15483568	10.1007/s11904-019-00450-9	https://www.proquest.com/scholarly-journals/current-future-prep-medications-modalities-on/docview/2258207726/se-2?accountid=8113	Purpose of ReviewPre-exposure prophylaxis (PrEP) is a potent HIV prevention strategy, but uptake of daily oral PrEP remains low. This review covers PrEP agents currently available and agents and modalities under investigation.Recent FindingsInfectable ARV preparations have high acceptability among users but are likely to require adherence to 8-week interval injections. Topical microbicide gels and rings have had disappointing results in randomized, placebo-controlled trials compared to oral PrEP. Oral PrEP is highly acceptable to MSM and PWID. Oral PrEP is highly effective in MSM and underperformed in randomized, placebo-controlled trials compared to expectations and subsequent real-world pragmatic use.SummaryOn-demand (2:1-1) dosing strategy for MSM and injectable PrEP seem to be acceptable among participants in clinical trials. These modalities are particularly compelling alternatives for individuals who either do not want to take a daily medication (both on-demand and injectable) and/or want to take PrEP without a long commitment (on-demand). Emerging modalities such as vaginal films, microneedles, and subdermal implants have numerous advantages but are still in early stages of development. Article	2019	Bielle K.B.; Edova A.; Salhoney P.; Bianchetti D.L.; Mimiaga M.J.; Draimoni M.L.; Childs E.S.; Buzzi A.R.	A missing perspective: injectable pre-exposure prophylaxis for people who inject drugs	AIDS Care	-	-	-	9540121	10.1080/09540121.2019.1587356	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062475694&doi=10.1080%2F09540121.2019.1587356&partnerID=40&md5=23aaa8351607e607f2e2f9f2207c3df8	Background: HIV incidence remains high among transgender women in Lima, Peru, most of whom report sex work. On the basis of a stakeholder analysis and health system capacity assessment, we developed, tested, and disseminated a multimedia intervention to promote PrEP. Methods: We developed a transgender-specific intervention—delivered by near-peer outreach workers, their stable partners, and their clients to estimate the impact and cost-effectiveness of combinations of interventions compared with the standard of care on reducing HIV incidence over a 10-year period. We simulated HIV transmission accounting for differences in sexual positioning in anal intercourse and condom use by partner type and fitted the model to HIV surveillance data using Latin hypercube sampling. The interventions we considered were 15% relative increase in condom use with clients and 10% relative increase with stable partners; increase in antiretroviral treatment (ART) coverage at CD4 count lower than 500 cells per mm [3] and greater than or equal to 500 cells per mm [3]; and 15% pre-exposure prophylaxis (PrEP) coverage using generic and branded formulations. We considered a basic scenario accounting for current the Peruvian HIV service delivery and an enhanced scenario assuming achievement of the UNAIDS 90-90-90 targets and general improvements in HIV services. The 50 best fits according to log-likelihood were used to give the minimum and maximum values of intervention effect for each combination. We used disability-adjusted life-years (DALYs) to measure the incremental health outcomes associated with HIV infection that could be averted by the interventions we investigated and calculated incremental cost-effectiveness ratios to compare their cost-effectiveness. Findings: Under the basic scenario, combining the four interventions of increasing condom use with clients and stable partners, increasing ART coverage, and scaling up PrEP to 15% coverage (2.7–3.1) could avert 41% (44–44) of new infections among this population with an incremental cost-effectiveness ratio of $1000 per DALY averted. Under both scenarios, implementation of this strategy would exceed 61% (64–64) of new infections among this population with an incremental cost-effectiveness ratio of $1000 per DALY averted. Under the enhanced scenario, implementation of the strategy approaches or surpasses the 50% incidence reduction goal and would represent a cost-effective use of country resources if generic PrEP drugs are used. The total cost of implementing this strategy under the enhanced scenario would be approximately $1 2 million per year over 10 years, corresponding to 10% of the current Global Fund's yearly contribution in Peru. Interpretation: Investments in HIV services among TWSW in Lima would be cost-effective, even under stringent cost-effectiveness criteria when accounting for setting-specific resource constraints. Notable improvements in HIV testing rates, innovative interventions to increase condom use, and reduced PrEP costs will be key to achieving the 50% incidence reduction goal. Modelling studies incorporating stakeholders' perspectives and health system constraints can bring added value to HIV policy making. Funding: National Institutes of Health. © 2019 The Author(s). Article	2019	Bielle K.B.; Pearce C.; Koskover D.S.; Marrow E.; Salton S.A.; Mimiaga M.J.; Hightow-Weidman L.; Sullivan P.; Mayer K.H.	A pre-exposure prophylaxis adherence intervention (Stempo) for young men who have sex with men: Protocol for a pilot randomized controlled trial	JMIR Research Protocols	19290748	10.2196/10661	https://www.researchprotocols.org/2019/1/e10661/	Background: New HIV infections occur at a disproportionately high rate among young men who have sex with men (YMSM). It is, therefore, essential that comprehensive HIV prevention strategies, specifically tailored to their needs and perceptions, are developed, tested, and disseminated. Antiretroviral pre-exposure prophylaxis (PrEP) is effective in decreasing HIV transmission among men who have sex with men; however, adherence is critical to its efficacy. In open-label studies among YMSM, adherence was suboptimal. Hence, behavioral approaches that address the unique challenges to YMSM PrEP adherence are needed. Objective: The aim of this study is to develop and pilot test a behavioral intervention to support PrEP adherence among YMSM, called Stempo (Swahili for "motor"). Methods: Stempo is a pre-exposure prophylaxis for young men who have sex with men (LAPN-1) Methods. This study includes the following 2 phases: formative qualitative interviews with approximately 20 YMSM and healthcare providers to inform the intervention adaptation and refinement and a pilot RCT of up to 50 YMSM to assess the feasibility, acceptability, and preliminary efficacy of the LAPN , compared with the PrEP standard of care, to improve PrEP adherence. Participants will be recruited at 3 iTech subject recruitment venues in the United States. Results: Phase 1 is expected to begin in June 2018, and enrollment of phase 2 is anticipated to begin in early 2019. Conclusions: Few rigorously developed and tested interventions have been designed to increase PrEP adherence among YMSM in community settings, despite this population's high HIV incidence. The long-term goal of this intervention is to develop scalable protocols to optimize at-risk YMSM's PrEP uptake and adherence to decrease the HIV incidence. © Katie B Bielle, Christina Pearce, Douglas S Koskover, Elliot Marrow, Steven A Salton, Matthew J Mimiaga, Lisa Hightow-Weidman, Patrick Sullivan, Kenneth H Mayer. Article	2019	Bielle, Katie B; Edova, Alberto; Montgomery, Madeline C; Almonte, Alex; Chan, Philip A	Risk Perception and Interest in HIV Pre-exposure Prophylaxis Among Men Who Have Sex with Men with Rectal Gonorrhea and Chlamydia Infection	Archives of Sexual Behavior	00040002	10.1007/s10508-018-1260-1	https://www.proquest.com/scholarly-journals/risk-perception-interest-hiv-pre-exposure/docview/2087790881/se-2?accountid=8113	Rectal gonorrhea and chlamydia infections are associated with significantly increased risk of HIV transmission among gay, bisexual, and other men who have sex with men (MSM). MSM diagnosed with rectal gonorrhea or chlamydia may benefit from pre-exposure prophylaxis (PrEP) for HIV prevention. We analyzed HIV risk perception, PrEP interest, and sexually transmitted infection (STI) test results among MSM presenting to a publicly funded STI clinic from 2014 to 2016. A total of 401 MSM were tested for rectal STIs during the study period. 18% were diagnosed with rectal gonorrhea and/or chlamydia infection. Patients who perceived themselves to be at medium or high risk for HIV were significantly more likely to express interest in PrEP compared to those who reported low or no perceived risk (OR 1.88, 95% CI 1.13–3.11, $p = .014$). However, there was no significant difference in perceived HIV risk between those who were diagnosed with a rectal STI and those who were not. Although rectal STIs are a significant risk factor for HIV infection, MSM diagnosed with a rectal STI did not perceive themselves to be at increased risk for HIV infection, indicating a potential barrier to successful PrEP implementation in this population. Article	2019	Bielle, Katie B; Marrow, Elliot; Mimiaga, Matthew J; Sullivan, Patrick; Highton-Weidman, Lisa; Mayer, Kenneth H	A Mobile-Based App (MyChoices) to Increase Uptake of HIV Testing and Pre-Exposure Prophylaxis by Young Men Who Have Sex With Men: Protocol for a Pilot Randomized Controlled Trial	JMIR Research Protocols	19294748	10.2196/10694	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6302961/	BACKGROUND: HIV incidence is growing most rapidly in the United States among young men who have sex with men (YMSM). Overwhelming evidence demonstrates that routine testing and expanded use of pre-exposure prophylaxis (PrEP) would dramatically reduce the population burden of HIV; however, uptake of both interventions is suboptimal among young adults. The use of mobile phone apps by YMSM is ubiquitous and may offer unique opportunities for public health interventions. MyChoices is a theory-driven app to increase HIV testing and PrEP uptake. It was developed by an interdisciplinary team based on feedback from a diverse sample of YMSM. OBJECTIVE: The aim of this paper is to describe the protocol for the refinement, beta testing, and pilot randomized controlled trial (RCT) to examine the acceptability and feasibility of the MyChoices app. METHODS: This 5-phase study includes 4 theater testing groups for app refinement with a total of approximately 30 YMSM, for beta testing, and a pilot RCT to examine preliminary efficacy. Participants will be recruited at 3 iTech subject recruitment venues in the United States. The pilot RCT will examine the preliminary acceptability and efficacy of the MyChoices app, compared with referrals only, in increasing HIV testing and PrEP uptake. All participants will be recruited at iTech clinical research sites in Boston, MA, and Bronx, NY. RESULTS: App refinement is underway. Enrollment for the pilot RCT began in October 2018. CONCLUSIONS: MyChoices is one of the first contemporary, theory-driven HIV prevention apps designed specifically for YMSM. If MyChoices demonstrates acceptability and feasibility in this pilot RCT, a multisite, 3-arm randomized controlled efficacy trial of the app and another youth-optimized app (LYNX) versus standard of care is planned within iTech. If shown to be efficacious, the app will be scalable, with the ability to reach YMSM across the United States as well as be geographically individualized, with app content integrated with local prevention and testing activities. Article	2019	Bien-Gund, Cedric H; Zhao, Peipei; Cao, Bolin; Tang, Weiming; Ong, Jason J; Baral, Stefan D; Beauchemin, José A; Yang, Li-Gang; Lee, Zhenzhou; Tucker, Joseph D	Providing competent, comprehensive and inclusive sexual health services for men who have sex with men in low- and middle-income countries: a scoping review	Sexual Health	-	-	-	1449-8987	10.1071/SH18191	https://dx.doi.org/10.1071/SH18191	Although men who have sex with men (MSM) are disproportionately affected by HIV and other sexually transmissible infections, sexual health services for MSM in low- and middle-income countries (LMIC) remain under-resourced and are poorly understood. A scoping review of literature on MSM sexual health in LMIC was conducted in order to identify key clinical services and gaps in knowledge. Three databases were searched, in addition to hand-reviewing key journals and bulletins, to identify literature with a focus on MSM sexual health. Key services related to providing care to MSM in LMIC that emerged from our review are described. These services include creation of safe and confidential clinic environments, HIV testing services, behavioural interventions, HIV pre-exposure prophylaxis (PrEP), rapid antiretroviral therapy (ART) initiation and STI services. Compared with high-income settings, major differences in LMIC include lack of diagnostic technology, unfavourable legal environments and lack of funding for MSM health. Innovative approaches to healthcare delivery, such as harnessing mobile technology, self-testing and crowdsourcing interventions, can improve health services among MSM in LMIC. There gaps in the evidence about how best to provide sexual health services to MSM in LMIC settings. Implementation research and scale-up of existing biomedical and behavioural interventions such as HIV/STI testing services, PrEP and early antiretroviral initiation are urgently needed in LMIC.	guidelines, HIV care continuum, HIV testing, sexually transmissible infections. Article	2019	Bienaise, Sarah; Roussillon, Benoit; Bellec, Laurence; Pirot, Hélène; Matta, Marc; Maka, A.; Pasch, J.; Tonen Wolyec, S.; Veyer, D.; Gravier, A.; Hocquelet, L.; Peytavin, T.	High Prevalence of Anal and Oral High-Risk Human Papillomavirus in Human Immunodeficiency Virus-Uninfected French Men Who Have Sex With Men and Use Pre-exposure Prophylaxis	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/ofid/ofz291	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071497706&doi=10.1093%2Fofid%2Fofz291&partnerID=40&md5=2baaa9354037e697f2e2f9f2207c3df8	Background: We assessed the prevalence and risk factors of anal and oral high-risk (HR) human papillomavirus (HPV) infection in human immunodeficiency virus-uninfected men who have sex with men (MSM) and take preexposure prophylaxis (PrEP) in France. Methods: Anal and oral samples were screened by multiplex real-time polymerase chain reaction (Anyplex II HPV 28; Seegene, Seoul, Korea). A total of 401 consecutive MSM (mean age, 36.3 years) were enrolled. Anal HPV and HR-HPV prevalences were 93.4% and 81.9%, respectively, and oral HPV and HR-HPV prevalences were 24.4% and 19.6%, respectively. HR-HPV type 33 was the most detected genotype, in both anal and oral samples. Among MSM, 68.8% carried ≥1 anal HPV type targeted by the 9-valent Gardasil-9 vaccine; all oral HPV-positive samples carried ≥1 strain included in the vaccine. Condomless receptive anal intercourse and history of anal gonorrhea were the main factors associated with increased risk for anal HPV infection (adjusted odds ratio, 16.6) and anal infection with multiple HR-HPV genotypes (≥3.7), respectively. Conversely, having had >10 partners in the last 12 months was associated with decreased risk for anal carriage of both multiple HPV (adjusted odds ratio, 0.19) and HR-HPV (0.17) types. Conclusion: French MSM using PrEP are at high risk for both anal and oral carriage of HR-HPV that could lead to HPV-related cancers. © 2019 The Author(s) 2019. Article	2019	Bourne, Adam; Alba, Beatrice; Garner, Alex; Spiteri, Gianfranco; Pharris, Anastasia; Noori, Teymur	Use of, and likelihood of using, HIV pre-exposure prophylaxis among men who have sex with men in Europe: Cross-sectional Euro Atlas findings from a 2017 large gronocial networking application survey.	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2018-053705	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6509613/	OBJECTIVE: Currently, seven European countries provide HIV pre-exposure prophylaxis (PrEP) through public health services, although there are numerous reports of off-licence use. The objective of this study was to examine current use of PrEP, likelihood of future use and indicators of potential PrEP candidacy among an opportunistic sample of men who have sex with men in Europe and Central Asia. METHODS: A survey was sent out in eight languages to users of the Hornet gay networking application in July and August 2017. Descriptive statistics, bivariate and multivariate regression analyses of correlates associated with PrEP use are examined using logistic and linear regressions. RESULTS: Of 12 053 participants whose responses came from 55 European and Central Asian countries, 10 764 (89%) were not living with diagnosed HIV. Among these, 1 579 (15%) were currently taking PrEP or had done so within the previous 3 months. Current or recent PrEP users were significantly more likely to have taken postexposure prophylaxis (adjusted OR (aOR)=16.22 (95% CI 13.55 to 19.45)) or received an STI diagnosis (aOR=4.53 (95% CI 3.77 to 5.44)) in the previous 12 months than those who had not. Of those not on PrEP and not using it recently, 2 911 (30%) reported that they would be likely to use PrEP in the next 6 months. Men who were older, more educated and earned more were more likely to have taken PrEP (aOR=1.71 (95% CI 1.59 to 1.89)). Nearly a quarter (22.3%) of those not on PrEP said they were likely to use it in the next 6 months. CONCLUSIONS: The majority of men using, or intending to use, PrEP appear to have a risk profile consistent with emerging guidance. A large proportion of these men are accessing PrEP outside of traditional healthcare settings, posing a challenge for routine monitoring. Article	2019	Bradley E.; Forsberg K.; Betts J.E.; Dehaca J.B.; Kamineni E.; Porter S.E.; Sipe T.A.; Hoover K.W.	Factors Affecting Pre-Exposure Prophylaxis Implementation for Women in the United States: A Systematic Review	Journal of Women's Health	-	-	-	15409996	10.1089/jwh.2018.7353	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072037726&doi=10.1089%2Fjwh.2018.7353&partnerID=40&md5=2ca8b2eb02d1b7f0cfcfce08dea4f5f2	Oral HIV pre-exposure prophylaxis (PrEP) is a highly effective pill that HIV-negative individuals can take once daily to prevent HIV infection. Although PrEP is a private, user-controlled method that empowered women to protect themselves without relying on a partner's behavior, women's PrEP use has been extremely low. We systematically reviewed the literature to identify and summarize factors that affect PrEP implementation for women in the United States. We searched PubMed, Embase, CINAHL, and PsycINFO databases for articles published between January 2012 and April 2018 that reported on PrEP implementation in the United States. Studies that met the inclusion criteria (MEDLINE, EMBASE, and CINAHL) and PubMed to identify post-scoreved studies published between January 2006 and April 2018 that reported U.S. women's or health care providers' PrEP knowledge or awareness, willingness to use or prescribe, attitudes, barriers and facilitators to use or prescription, or PrEP adherence and discontinuation influences. Thirty-nine studies (26 women, 13 providers) met the eligibility criteria. In these studies, 0%–33% of women had heard of PrEP. Between 51% and 97% of women were willing to try PrEP, and 60%–82% of providers were willing to prescribe PrEP to women. Implementation barriers included access, cost, stigma, and medical distrust. Three studies addressed adherence or discontinuation. PrEP knowledge is low among women and providers. However, women and providers generally have positive views when aware of PrEP, including a willingness to use or prescribe PrEP to women. Most of the implementation barriers highlighted in studies were social or structural factors (e.g., access). Additional studies are needed to address research gaps, including studies of PrEP adherence and discontinuation. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019. Article	2019	Braksmajer A.; Leblanc N.M.; El-Bassel N.; Urban M.A.; McMahon J.M.	Feasibility and acceptability of pre-exposure prophylaxis use among women in violent relationships	AIDS Care	-	-	-	9540121	10.1080/09540121.2018.1503634	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85050683386&doi=10.1080%2f09540121.2018.1503634&partnerID=40&md5=6c7086947a95427271d0fb8f7f694d88	Intimate partner violence (IPV) is associated with a high risk of HIV acquisition. Pre-exposure prophylaxis (PrEP), which does not require partner knowledge or consent, is a promising HIV risk reduction option for women experiencing IPV. Drawing on semi-structured interviews with 26 women experiencing IPV within the last six months, this study explored the feasibility and acceptability of PrEP use in this population. Slightly more than half of the women in this study expressed interest in taking PrEP when in a relationship with an abusive partner. Potential barriers to PrEP, discussed regardless of women's expressed interest in PrEP, included fear of side effects and long-term health concerns, low risk perceptions, potential partner interference, and prioritizing coping with the relationship over HIV prevention. When offering PrEP counseling, providers should inquire about IPV, as women in violent relationships may require tailored counseling to address barriers and concerns specific to their situation. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	intimate partner violence; Pre-exposure prophylaxis; PrEP; women	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2019	Brantley M.L.; Rebeiro P.F.; Pettit A.C.; Sanders A.; Cooper L.; McGoy S.; Morrison M.	Temporal Trends and Sociodemographic Correlates of PrEP Uptake in Tennessee, 2017	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02657-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071751451&doi=10.1007%2fs10461-019-02657-8&partnerID=40&md5=1e6383f3b8e5fa374d4c186deaf50dc3	Client-level data from two Tennessee-based PrEP navigation demonstration projects reported to the Tennessee Department of Health from January to December 2017 were evaluated to determine the proportion of clients who accepted, were linked to, and were prescribed PrEP. Disparities by age, race, transmission risk, and geographic region as well as trends over time were examined via bivariate and multivariable modified Poisson regression models accounting for potential confounders. Among 1385 PrEP-eligible individuals, 50.5% accepted, 33.4% were linked, and 27.3% were prescribed PrEP. PrEP uptake varied by age, race, and HIV transmission risk, and most disparities persisted across Tennessee throughout evaluation period. Multivariable regression models revealed significant independent associations between age, race/ethnicity, transmission risk, and region and PrEP acceptance and linkage. While differences in PrEP acceptance by race narrowed over time, success among black MSM was limited, underscoring a significant need to improve upstream PrEP continuum outcomes for this important population. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Bremer V.; Koppe U.; Marcus U.; Jansen K.	Current state of research on HIV-PrEP: HIV prevention and dissemination of other STI; Aktueller Forschungsstand zur HIV-PrEP: HIV-Prävention und Verbreitung anderer STI	Zeitschrift fur Sexualforschung	-	-	-	9328114	10.1055/a-1028-0559	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076878867&doi=10.1055%2fa-1028-0559&partnerID=40&md5=5333b2edee34d3c6d1cf766ca471d8cd	Introduction Infection with HIV can be effectively prevented by taking HIV pre-exposure prophylaxis (PrEP). However, taking HIV-PrEP does not provide protection against other sexually transmitted infections (STI). Objectives The aim of this research overview is to answer two questions: 1. How common is PrEP and how does it affect HIV prevalence? 2. Is there an epidemiologically relevant increase in other STI in the course of PrEP intake due to a possible increase in condomless sex? Methods A literature search on studies on PrEP, HIV and other STI was carried out, and reporting data from the USA, Great Britain and Australia as well as our own data from Germany were analyzed. Results Both the previously published data from abroad and our own data from Germany show that PrEP is spreading as an effective HIV prophylaxis, especially among MSM. At the same time, the data show that there has been a sharp increase in STI diagnoses in recent years. However, this had already been observed before the introduction of the PrEP and is probably due both to an increase in condomless anal sex among MSM as well as to an increase in low-threshold STI testing. The causal effect of PrEP in this context has not yet been conclusively demonstrated. Conclusion Improved STI testing and the connection of PrEP users to the medical care system offer the opportunity to effectively limit the increase in STI. It is therefore important that PrEP users- A nd other populations-have access to regular free STI tests including counselling, as has been provided for in the Terminservice-und Versorgungsgesetz (TSVG) since the second half of 2019. © 2019 Georg Thieme Verlag KG Stuttgart • New York. Article	2019	Brinkley-Rubinstein L.; Peterson M.; Zaller N.D.; Wohl D.A.	Best practices for identifying men who have sex with men for corrections-based pre-exposure prophylaxis provision	Health and Justice	-	-	-	21947899	10.1186/s40352-019-0088-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064339138&doi=10.1186%2fs40352-019-0088-7&partnerID=40&md5=74a48a2ce84d21159a17feb63fff2c68	Purpose: Men who have sex with men (MSM) who are incarcerated are at increased risk for HIV acquisition, yet there are challenges associated with disclosing sexual identity/orientation among people who are incarcerated. Methods: The current study used semi-structured, qualitative interviews to explore attitudes and awareness of pre-exposure prophylaxis (PrEP) among 26 MSM who were incarcerated at the Rhode Island Department of Corrections. Results: Participants noted variable levels of willingness to disclose sexual identity/orientation. Conclusions: CJ institutions should consider involving medical staff and outside agencies when using the CDC PrEP guidelines or consider a WHO-based, rather than behavior-based, approach to determining candidacy for PrEP. © 2019 The Author(s). Article	2019	Brisson, Julien	Reflections on the history of bareback sex through ethnography: the works of subjectivity and PrEP	Anthropology & Medicine	-	-	-	13648470	10.1080/13648470.2017.1365430	https://www.proquest.com/scholarly-journals/reflections-on-history-bareback-sex-through/docview/2325350360/se-2?accountid=8113	Throughout the history of bareback sex (condomless sex between men), 'subjects' have been created, particularly through scientific literature, to characterise the men who engage in the sexual practice. For example, a gay man who does not use a condom may be framed as a pathologised subject. This paper first presents this history. Afterwards, by relying upon ethnographic data such as interviews collected from fieldwork research done in Toronto in 2014 with young gay men who have bareback sex, it shows exactly how these young gay men related themselves to those subjects. Then, it focuses on the pre-exposure prophylaxis (PrEP) Truvada as a new HIV prevention technology. Although PrEP can allow condomless sex to occur while diminishing the risk of HIV transmission, at the time of the research, none of the young gay men were interested in using this tool despite being the subjects for whom the drug is tailored. This paper argues that PrEP and subjectivity are coproduced and can have conflicting meanings. This contradiction of meanings is a result of the various representations and symbols of bareback sex and the men who engage in the practice that have been produced throughout the history of bareback sex. Article	2019	Brisson, Julien; Ravitsky, Vardit; Williams-Jones, Bryn	Towards an Integration of PrEP into a Safe Sex Ethics Framework for Men Who Have Sex with Men.	Public Health Ethics	-	-	-	1754-9973	10.1093/phe/phy018	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6431242	The ethics of safe sex in the gay community has, for many years, been focused on debates surrounding the responsibility (or lack thereof) regarding the use of condoms to prevent HIV transmission, once the only tool available. With the development of Truvada as a pre-exposure prophylaxis (PrEP) for HIV, for the first time in the history of the HIV/AIDS epidemic there is the potential to significantly reduce the risk of HIV transmission during sex without the use of condoms (without taking into consideration 'treatment as prevention' with HIV-positive people). The introduction of PrEP necessitates a renewed discussion about the politics and ethics of safe sex for men who have sex with men (MSM). We present the arguments of authors who hold radically opposite positions with regard to the ethics of condom use by gay men, but who currently both criticize the use of PrEP. We offer a critique of their arguments and advance the position that the use of PrEP, even without condoms, can be acceptable and part of a safe sex ethics framework for MSM. Article	2019	Brogan, N.; Paquette, D. M.; Lachowsky, N. J.; Blais, M.; Brennan, D. J.; Hart, T. A.; Adam, B.	Canadian results from the European Men-who-have-sex-with-men Internet survey (EMIS-2017).	Canada Communicable Disease Report = Relevé des maladies transmissibles au Canada	-	-	-	1188-4169 1481-8531	10.14745/ccdr.v45i11a01	https://pubmed.ncbi.nlm.nih.gov/31755878/	BACKGROUND: In 2017, the international European Men-who-have-sex-with-men Internet Survey (EMIS-2017) collected data from 50 countries, including Canada for the first time. OBJECTIVE: To provide an overview of the Canadian EMIS-2017 data to describe the sexually transmitted and other bloodborne infection (STBBI) related needs of gay, bisexual and other men who have sex with men (gbMSM). METHODS: The EMIS-2017 questionnaire was an updated version of EMIS-2010. It included self-reported sociodemographic data, experience of discrimination, mental health and substance use, knowledge of preexposure prophylaxis (PrEP) for HIV, sexual practices and history of STBBI testing and diagnosis. Analysis was largely descriptive. RESULTS: Of the 6,059 respondents from Canada, 5,165 participants met the inclusion criteria for this analysis. The majority of participants were born in Canada (79.3%); and over half of the respondents (56.7%) were under the age of 39. In terms of discrimination related to their attraction to other men, participants reported high levels of intimidation (31.9%), verbal abuse (22.1%) and physical violence (1.5%) in the previous year. Regarding mental health, 23.9% had a moderate to severe depression/anxiety score. Almost two-thirds (64.1%) indicated substance use and one-fifth (21.5%) reported chemsex (or the use of stimulant drugs to make sex more intense or last longer). Only 8.4% of participants reported use of PrEP for HIV; however, 51.7% reported being likely to use PrEP if it was available and affordable. Sexual practices, such as condom use, varied by PrEP use with 91.3% of men using PrEP reporting condomless anal intercourse (CAI) compared with 71.5% of men not on PrEP. In terms of STBBI testing, 1.5% reported being diagnosed with hepatitis C and 9.0% reported an HIV diagnosis. Of those with an HIV diagnosis, most were on treatment (99.1%) and had an undetectable viral load (96.7%). CONCLUSION: gbMSM in Canada experienced stigma, discrimination and mental health problems; substance use was high as were high-risk sexual practices, such as CAI, among some groups of men. There was a gap between the proportion of men who were interested in PrEP and those who actually used it; and comprehensive STBBI testing was low.These findings can inform public health action and provide a baseline to examine the impact of current and new interventions. Article	2019	Brooks B.; Park S.H.; Guilamo-Ramos V.; Schneider J.A.; Harry-Hernandez S.; Mgbako O.; Dubin S.; Duncan D.T.	Sex Tourism and Pre-Exposure Prophylaxis Modality Preferences Among Men Who Have Sex With Men	Journal of Sex Research	-	-	-	224499	10.1080/00224499.2018.1515343	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053906270&doi=10.1080%2f00224499.2018.1515343&partnerID=40&md5=b35ce892533e2734a5677e2b78af045c	Sex tourism among men who have sex with men (MSM) has been associated with increased risk for human immunodeficiency virus (HIV) due to sexually scripted environments characterized by multiple sexual partners, increased availability of alcohol and drugs, and limited availability of HIV-prevention services. The current study examined the knowledge of and likelihood of using different modalities of pre-exposure prophylaxis (PrEP), an important biomedical HIV-prevention strategy, among MSM in Paris who have engaged in sex tourism. A sample of 580 MSM from a highly popular geosocial-networking smartphone application in Paris, France, participated in the survey. Of the 580 MSM, 444 participants reported an HIV-negative status and represent the analytic sample for this study. Approximately 27% reported engaging in sexual tourism. MSM who engaged in sex tourism were more likely to aware of on-demand PrEP and more likely to express interest in using on-demand PrEP (adjusted risk ratio aRR = 1.26; 95% confidence interval CI = 1.03–1.53, aRR = 1.29; 95% CI = 1.04–1.61, respectively) than MSM who never engaged in sex tourism. Moreover, participants who engaged in sex tourism were more likely to express interest in rectal microbicides or both rectal and penile microbicides (aRR = 1.34; 95% CI = 1.13–1.59, aRR = 1.26; 95% CI = 1.03–1.55, respectively) than participants who had not engaged in sex tourism. With the high likelihood of interest in using alternative forms of PrEP in MSM who engage in sex tourism, this study suggests potential benefits for these alternative forms of PrEP for this specific population and underscores the importance of their continued development. © 2019, © 2019 The Society for the Scientific Study of Sexuality.	adultattitude to healthhumanmalepre-exposure prophylaxissexual behaviortravel	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Brooks R.A.; Landrian A.; Nieto O.; Fehrenbacher A.	Experiences of Anticipated and Enacted Pre-exposure Prophylaxis (PrEP) Stigma Among Latino MSM in Los Angeles	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02397-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060144139&doi=10.1007%2fs10461-019-02397-9&partnerID=40&md5=d64f3863228c4e348122fea90be2a96f	Latino men who have sex with men (MSM) are a group critically affected by HIV. Pre-exposure Prophylaxis (PrEP) is a biomedical prevention strategy that can help reduce new infections in this population. However, PrEP use may expose users to experiences of PrEP-related stigma. In-depth interviews conducted with Latino MSM PrEP users (N = 29) were analyzed using thematic analysis to explore experiences of PrEP stigma. Six themes emerged related to anticipated and enacted PrEP stigma: (1) Perception that PrEP users engage in risky sexual behaviors; (2) PrEP-induced conflict in relationships; (3) Perception that PrEP users are HIV-positive; (4) Generational differences in attitudes toward HIV prevention; (5) Experiences of discomfort, judgment, or homophobia from medical providers; and (6) Gay stigma related to PrEP disclosure to family. Manifestations of stigma included disapproving judgment, negative labeling, rejection, and devaluing individuals. The social consequences associated with using PrEP may deter uptake and persistence among Latino MSM. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Brooks, Ronald A; Cabral, Alejandra; Nieto, Omar; Fehrenbacher, Anne; Landrian, Amanda	Experiences of Pre-Exposure Prophylaxis Stigma, Social Support, and Information Dissemination Among Black and Latina Transgender Women Who Are Using Pre-Exposure Prophylaxis	Transgender Health	-	-	-	2688-4887	10.1089/trgh.2019.0014	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6716188	Purpose: In the United States, HIV disproportionally affects Black and Latina transgender women (BLTW). Pre-exposure prophylaxis (PrEP) is a proven biomedical method for preventing HIV acquisition. However, the social stigma attached to using PrEP may deter uptake and persistence of PrEP among BLTW, two highly vulnerable populations. The purpose of this study was to explore the experiences of PrEP stigma among BLTW who are using PrEP in Los Angeles County. Methods: In-depth, semistructured interviews were conducted with BLTW PrEP users (N=19) to explore experiences of anticipated, enacted, and internalized PrEP stigma within the context of their unique social and contextual factors. A thematic analysis approach was used in the analysis of qualitative data. Results: We noted an underlying theme of HIV stigma related to participants' identification as trans women that served as the social context for other experiences. In addition, our data revealed five themes related to the experience of using PrEP. Three themes were specifically related to PrEP stigma and included: (1) Perception that BLTW PrEP users are HIV-positive; (2) perception that BLTW PrEP users engage in elevated sexual risk behaviors; and (3) negative labels ascribed to BLTW PrEP users. A fourth theme identified the positive experiences of social support after PrEP disclosure reported by BLTW. Our fifth theme identified involved the dissemination of PrEP information by BLTW to friends/peers and sex partners. Conclusion: BLTW experience PrEP stigma within the context of PrEP disclosure. This experience is underscored by existing experiences of HIV stigma connected to their identity as trans women. PrEP providers should prepare BLTW to use selective disclosure practices when revealing their PrEP use to help minimize experiences of PrEP stigma or potential physical harm. PrEP implementation programs should also support peer-to-peer PrEP education programs for transgender women to promote positive views of PrEP and help facilitate PrEP uptake in this population. Article	2019	Brooks, Ronald A; Nieto, Omar; Landrian, Amanda; Donohoe, Thomas J	Persistent stigmatizing and negative perceptions of pre-exposure prophylaxis (PrEP) users: implications for PrEP adoption among Latino men who have sex with men	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2018.1499864	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6338523	The Centers for Disease Control and Prevention (CDC) estimates the lifetime HIV risk is one in four for Latino men who have sex with men (MSM). Pre-Exposure Prophylaxis (PrEP) is an efficacious biomedical prevention strategy to help prevent the acquisition of HIV. At present, there has been limited uptake of PrEP by Latino MSM. Unfortunately, the negative perceptions and social stigma surrounding PrEP and those who use it may deter uptake of this novel prevention strategy, particularly among high-risk Latino MSM. In this qualitative study, we explore the experiences of using PrEP among Latino MSM. Participants were recruited using gay-oriented social and sexual networking apps to complete an interviewer-administered, semi-structured qualitative interview. Thematic analysis was used to identify emerging themes relating to perceptions of PrEP users and PrEP as an HIV prevention strategy. Major themes included: feelings of protection and sexual freedom; negative and stigmatizing labels associated with PrEP use; assumptions about sexual behaviors and perceptions of sexual risk taking and irresponsibility; and attitudes related to PrEP use in relationships. A striking but not prevalent theme was the perception reported by participants that monolingual Spanish-speaking Latino MSM are skeptical about the effectiveness of PrEP. These findings suggest that efforts are needed to address the stigmatizing and negative perceptions of PrEP that persist in the gay community that may deter adoption among Latino MSM. Article	2019	Buchbinder, Susan P; Havlir, Diane V	Getting to Zero San Francisco: A Collective Impact Approach.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000002200	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6880800	BACKGROUND: Building on several decades of innovative HIV prevention and treatment programming in San Francisco, in 2014, a small group of academic, civic, and community leaders launched Getting to Zero San Francisco, a city-wide consortium focused on getting to zero HIV infections, zero HIV-related deaths, and zero HIV stigma and discrimination. SETTING: San Francisco city and county. METHODS: The consortium operates under the principles of collective impact composed of 5 components: a common agenda, shared measurement, mutually reinforcing activities, continuous communication, and organization backbone. Two flagship initiatives are described: citywide scale-up of pre-exposure prophylaxis and rapid antiretroviral therapy upon diagnosis. RESULTS: The number of new HIV diagnoses declined by over 50% from 399 to 197 from 2013 to 2018; the time from diagnosis to viral suppression decreased from 134 to 62 days during that period. However, continued racial/ethnic disparities in new HIV diagnoses and viral suppression rates point to the need for the Getting to Zero San Francisco committees to focus on racial/ethnic equity as a primary focus. Cisgender and transgender women, people who inject drugs, and people who are homeless also have lower viral suppression rates; ongoing initiatives are attempting to address these disparities. CONCLUSION: A collective impact implementation strategy that operates by unifying municipal organizations toward a common goal was associated with citywide gains in reducing new HIV diagnosis and time to viral suppression in San Francisco. Formal evaluation of this strategy will help elucidate under which conditions this approach is most likely to succeed. Article	2019	Bullinger, Johannes; Reyniers, Thijs; Vuylsteke, Bea; Laga, Marie; Nöstlinger, Christiana	Congruence between Hypothetical Willingness to Use Pre-Exposure Prophylaxis (PrEP) and Eligibility: An Online Survey among Belgian Men Having Sex with Men	International Journal of Environmental Research and Public Health	-	-	-	1660-4601	https://doi.org/10.3390/ijerph16224411	https://www.mdpi.com/1660-4601/16/22/4411	Men who have sex with men (MSM) are at high risk for acquiring HIV in Belgium. This study explores MSMs' hypothetical willingness to use pre-exposure prophylaxis (PrEP), assesses it against formal PrEP eligibility criteria, and identifies factors associated with incongruence between eligibility and willingness. We used data from an online survey of = 1444 self-reported HIV-negative MSM. Participants were recruited through social media of MSM organizations and dating apps. Univariate analysis described PrEP willingness and eligibility; bivariate analyses examined how specific co-variates (socio-demographic, knowledge-related, and attitudinal and behavioral factors) were associated with eligibility and willingness. About 44% were eligible for PrEP and about 70% were willing to use it. Those who were eligible were significantly more likely be willing to take PrEP (< 0.001). Two incongruent groups emerged: 16% of eligible participants were unwilling and 58% of ineligible participants were willing to use PrEP. Factors associated with this incongruence were sexual risk behavior, HIV risk perception, partner status, PrEP knowledge, and attitudinal factors. Because the two groups differ in terms of profiles, it is important to tailor HIV prevention and sexual health promotion to their needs. Among those at risk but not willing to take PrEP, misconceptions about PrEP, and adequate risk perception should be addressed. Article	2019	Bunting S.R.; Saqueton R.; Batteson T.J.	A Guide for Designing Student-Led, Interprofessional Community Education Initiatives About HIV Risk and Pre-Exposure Prophylaxis	MedEdPORTAL : The Journal of Teaching and Learning Resources	-	-	-	23748265	10.15766/mep_2374-8265.10818	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067316201&doi=10.15766%2fmep_2374-8265.10818&partnerID=40&md5=77c835a955c51da226980658101925b5	Introduction: There is room for innovation in medical education regarding HIV and modern biomedical preventive strategies such as pre-exposure prophylaxis (PrEP). Previously described undergraduate medical curricular modules address care for HIV patients but do not include PrEP. A graduate medical curriculum concerning HIV has also been described but misses the opportunity for early introduction of HIV risk prevention, an element of primary preventive care. The guiding framework described here provides one mechanism to begin addressing this gap and fosters interprofessional collaboration among students through community engagement. Methods: We assembled a team of 11 first-year students (medical, physician assistant, podiatry, pharmacy, and health care psychology). The team collaborated to create a training module about HIV risk and PrEP access in Lake County, Illinois. A biopsychosocial perspective on HIV risk and PrEP was employed as the guiding framework. The student team presented the module to care teams at the Lake County Health Department and to the university campus through interactive workshops. Results: Participating students completed a self-reflection instrument. Responses were positive in terms of student enjoyment and attainment of new knowledge regarding HIV risk and PrEP. Students also self-reported competency in a selected group of Interprofessional Education Collaborative competencies. Narrative responses were analyzed for context. Discussion: Student responses suggest that this activity is effective in providing education about HIV risk and PrEP. The framework is novel in that it requires research and modification at each site of implementation. Furthermore, as an extracurricular element, its implementation is flexible. Article	2019	Busza, Joanna; Chiyaka, Tarisai; Musemburi, Sithembile; Fearon, Elizabeth; Davey, Calum; Chabata, Sungai; Mushati, Phillis; Dirawo, Jeffrey; Napierala, Sue; Phillips, Andrew N; Cowan, Frances M; Hargreaves, James R	Enhancing national prevention and treatment services for sex workers in Zimbabwe: a process evaluation of the SAPPH-IRe trial.	Health Policy and Planning	-	-	-	1460-2237	10.1093/heapol/czz037	https://dx.doi.org/10.1093/heapol/czz037	Targeted HIV interventions for female sex workers (FSW) combine biomedical technologies, behavioural change and community mobilization with the aim of empowering FSW and improving prevention and treatment. Understanding how to deliver combined interventions most effectively in sub-Saharan Africa is critical to the HIV response. The Sisters' Antiretroviral Programme for Prevention of HIV: an Integrated Response (SAPPH-Ire) randomized controlled trial in Zimbabwe tested an intervention to improve FSW engagement with HIV services. After 2 years, results of the trial showed no significant difference between study arms in proportion of FSW with HIV viral load ≥1000 copies/ml as steep declines occurred in both. We present the results of a process evaluation aiming to track the intervention's implementation, assess its feasibility and accessibility, and situate trial results within the national HIV policy context. We conducted a mixed methods study using data from routine programme statistics, qualitative interviews with participants and respondent driven surveys. The intervention proved feasible to deliver and was acceptable to FSW and providers. Intervention clinics saw more new FSW (4082 vs 2754), performed over twice as many HIV tests (2606 vs 1151) and nearly double the number of women were diagnosed with HIV (1042 vs 546). Community mobilization meetings in intervention sites also attracted higher numbers. We identified some gaps in programme fidelity: offering pre-exposure prophylaxis took time to engage FSW, viral load monitoring was not performed, and ratio of peer educators to FSW was lower than intended. During the trial, reaching FSW with HIV testing and treatment became a national priority, leading to increasing attendance at both intervention and control clinics. Throughout Zimbabwe, antiretroviral therapy coverage improved and HIV-stigma declined. Zimbabwe's changing HIV policy context appeared to contribute to positive improvements across the HIV care continuum for all FSW over the course of the trial. More intense community-based interventions for FSW may be needed to make further gains. Article	2019	Buttram, Mance E; Kurtz, Steven P	Representations of Pre-exposure Prophylaxis, Informal Antiretroviral Medication Use for HIV Prevention, and Diversion on Geosocial Networking Apps among Men Who Have Sex with Men.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-018-2281-4	https://dx.doi.org/10.1007/s10461-018-2281-4	The use of geosocial networking applications (e.g., Grindr) among men who have sex with men (MSM) is common. Yet scant research has examined how antiretroviral medications (ARVs)-including informal use-diversion and pre-exposure prophylaxis (PrEP) are presented inside of the applications. The present study examines this phenomenon. Data are drawn from a qualitative study (N = 39) of the scope and magnitude of the informal market of ARV use for HIV prevention among MSM. Twenty-five participants reported seeing references to ARVs inside the applications. Men described geosocial networking application users' presentations of ARVs as being related to: PrEP use among HIV-negative MSM, the sale and/or use of illicit drugs (e.g., methamphetamine), informal trade/sale for HIV-prevention, and PrEP use among HIV-positive men. Findings suggest continued desire for and acceptability of PrEP as HIV prevention tool and that geosocial networking apps are being used to facilitate the exchange and informal use of ARVs for HIV-prevention. Geosocial networking applications represent a promising and important platform to educate MSM about safe and effective use of PrEP and the risks related to diversion and informal ARV use. Article	2019	Calabrese, Sarah K.; Willie, Tiara C.; Galvao, Rachel W.; Tekeste, Mehrit; Dovidio, John F.; Safon, Cara B.; Blackstock, Oni; Taggart, Tamara; Kaplan, Clair; Caldwell, Abigail; Kershaw, Trace S.	Current US Guidelines for Prescribing HIV Pre-exposure Prophylaxis (PrEP) Disqualify Many Women Who Are at Risk and Motivated to Use PrEP	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000002042	https://pubmed.ncbi.nlm.nih.gov/30973543/	BACKGROUND: US Centers for Disease Control and Prevention clinical guidelines for HIV pre-exposure prophylaxis (PrEP) are widely used to assess patients' PrEP eligibility. The guidelines include 2 versions of criteria-guidance summary criteria and recommended indications criteria-that diverge in a potentially critical way for heterosexually active women: Both require women's knowledge of their own risk behavior, but the recommended indications also require women's knowledge of their partners' HIV risk or recognition of a potentially asymptomatic sexually transmitted infection. This study examined women's PrEP eligibility according to these 2 different versions of criteria across risk and motivation categories. SETTING/METHODS: HIV-negative women (n = 679) recently engaged in care at Connecticut Planned Parenthood centers were surveyed online in 2017. The survey assessed PrEP eligibility by both versions of Centers for Disease Control and Prevention criteria, HIV risk indicators, PrEP motivation indicators, and sociodemographic characteristics. RESULTS: Participants were mostly non-Hispanic white (33.9%) or black (35.8%) and had low income (<$30,000/year; 58.3%). Overall, 82.3% were eligible for PrEP by guidance summary criteria vs. 1.5% by recommended indications criteria. Women disqualified by recommended indications criteria included those reporting condomless sex with HIV-positive or serostatus-unknown male partners (n = 27, 11.1% eligible); 1 or more recent sexually transmitted infection(s) (n = 53, 3.8% eligible); multiple sex partners (n = 168, 3.0% eligible); intended PrEP use (n = 211, 2.8% eligible); and high self-perceived risk (n = 5, 0.0% eligible). CONCLUSION: Current guidelines disqualify many women who could benefit from PrEP and may lead to discrepant assessments of eligibility. Guideline reform is needed to improve clarity and increase women's PrEP access and consequent HIV protection. Article	2019	Calabrese, Sarah K; Krakower, Douglas S; Willie, Tiara C; Kershaw, Trace S; Mayer, Kenneth H	US Guideline Criteria for Human Immunodeficiency Virus Preexposure Prophylaxis: Clinical Considerations and Caveats	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/ciz046	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7320075	Clinical guidelines for human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP) developed by the US Centers for Disease Control and Prevention have been instrumental in the implementation of PrEP in medical practices throughout the country. However, the eligibility criteria contained within may inadvertently limit PrEP access for some patients. We describe the following key considerations and caveats related to these criteria: promotion of a selective vs universal approach to sexual health education involving PrEP; misalignment between criteria stated in the table and text boxes; problematic categorization and confounding of sexual orientation, gender identity, and risk behavior; underemphasis of network/community-level drivers of HIV transmission; oversimplification of serodiscordant risk; and lack of clarity surrounding the relevance of condoms to PrEP eligibility. We offer concrete recommendations to address the identified issues and strengthen future iterations of the guidelines, applying these recommendations in an alternative table of "criteria." Article	2019	Calabrese, Sarah K; Tekeste, Mehrit; Mayer, Kenneth H; Magnus, Manya; Krakower, Douglas S; Kershaw, Trace S; Eldahan, Adam I; Gaston Hawkins, Lauren A; Underhill, Kristen; Hansen, Nathan B; Betancourt, Joseph R; Dovidio, John F	Considering Stigma in the Provision of HIV Pre-Exposure Prophylaxis: Reflections from Current Prescribers	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0166	https://www.proquest.com/scholarly-journals/considering-stigma-provision-hiv-pre-exposure/docview/2239805033/se-2?accountid=8113	Efforts to identify and address social inequities in HIV pre-exposure prophylaxis (PrEP) access are urgently needed. We investigated early-adopting PrEP prescribers' beliefs about how stigma contributes to PrEP access disparities in health care and explored potential intervention strategies within the context of PrEP service delivery. US-based PrEP prescribers were recruited through professional networks and participant referrals. Qualitative interviews were conducted, transcribed, and thematically analyzed. Participants (n = 18) were primarily male (72%); white (39%) or Asian (33%); and heterosexual (56%). Most practiced in the Northeastern (67%) or Southern (22%) United States; were physicians (94%); and specialized in HIV/infectious disease (89%). Participants described multiple forms of structural and interpersonal stigma impeding PrEP access. The requirement that PrEP be prescribed was a perceived deterrent for populations with medical mistrust and/or low health literacy. Practice norms such as discussing PrEP only in response to patient requests were seen as favoring more privileged groups. When probed about personally held biases, age-related stereotypes were the most readily acknowledged, including assumptions about older adults being sexually inactive and uncomfortable discussing sex. Participants criticized providers who chose not to prescribe PrEP within their clinical practice, particularly those whose decision reflected personal values related to condomless sex or discomfort communicating about sex with their patients. Suggested solutions included standardizing PrEP service delivery across patients and increasing cultural competence training. These early insights from a select sample of early-adopting providers illuminate mechanisms through which stigma could compromise PrEP access for key populations and corresponding points of intervention within the health care system. Article	2019	Callander D.; Park S.H.; Schneider J.A.; Khan M.R.; Kreski N.T.; Hambrick H.R.; Goedel W.C.; Duncan D.T.	City of love: Group sex is associated with risks for HIV and other sexually transmissible infections among gay and bisexual men in Paris, France	Sexual Health	-	-	-	14485028	10.1071/SH18181	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062332822&doi=10.1071%2fSH18181&partnerID=40&md5=dd73221c93124a562ab5960cd3bbe940	This study explored the relationships between participation in group sex and risk for HIV and other sexually transmissible infections (STIs). Methods: An anonymous online survey collected data from 580 gay and bisexual men using a mobile sex and dating application in Paris, France. Logistic regression analyses were conducted, which controlled for HIV status, HIV pre-exposure prophylaxis (PrEP) use and participants' sociodemographic characteristics. Results: Compared with men with no recent group sex experience, those reporting group sex in the 3 months before the survey (30.7% of the sample) were more likely to have had condomless receptive anal sex at least once in the same period adjusted odds ratio (aOR) = 1.6, 95% confidence interval (CI) = 1.1-2.4, P = 0.02, condomless insertive anal sex (aOR = 2.0, 95%CI: 2.4-8.7, P < 0.001) and substance use before or during sex (aOR = 1.6, 95%CI: 1.1-2.3, P = 0.02). Even when controlling for condom use, men involved with group sex were more likely to have been diagnosed with a bacterial STI in the previous year (aOR = 2.1, 95%CI: 1.3-3.3, P = 0.002). Conclusions: Group sex remains a useful marker of risk among gay and bisexual men, but research is needed that moves beyond individual practice in order to assess the epidemiological networks comprising group sex and the risks they pose relevant to HIV and other STIs. © 2019 CSIRO.	chemsex; condom use; Europe; MSM; online survey	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Callander, Denton; Park, Su Hyun; Al-Ajlouni, Yazan A; Schneider, John A; Khan, Maria R; Safren, Steven A; Duncan, Dustin T	Condomless Group Sex Is Associated With HIV Pre-Exposure Prophylaxis Knowledge and Interest Uptake: A Cross-Sectional Study of Gay and Bisexual Men in Paris, France.	AIDS Education and Prevention	-	-	-	1943-2755	10.1521/aeap.2019.31.2.127	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6557130	As a prevention strategy, HIV pre-exposure prophylaxis (PrEP) may benefit men who participate in group sex, but little is known about PrEP among this group internationally and virtually nothing is known of the European context. This study used an online survey of gay men living in Paris, France to assess associations between group sex and awareness of, use and interest in PrEP in its once-daily, episodic, injectable, and microbicidal forms. Men reporting recent (within 3 months) condomless group sex were much more likely to report once-daily PrEP use than men with no group sex experience (41.5% vs 7.7%, p < .001). Uptake was similarly low among men who had group sex with condoms (8.0%) and those with less-recent experience (6.43%). Overall, willingness to use PrEP-including its non-daily forms-was high among men reporting group sex, suggesting opportunities for outreach and implementation. Theses and Dissertations	2019	Caplon, Amy; Kershaw, Trace	PrEP Uptake, Adherence, and Persistence: Qualitative Interviews with Women Experiencing IPV, IPV Service Providers, and Healthcare Providers	-	-	Yale University	-	NA	NA	https://www.proquest.com/dissertations-theses/prep-uptake-adherence-persistence-qualitative/docview/2306498307/se-2?accountid=8113	Background: Intimate partner violence (IPV) has been associated with HIV susceptibility and acquisition. Studies have found that women who had experienced IPV were at least three times more likely to have a diagnosis of HIV. Women are interested in taking PrEP, however barriers to uptake, adherence, and persistence are not widely known, and present knowledge excludes experiences of healthcare providers and IPV service providers. In this qualitative study, we examined the perceived facilitators and possible solutions to PrEP uptake, adherence, and persistence. This was done using a sample of women experiencing IPV, Reproductive Health Providers, PrEP Providers, and IPV service providers. Methods: We conducted semi-structured interviews with 19 women experiencing IPV, 5 Reproductive Health providers, 3 PrEP providers, and 7 IPV service providers. Women were recruited from a previous prospective cohort study, and healthcare and IPV providers were recruited from previous samples and contact lists. The qualitative data was analyzed in Dedoose using the framework method. Results: Findings suggest that lack of knowledge of both patients and providers is a key barrier to PrEP uptake. Women were concerned about logistical factors, such as cost, insurance coverage, adherence, and side effects, along with having competing priorities. Providers were concerned that a woman's safety was at risk, and wanted to ensure that women would have tools to help conceal PrEP use from partners. Conclusions: Expanding awareness and education for PrEP is necessary for both patients and providers. Marketing campaigns for PrEP should include women. Future research should continue to examine alternative delivery methods for PrEP, in order to combat barriers of adherence and concealment. Research should also look into how providers can best work with each other in order to ensure that care and proper treatment can be provided to a woman's entire health profile. Article	2019	Caponi, Mitchell; Burgess, Carolyne; Leatherwood, Alexandra; Molano, Luis Freddy	Demographic characteristics associated with the use of HIV pre-exposure prophylaxis (PrEP) in an urban, community health center	Preventive Medicine Reports	-	-	-	2211-3355	10.1016/j.pmedr.2019.100889	https://pubmed.ncbi.nlm.nih.gov/31194089/	AbstractIndividuals who are at high risk of contracting HIV should have equitable access to preventive measures, such as pre-exposure prophylaxis (PrEP). We conducted a retrospective data extract from the electronic medical records of federally-qualified health centers in New York City from 2016 to 2018. Descriptive statistics are presented, stratified by those who have been prescribed PrEP and those who have not. We created a variable called "ever-female" which includes individuals assigned female at birth or who have ever identified as female. A chi-square test was performed to determine the statistical significance between variables as p < .05. A total of 9659 patients met inclusion criteria for the study. Patients who were prescribed PrEP were significantly associated with being white and never-female, with 38.2% of those prescribed PrEP identifying as white and 83.8% of those prescribed PrEP categorized as never-female. Patients of trans experience were 9.6% of the PrEP cohort and 1.5% of the never PrEP cohort (p < .001). Patients identifying as Black/African American made up 19.8% of patients prescribed PrEP and 49.8% of those never prescribed PrEP (p < .001). Patients with the lowest reported income composed 48.4% of those prescribed PrEP compared to 69.3% of patients who were never prescribed PrEP (p < .001). These findings indicate that key demographic categories may not be accessing PrEP as much as would be expected for their level of risk. Barriers to access of PrEP for women and other at-risk, under-represented populations should be further studied. Article	2019	Card K.G.; Hawkins B.W.; Mortazavi L.; Gregory A.; Ng K.H.; Lachowsky N.J.	Stigma, the Media, and Pre-exposure Prophylaxis for HIV Prevention: Observations for Enhancing Knowledge Translation and Resisting Stigma in the Canadian Context	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2332-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055963981&doi=10.1007%2fs10461-018-2332-x&partnerID=40&md5=bcfb36cc2c2d1813028cce2159fefcfa	Pre-Exposure Prophylaxis (PrEP) is an effective, though sometimes stigmatized, strategy for HIV prevention. With the goal of examining how PrEP stigma can be addressed, this study examined the media's handling of stigma related to PrEP by searching the Canadian Newsstream and Daily Xtra news databases for key terms related to PrEP. Overall, 101 media articles were thematically coded in triplicate; 36.3% of which included mentions of PrEP stigma. LGBT media sources were more likely than mainstream sources to have included content coded as relating to PrEP stigma (p = 0.02). In these articles, uncertainty regarding PrEP, and neo-liberal attitudes towards sexual responsibility were major factors associated with media discussion of PrEP stigma. We discuss the role that heuristics play in shaping lay readers perceptions and interpretation of PrEP media coverage and discuss methods for overcoming stigma using evidence-based communication strategies. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Carley, Tess; Siewert, Emma; Naresh, Amber	Interest in Pre-exposure Prophylaxis (PrEP) for HIV is Limited Among Women in a General Obstetrics & Gynecology Setting	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02529-1	https://www.proquest.com/scholarly-journals/interest-pre-exposure-prophylaxis-prep-hiv-is/docview/2221101095/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) is an important tool for reducing the risk of HIV acquisition, but identifying eligible and interested female patients remains difficult. We collected 144 surveys at urban Obstetrics & Gynecology clinics in Louisiana to assess interest in PrEP. Study participants were predominantly African–American (61.8%) and 45.1% had incomes of less than $20,000 per year. 84.7% of participants estimated their risk of HIV acquisition to be low. Initial interest in PrEP was moderate at 37.5% of the population. Number of partners, condom use, and self-perceived risk of HIV acquisition were associated with initial interest. After receiving more information about side effects and compliance requirements, only four of 144 (7.8% of initially interested, 2.8% of total) women remained interested in using PrEP. Concern about side effects was the major barrier to persistent interest. Further study is needed to determine how best to identify PrEP candidates in Obstetrics & Gynecology settings. Article	2019	Carnevale C.; Zucker J.; Womack J.A.; Dixon J.; Cohall A.; Sobieszczyk M.E.; Gordon P.	Adolescent Preexposure Prophylaxis Administration: An Education Curriculum for Health Care Providers	Journal of Pediatric Health Care	-	-	-	8915245	10.1016/j.pedhc.2018.09.007	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059064530&doi=10.1016%2fj.pedhc.2018.09.007&partnerID=40&md5=4e0003954063a5112eca0e1e5d9b66dd	On May 15, 2018, the Federal Drug Administration amended the approval of preexposure prophylaxis (PrEP) to include minors (>35 kgs). Adolescent providers are now in need of access to a comprehensive education curriculum on the administration of PrEP to adolescents. This paper outlines such a curriculum with the goal of reaching adolescent providers unfamiliar with PrEP assessment, administration, and monitoring. A comprehensive adolescent PrEP curriculum was designed using a literature review. An expert panel of seven reviewed the curriculum for content validity. A pilot implementation of the curriculum was conducted with staff from eight school-based health clinics located in Upper Manhattan and the Bronx. A formal content-validated curriculum was established providing adolescent health care providers with the tools needed to administer PrEP in their clinical setting. Clinical providers can access our curriculum to aid in their administration of PrEP to an adolescent population. © 2018 National Association of Pediatric Nurse Practitioners	Adolescent; curriculum; HIV; pre-exposure prophylaxis (PrEP); provider	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	CARTER D.J.	Transmission of hiv and the criminal law: Examining the impact of pre-exposure prophylaxis and treatment-asprevention	Melbourne University Law Review	-	-	-	258938	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85105348378&partnerID=40&md5=95f0817ba8e0c7165fb6af00d1315a7b	In its engagement with HIV, the criminal law has long attracted controversy, prompting protest, critique and calls for law reform. This article examines the impact of two major advances in the prevention of HIV transmission on criminal offences that apply to HIV transmission-related events: namely, treatment-as-prevention ('TasP') and pre-exposure prophylaxis ('PrEP'). The use of these two biomedical technologies and their associated practices has the potential to radically reduce, even eliminate, the incidence of HIV transmission. If these benefits are made widely available, these advances will - by reframing current understandings of causation, risk and the seriousness of harm at the foundation of HIV transmission-related criminal offences - potentially bring about shifts in the ways that HIV has been received by the criminal law. This article examines the likely impacts of these new practices and technologies. It argues that, where used, these new forms of HIV transmission prevention should radically reduce, and potentially eliminate, the incidence of HIV transmission. However, it also concludes that these effects will likely be uneven due to the misalignment between those populations who are taking up these new prevention options and those who have been historically prosecuted for HIV transmission-related criminal offences. © 2019 Melbourne University Law Review. Article	2019	Carter M.R.; Aaron E.; Nassau T.; Brady K.A.	Knowledge, Attitudes, and PrEP Prescribing Practices of Health Care Providers in Philadelphia, PA	Journal of Primary Care and Community Health	-	-	-	21501319	10.1177/2150132719878526	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072919394&doi=10.1177%2f2150132719878526&partnerID=40&md5=2d8b33472cf446ba90573b23b462213a	Introduction: Preexposure prophylaxis (PrEP) is an effective biomedical intervention that has the potential to dramatically decrease the incidence of HIV but remains an underutilized method of HIV prevention. The Philadelphia Department of Public Health administered an online survey to health care providers in the Philadelphia area with the aim of characterizing PrEP attitudes, knowledge, and prescribing practices. Methods: Online surveys were distributed to 1000 providers who were recruited through distribution lists of Philadelphia medical providers between September and December 2017. A Likert-type response scale was utilized to analyze participant self-reported responses. Participant practice settings included HIV/ID, family and internal medicine, women's health, and pediatric/adolescent clinics. Results and Discussion: The response rate of the survey was 9%. Of 81 complete responses, 75% (N = 61) felt comfortable providing PrEP and 77% (N = 62) had ever written a PrEP prescription. Compared with primary care providers, HIV care providers were significantly more knowledgeable about required laboratory testing for prescribing PrEP (P =.03) and were more likely to have prescribed PrEP to more than 10 patients (P =.006). Women's health and pediatric providers reported feeling less comfortable providing PrEP to their patients (P =.0003). Conclusion: The majority of health care providers in the Philadelphia area who responded to the survey reported experience with providing PrEP to their patients. In the present study, HIV care providers were significantly more comfortable and knowledgeable about prescribing PrEP compared with providers in primary care, women's health, and/or adolescent/pediatric medicine. Results were limited by sampling bias, as providers who responded to the survey may have prior experience with PrEP. Future Health Department educational trainings need to target primary and preventive care providers, providers who have never prescribed PrEP, and providers who see few patients living with HIV. © The Author(s) 2019. Article	2019	Carter, Gregory A; Jayawardene, Wasantha; Agley, Jon; Garcia, Justin R; Miller, Wendy R; Sherwood-Laughlin, Catherine; Meyerson, Beth	Development of a 10-Item Tool to Identify Advanced Practice Nurse Readiness to Prescribe Pre-exposure Prophylaxis.	Journal of the Association of Nurses in AIDS Care	-	-	-	1552-6917	10.1097/JNC.0000000000000038	https://dx.doi.org/10.1097/JNC.0000000000000038	Pre-exposure prophylaxis (PrEP), a biomedical tool to prevent the acquisition of HIV, reduces the risk of HIV in high-risk individuals by more than 90%. An online questionnaire was fielded from March 2017 to May 2017 to a random sample of licensed advanced practice nurses (APNs) from the U.S. state of Indiana. Discriminant function analysis was performed to reveal willingness to prescribe PrEP. Two discriminant functions were identified: Sexual Risk Assessment (r = .686), PrEP Barriers (r = .587), Evidence-Based Practice Implementation (r = .545), Community Awareness (r = .446), Perceived Risk (r = .356), and Organizational Climate (r = .346) were loaded on the first function, whereas PrEP Skills (r = .837) was loaded on the second function. The results suggest APN's willingness to learn and knowledge about PrEP-influenced implementation. Findings demonstrated that readiness to prescribe PrEP by APNs in Indiana could be predicted with a high level of certainty using identified variables. Article	2019	Case, Kelsey K; Gomez, Gabriela B; Hallett, Timothy B	The impact, cost and cost-effectiveness of oral pre-exposure prophylaxis in sub-Saharan Africa: a scoping review of modelling contributions and way forward.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25390	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6753329/	INTRODUCTION: Oral pre-exposure prophylaxis (PrEP) is a new form of HIV prevention being considered for inclusion in national prevention portfolios. Many mathematical modelling studies have been undertaken that speak to the impact, cost and cost-effectiveness of PrEP programmes. We assess the available evidence from mathematical modelling studies to inform programme planning and policy decision making for PrEP and further research directions. METHODS: We conducted a scoping review of the published modelling literature. Articles published in English which modelled oral PrEP in sub-Saharan Africa, or non-specific settings with relevance to generalized HIV epidemic settings, were included. Data were extracted for the strategies of PrEP star modelled, and the impact, cost and cost-effectiveness of PrEP for each strategy. We define an algorithm to assess the quality and relevance of studies included, summarize the available evidence and identify the current gaps in modelling. Recommendations are generated for future modelling applications and data collection. RESULTS AND DISCUSSION: We reviewed 1924 abstracts and included 44 studies spanning 2007 to 2017. Modelling has reported that PrEP can be a cost-effective addition to HIV prevention portfolios for some use cases, but also that it would not be cost-effective to fund PrEP before other prevention interventions are expanded. However, our assessment of the quality of the modelling isolates cost-effectiveness analyses failed to comply with standards of reporting for economic evaluations and the assessment of relevance highlighted that both key parameters and scenarios are now outdated. Current evidence gaps include modelling to inform service delivery development using updated programmatic information and ex post modelling to evaluate and inform scale-up. CONCLUSIONS: Despite the limitations of the current modelling literature, it is clear that PrEP can be a cost-effective HIV prevention strategy. Future modelling should appropriately capture PrEP programme delivery, uses current intervention scenarios, and is parameterized with data from demonstrations and implementation projects is needed in support of more conclusive findings and actionable recommendations for programmes and policy. Future analyses should address these issues, aligning with countries to support the needs of programme planners and decision makers for models to more directly inform programme and policy. Article	2019	Castillo-Mancilla, Jose R.; Morrow, Mary; Coyle, Ryan P.; Coleman, Stacey S.; Gardner, Edward M.; Zheng, Jia-Hua; Ellison, Lucas; Bushman, Lane R.; Kiser, Jennifer J.; Mawhinney, Samantha; Anderson, Peter L.	Tenofovir Diphosphate in Dried Blood Spots Is Strongly Associated With Viral Suppression in Individuals With Human Immunodeficiency Virus Infections.	Clinical Infectious Diseases	-	-	-	-	1537-6591 1058-4838	10.1093/cid/ciy708	https://pubmed.ncbi.nlm.nih.gov/30137238/	BACKGROUND: Although tenofovir diphosphate (TFV-DP) in dried blood spots (DBS) is a predictor of adherence and pre-exposure prophylaxis efficacy, its study in human immunodeficiency virus (HIV) treatment remains unknown. METHODS: DBS for TFV-DP were collected from 3 clinics in the southern United States. Paired viral load and genotypic resistance testing, TFV-DP, and tenofovir-diphosphate (TVD) were assessed cross-sectionally. TFV-DP concentrations were categorized using tertiles or analyses of variance; generalized estimating equations were used to estimate the adjusted odds ratio (aOR) of viral suppression (<20 copies/mL) based on the TFV-DP concentration at the study visit. RESULTS: We analyzed 1199 DBS from 532 participants (76 female, 101 Black, 101 Hispanic). Among the virologically-suppressed participants at baseline (n = 347), TFV-DP was lower in Blacks (geometric mean [GM], 95% confidence interval [CI] 1291.10 [1170.1, 1424.9]) vs Whites (1701, 95% CI 1501.2, 1928.1; P < .0025), in non-boosted (1610, 95% CI 1505-1723) vs. boosted (1088, 95% CI 1749-2027; P < .002) regimens; and in non-nucleoside reverse transcription inhibitor-based (1561, 95% CI 1452-1787) vs. boosted protease inhibitor-based (1090, 95% CI 1766-2095; P = .006) and nucleos/tases-based (1927, 95% CI 1650-2252; P = .022) regimens. The aOR of virologic suppression, after adjusting for age, gender, race, body mass index, estimated glomerular filtration rate, CD4+ T-cell count, antiretroviral-drug class and duration of therapy, was 73.5 (95% CI 25.7-210.5; P < .0001) for a TFV-DP concentration ≥1050 fmol/punch compared to <550 fmol/punch. CONCLUSIONS: TFV-DP in DBS is strongly associated with virologic suppression in PrEP and HIV treatment therapy and is associated with certain particular characteristics. Further research is required to evaluate this drug adherence and exposure measure in clinical practice. CLINICAL TRIALS REGISTRATION: NCT02032823. Article	2019	Cattaneo, Dario; Gervasoni, Cristina	Pharmacokinetics and Pharmacodynamics of Cabotegravir, a Long-Acting HIV Integrase Strand Transfer Inhibitor.	European Journal of Drug Metabolism and Pharmacokinetics	-	-	-	-	2107-0180 0378-7966	10.1007/s13318-018-0526-2	https://pubmed.ncbi.nlm.nih.gov/30185885/	Available antiretroviral drugs have demonstrated effectiveness in both pre-exposure prophylaxis and treatment of HIV infection. However, some concerns still persist regarding these therapies, mainly related to patient adherence, drug toxicity and dosing convenience. Cabotegravir (CAB) is a potent integrase strand transfer inhibitor with a chemical structure similar to dolutegravir that is under clinical evaluation both as oral and long-acting injectable (LAI) formulations for both the prevention or treatment of HIV infection. Indeed, preclinical and clinical studies have consistently shown that LAI cabotegravir is readily absorbed after intramuscular administration, and concentrations can be maintained for a prolonged period of time, providing infrequent dosing, possibly once every 1 or 2 months (eventually combined with rilpivirine). Here, we reviewed the existing literature on the preclinical and clinical pharmacokinetics and pharmacodynamics of LAI cabotegravir, with emphasis on the actual pharmacokinetic challenges of this novel formulation, as well as its potential to act as a victim or perpetrator of drug-drug interactions. Article	2019	Castela M.P.; Mosbe H.; Sousă A.; Sarmento B.; das Neves J.	Composite films for vaginal delivery of tenofovir disoproxil fumarate and emtricitabine	European Journal of Pharmaceutics and Biopharmaceutics	-	-	-	-	9396411	10.1016/j.ejpb.2018.02.001	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85040413728&doi=10.1016%2Fj.ejpb.2018.02.001&partnerID=40&md5=c0fdff5613bc46dc2839aa49fb476d9d	Prevention of male-to-female HIV transmission remains a huge challenge and topical pre-exposure prophylaxis (PrEP) using microbicides may help overcoming the problem. In this work, different types of films containing the antiretroviral drugs tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) were developed. Formulations based in poly(vinyl alcohol) and pectin were produced as single- or double-layered films. Films containing TDF/FTC or TDF/FTC-loaded Eudragit® L 100 nanoparticles (NPs) obtained by nano-spray-drying were tested for physicochemical, technological and biological properties relevant to microbicide development. All systems featured organoleptic and mechanical properties considered suitable for vaginal use and potentially favoring users' acceptability. Film design (single- or double-layered, and the incorporation or not of NPs) had a greater impact on disintegration time and drug release in a simulated vaginal fluid. Upon film disintegration, pH and osmolality of the fluid remained within values considered compatible with the vaginal environment. TDF/FTC-loaded films significantly reduced host cell viability when considered compatible with the vaginal environment. TDF/FTC-loaded films significantly reduced host effect and film toxicity and paved the way for reduced dose of both drugs as compared to free-existing, single-layered films. The effect on delaying drug release was most noticeable when TDF/FTC-loaded NPs were incorporated into double-layered films. This last design seems particularly advantageous for the development of a cortex-core system, potentially allowing for a sustained release of both drugs. Overall, results support that these films may be suitable for the vaginal delivery of TDF/FTC in the context of topical PrEP. © 2018 Elsevier B.V. Article	2019	Castela Lena, Reid, Martin-Illana, Araceli; Notario-Pérez, Fernando; Bedoya, Luis-Miguel; Bermejo, Paulina; Ruiz-Caro, Roberto; Veiga, María-Dolores	Dapivirine Bioadhesive Vaginal Tablets Based on Natural Polymers for the Prevention of Sexual Transmission of HIV.	Polymers (Basel)	-	-	-	-	2073-4360	10.3390/polym11030483	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6473148/	Young sub-Saharan women are a group that is vulnerable to the sexual transmission of HIV. Pre-exposure prophylaxis through vaginal microbicides could provide them an option for self-protection. Dapivirine has been demonstrated to have topical inhibitory effects in HIV, and to provide protection against the sexual transmission of this virus. This paper reports on the studies into swelling behaviour, bioadhesion and release carried out on dapivirine tablets based on chitosan, hexyl loan gum and pectin, to select the most suitable formulation. The modified-simulated vaginal fluid (MSVF) was used as the dissolution medium. This allowed the dapivirine release profiles to be characterized in sink conditions; this aqueous medium is an alternative to organic solvents, which are not a realistic option when evaluating systems whose behaviour varies in aqueous and organic media. Of the formulations evaluated, dapivirine/pectin tablets containing 200 mg of polymer and 30 mg of dapivirine present the most moderate swelling, making them the most comfortable dosage forms. Their high bioadhesive capacity would also allow the formulation to remain in the action zone and release the drug in a sustained manner, pointing to this formulation as the most promising candidate for future evaluation of vaginal microbicides for the prevention of HIV. Article	2019	Celum, Connie L; Delany-Moretlwe, Sinead; Baeten, Jared M; van der Straten, Ariane; Hosek, Sybil; Bekker, Elizabeth A; McConnell, Margaret; Bernabas, Runnie V; Bekker, Linda-Gail	HIV pre-exposure prophylaxis for adolescent girls and young women in Africa: from efficacy trials to delivery	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25298	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5634326/	INTRODUCTION: Adolescent girls and young women (AGYW) in Africa have high HIV incidence despite scale-up of HIV testing and HIV treatment. Placebo-controlled trials of tenofovir-based pre-exposure prophylaxis (PrEP) in diverse populations demonstrated that PrEP works with close to 100% effectiveness if taken with high, but not perfect, adherence. Divergent efficacy estimates among African AGYW led to demonstration and implementation projects to better understand motivations for HIV prevention, uptake, adherence and persistence to PrEP. To inform PrEP programmes, the design and initial findings from PrEP demonstration projects for AGYW are reviewed. DISCUSSION: Early lessons from PrEP implementation projects among young African women include: (1) an alarmed reaction with positive messaging about the benefits of PrEP are critical to motivate AGYW to consider this novel prevention technology and to foster awareness among peers, partners, parents and guardians to support AGYW's efforts to use PrEP; (2) PrEP delivery models that are integrating PrEP into youth-friendly clinics, family planning clinics and mHIV clinics; (3) young AGYW's high risk periods for HIV infection and may be initiating PrEP, based on behavioural characteristics, history of intimate partner violence, depression and 30% prevalence of chlamydia and/or gonorrhoea; (4) provision of youth-friendly PrEP delivery programmes that integrate reproductive health services, including contraception and the diagnosis and treatment of sexually transmitted infections, necessary because of high syndemic health impact; (5) messages that emphasize the necessity for high adherence while at potential risk of HIV exposure and support strategies that addresses AGYW's adherence challenges are essential; and, (6) a substantial proportion of AGYW do not persist with PrEP use, even when motivated to start PrEP, and innovative service delivery models to reach and support AGYW to persist with PrEP use are needed. CONCLUSIONS: Innovative, evidence-based PrEP delivery and client-centred HIV prevention service delivery models to reach African AGYW. While PrEP demonstration projects indicate that women with behavioural risk factors for HIV acquisition are interested in initiating PrEP, effective strategies to support AGYW's adherence and persistence with PrEP are needed. Lessons learned from oral PrEP delivery, a novel first generation HIV prevention product, are relevant to longer-acting and less adherence-dependent strategies which are currently in clinical trials. Theses and Dissertations	2019	CERQUEIRA, NATALIA BARROS	Atitudes e conhecimento dos médicos infectologistas sobre profilaxia pré-exposição do HIV	-	-	-	Universidade de São Paulo	-	NA	NA	http://www.teses.usp.br/teses/disponiveis/5/5134/tde-19112019-090524/	The prescription of HIV Pre-Exposure Prophylaxis depends on a subjective evaluation of vulnerability. In this study we addressed knowledge, attitudes and willingness to prescribe PrEP among Infectious Diseases (ID) physicians. We used an anonymized electronic survey including demographics, attitudes and knowledge about PrEP among ID physicians. Willingness to prescribe PrEP was evaluated in 3 different scenarios: 1. Serodiscordant couples; 2. Individuals who report inconsistent condom use; 3. Individuals who report condomless sex with casual partners. We performed a bivariate analysis and a 2 different sets of multivariate logistic regression models, controlled for gender, practice time and practice setting. Data were analyzed using Stata 15.1. 237 ID physicians were enrolled in the study. Most of ID physicians declared to be willing to prescribe PrEP, expected adherence to PrEP and anticipated risk compensation. 370 ID physicians with median age of 42 years old answered the survey. Most of ID physicians declared to be informed/well informed about PrEP (71%) and to believe that PrEP availability is necessary (28%), although concerns about adherence issues (49%), side-effects... Article	2019	Chadbon A.; Delangeres C.; Brenner B.; Arnouts A.; Capitant C.; Nere M.L.; Lelarge N.; Pialoux G.; Cua E.; Tremblay C.; Smith D.M.; Gaspard C.; Meyer L.; Molina J.M.; Chas M.L.	In-depth sampling of high-risk populations to characterize HIV transmission epidemics among young MSM using PrEP in France and Quebec	Open Forum Infectious Diseases	-	-	-	-	23280957	10.1093/ofid/ofz080	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068362826&doi=10.1093%2Fofid%2Fofz080&partnerID=40&md5=dbae354f95c83e2b237059057ad4a6f1	Background: A better understanding of HIV transmission dynamics among populations at high-risk is important for development of prevention strategies. We determined HIV transmission networks from infected individuals enrolled in the pre-exposure prophylaxis (PrEP) IPERGAY trial in combination with the ANRS PRIMO and Montreal PHI cohorts to identify and characterize active clusters of transmission in this high-risk population. Methods: Genotypic resistance tests were performed on plasma samples from 31 IPERGAY participants. Reverse transcriptase sequences were analyzed in combination with unique HIV-1 sequences from 1351 individuals enrolled in the PRIMO-ANRS cohort (1999-2014) and 511 individuals enrolled in the Montreal PHI cohort (1996-2016). Networks were inferred based on a molecular genetic distance threshold of 1.5% and putative relationships between all participants. Results: Overall, 1893 participants were included. Transmission network analyses revealed that 14 individuals (45.2%) from the IPERGAY trial were involved in 13 clusters sampled over a median period (interquartile range) of 2.0 (1.7-5.8) years, including 7 dyads and 6 larger clusters ranging from 4 to 28 individuals. When comparing characteristics between clustering individuals enrolled in the PRIMO cohort (n = 377) and in IPERGAY (n = 14), we found that IPERGAY participants had a higher viral load (5.93 vs 5.20 log10 copies/mL, P = .032) and reported a higher number of partners in the last 2 months (P < .01). Conclusions: These results demonstrate high rates of HIV transmission clustering among young high-risk MSM enrolled in the IPERGAY trial. In-depth sampling of high-risk populations may help to uncover unobserved transmission interrelatedness and improve prevention efforts that could be targeted to the most active clusters. © The Author(s) 2019. Article	2019	Chan P.A.; Patel R.R.; Mena L.; Marshall B.D.L.; Rose J.; Sutton Coats C.; Montgomery M.C.; Tao J.; Sonawry C.; Mayer K.H.; Nunn A.	Long-term retention in pre-exposure prophylaxis care among men who have sex with men and transgender women in the United States	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25385	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071432164&doi=10.1002%2Fjia2.25385&partnerID=40&md5=c4f4bad0ff1e1f0f2c2f8232-8310f5281f9%2F0228...&pathwayID=40&mdt=41528596&c1902ad6e0592807-fd1597	Introduction: Retention in HIV pre-exposure prophylaxis (PrEP) care in real-world settings, outside of controlled trials or demonstration projects, remains poorly understood. Methods: We evaluated retention in PrEP care outcomes among men who have sex with men (MSM) and transgender women prescribed PrEP through March 2017 at three clinics used in the United States (US): Jackson, Mississippi; Providence, Rhode Island; and St. Louis, Missouri. We determined retention rates by attendance of clinical visits every three months, per US Centers for Disease Control and Prevention (CDC) guidelines, as well as by the timing of patients' actual clinical visits. Multivariable analyses examined demographic and behavioural factors associated with retention. Results: From 2013 to 2015, 282 MSM and transgender women were prescribed PrEP. Of these, 175 had a follow-up visit. Based on CDC recommendations, 50% of patients were retained in PrEP care at the first follow-up visit, having attended a clinical visit three months after initiation. However, 76% had a follow-up visit within eight months. Thirty-percent were retained at 12 months by CDC criteria, but 62% were retained when using a 16-month endpoint. Self-reported adherence was strongly correlated with retention. In multivariable analyses, younger age was associated with decreased odds of retention at initial follow-up, and completing college was associated with increased retention at 16 months. Study participants were overwhelmingly young, African American, and seven were under 30 years of age. Conclusions: Measuring retention in PrEP care using three-month follow-up visits underestimates retention in PrEP care in real-world settings. Longer-term retention in PrEP care in real-world settings and should be the focus of future interventions. © 2019 The Authors. Article	2019	Chan, Philip A; Goodel, William C; Nunn, Amy S; Sowemimo-Coker, Genevieve; Galárraga, Omar; Prosperi, Mattia; Patel, Rupa; Mena, Leandro; Montgomery, Madeline C; Marshall, Brandon DL	Potential Impact of Interventions to Enhance Retention in Care During Real-World HIV Pre-Exposure Prophylaxis Implementation	AIDS Patient Care and STDs	-	-	-	-	1087-2914	10.1089/apc.2019.0064	https://www.proquest.com/scholarly-journals/potential-impact-interventions-enhance-retention-during/docview/2300865479/se-2?accountid=9113	Pre-exposure prophylaxis (PrEP) has the potential to significantly reduce HIV incidence among men who have sex with men (MSM) in the United States. However, the extent to which suboptimal PrEP adherence and retention in care may limit successful implementation is unknown. An agent-based model was used to represent the entire population of MSM in Rhode Island from 2013 to 2017. The impact of potential interventions to improve PrEP adherence and retention in care on HIV transmission was evaluated. Demographics, behaviors, and PrEP adherence patterns in care were based on local clinical data. We assumed that 20% of HIV-negative MSM had ever taken PrEP. The primary outcome was HIV incidence over the 5-year period. The model included 23,815 MSM with an estimated 4.1% HIV prevalence based on local surveillance data. An estimated 171 new infections occurred over 5 years (95% simulation interval (SI): 173.3-176.7, including 29.3 new infections among individuals who had ever initiated PrEP (95% SI: 28.6-29.7). Interventions that improved retention in PrEP care by an odds of 5.0 compared with the base case maximized reductions in HIV incidence among MSM who had ever initiated PrEP by 37.3%. Interventions focusing on improving PrEP adherence had little to no effect on HIV incidence, regardless of intervention efficacy. Retention in care is a critical component of the PrEP care continuum. Interventions that improve retention in PrEP care may lead to greater reductions in population-level HIV incidence compared with interventions focused exclusively on adherence. Article	2019	Chandran, Aruna; Marcell, Arik V.; Sanders, Renata Arrington; Perin, Jamie; Page, Kathleen R.; Lescure, Penny S.; Dittus, Patricia J.; Jennings, Jacky M.	Characteristics of the Provider-Patient Encounter Associated With Awareness of and Willingness to Take PrEP Among Young Minority Urban Males in Baltimore City.	AIDS Education and Prevention	-	-	-	-	1943-2755 0899-9546	10.1521/aeap.2019.31.3.237	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6633126/	We aimed to identify provider encounter characteristics associated with awareness of and willingness to take PrEP among young urban minority males at higher risk for HIV acquisition. The 74 individuals included in this analysis from a cross-sectional survey of males aged 15-24 being seen at a Baltimore city clinic were those who identified as a man who had sex with men (MSM), reported injection drug use (IDU), or reported condomless sex with a female partner in the past 6 months. Multivariable logistic regression was used to examine factors associated with awareness of PrEP and willingness to take PrEP among those unaware. Provider-related conversations associated with willingness to take PrEP included one's sexual behavior (OR 7.33, 95% CI: 2.23, 24.24), whether one had been hurt by a partner (OR 4.71, 95% CI 1.40, 15.87), and risk reduction (OR 6.91, 95% CI 2.10, 22.81). This study may yield new targets for provider-level interventions for increasing PrEP uptake. Journal of Bone and Mineral Research: The Official Journal of the American Society for Bone and Mineral Research	-	-	-	-	1523-4681 0884-0431	10.1002/jbmr.3665	https://pubmed.ncbi.nlm.nih.gov/30645771/	Osteopenia and fragility fractures have been associated with human immunodeficiency virus (HIV) infection. Tenofovir, a common antiviral in HIV treatment, also leads to increases in bone catabolism markers and decreased BMD in children and young adults. In murine models and human cell lines, tenofovir diphosphate triphosphate (tenofovir) induces osteoclastogenesis and osteolysis. Adenosine and adenosine A2A receptor antagonists, such as dipyridamole, and increase cAMP, decrease osteoclastic concentration and osteolysis, so agents that increase adenosine concentration could counteract tenofovir osteotoxicity. We hypothesized that dipyridamole may be a useful treatment to counteract the deleterious effect of tenofovir. Tenofovir-induced osteoclastogenesis was evaluated in RAW264.7 cells and osteoclast precursors from bone marrow cells and quantified by TRAP staining. Dipyridamole was tested in combination with dipyridamole. Differentiation markers were studied by RT-PCR and MAPK/NFkB expression by Western blot. Male C57bl6 mice were treated as follows: saline 0.9% (control), tenofovir 75 mg/kg/day, dipyridamole 25 mg/kg/day, combination tenofovir+dipyridamole (n = 10, 4 weeks). Calcein-Alizarin Red double-labeling of newly formed bone was performed. Bone histomorphometry was done by computed tomography (µCT)/histology. Tenofovir produced a dose-dependent increase in osteoclast differentiation (EC_{50}) = 44.5nM) that was reversed by dipyridamole (IC_{50}) = 0.3 µM). Tenofovir increased cathepsin K and NFATc1 mRNA levels and dipyridamole reversed the effect. Dipyridamole reversed the effect of tenofovir on pERK1/2, pp38, and NFkB nuclear translocation. Mice treated with tenofovir lost nearly 10% of their body weight ($p < 0.001$). µCT revealed decreased BMD and altered trabecular bone in tenofovir-treated mice, reversed by dipyridamole. TRAP-staining showed increased osteoclast number and surface in tenofovir mice, which was reversed by dipyridamole. Histology revealed that tenofovir increased osteoid thickness and CTSK, RANKL expression and decreased osteoprotegerin, whereas osteoprotegerin-positive cells were decreased; both effects were reversed by dipyridamole. These results suggest that treatment with agents that increase local adenosine concentrations, like dipyridamole, might prevent bone loss following tenofovir treatment. © 2019 American Society for Bone and Mineral Research. Sexual safety and HIV prevention in travel medicine: Practical considerations and new approaches	Travel Medicine and Infectious Disease	-	-	-	-	14778939	10.1016/j.tmaid.2018.12.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059143274&doi=10.1016%2Fj.tmaid.2018.12.006&partnerID=40&md5=323ba666c33c7331993c1708bbe974f4	Travellers who engage in sexual contact with a new sexual partner abroad may be at high risk of HIV and other sexually transmitted infections (STIs), but these risks can be reduced through appropriate planning during the pre-travel clinic visit. Here we discuss strategies available to the clinician to maximize travellers' sexual safety during travel. Strategies may include immunizations, condoms, HIV pre-exposure prophylaxis (PrEP), HIV post-exposure prophylaxis (PEP), self-initiated treatment of symptomatic bacterial STIs, post-exposure prophylaxis for bacterial STIs and hormonal contraception. We discuss the role of these different strategies for travellers, and provide resources to assist clinicians in making clinical decisions and in educating travellers about sexual safety. © 2018 Elsevier Ltd	Anti-bacterial agents; HIV; Immunization; Post-exposure prophylaxis; Pre-exposure prophylaxis; Sexually transmitted diseases	English	Netherlands	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review

Article	2019	Cortopassi, Andrew C.; Driver, Redd; Eaton, Lisa A.; Kalichman, Seth C.	A New Era of HIV Risk: It's Not What You Know, It's Who You Know (and How Infectious)	Annual Review of Psychology	-	-	-	-	0066-4308	10.1146/annurev-psych-010418-102927	https://doi.org/10.1146/annurev-psych-010418-102927	HIV is transmitted in social and sexual relationships, and HIV transmission risks, as well as protective actions, are evolving as HIV epidemics unfold. The current focus of HIV prevention is centered on antiretroviral medications used to reduce HIV infectiousness in persons already infected with HIV treatment as prevention (TasP). The same medications used to treat infected persons can also be used by uninfected persons as pre-exposure prophylaxis (PrEP) to reduce the infectivity of HIV. Both PrEP and TasP are effective when adherence is high and individuals do not have co-occurring sexually transmitted infections. HIV prevention is most effective and efficient when delivered within sexual networks with high HIV prevalence. Specific network characteristics are recognized as important facilitators of HIV transmission; these characteristics include the degree of similarity among network members (homophily), gender role norms, and belief systems. Since 2011, HIV risk has been redefined based on infectiousness and infectivity, ushering in a new era of HIV prevention with the potential to end HIV epidemics. Theses and Dissertations	2019	Costa, Stéphanie Lyanie de Melo e	Risco, biomedicalização e AIDS: cobertura jornalística sobre métodos biomédicos de prevenção ao HIV	-	-	-	FIOCRUZ	-	-	NA	https://acervo.escea.usp.br/iscapia/public/consultaPublicaVisualizarDocumento.xhtml?cid=1&idDocumento=&jsessionid=&popup=true&id_trabalho=8255565	Nos sociedades contemporâneas, marcadas pela valorização da saúde e pela medicalização, a média tem exercido papel central na construção do discurso do risco e na ampliação à eventual adoção de medidas preventivas pelos sujeitos. Este tese analisa a cobertura nos jornais de O Globo e da Folha de S.Paulo acerca da circuncisão masculina, da PrEP (profilaxia pré-exposição ao HIV), da PEP (profilaxia pós-exposição ao HIV) e do TasP (tratamento como prevenção) como métodos preventivos ao HIV, desde o surgimento de cada um deles nos jornais até 31/12/2017. Empreendemos dois movimentos de análise. No primeiro, observamos, os jornalistas assinantes, as fontes mais ouvidas, os recursos gráficos mais utilizados, a quantidade de textos por método e sua distribuição no tempo, e tomamos medias dos espaços ocupados e a menção a outros métodos preventivos. Observamos somente para a PrEP, os editorias nas quais foi publicada, as chamadas de capa e a autoria dos textos opinativos. Em um segundo movimento de análise, sob o aporte da Análise do Discurso Francesa (Pêcheux e Orlandi), investigamos como a lógica do risco mantém-se na cobertura dos métodos preventivos. Nesse segundo momento, discutimos o papel conceito de risco nas explicações sobre a epidemia, na definição das populações mais vulneráveis e na atribuição de responsabilidades individuais e coletivas na assistência jornalística; fez mapear a biomedicalização do HIV/AIDS, compreendida como a ampliação do uso de tecnologias biomédicas para a prevenção e tratamento do HIV/AIDS, e a consequente normatização de sujeitos. A cobertura é motivada mais pelo ritmo das descobertas científicas e das ações das organizações internacionais e estatais ligadas à aids, em detrimento das ações locais, embora a atenção dos internacionais sociais, dos profissionais do serviço público de saúde e das pessoas comuns, e a despeito dos interesses de indústria farmacêutica. Ao ouvir mais os representantes do saber especializado, os jornais privilegiam os sentidos por das atribuídos ao risco e à aids. No cobertura JO Globo sobre a PrEP, o discurso do risco dá ao não pela retórica da ptínico e do medo, que marcou o tom do interesse no início da epidemia, mas por outras estratégias discursivas que incentem a responsabilidade individual pela saúde – e que, portanto, culpabilizam o sujeito pela contimidade da epidemia, sobretudo aquele que se enquadra nas —populações-chave‖, por vezes também ainda designadas de —grupos de risco‖. Essa responsabilização individual do se em nele ao contexto neoliberal e de capitalismo de consumo, no qual convivem restrições ao argumento público no enfrentamento à epidemia, ao lado do fomento a certo mercado, precipuamente de tecnologias biomédicas e farmacêuticas, que une o indivíduo responsável ao indivíduo consumidor – sobretudo de produtos que dialogam com seu gosto. Entretanto, também identificamos nO Globo discretos contra-hegemônicos, ligados à ideia de vulnerabilidade, que apontam para responsabilidades também coletivas no enfrentamento à epidemia e que questionam a excessiva biomedicalização do aids, ctmendo pelo fortalecimento a métodos biomédicos preventivos como —bala mágica‖ para solucionar esse problema de saúde pública, sem investimento em políticas que combatam as desigualdades e as intolerâncias sociais dele	HIV/AIDS,Jornalismo/Discurso/Biomedicalização/Análise de discurso/Prevenção	Portuguese	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	-	-	Qualitative

Article	2019	Coudray M.; Kiplagat S.; Sauereil F.; Madhivanan P.	Sexually transmitted infections among high-risk populations that use treatment as prevention or pre-exposure prophylaxis: A protocol for a systematic review	BMJ Open	-	-	-	-	20440055	10.1136/bmjopen-2019-032054	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076295773&doi=10.1136%2Fbmjopen-2019-032054&partnerID=40&md5=5bc9a2fe7623247c1e6f2ae0f029a	Background Among men who have sex with men, pre-exposure prophylaxis (PrEP) reduces the risk of HIV by 95%. Based on the documented benefits, the Centre for Disease Control and Prevention has recommended PrEP for all men who have sex with men. However, the uptake of PrEP remains low among this population. Therefore, this review aims to identify the factors that are associated with PrEP uptake and HIV. Methods and analysis This systematic review protocol was reported according to the Preferred Reporting Items for Systematic reviews and Analyses (PRISMA-P Statement). Medline (1980-present), EMBASE (1980-present), CINAHL (1980-present), Cochrane Central Register of Controlled Trials and clinicaltrials.gov will be used to identify relevant articles based on a piloted search strategy. Peer-reviewed observational and experimental studies will be included. A narrative style will be used to describe descriptive data. A meta-analysis will be conducted if heterogeneity is not significant. Ethics and dissemination Recent evidence suggests that there is an increased risk of sexually transmitted infections (STIs) among high-risk persons that use PrEP. Furthermore, there is a paucity of data on the relationship of treatment as prevention and incidence of STIs. The findings of this review will assess this emerging public health phenomenon and serve to inform future public health policy. No formal ethical review is required for this protocol. All findings will be published in a peer reviewed journal. PROTOCOL registration number CRD42019125720. © Author(s) (or their employer(s)) 2019. Re-use permitted under CC-BY-NC. No commercial re-use. HIV-1 genetic diversity re-estimate time of infection and infer adherence to preexposure prophylaxis	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002290	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075397614&doi=10.1097%2FQAD.0000000000002290&partnerID=40&md5=f2b15c61417c8a2562b9a0ea61f6d	Objective:To estimate time of HIV infection in participants from the Bangkok Tenofovir Study (BTS) with daily oral tenofovir disoproxil fumarate (TDF) for preexposure prophylaxis (PrEP) and infer infection with adherence patterns.Design:We used the density structure of the virus population at the first HIV DNA-positive sample to estimate the date of mapped these mutations to multicistron discrete obtained under daily DOT were then used to compute the number of missed TDF doses at the approximate date of infection.Results:Fifteen of the 17 PrEP breakthrough infections were successfully amplified. Of these, 13 were initiated by a single genetic variant and generated reliable estimates of time since infection (median = 47 IQR = 35 days). Eleven of these 13 were under daily DOT at the estimated time of infection. Analysis of medication diaries in these 11 participants showed 100% adherence in five, 90-95% adherence in two, 55% adherence in one, and nonadherence in three.Conclusion:We estimated time of infection in participants from BTS and found several infections when high levels of adherence to TDF were reported. Our results suggest that the biological efficacy of daily TDF against parenteral HIV exposure is not 100%. Copyright © 2019 Wolters Kluwer Health, Inc. All rights reserved. Article	2019	Coy K.C.; Hazen R.J.; Kirkham H.S.; Delpino A.; Siegler A.J.	Persistence on HIV preexposure prophylaxis medication over a 2-year period among a national sample of 7148 PrEP users, United States, 2015 to 2017	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25252	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062054436&doi=10.1002%2Fjia2.25252&partnerID=40&md5=29621a0a51f6e0f8aea95d2929259a18b	Introduction: Persistence on preexposure prophylaxis for HIV prevention (PrEP) medication has rarely been reported for periods greater than one year, or in real-world settings. This study used pharmacy fill data from a US PrEP demonstration project to estimate persistence on PrEP medication for up to two years and to identify factors associated with persistence.Methods: We analysed de-identified pharmacy fill records of 7148 eligible individuals who initiated PrEP in 2015 at a national chain pharmacy. A standard algorithm was employed to identify TDF-FTC use for PrEP indication. We considered three time periods for persistence, defined as maximising refills in PrEP-care: year 1 (zero to twelve months), year 2 (three to twenty-four months) and initiator to year 2 (zero to twenty-four months). Individuals with ≥ 80% mean days of TDF-FTC PrEP dispensed in a 1-month period for at least three-quarters of a given time period (nine of twenty-four months) were classified as persistent on PrEP medication for the period. Results: Persistence was 56% in year 1, 63% in year 2 and 41% from initiation to year 2. Individuals aged 18 to 24 had the lowest persistence, with 29% from initiation to year 2. Men had higher persistence than women, with 42% compared to 29% persistent from initiation to year 2. Individuals with commercial insurance and individuals who utilised a community-based specialty pharmacy from the national chain also had higher persistence. Male gender, age >18 to 24 years, average monthly copay of $20 or less, commercial insurance, and utilization of a community-based specialty pharmacy were positively associated in adjusted models with persistence in year 1 and from initiation to year 2; the same correlates, with the exception of utilization of a community-based specialty pharmacy, were associated with higher persistence in year 2. Conclusions: We found substantial non-persistence on PrEP medication in both year 1 and year 2. Our findings suggest that the use of a specialty pharmacy may support persistence on PrEP medication and that additional interventions are needed to support persistence among young adults. Our findings further explore how social, structural or individual factors may undermine or enhance persistence on PrEP, and to develop interventions to assist persistence on PrEP. © 2019 The Authors. Theses and Dissertations	2019	Cramer, Rodé; Johnson, Amber	Investigating Stigma as a Barrier to PrEP Adoption by Transgender Women of Color Who Engage in Sex Work	-	-	-	Chapman University	-	n/A	NA	https://www.proquest.com/dissertations-theses/investigating-stigma-as-barrier-prep-adoption/docview/2322186308/se-2?accountid=9113	Despite decreases in HIV rates overall, research indicates that transgender women of color continue to bear a disproportionate burden of HIV in the United States. One of the factors that can place transgender women at higher risk for HIV infection is sex work. In 2012 the FDA approved the medication Truvada for daily use as pre-exposure prophylaxis (PrEP) for the prevention of sexually acquired HIV infection in uninfected adults who engage in high risk behaviors. Truvada as PrEP would be an effective method for mitigating the risk of HIV infection among transgender women of color who engage in sex work. However, transgender women of color may be adopting PrEP at rates lower than other groups. Previous research suggests that a significant barrier to PrEP adoption may be stigma. This thesis aimed to investigate whether the low PrEP adoption rates among transgender women of color who engage in sex work may be related to experiences of social and structural level stigma. To this end, the Stigma-High-Risk Sex Scale was developed and tested with a sample of transgender women of color who engage in sex work. Interviews conducted with 12 transgender women of color in Southern California, half of whom have engaged in sex work. There were no significant differences among these individuals; stigma was not largely responsible for low PrEP adoption rates. Instead, the most common reason participants cited for not adopting Truvada as PrEP was insufficient information on the possible long-term health effects of this medication.	-	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Qualitative
Article	2019	Delbourgo M.; Pereyre S.; Pages M.; Bébéar C.; Douclaux A.; Hessamfar M.; Le Roy C.; Le Marrec F.; Dubo F.; Cazanave C.	High prevalence of Mycoplasma genitalium infection and macrolide resistance in patients enrolled in HIV pre-exposure prophylaxis program; Prévalence élevée d'infection à Mycoplasma genitalium et de résistance aux macrolides chez les usagers de la prophylaxie pré-exposition contre l'infection VIH	Médecine et Maladies Infectieuses	-	-	-	-	0399077X	10.1016/j.medmal.2019.03.007	https://doi.org/10.1016/j.medmal.2019.03.007	Objectives: Limited data on Mycoplasma genitalium infection has been reported among PrEP users. The aim of this study was to estimate the prevalence and macrolide resistance of M. genitalium infection among enrollees in a French PrEP program. Patients and methods: M. genitalium infection screening was systematically and prospectively proposed to patients of the Bordeaux PrEP program (between January 2016 and March 2017). We collected urogenital, anal and pharyngeal samples for M. genitalium-positive patients. Results: Among 89 clients, M. genitalium infection prevalence was 10% (usually asymptomatic). Macrolide resistance was found in 78% (7/9) of the M. genitalium-positive samples. Conclusion: In the context of macrolide resistance, a systematic search for M. genitalium macrolide resistance associated mutations may be recommended in PrEP users before initiating the antibiotic therapy. © 2019 Elsevier Masson SAS	Macrolides; Mycoplasma genitalium; Pre-exposure prophylaxis	English	France	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Clinical
Article	2019	Dehlin J.M.; Inzeme R.; Eavou R.; Pickett J.; Akin L.; Brewer R.; Schneider J.A.	The motivational prep cascade guides interpretation of early prep linkage to care for young black men who have sex with men: The case of chicago's peptlne	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2019.31.4.491	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076275956&doi=10.1521%2Faeap.2019.31.4.491&partnerID=40&md5=9975656c2afb90d53403560b720ac6f7	Pre-exposure prophylaxis (PrEP) uptake remains low among Black men who have sex with men (BMSM). PrEP Life!, launched in August 2015, based on Chicago, was developed to increase PrEP linkage among BMSM. PrEPLife uses movie clients through the Motivational PrEP Cascade, addresses barriers, and tracks outcomes. Study findings suggest that three variables (i.e., being gay/same gender loving, living more than 15 miles from a clinic location, rescheduling an appointment) demonstrated a significant positive associations with initiating PrEP. A subanalysis of BMSM found that two variables (i.e., living on the West Side of Chicago relative to those living on the South Side, and among those living in communities with a higher rate of poverty more than 30%, relative to those living in communities with a lower rate of poverty less than 20%) demonstrated a significant negative association with initiating PrEP. © 2019 The Guilford Press. Article	2019	Dehlin, Jessica M; Sidhwaney, Ryan; Pickett, Jim; Kome, Lance; Schneider, John A	#PrEPinLove: An Evaluation of a Sex-Positive HIV Prevention Campaign.	JMIR Public Health and Surveillance	-	-	-	-	2369-2960	10.2196/12822	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6691691/	BACKGROUND Pre-exposure prophylaxis (PrEP) is an effective but underutilized method for preventing HIV transmission in communities vulnerable to HIV. Public health campaigns aimed at increasing PrEP awareness and access have few evaluation data. OBJECTIVE The aim of this study was to evaluate Chicago's PrEP campaign, PrEP4Love (P4L), a campaign that uses health equity and sex-positivity approaches for information dissemination. METHODS P4L launched in February 2016 and remains an active campaign to date. The analysis period for this paper was from the launch date to February 2016 through May 15, 2016. Our analysis reviews the Web-based reach of the campaign through views on social media platforms (Facebook and Instagram), smart ads, or ads served to individuals across a variety of Web platforms based on their demographics and browsing history, and P4L website clicks. RESULTS. In total, 40,913,560 unique views were generated across various social media platforms. A total of 24,548 users clicked on P4L ads and 32,223,987 views were received from smart ads. The 3 most clicked on ads were STD Signs & Symptoms-More Information on STD Symptoms, HIV & AIDS Prevention, and HIV Prevention Medication. An additional 8,970,127 views were gained through Facebook and another 1,719,446 views through Instagram. There was an average of 182 clicks per day on the P4L website, with 1,000 clicks on May 15, 2016. The study results demonstrate a high reach of the campaign, with a high number of clicks on the P4L website, especially millions of individuals. More studies of PrEP social marketing are needed to evaluate the relationship of targeted public health campaigns on stigma and to guide future PrEP prevention implementation.	pre-exposure prophylaxis, public health, health equity, health promotion	English	Canada	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Densmeiuds, Nicklas; Ingemiansdotter Persson, Kristina; Thomson, Sarah; Forsberg, Birger C.	"You can smell the freedom": a qualitative study on perceptions and experiences of sex among Swedish men who have sex with men in Berlin.	BMJ Open	-	-	-	-	2044-6055	10.1136/bmjopen-2018-024039	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6576011/	PURPOSE The purpose of this study was to explore the perceptions and experiences of sex among Swedish Men who have Sex with Men (MSM) in Berlin. BACKGROUND. MSM are disproportionally affected by HIV. Berlin is also a key destination when looking into where Swedish MSM seek comfort, while travelling. METHOD. A qualitative study with semi-structured interviews using open-ended questions with participants recruited through network sampling. Data were analysed with content analysis. PARTICIPANTS. 15 Swedish citizens age in non-probability sample of 25-44 years, who travelled to or were living in Berlin. To be included in the study, the participants had to be cis-MSM, Swedish citizens, spending time in Berlin and having sex in both settings. RESULTS. For a majority of the participants, sex was the main reason for going to Berlin but cultural aspects like art and the techno scene were also important. Berlin was perceived as a sex-orientated city where respondents did not have to care about reputation and status and where social and sexual spaces co-existed side by side. This is sharp contrast to Sweden, which represented a limiting environment with regard to sex and sexuality. Participants described sex in Berlin as free, uncomplicated, exciting and sometimes dangerous, in contrast to sex in Sweden, described as boring and at home. However, the behaviour was amplified in Berlin. The sites did not show much HIV-prevalence, depending on if they had sex in Swedish or Berlin. The high mobility and vulnerability for HIV/sexually transmitted infection (STI) among these men highlights the need of increased access to antiretroviral treatment, pre-exposure prophylaxis for HIV and low-threshold HIV/STI testing services in Europe. Article	2019	Desrosiers A.; Levy M.; Dright A.; Zamer M.; Jalloh N.; Kue L; Magnus M.; Siegel M.	A Randomized Controlled Pilot Study of a Culturally-Tailored Counseling Intervention to Increase Uptake of HIV Pre-exposure Prophylaxis Among Young Black Men Who Have Sex with Men in Washington, DC	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2264-5	https://doi.org/10.1007/s10461-018-2264-5&partnerID=40&md5=527f6cd085a0913ef9d21f4c9c3bbe7	Daily emtricitabine/tenofovir is effective at preventing HIV acquisition and is approved for HIV pre-exposure prophylaxis (PrEP). Blacks in the United States have a disproportionately high rate of HIV, and uptake of PrEP has been very low in this population. We conducted a pilot study in a high-prevalence city to test whether a culturally-tailored counseling center for young Black men who have sex with men (YBMSM) could increase PrEP uptake. Participants were randomized to receive either a culturally-tailored counseling intervention or standard of care. Our primary outcome was uptake of PrEP prescription. At the end of 3 month study, participants in the intervention group compared with some in the control group had attained PrEP ($p = 0.02$). The pilot study demonstrates that a culturally-tailored counseling center might be an effective at increasing the uptake of PrEP in young BMSM. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Dettinger J.C.; Kinuthia J.; Pintye J.; Abuna F.; Begnel E.; Mugwanya K.; Sila J.; Lagat H.; Baeten J.M.; John-Stewart G.	Perinatal outcomes following maternal pre-exposure prophylaxis (PrEP) use during pregnancy: results from a large PrEP implementation program in Kenya	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25378	https://www.proquest.com/scholarly-journals/perinatal-outcomes-following-maternal-pre/docview/2269849371/se-2?accountid=9113	Introduction:The World Health Organization, while recommending pre-exposure prophylaxis (PrEP) for HIV-negative pregnant and postpartum women in HIV high-burden settings, advocates for continued safety evaluation of PrEP in this population. Methods: The PrEP Implementation in Young Women and Adolescents (PrIYA) program delivered PrEP to pregnant women integrated within routine maternal and child health clinics (MCH) at 16 sites in Western Kenya. PrEP exposure and perinatal outcome data were collected among women obtaining postnatal services during programme evaluation. PrEP use was self-reported and confirmed with clinical records. Perinatal outcomes including gestational age at birth, birthweight, congenital malformations and infant growth were abstracted from clinical records for mother-infant pairs attending the six week visit. Associations between infant outcomes and maternal prenatal PrEP use were assessed using univariate and multivariate logistic and linear regression models. The PrIYA evaluation identified 1536 postpartum mother-infant pairs with data on prenatal PrEP exposure; 208 with prenatal PrEP use, 1328 without. Median maternal age was 28 years in both groups. PrEP users (any reported PrEP use) were significantly more likely to report HIV risk factors such as: intimate partner violence, sexually transmitted infections and having a partner living with HIV. Median gestational age at birth was 38.9 weeks in PrEP users and 39.1 weeks in non-users (p = 0.03). PrEP users were 1.5 times more likely to deliver a baby with a gestational age at birth less 36.5 weeks in both groups. There were no major differences between PrEP-exposed and unexposed infants in rates of preterm birth and low birthweight. There were no congenital malformations identified in the PrEP-exposed group and five reported in the PrEP-unexposed group. At six weeks postpartum, infants in both groups had similar growth. No differences in infant outcomes were found by duration PrEP exposure, trimester of PrEP initiation, a subset analysis of women 15 to 24 years old or in multivariate analyses. The analysis demonstrates that monitoring of infant outcomes is feasible within large-scale programmatic implementation of PrEP among pregnant and postpartum populations. Conclusions: Pregnancy outcomes and early infant growth did not differ by PrEP exposure. © 2019 The Authors. Article	2019	Dettinger J.C.; Kinuthia J.; Pintye J.; Mwongkli N.; Gómez L.; Richardson B.A.; Bamuhiiz R.; Wagner A.D.; O'Malley G.; Baeten J.M.; John-Stewart G.	PrEP Implementation for Mothers in Antenatal Care (PrIMA): Study protocol of a cluster randomised trial	BMJ Open	-	-	-	-	2044-6055	10.1136/bmjopen-2018-025122	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062089684&doi=10.1136%2Fbmjopen-2018-025122&partnerID=40&md5=885e63aeed1fd03ec67c2b70763f8	Introduction Women in regions with high HIV prevalence are at high risk of HIV acquisition during pregnancy and postpartum, and acute maternal HIV contributes a substantial proportion of infant HIV infections. Pre-exposure prophylaxis (PrEP) could prevent HIV during pregnancy/postpartum; however, identifying women who would most benefit from PrEP in this period is challenging. Women may not perceive risk, may not know partner HIV status and partners may have external partners during this period. PrEP offer in pregnancy could be operational and scaled. Methods and analysis The PrEP Implementation for Mothers in Antenatal Care (PrIMA) study is a cluster randomised trial that aims to determine the best model for PrEP implementation in pregnancy, among women attending public sector antenatal clinics in Kisumu, Kenya. Eligible pregnant women ≥18 years, ≤28 weeks gestation, HIV-uninfected, without contraindication to PrEP, and perceived risk of HIV (self-report of not screening with partner self-test option (a CT-targeted test 10 clinics). Four thousand women will be enrolled and followed through 9-month postpartum. The primary analysis will be intention to treat. Outcomes will reflect the balance between HIV preventive effectiveness and avoiding unnecessary PrEP exposure to women at low risk and include: maternal HIV incidence, PrEP uptake, PrEP adherence, PrEP duration, and if appropriate PrEP use (among women with objective evidence of potential risk), infant birth outcomes, infant growth and partner self-testing uptake. To better understand the feasibility and acceptability of the provision of PrEP in these settings, qualitative interviews and cost-effectiveness analyses will be conducted. Ethics and dissemination The protocol was approved by the institutional review boards at Kenyatta National Hospital and the University of Washington. An external advisory panel monitors adverse and social harm events. Results will be disseminated through peer-reviewed journals, presentations at local and international conferences to national and *global policy* makers, community and participants. Article	2019	Doblecki-Lewis S.; Butts S.; Botero V.; Klose K.; Cardenas G.; Feaster D.	A Randomized Study of Passive versus Active PrEP Patient Navigation for a Heterogeneous Population at Risk for HIV in South Florida	Journal of the International Association of Physicians in AIDS Care	-	-	-	-	-	23259574	10.1177/2325957419848848	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066822710&doi=10.1177%2F2325957419848848&partnerID=40&md5=a8e5c0c0595e4296a20d6fcbd2ce	Effective approaches to promoting pre-exposure prophylaxis (PrEP) and linkage to PrEP care among those who may benefit from PrEP has proven to be a major challenge. We designed and pilot tested a strategic-based case management (SBCM) intervention for PrEP linkage. Adults interested in PrEP and meeting criteria (n = 61) were randomized to passive referral (control) or active SBCM (treatment). Outcomes measured were completion of provider visit, initiation of PrEP, and time to initiation of PrEP. Overall, 34% initiated PrEP by 12 weeks: 9 (29%) in the control group and 12 (40%) in the treatment group. The mean time to PrEP initiation was 13.1 weeks (95% confidence interval, 12.8-14.2) with no difference between groups (P = .382). There was a 21% difference in achieving a provider visit between the treatment and control groups (53.3% versus 32.3%) by 12 weeks (P = .096). Participants encountered financial, logistical, social, and provider-related barriers to PrEP access. Strengths-based case management–based patient navigation is a promising strategy for assisting PrEP seekers in obtaining a medical provider visit and initiating PrEP. © The Author(s) 2019.	access to care; HIV prevention; navigation; pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Dominguez Islas, Clara P; Brown, Elizabeth R	Crossover and Repeated Randomization in Event Driven Trials for HIV Prevention: Addressing the Impact of Heterogeneity in Risk in the Trial Design	Statistical Communications in Infectious Diseases	-	-	-	-	-	21944110	10.1515/scid-2019-0009	https://www.proquest.com/scholarly-journals/crossover-repeated-randomization-event-driven/docview/2271310012/se-2?accountid=9113	The availability of effective Pre-Exposure Prophylaxis (PrEP) for HIV introduces new challenges for testing novel on-demand, user-controlled HIV prevention products, including lower placebo arm incidence and increased between-participant variability in HIV risk. In this paper, we discuss how low HIV incidence may result in longer trials in which the variability in participants' risk may impact the estimates of risk reduction. We propose a design that addresses these challenges by allowing for repeated randomization of participants to different treatments over time, a crossover design. We propose a design that could target better the parameter of interest: the crossover and the re-randomization designs. We propose three different ways in which crossover and re-randomization of intervention assignments could be implemented in event-driven trials. We evaluate the performance of these designs through a simulation study, finding that they allow for better estimation and higher power than the traditional event-driven parallel arm design. We conclude by discussing future work, practical challenges and ethical considerations that need to be addressed to take these designs from theory to practice. Article	2019	Donnell, Deborah	Current and Future Challenges in Trial Design for Pre-Exposure Prophylaxis in HIV Prevention	Statistical Communications in Infectious Diseases	-	-	-	-	-	21944110	10.1515/scid-2019-0008	https://www.proquest.com/scholarly-journals/current-future-challenges-trial-design-pre/docview/2271310022/se-2?accountid=9113	Success in establishing efficacy of antiretroviral drugs to prevent acquisition of HIV infection has fundamentally changed the trial design considerations for future experimental drugs. Current trials of potential new antiretroviral agents for pre-exposure prophylaxis are using active control designs - where all trial participants receive an active antiretroviral drug. Current trials of other experimental approaches, such as vaginal microbicides and vaccines, are using placebo-controlled designs. Although ethically feasible, placebo-controlled designs are challenging because the placebo arm incidence is low and would anticipate very few infection events and not provide statistically robust evidence. A potential alternative is to conduct placebo-randomized trials limited to participants for whom current prevention tools are not acceptable. Article	2019	Donnelly J.A.; Deem T.T.; Duffy M.A.; Watkins A.K.; Al-Tayyib A.A.; Shodell D.J.; Theus M.; Rowan S.E.	Applying national estimates of adults with indications for pre-exposure prophylaxis to populations of men who have sex with men and people who inject drugs in colorado: Modelling study	JMIR Public Health and Surveillance	-	-	-	-	-	23692960	10.2196/11113	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057170900&doi=10.2196%2F11113&partnerID=40&md5=067864ba8a0c7c7b39f7c3213805b8a8	Background: Oral pre-exposure prophylaxis (PrEP) is a highly effective option for HIV prevention. To realize the full benefit of PrEP at the population level, uptake must reach those at the greatest risk of HIV acquisition. Guidance published by Centers for Disease Control and Prevention (CDC) suggests that the number of individuals with indications for PrEP is 1.1-1.2 million nationally based on survey data of key populations and local transmission patterns. We applied these estimates at state and county levels to determine the number of individuals who might benefit from PrEP locally and compared our estimates to CDC-published estimates for Colorado. Objective: This analysis aimed to produce estimates of key populations with indications for PrEP in Colorado as a whole and by county type. These estimates will be used for public health strategic planning for HIV prevention goals at the state and county jurisdictional levels. Methods: Colorado population estimates were obtained from the state demography office, which produces single-year-of-age estimates for each county. Data on men who have sex with men (MSM) and people who inject drugs (PWID) were obtained from the Behavioral Risk Factor Surveillance System surveys. We produced estimates of HIV-negative men who have sex with men (MSM) and people who inject drugs (PWID) in Colorado. These percentages were applied to the state and to each county by its rural-urban designation. Finally, CDC-derived percentages of MSM and PWID with indications for PrEP were applied to these estimates to determine numbers of MSM and PWID who may benefit from PrEP use. Results: In 2015, 2,232,648 adults aged 18-70 years were living in Colorado. By applying published estimates of percentages of men who had sex with other men in the past 12 months, we determined that 41,353-49,624 adult males could be considered sexually active MSM. We estimated that 9738-13,011 adults aged 18-59 years were likely to have injected drugs in the past 12 months. By accounting for numbers of people living with HIV in these categories and applying the CDC PrEP percentages of MSM and PWID with indications for PrEP nationally, we estimated that 8792-12,528 MSM and PWID in Colorado had indications for PrEP; this number is smaller than that estimated by CDC, although within the lower CI limit. Conclusions: By employing a simple framework consisting of census data, literature review, population estimates, and national estimates for PrEP indicators, we derived estimates for potential PrEP use in our state. Statewide estimates of key populations by state and county type will enable health officials to set informed goals and track progress toward optimizing PrEP uptake. This formula may be applicable to other states with similar epidemics and resources. © 2022 JMIR Cancer. All Rights Reserved. Editorial	2019	Döring N.	Medikamentöser HIV-Schutz mittels PrEP: Aktueller Diskussions- und Forschungsstand	Zeitschrift für Sexualforschung	-	-	-	-	-	9328114	10.1055/a-1023-6196	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076935224&doi=10.1055%2Fa-1023-6196&partnerID=40&md5=9b98857c5ff7e5e0f1ecab9032cecbeb	Seit September 2019 wird in Deutschland gemäß sexuell heute Terminservice- und Versorgungsgesetz (TSVG) der medikamentöse Schutz vor einer HIV-Infektion wie den gesetzlichen Krankenkassen übernommen. Technisch gesprochen geht es um die HIV-PrEP (Expositions-Prophylaxe (kurz: HIV-PrEP oder PrEP). Die HIV-PrEP bedeutet ein antiretrovirales Medikament oder eine Kombination von Medikamenten, die ein substanzielles HIV-Übertragungsrisiko haben. Wenn sie täglich die „Anti-HIV-Pille“ einnehmen, erreichen sie einen klinisch nachgewiesen sehr hohen HIV-Infektionsschutz von bis zu 99 %. [2] (DC 2019). Neben der dauerhaften bzw. täglichen Einnahme von PrEP gibt es auch eine anlassbezogene Einnahme möglich (Short-term PrEP, Event-driven PrEP, Episodic PrEP = Epi PrEP). Die anlassbezogene PrEP kann beispielsweise gerade für Partys, Festivals oder Reisen eingenommen werden, bei denen riskante Sexkontakte erwartet werden. Wer die verschreibungspflichtige PrEP einnimmt, muss alle drei Monate auf HIV, andere sexuell übertragbare Infektionen (Sexually Transmitted Infections: STIs und die Nierenfunktion untersucht werden. Eine gute medizinische Begleitung gehört zur PrEP also dazu.	sa	German	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Other
Article	2019	Döring N.; Walter R.; Knudsen K.	Media Representations of the HIV–PrEP Controversy: Empirical Findings on Press, Web and Social Media; Mediendarstellungen der HIV-PrEP: Inhaltsanalytische Befunde zu Presse, Web und Sozialen Medien	Zeitschrift für Sexualforschung	-	-	-	-	-	9328114	10.1055/a-1027-2806	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076891826&doi=10.1055%2Fa-1027-2806&partnerID=40&md5=3930187052e014a4b6f57557bbb87	Introduction Oral HIV pre-exposure prophylaxis (short: HIV-PrEP, PrEP) is a relatively new method of HIV prevention. It is a drug with which HIV-negative persons can protect themselves against HIV transmission, for example during condomless sex with an HIV-positive person. The development and introduction of the PrEP has been and continues to be accompanied by controversial professional and media debates. Previous studies have pointed to a predominantly negative framing of the PrEP in Anglo-American media reports. Objectives Against the background of framing theory it was the aim of this study to find out, if the PrEP debate in German-speaking countries is comparably negative. Methods Using the method of quantitative content analysis, 1,000 articles (N = 150 articles each from framing, argument in favor of and against PrEP (topic-specific PrEP sub-themes) as well as the PrEP target groups addressed. Methods Using mixed-methods content analysis, a sample of N = 150 press articles and N = 150 websites featuring the PrEP were examined with a codebook tested for reliability. In addition, PrEP-related content on YouTube, Facebook and Twitter was qualitatively explored. The study follows the Open Science approach it was pre-registered and all instruments, datasets and statistical analysis scripts are available on the server of the Open Science Foundation (https://osf.io/ab6ry/). Results It was found that the PrEP appears in a more positive frame of meaning in German-language media than in Anglo-American media. Compared to the press articles, the PrEP was presented more positively on the examined websites. A stigmatization of PrEP users as irresponsible took place twice as often in the press as on the web. In the web posts and on the web, the most often mentioned PrEP target group were men who have sex with men. German-language PrEP information in Social Media is sometimes extremely rare (e. g. on YouTube). Conclusion In order to advance the PrEP education of the general population, a more intensive and differentiated representations of the PrEP in old and new media is desirable. © 2020 American Society of Civil Engineers (ASCE). Article	2019	Doik D.; Barratt H.; Templeton D.J.; O'Connor C.C.; Gracey D.M.	Renal function and risk factors for renal disease for patients receiving HIV pre-exposure prophylaxis at an inner metropolitan health service	PLOS One	-	-	-	-	-	19326203	10.1371/journal.pone.0210106	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060158426&doi=10.1371%2Fjournal.pone.0210106&partnerID=40&md5=7510ae4a4ec367dfb5f9913f63e8bcf58	Background Pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate/emtricitabine (TDF/ FTC) significantly reduces the risk of HIV acquisition. TDF is a known nephrotoxin however, renal dysfunction from TDF is mostly reversible following discontinuation. Aims To describe the renal function, risk factors for renal disease and associated clinical/ testing practices in a cohort of PrEP patients. Methods A retrospective review was conducted of all PrEP patients commenced on TDF/FTC at an inner metropolitan sexual health clinic in Sydney, Australia between April 2016 and July 2017, with follow-up data obtained at 3-monthly intervals until 18 months. Results 525 patients were included in the analysis. Baseline eGFR was available for 525 patients (median 106 mL/min/1.73m2 [IQR 96-116]). Two patients had an estimated glomerular filtration rate (eGFR) <70 mL/min/1.73m 2 A small significant drop in eGFR of -2.5 mL/min/1.73m 2 per month (95%CI: -3.6 to -1.5; p<0.05) occurred between PrEP commencement and the first follow-up period, followed by a progressive decline in eGFR of -0.34 mL/min/1.73m 2 per month (95%CI: -0.57 to -0.20; p<0.001). Renal impairment (eGFR <70 mL/min/1.73m 2) occurred in 6.5% of patients and persisted across consecutive follow-up periods in five (1.0%) patients. Age (aOR 1.04, 95% CI 1.01-1.07; p=0.002) and baseline eGFR (aOR 0.95, 95% CI 0.93-0.97; p<0.001) were significant risk factors for renal impairment. Proximal tubulopathy was identified in two patients (0.4%) due to renal function concerns. Conclusion PrEP use led to an initial drop in eGFR and a more gradual progressive decline subsequently, but significant renal impairment remained uncommon up to 18 months of follow-up. © 2019 Doik et al. Essay	2019	Dubin S.	PrEP and the judgment of prevention	AMA Journal of Ethics	-	-	-	-	-	23760980	10.1001/amajethics.2019.536	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062143468&doi=10.1001%2Famajethics.2019.536&partnerID=40&md5=dfb1349f54c8ca9c8232350f6ad0e1e3	Medicine sometimes fails to address social, economic, and political determinants of health. But how far beyond clinical encounters should intervention efforts extend? Because prevention efforts can navigate patients by stigmatizing certain behaviors, interrogating the scope of medicine's prevention obligations is important. Additionally, it is important to distinguish clinician preferences regarding patients' personal behaviors (presumably based on clinicians' hopes for patients' positive health outcomes) from clinician biases expressed (consciously or unconsciously) about those behaviors. Illustrate the urgency of asking how far medicine should be expected to go to prevent disease by sharing how my own medical training has stoked my personal fear of acquiring HIV. Article	2019	Dubin S.; Gestodi W.C.; Park S.H.; Hambrick H.R.; Schneider J.A.; Duncan D.T.	Perceived Candidacy for Pre-exposure Prophylaxis (PrEP) Among Men Who Have Sex with Men in Paris, France	AIDS and Behavior	-	-	-	-	-	10907165	10.1007/s10461-018-2279-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053823736&doi=10.1007%2Fs10461-018-2279-y&partnerID=40&md5=df3e7b044c497ec75383b0b6f76b1b0	Low perception of HIV risk is a challenge to PrEP implementation. We analyzed association between perceptions of PrEP candidacy, behavioral indications for PrEP, and sexual behavior. We recruited a sample of 1,000 men who have sex with men (MSM) in Paris, France, in 2016 using time-location sampling. Participants completed questionnaires about perceived candidacy for PrEP and biobehavioral indications for PrEP, and relationships among engagement in group sex, transactional sex, HIV test history, and indications for PrEP. Adjusted risk ratios (aRR) and 95% confidence intervals (CIs) were calculated. For the outcome of perceived candidacy for PrEP, a multinomial logistic regression was performed, and adjusted relative risk ratios (aRRR) were calculated. Multivariate analyses were adjusted for socio-demographics. Respondents who considered themselves PrEP candidates were more likely to meet PrEP eligibility criteria compared to those who did not consider themselves candidates for PrEP (aRR 1.68, 95% CI 1.34–2.03). Those who had engaged in group or transactional sex were more likely to have behavioral indications for PrEP (aRR 1.27, 95% CI 1.07–1.50, aRR 1.32, 95% CI 1.13–1.56, respectively), whereas HIV test history was not significantly associated with behavioral indications for PrEP. Respondents who had engaged in group sex or transactional sex were more likely to perceive themselves as candidates for PrEP (aRRR 2.16, 95% CI 2.03–4.16, aRRR 2.58, 95% CI 1.09–6.13, respectively), although those never tested for HIV were less likely to perceive themselves as candidates for PrEP (aRRR 0.18, 95% CI 0.03–0.91). The elucidation of candidacy perceptions and risk behaviors is key to furthering the effective implementation of PrEP engagement interventions. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Dubov A.; Ogunbajo A.; Altice F.L.; Fraenkel L.	Optimizing access to PrEP based on MSM preferences: results of a discrete choice experiment	AIDS Care	-	-	-	-	-	9540121	10.1080/09540121.2018.1557590	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058815034&doi=10.1080%2F09540121.2018.1557590&partnerID=40&md5=a3e0566305872e1fa4a2702e7a41c012	Introduction: Despite documented effectiveness of pre-exposure prophylaxis (PrEP), PrEP uptake remains low among men who have sex with men (MSM), the population bearing the highest HIV burden in the US. This study aimed to identify preferences for PrEP delivery among MSM using a discrete choice experiment (DCE). Methods: Participants were recruited through Facebook and Craigslist mobile applications to complete a mixed preference choice-based conjoint (CBC) survey. Respondents completed 14 choice tasks presenting experimentally varied combinations of five attributes related to PrEP administration (dosing frequency, dispensing venue, prescription practices, adherence support, and costs). Latent class analysis was used to estimate the relative importance of each attribute and preference scores across possible PrEP delivery programs. Results: Preferences clustered into five groups. PrEP affordability was the most influential attribute across groups. Group 1 (n = 307) preferred the non-daily pill over daily and on-demand PrEP equally (n = 74) while the other four groups disliked the on-demand intermittent option. Monthly injectable PrEP is preferred by two (n = 210) out of the five groups, including young MSM. Two groups (n = 267) were willing to take PrEP across all the hypothetical programs. One group (n = 183) almost exclusively considered costs in their decision-making. Participants in the most racially diverse among groups (n = 88) had a very low level of interest in PrEP initiation. Conclusion: Our data suggest that PrEP uptake will be maximized by making daily PrEP affordable to MSM and developing PrEP formulation variants for young MSM. Young MSM should be prioritized for injectable PrEP when it becomes available. A successful PrEP program will spend resources on removing structural barriers to PrEP access and educating MSM of color, and will emphasize protection of privacy to maximize uptake among rural/suburban MSM. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	conjoint analysis; HIV/AIDS; implementation science; men who have sex with men; patient preferences; pre-exposure prophylaxis	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Quantitative

Individual-level characteristics, including sexual behaviors and socioeconomic status, do not fully account for racial/ethnic disparities in HIV among MSM. We hypothesize that neighborhood contexts and network characteristics influence risk for HIV infection as well as HIV-related prevention and care behaviors. As such, the study design includes the use of real-time geospatial methods and in-depth assessments of multiple network typologies to investigate the impact of neighborhood and network-level factors on HIV prevention and care outcomes among Black MSM. Methods/Design: We will enroll 600 Black MSM (200 each in Chicago, Illinois; New Orleans, Louisiana; and Durham, North Carolina) ages 18–39 (Chicago) or 18–44 (New Orleans and Durham) years old, who are HIV-negative or of unknown HIV status. Participants will complete (1) a baseline audio computer-assisted self-interview (ACASI) survey, (2) a social network ACASI survey, and (3) a 30-day geospatial assessment using ecological momentary assessment (EMA) methodology. We will also conduct in-depth interviews with a subset of participants ($n = 60$) to explore the meanings of PrEP stemming from its effectiveness for HIV prevention. Relevant content was represented as descriptive categories.Results/Discovery of HIV serodiscordance resulted in fear of HIV transmission for couples, which led to loss of sexual intimacy in committed relationships, and to abandonment of plans for children. As a result, partners became alienated from each other. PrEP countered the threat to the relationship by reducing fear and reinstating hopes of having children together. Condom use worked against the re-establishment of intimacy and closeness. By increasing couples' sense of protection against HIV infection, and raising the prospect of a return to "the way" sex without condoms), PrEP was perceived by couples as solving the problem of serodiscordance and preserving committed relationships.Conclusions:The most effective demand creation strategies for PrEP may be those that address the everyday life priorities of potential users in addition to HIV prevention.Clinical Trial NumberNCT02771929	HIV; Africa; Uganda; South Africa; Kenya; Pre-exposure prophylaxis; PrEP; prevention; Disease prevention; serodiscordant couples; Proxy Qualitative research; Interviews; Disease transmission; Studies; Infectious diseases; Couples; demand creation; East Africa; Human immunodeficiency virus - HIV; Sex industry; United States--US; Acquired immune deficiency syndrome--AIDS; Data collection; Medical Sciences; Initiatives	English	United States	Western and Central Europe and North America	Uganda	Eastern and Southern Africa	United States	Western and Central Europe and North America	Qualitative
Article	2019	Edith Nakiko Jolobe; Pisarski, Emily E; Wyatt, Monique A; Morovonge, Timothy R; Asiimwe, Stephen; Cohen, Connie L; Burton, Jared M; Kandiwa, Elly T; Ware, Norma C	Beyond HIV prevention: everyday life priorities and demand for Pr EP among Ugandan HIV serodiscordant couples	Journal of the International AIDS Society	-	-	-	-	-	1758-2652	10.1002/jia2.25225	https://www.proquest.com/scholarly-journals/beyond-hiv-prevention-everyday-life-priorities/docview/2290185081/se-2?accountid=9113	IntroductionPre-exposure prophylaxis (PrEP) to prevent HIV infection is being rolled out in Africa. The uptake of PrEP to date has varied across populations and locations. We seek to understand the drivers of demand for PrEP through analysis of qualitative data collected in conjunction with a PrEP demonstration project involving East African HIV serodiscordant couples. Our goal was to inform demand creation by understanding what PrEP means - beyond HIV prevention - for the lives of users.MethodsThe Partners Demonstration Project evaluated an integrated strategy of PrEP and antiretroviral therapy (ART) delivery in which home-based PrEP served as a "bridge" to long-term ART. Unenrolled partners in HIV serodiscordant couples were offered PrEP at home-based visits. Participants were followed for 48 weeks after partners had taken ART for six months. We conducted 274 open-ended interviews with 93 couples at two Ugandan research sites. Interviews took place one month (T1), three months (T2) and six months (T3) after PrEP initiation. Interviews were audio-recorded and transcribed. We used an inductive, content analysis approach to characterize meanings of PrEP stemming from its effectiveness for HIV prevention. Relevant content was represented as descriptive categories.ResultsDiscovery of HIV serodiscordance resulted in fear of HIV transmission for couples, which led to loss of sexual intimacy in committed relationships, and to abandonment of plans for children. As a result, partners became alienated from each other. PrEP countered the threat to the relationship by reducing fear and reinstating hopes of having children together. Condom use worked against the re-establishment of intimacy and closeness. By increasing couples' sense of protection against HIV infection, and raising the prospect of a return to "the way" sex without condoms), PrEP was perceived by couples as solving the problem of serodiscordance and preserving committed relationships.ConclusionsThe most effective demand creation strategies for PrEP may be those that address the everyday life priorities of potential users in addition to HIV prevention.Clinical Trial NumberNCT02771929	HIV; Africa; Uganda; South Africa; Kenya; Pre-exposure prophylaxis; PrEP; prevention; Disease prevention; serodiscordant couples; Proxy Qualitative research; Interviews; Disease transmission; Studies; Infectious diseases; Couples; demand creation; East Africa; Human immunodeficiency virus - HIV; Sex industry; United States--US; Acquired immune deficiency syndrome--AIDS; Data collection; Medical Sciences; Initiatives	English	United States	Western and Central Europe and North America	Uganda	Eastern and Southern Africa	United States	Western and Central Europe and North America	Qualitative
Article	2019	Efremova O.S.; Yurin O.G.	Pre-exposure prophylaxis of hiv infection	Infektsionnye Bolezni	-	-	-	-	-	17299225	10.20953/1729-9225-2019-1-72-76	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063617588&doi=10.20953%2F1729-9225-2019-1-72-76&partnerID=40&md5=ad24b67f344fc3a4734ae0d6a9363e3c	Pre-exposure prophylaxis of HIV infection (PREP) the world health organization (WHO) and the joint United Nations programme on HIV/AIDS (UN AIDS) are now seen as a promising undertaking whose widespread adoption, along with the Treatment as prevention strategy, should halt the HIV pandemic. The basis for the development of the prep methodand and the study of the effectiveness were data on the effectiveness and safety of actively used methods of prevention of mother-to-child transmission of HIV and post-exposure prevention of HIV infection. Closed and open randomized trials conducted in different regions of the world have shown the effectiveness of prep in groups of men who have sex with men (MSM), heterosexual men and women, and injecting drug users. Shows close relationship of the effectiveness of the PREP with the commitment of the participants in the study receiving need for prevention of drugs. Currently, the ORT is becoming more widespread, mainly among MSM in economically developed countries. In Russia, the introduction of the PREP is hampered by the lack of a regulatory framework for the treatment of HIV infection and related diseases approved by the Plenum of the Board of the National scientific society of infectious diseases on 16.08.2018. © 2019, Dynasty Publishing House. Article	2019	Eisinger, Robert W; Dieffenbach, Carl W; Fauci, Anthony S	Role of Implementation Science: Linking Fundamental Discovery Science and Innovation Science to Ending the HIV Epidemic at the Community Level.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	-	1944-7884	10.1097/QAI.0000000000002227	https://dx.doi.org/10.1097/QAI.0000000000002227	BACKGROUND During the past 4 decades, substantial progress has been made in the development of strategies for HIV prevention, treatment, and care resulting from observational science, discovery and innovation science, and implementation science. Building on these fundamental discoveries, innovation science has led to novel, safe, and effective modalities for HIV treatment and prevention, including combination antiretroviral therapy and treatment as prevention and pre-exposure prophylaxis, respectively. SETTING In the United States and globally, there remains a major challenge in the optimal implementation of the strategies that we already have in the areas of HIV prevention, diagnosis, treatment, and care. METHODS Implementation science will be essential to the successful achievement of ending the global HIV epidemic by translating evidence-based interventions, resulting from discovery and innovation science, into real-world practice. Strategies are needed that integrate and implement the biomedical tools currently available within the social and structural contexts and across all stages of the HIV prevention and care continuum. Several of the latest methodologies and analytical approaches that are being actively pursued, as well as the research challenges and opportunities to conducting implementation science in the context of both the global and domestic responses to HIV, are the focus of this special supplement to the Journal of AIDS. ©2019,LLWHO Knowledge resulting from implementation science will be critical to define and refine the approaches to successfully bring HIV prevention and treatment interventions to scale and achieve the goal of ending the HIV epidemic in the United States and worldwide.	sa	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2019	Elion R.A.; Kabiri M.; Mayer K.H.; Wohl D.A.; Cohen J.; Beaubrun A.C.; Altice F.L.	Estimated impact of targeted pre-exposure prophylaxis: Strategies for men who have sex with men in the United States	International Journal of Environmental Research and Public Health	-	-	-	16617827	10.3390/ijerph16091592	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065778695&doi=10.3390%2fijerph16091592&partnerID=40&md5=4a9ab54493b6f5ede3d178d951a8e56c	Pre-exposure prophylaxis (PrEP) effectively reduces human immunodeficiency virus (HIV) transmission. We aimed to estimate the impact of different PrEP prioritization strategies among Black and Latino men who have sex with men (MSM) in the United States, populations most disproportionately affected by HIV. We developed an agent-based simulation to model the HIV epidemic among MSM. Individuals were assigned an HIV incidence risk index (HIRI-MSM) based on their sexual behavior. Prioritization strategies included PrEP use for individuals with HIRI-MSM ≥10 among all MSM, all Black MSM, young (≤25 years) Black MSM, Latino MSM, and young Latino MSM. We estimated the number needed to treat (NNT) to prevent one HIV infection, reductions in prevalence and incidence, and subsequent infections in non-PrEP users avoided under these strategies over 5 years (2016–2020). Young Black MSM eligible for PrEP had the lowest NNT (NNT = 10) followed by all Black MSM (NNT = 33) and young Latino MSM (NNT = 35). All Latino MSM and all MSM had NNT values of 63 and 70, respectively. Secondary infection reduction with PrEP was the highest among young Latino MSM (53.2%) followed by young Black MSM (37.8%). Targeting all MSM had the greatest reduction in prevalence (14.7% versus 2.9%–3.9% in other strategies) and incidence (49.4% versus 9.4%–13.9% in other groups). Using data representative of the United States MSM population, we found that a strategy of universal PrEP use by MSM was most effective in reducing HIV prevalence and incidence of MSM. Targeted use of PrEP by Black and Latino MSM, however, especially those ≤25 years, had the greatest impact on HIV prevention. © 2019 by the authors. Licensee MDPI, Basel, Switzerland. Article	2019	Elliott T.; Sanders E.J.; Doherty M.; Ndung'u T.; Cohen M.; Patel P.; Cairns G.; Rutstein S.E.; Ananworanich J.; Brown C.; Fidler S.	Challenges of HIV diagnosis and management in the context of pre-exposure prophylaxis (PrEP), post-exposure prophylaxis (PEP), test and start and acute HIV infection: a scoping review	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25419	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076860891&doi=10.1002%2fjia2.25419&partnerID=40&md5=53dc22e621b38e41c8b6861eb85387bd	Introduction: Knowledge of HIV status relies on accurate HIV testing, and is the first step towards access to HIV treatment and prevention programmes. Globally, HIV-status unawareness represents a significant challenge for achieving zero new HIV infections and deaths. In order to enhance knowledge of HIV status, the World Health Organisation (WHO) recommends a testing strategy that includes the use of HIV-specific antibody point-of-care tests (POCT). These POCTs do not detect acute HIV infection, the stage of disease when viral load is highest but HIV antibodies are undetectable. Complicating things further, in the presence of antiretroviral therapy (ART) for pre-exposure prophylaxis (PrEP) or post-exposure prophylaxis (PEP), other currently available testing technologies, such as viral load detection for diagnosis of acute HIV infection, may yield false-negative results. In this scoping review, we evaluate the evidence and discuss alternative HIV testing algorithms that may mitigate diagnostic dilemmas in the setting of increased utilization of ART for immediate treatment and prevention of HIV infection. Discussion: Missed acute HIV infection prevents people living with HIV (PLHIV) from accessing early treatment, increases likelihood of onward transmission, and allows for inappropriate initiation or continuation of PrEP, which may result in HIV drug resistance. While immediate ART is recommended for all PLHIV, studies have shown that starting ART in the setting of acute HIV infection may result in a delayed or complete absence of development of HIV-specific antibodies, posing a diagnostic challenge that is particularly pertinent to resource-limited, high HIV burden settings where HIV-antibody POCTs are standard of care. Similarly, ART used as PrEP or PEP may supress HIV RNA viral load, complicating current HIV testing algorithms in resource-wealthy settings where viral detection is included. As rollout of PrEP continues, HIV testing algorithms may need to be modified. Conclusions: With increasing use of PrEP and ART in acute infection we anticipate diagnostic challenges using currently available HIV testing strategies. Research and surveillance are needed to determine the most appropriate assays and optimal testing algorithms that are accurate, affordable and sustainable. © 2019 The Authors. Article	2019	Ellison J.; Van Den Berg J.J.; Montgomery M.C.; Tao J.; Pashankar R.; Mimiaga M.J.; Chan P.A.	Next-generation HIV pre-exposure prophylaxis preferences among men who have sex with men taking daily oral pre-exposure prophylaxis	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2019.0093	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074445426&doi=10.1089%2fapc.2019.0093&partnerID=40&md5=4983a70c9225c792c2b9d9f47202d84e	Next-generation forms of HIV pre-exposure prophylaxis (PrEP) currently in development, including long-acting injectables (LAIs), rectal microbicides (RMs), antibody infusions (AIs), and subdermal implants (SIs), may address barriers to daily oral PrEP uptake and adherence. The purpose of this study was to evaluate barriers to oral PrEP, preferences for next-generation PrEP modalities, sociodemographic characteristics and sexual behaviors associated with preferences, and reasons for wanting or not wanting each formulation among a sample of men who have sex with men (MSM). We administered a cross-sectional survey to a diverse sample of MSM currently taking oral PrEP (n = 108) at two sexually transmitted disease clinics. We used logistic multivariate analyses to explore preferences, relative to oral PrEP, for each formulation across sociodemographic and sexual behaviors. The most commonly endorsed barriers were finding a PrEP provider and making appointments to get PrEP. Participants were most likely to prefer the SI (45%), followed by the LAI (31%), pill (21%), RM (1%), and AI (1%). Black/African American and Hispanic/Latino MSM were more likely to prefer the LAI over daily oral PrEP (odds ratio: 2.45, 95% confidence interval: 0.86-6.89), and sexual behaviors were most commonly associated with preference for the SI. Top reasons for wanting or not wanting each formulation were most commonly related to perceived ease of use. These findings demonstrate variations in preferences for next-generation PrEP modalities, highlighting a need to ensure comprehensive access to all formulations once they become available. © Copyright 2019, Mary Ann Liebert, Inc., publishers. Article	2019	Epps, Puja Van, MD; Wilson, Brigid M, PhD; Garner, Will, MD; Beste, Lauren A, MD; Maier, Marissa M, MD; Ohl, Michael E, MD	Incidence of HIV in a Nationwide Cohort Receiving Pre-exposure Prophylaxis for HIV Prevention: JAIDS	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000002186	https://www.proquest.com/scholarly-journals/incidence-hiv-nationwide-cohort-receiving-pre/docview/2319169847/se-2?accountid=8113	Background: Cases of HIV, while infrequent, have been reported during tenofovir disoproxil fumarate/emtricitabine use as pre-exposure prophylaxis (PrEP). We describe the incidence of HIV and patterns of PrEP use within the Veterans Health Administration (VHA). Methods: We conducted a retrospective cohort study among persons initiating PrEP in the VHA between July 2012 and April 2016 using national VHA data. We defined time on PrEP and time at risk of HIV exposure as the total time from the first PrEP fill to exhaustion of supply of the final PrEP prescription. We identified incident cases of HIV infection after PrEP initiation based on laboratory data. Medication adherence measures and days without pills were calculated using pharmacy fill data. We used a chart review to determine patient-reported PrEP use around the time of diagnosis. Results: We identified 825 unique patients initiating PrEP; they were 97% men and 67% white, with a mean age of 41 years. Six HIV infections were observed during the study period, yielding an HIV incidence of 0.8 (Poisson exact 95% confidence interval: 0.3 to 1.8) cases per 100 person-years. Two cases occurred during active PrEP use by self-report and perfect adherence based on fill data. Both were infected with viruses containing the M184V mutation. Four additional cases were diagnosed after self-reported discontinuation. Conclusions: HIV infection was rare in a nationwide cohort of PrEP users. Although most of the infections occurred during inconsistent PrEP use, infections during periods of high measured adherence were also observed. These findings highlight the importance of PrEP persistence during periods of risk. Article	2019	Escudero, Daniel Javier; Bennett, Brady; Suarez, Sarah; Darrow, William Ward; Mayer, Kenneth Hugh; Seage, George Richard 3rd	Progress and Challenges in "Getting to Zero" New HIV Infections in Miami, Florida.	Journal of the International Association of Physicians in AIDS Care	-	-	-	2325-9582 2325-9574	10.1177/2325958219852122	https://pubmed.ncbi.nlm.nih.gov/31131664/	OBJECTIVES: Miami has the highest rate of new HIV diagnoses in the United States. We examined the early successes and challenges in fulfilling recommendations made by the Miami-Dade County HIV/AIDS Getting to Zero Task Force, formed by local experts in 2016. METHODS: We used a host of surveillance data, published empirical studies, public reports, and unpublished data from partners of the Task Force to evaluate progress and challenges in meeting the recommendations. RESULTS: Improvements in prevention and care included routinized HIV testing in emergency departments, moving the linkage-to-care benchmark from 90 to 30 days, increased viral suppression, and awareness of pre-exposure prophylaxis. However, treatment enrollment, viral suppression, and pre-exposure prophylaxis uptake remained low. CONCLUSIONS: Recommendations from the Task Force provide excellent guidance for implementing evidence-based HIV prevention in Miami, yet success in achieving the recommendations will require continued or increased support in many public health sectors in South Florida. Theses and Dissertations	2019	Escudero, Jaclyn	Community perceptions about use of pre-exposure prophylaxis (PrEP) among adolescent girls and young women: A qualitative analysis	-	-	University of Washington	-	-	NA	https://digital.lib.washington.edu/researchworks/items/89283b04-9bb7-4db7-a9f7-86e2f766b8cf	Objectives: Adolescent girls and young women (AGYW) experience disproportionately higher rates of HIV acquisition compared to males of the same age, but PrEP uptake and continuation are low in this population. This study explored community perceptions around PrEP use among AGYW in Western Kenya. Design: Semi-structured in-depth focus group discussions (FGDs) were conducted with Community Advisory Board (CAB) members affiliated with two PrEP implementation projects targeting young women. Methods: FGDs were audio recorded, translated, and transcribed. Conventional content analysis and thematic networks analysis were used to identify themes relating to community perceptions of PrEP use among AGYW. Results: Four FGDs were conducted with 26 CAB members. Barriers to PrEP awareness among AGYW included lack of PrEP education in school HIV curriculum and failure of community leaders to sensitize and engage AGYW. Low uptake was thought to be associated with PrEP myths, and inaccurate understanding of who could benefit from PrEP and duration of use. AGYW may believe that PrEP is only for married/pregnant women or must be taken for life. PrEP use was viewed as unacceptable for AGYW in some communities because PrEP would increase "promiscuous" behavior, leading to decreased use of condoms and contraception, and increased STI incidence and pregnancy rates. Other barriers to uptake included confusion between PrEP and HIV treatment, lack of youth-friendly services at facilities, fear of HIV testing, and ease of access to condoms compared to PrEP. CAB members recommended integrating PrEP delivery into maternal and child health and family planning services, training community health volunteers to sensitize and deliver PrEP, and involving AGYW in policymaking as ways to improve access and uptake among AGYW. Conclusion: PrEP scale-up among AGYW will require community sensitization of AGYW to reduce stigma and clarify misperceptions. Article	2019	Ezennia, Ogochukwu; Geter, Angelica; Smith, Dawn K	The PrEP Care Continuum and Black Men Who Have Sex with Men: A Scoping Review of Published Data on Awareness, Uptake, Adherence, and Retention in PrEP Care	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02641-2	https://www.proquest.com/scholarly-journals/prep-care-continuum-black-men-who-have-sex-with/docview/2281579212/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) has demonstrated high efficacy to reduce HIV infections, however, racial/ethnic HIV disparities continue among black MSM. The purpose of this review was to assess available data to inform interventions to increase PrEP awareness, uptake, and adherence among black MSM. Of the 3024 studies retrieved, 36 met final inclusion criteria and were categorized into the PrEP care continuum: (1) awareness (n = 16), (2) uptake (n = 9), and (3) adherence (n = 12). Only 26 of the studies presented analytical findings by race/ethnicity. Key barrier themes included cost, HIV-related stigma, and fear of potential side effects. A key facilitator theme identified by black MSM included gaining PrEP awareness from social and sexual networks. There are significant gaps in research on black MSM and PrEP utilization, especially regarding PrEP uptake and adherence. These data are needed to inform interventions to address current inequities in PrEP services, to help improve care outcomes for black MSM. Article	2019	Facente, Shelley N; Busch, Michael P; Grebe, Eduard; Pilcher, Christopher D; Welte, Alex; Rice, Brian; Murphy, Gary	Challenges to the performance of current HIV diagnostic assays and the need for centralized specimen archives: a review of the Consortium for the Evaluation and Performance of HIV Incidence Assays (CEPHIA) repository.	Gates Open Research	-	-	-	2572-4754	10.12688/gatesopenres.13048.1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6706958	Background: New challenges for diagnosis of HIV infection abound, including the impact on key viral and immunological markers of HIV vaccine studies, pre-exposure prophylaxis usage and breakthrough infections, and very early initiation of anti-retroviral treatment. These challenges impact the performance of current diagnostic assays, and require suitable specimens for development and evaluation. In this article we review and describe an archive developed by the Consortium for the Evaluation and Performance of HIV Incidence Assays (CEPHIA), in order to identify the critical features required to create a centralized specimen archive to support these current and future developments. Review and Findings: We review and describe the CEPHIA repository, a large, consolidated repository comprised of over 31,000 highly-selected plasma samples and other body fluid specimen types, with over 50 purposely designed specimen panels distributed to 19 groups since 2012. The CEPHIA repository provided financial return on investment, supported the standardization of HIV incidence assays, and informed guidance and standards set by the World Health Organization and UNAIDS. Unified data from extensively characterized specimens has allowed this resource to support biomarker discovery, assay optimization, and development of new strategies for estimating duration of HIV infection. Critical features of a high-value repository include 1) extensively-characterized samples, 2) high-quality clinical background data, 3) multiple collaborations facilitating ongoing sample replenishment, and 4) sustained history of high-level specimen utilization. Conclusion: With strong governance and leadership, a large consolidated archive of samples from multiple studies provides investigators and assay developers with easy access to diverse samples designed to address challenges associated with HIV diagnosis, helping to enable improvements to HIV diagnostic assays and ultimately elimination of HIV. Its creation and ongoing utilization should compel funders, institutions and researchers to address and improve upon current approaches to sharing specimens.	na	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Review
Theses and Dissertations	2019	Fadane, Noluthando Precious Nomalungisa.	The role of community leaders in the effective implementation of oral pre-exposure prophylaxis in Vulindlela, KwaZulu-Natal.	-	-	University of KwaZulu-Natal	-	na	NA	https://researchspace.ukzn.ac.za/handle/10413/19159	Oral pre-exposure prophylaxis (PrEP) is a great stride in the HIV prevention field, particularly for the vulnerable populations including adolescent girls and young women (AGYW) aged 15-24 years who are the hardest hit group with high HIV infection rates due to structural and cultural factors. This study sought to investigate the role that community leaders, as key opinion leaders and gatekeepers, play in the effective implementation of oral PrEP. The SEMCHB was used as the theoretical framework that underpinned the study, further exploring Health Belief Model at individual level of the SEMCHB and CCA at community level of the framework. Purposive sampling was used to select the study participants. A total of 10 participants, 6 councillors and 4 traditional leaders in Vulindlela were sampled and interviewed through the use of in-depth interviews. The data collected through the interviews was analysed thematically, identifying key themes that emerged from the research. The main findings were around the knowledge of oral PrEP in the community, the perceived benefits and barriers of oral PrEP, and the extent to which community leaders were willing to support and promote the implementation of oral PrEP for young women in the community. These findings support the need to empower community leaders with knowledge about oral PrEP so they can play an effective role in the implementation of oral PrEP. Article	2019	Faria, Maria J; Machado, Raul; Ribeiro, Artur; Gonçalves, Hugo; Real Oliveira, Maria Elisabete C D; Viseu, Teresa; das Neves, José; Lúcio, Marlene	Rational Development of Liposomal Hydrogels: A Strategy for Topical Vaginal Antiretroviral Drug Delivery in the Context of HIV Prevention.	Pharmaceutics	-	-	-	1999-4923	10.3390/pharmaceutics11090485	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6781289	HIV/AIDS stands as a global burden, and vaginal microbicides constitute a promising strategy for topical pre-exposure prophylaxis. Preceding the development of a microbicide containing tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC), in silico and in vitro studies were performed to evaluate the physicochemical characteristics of both drugs, and to study their biophysical impact in lipid model systems. Results from these pre-formulation studies defined hydrogels as adequate vehicles to incorporate TDF-loaded liposomes and FTC. After studying interactions with mucin, zwitterionic liposomes with a mean diameter of 134 ± 13 nm, an encapsulation TDF efficiency of approximately 84%, and a transition temperature of 41 °C were selected. The chosen liposomal formulation was non-cytotoxic to HEC-1-A and CaSki cells, and was able to favor TDF permeation across polysulfone membranes (Jss = 9.9 µg·cm-2·h-1). After the incorporation of TDF-loaded liposomes and FTC in carbomer hydrogels, the drug release profile was sustained over time, reaching around 60% for both drugs within 3-6 h, and best fitting the Weibull model. Moreover, liposomal hydrogels featured pseudoplastic profiles that were deemed suitable for topical application. Overall, the proposed liposomal hydrogels may constitute a promising formulation for the vaginal co-delivery of TDF/FTC.	drug release, emtricitabine, hydrogels, liposomes, microbicides, nanomedicine, tenofovir disoproxil fumarate, topical PrEP	English	Switzerland	Western and Central Europe and North America	Portugal	Western and Central Europe and North America	portugal	Western and Central Europe and North America	Clinical
Article	2019	Farmer, Eric K; Koren, David E; Cha, Agnes; Grossman, Katlyn; Cates, Drew W	The Pharmacist's Expanding Role in HIV Pre-Exposure Prophylaxis	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0294	https://www.proquest.com/scholarly-journals/pharmacists-expanding-role-hiv-pre-exposure/docview/2231829865/se-2?accountid=8113	The efficacy of pre-exposure prophylaxis (PrEP) to prevent HIV has been firmly established; however, the success of PrEP largely depends on access to care as well as high levels of medication adherence. One of the key areas of focus for the National HIV/AIDS Strategy for 2020 in the United States calls for full access to comprehensive PrEP services where appropriate and desired, with support for medication adherence. Despite advances and advocacy for PrEP since approval for adults in 2012, large rates of prescribing disparity exist among gender and race/ethnicity. In 2016, only 3.7% of all PrEP users were women and only 11.2% were black. As one of the most widely accessible health care resources, pharmacists are well positioned to improve patient understanding, promote medication adherence, provide key risk reduction counseling, and enhance PrEP efficacy. Pharmacists' knowledge and accessibility in nearly every urban and rural community can be leveraged as part of a comprehensive HIV prevention strategy to expand access to care and improve population health. As trusted health care professionals, pharmacists develop a strong rapport with patients and may be the key to address current disparities in PrEP prescribing patterns as well as serve as an essential liaison between patients and other members of the multi-disciplinary care team. The purpose of this review is to summarize available data on pharmacist involvement in various models of care providing PrEP services and to identify opportunities to maximize and expand the role of the pharmacist to improve access to PrEP. Article	2019	Farthing H.; Rodriguez A.; Armstrong M.; Iyengar S.; Nigh E.; Potter J.; Doblecki-Lewis S.	Discomfort discussing HIV/AIDS and lack of awareness are barriers to partner-to-partner pre-exposure prophylaxis education	International journal of STD & AIDS	-	-	-	9564624	10.1177/0956462418799174	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060147967&doi=10.1177%2f0956462418799174&partnerID=40&md5=89bb2a70f1a6709d9aa45b440e854e33	We suggest that people living with HIV (PLWH) may serve as pre-exposure prophylaxis (PrEP) educators for partners when informed about PrEP. Participants in this study were a convenience sample of PLWH at a public hospital in Miami. A cross-sectional survey assessed the frequency of serostatus disclosure, PrEP awareness, and willingness to recommend PrEP to intimate partners. To evaluate stigma surrounding human immunodeficiency virus (HIV), comfort discussing HIV with family, friends and intimate partners was interrogated. Surveys were completed by 137 participants; 39.5% had potentially sero-discordant sexual partners. Among respondents, 29.2% reported that they 'occasionally' or 'never' disclose HIV status to sexual partners. In all, 66.4% of patients reported that they had never heard of PrEP. After being educated about PrEP, 86.0% of respondents reported that they would encourage partners to use it. Participants were asked how often the subject of HIV comes up in conversations. Most indicated that 'rarely' or 'never' does it come up with friends and family; 46.1% indicated that 'never' or 'rarely' does it come up with partners. In bivariate analyses, participants with prior awareness of PrEP were more likely to indicate higher frequency of conversations regarding HIV with intimate partners. It is concluded that interventions which utilize partner education to increase PrEP uptake should address stigma and knowledge among other barriers. © The Author(s) 2018. Article	2019	Fearon E.; Phillips A.; Mtetwa S.; Chabata S.T.; Mushati P.; Cambiano V.; Busza J.; Napierala S.; Hensen B.; Baral S.; Weir S.S.; Rice B.; Cowan F.M.; Hargreaves J.R.	How Can Programs Better Support Female Sex Workers to Avoid HIV Infection in Zimbabwe? A Prevention Cascade Analysis	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001980	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064721738&doi=10.1097%2fQAI.0000000000001980&partnerID=40&md5=c8cee622fc68903c11ad2ab6ee24bbe6	Background:"HIV prevention cascades" have been proposed to support programs by identifying gaps in demand for, access to, and capability to adhere to HIV prevention tools, but there are few empirical examples to guide development. We apply a prevention cascade framework to examine prevention coverage and factors associated with condoms and/or PrEP adherence among female sex workers.Setting:Seven sites across Zimbabwe.Methods:Seven respondent-driven sampling surveys from the intervention sites of a pragmatic cluster-randomized trial in Zimbabwe in 2016 were analyzed, and 611/1439 women testing HIV-negative included. We operationalized key components of an HIV prevention cascade including demand, supply, and capability to adhere to 2 tools for HIV prevention: condoms and pre-exposure prophylaxis (PrEP). We used adjusted logistic regression to identify determinants of adherence to condoms and PrEP in turn, examining the effect of adherence to one tool on adherence to the other.Results:There were 343/611, 54.7%, women reporting adherence to condoms and/or PrEP, leaving almost half uncovered. Although women were aware that condoms prevented HIV and reported good access to them, only 45·5% reported full adherence to condom use. For PrEP, a new technology, there were gaps along all 3 domains of demand, supply, and adherence. Alcohol use decreased adherence to PrEP and condoms. Younger and newer entrants to sex work were less likely to take PrEP every day.Conclusions:HIV prevention programming among female sex workers in Zimbabwe could consider increasing awareness of PrEP alongside supply, alcohol use interventions, and approaches to engaging younger women. Article	2019	Feng, Hwa-Ping; Guo, Zifang; Fandozzi, Christine; Panebianco, Deborah; Caro, Luzelena; Wolford, Dennis; Dreyer, Daniel P.; Valesky, Robert; Martinho, Monika; Rizk, Matthew L.; Iwamoto, Marian; Yeh, Wendy W.	Pharmacokinetic Interactions Between the Fixed-Dose Combinations of Elvitegravir/Cobicistat/Tenofovir Disoproxil Fumarate/Emtricitabine and Elbasvir/Grazoprevir in Healthy Adult Participants.	Clinical Pharmacology in Drug Development	-	-	-	2160-7648 2160-763X	10.1002/cpdd.702	https://pubmed.ncbi.nlm.nih.gov/31173673/	Treatment of individuals coinfected with human immunodeficiency virus (HIV) and hepatitis C virus (HCV) requires careful consideration of potential drug-drug interactions. The pharmacokinetic interaction of the HCV fixed-dose combination treatment of elbasvir/grazoprevir (EBR/GZR) when coadministered with the fixed-dose combination HIV treatment of elvitegravir/cobicistat/tenofovir disoproxil fumarate/emtricitabine (EVG/COB/TDF/FTC) was evaluated in 22 healthy adults. In period 1, oral doses of EVG/COB/TDF/FTC (150 mg/150 mg/300 mg/200 mg) were administered once daily for 7 days. In period 2, oral doses of EBR/GZR (50 mg/100 mg) were administered once daily for 10 days. In period 3, oral doses of EVG/COB/TDF/FTC were coadministered with EBR/GZR once daily for 10 days. The pharmacokinetics of EVG/COB/TDF/FTC were not clinically meaningfully altered by concomitant EBR/GZR administration. Geometric mean ratios (90%CIs) for area under the plasma concentration-time curve from time 0 to 24 hours (AUC(0-24)) in the presence/absence of EBR/GZR were 1.1 (1.0, 1.2) for elvitegravir; 1.1 (1.0, 1.1) for emtricitabine; 1.2 (1.1, 1.2) for tenofovir; and 1.5 (1.4, 1.6) for cobicistat. In comparison, the AUC(0-24) of elbasvir was ~2 times higher and the AUC(0-24) of grazoprevir was ~5 times higher following concomitant administration of EVG/COB/TDF/FTC and EBR/GZR. Geometric mean ratios (90%CI) for AUC(0-24) in the presence/absence of EVG/COB/TDF/FTC were 2.2 (2.0, 2.4) for elbasvir and 5.4 (4.5, 6.4) for grazoprevir. Coadministration of EVG/COB/TDF/FTC and EBR/GZR was generally well tolerated in healthy adults in this study. Nevertheless, because of the increased GZR exposure that occurs with coadministration of EVG/COB/TDF/FTC and EBR/GZR, coadministration of this combination is not recommended in those coinfected with HIV and HCV. Theses and Dissertations	2019	FERRARI, FELIPE CAVALCANTI	Perseguindo uma inovadora promessa em tempos de retrocessos: o debate público sobre HIV/AIDS em Porto Alegre e a emergência da Profilaxia Pré-Exposição (PREP)	-	-	UFJF	-	-	NA	NA	Esta dissertação tem por objetivo explorar a emergência da Profilaxia Pré-Exposição (PrEP), enquanto uma importante "inovação" biomédica no campo da prevenção ao HIV/AIDS, considerando a proeminência de um debate público mais amplo sobre a epidemia na cidade de Porto Alegre. Tal "inovação" biomédica recentemente foi incorporada ao Sistema Único de Saúde (SUS) do Brasil. Parte-se de discussões acerca do processo de biomedicalização da resposta à epidemia e da presença de movimentos sociais na constituição do que chamo de um debate público, entendido como parte integrante das políticas de produção do conhecimento que cercam o HIV/AIDS. Nesse sentido, procura-se reconhecer e explorar diferentes temporalidades associadas a um momento em que se manifesta a consolidação de importantes promessas no campo, ao mesmo tempo em que são notados retrocessos marcantes na política nacional de resposta à epidemia. Explorando essas temporalidades, a presente investigação procura evidenciar performances específicas da promessa carregada pela PrEP e como esta promessa participa desse debate público. A etnografia foi realizada se valendo de diferentes abordagens teórico-metodológicas, incindindo em técnicas como a análise documental, a observação participante e o recurso a entrevistas semi-estruturadas. Foram analisados documentos relativos ao processo de incorporação da PrEP pela via da Comissão Nacional de Incorporação de Tecnologias no SUS (Conitec), além de reportagens, artigos científicos e outras publicações que pudessem ser úteis para uma descrição do processo de incorporação da tecnologia de prevenção. São descritos eventos marcantes que ocorreram na cidade de Porto Alegre, a fim de evidenciar quais são os termos do debate público sobre HIV/AIDS, num momento em que a PrEP começa a se consolidar enquanto política pública no sistema de saúde. Nota-se a partir das entrevistas realizadas com voluntários do Grupo de Apoio à Prevenção da AIDS do Rio Grande do Sul (GAPA-RS) e de um comitê que assessora um ensaio clínico internacional envolvendo a PrEP em Porto Alegre, os sentidos que ganham a prevenção ao HIV/AIDS e a intervenção biomédica em meio a esse debate público, por parte da histórica participação dos movimentos sociais na resposta à epidemia. Article	2019	Ferreira, Ana Cristina Garcia; Coelho, Lara Esteves; Jalil, Emilia Moreira; Luz, Paula Mendes; Friedman, Ruth K; Guimarães, Maria Regina C; Moreira, Rodrigo C; Eksterman, Leonardo F; Cardoso, Sandra Wagner; Castro, Cristiane V; Derrico, Monica; Moreira, Ronaldo I; Fernandes, Biancka; Monteiro, Laylla; Kamel, Luciana; Pacheco, Antonio G; Veloso, Valdilea G; Grinsztejn, Beatriz	Transcendendo: A Cohort Study of HIV-Infected and Uninfected Transgender Women in Rio de Janeiro, Brazil.	Transgender Health	-	-	-	2688-4887	10.1089/trgh.2018.0063	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6455979	Purpose: Worldwide, the burden of adverse health conditions is substantial among travestis and transgender women (trans women). Transcendendo, the first trans-specific cohort in a low- or middle-income country, is an open cohort established in August 2015 to longitudinally evaluate the health aspects of trans women aged ≥18 years in Rio de Janeiro, Brazil. Methods: Study visits occur on an annual basis. Data on sociodemographics, behavioral, gender transition, affirmation procedures, hormone use, discrimination, violence, clinical and mental health, HIV prevention, and care (for those HIV-infected) are collected. Physical examination, anthropometric measurements, and laboratory tests are performed. Results: As of July 2017, 322 trans women were enrolled in the cohort with a median age of 31.5 years (interquartile range 25.7-39.5), of whom 174 (54%) were HIV-infected. The Transcendendo baseline information reinforces the scenario of marginalization and deprivation surrounding trans women. Most participants had low income (62.0% were living with below US$ 10.00/day), showed a very high engagement in sex work (78.6%), and reported increased occurrence of sexual (46.3%) and physical (54.0%) violence. Pre-exposure prophylaxis (PReP) was used by 18.8% of the HIV-uninfected trans women, only through research participation. Positive screening for depression (57.8%) and problematic use of tobacco (56.6%), cannabis (28.9%), cocaine (23.8%), and alcohol (21.5%) were high. Almost all participants (94.8%) reported hormone use at some point, mostly without medical supervision (78.7%). Conclusion: Our results describe a context of exclusion experienced by trans women, exposing vulnerabilities of this population in a middle-income country, with poor access to trans-specific care, HIV prevention and care, and mental health care. Addressing transgender experiences and needs can help the development of strategies to diminish stigma, improve health care environment, guide future research on trans morbidities, substance use, and trans-specific interventions to support health-related recommendations. Ultimately, it contributes to close the gaps concerning transgender health and reinforces that trans care cannot be disentangled from the social environment that surrounds trans women.	cohort, HIV, transgender health, transgender person, transgender woman	English	United States	Western and Central Europe and North America	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Clinical
Article	2019	Fina L.; Phillips A.L.; Jones A.T.; Couzens Z.M.; Drayton R.; Thomas D.R.; Shankar A.G.	Early experience of implementing a national HIV pre-exposure prophylaxis service in Wales, United Kingdom 2017	Sexual Health	-	-	-	14485028	10.1071/SH18091	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057760216&doi=10.1071%2fSH18091&partnerID=40&md5=ee9cc0ce88c243d4bfe84453ae395836	Background: Pre-exposure prophylaxis (PrEP) was introduced in Sexual Health Services of the Welsh National Health Service (NHS Wales) in July 2017 as a 3-year pilot service. Methods: Data were collected through the pre-existing Sexual Health in Wales Surveillance System, to which codes were added to capture PrEP eligibility, outcome of offer of PrEP, reasons for declining and adherence. Eligibility categories were defined based on nationally agreed criteria: men who have sex with men (MSM) and transgender people at high risk of HIV acquisition partners of HIV-positive individuals not known to be virally suppressed and heterosexuals reporting condomless intercourse with a HIV-positive individual not known to be virally suppressed. Results: During the first 6 months, 516 people were eligible, 96% of which were MSM. Overall, 57% of those eligible (296/516) started PrEP. Reasons for declining PrEP were given by 88 (56%) of 157 people 50 (57%) of whom did not believe themselves to be at risk. Of the available adherence assessments, 89% considered that all risk episodes had been covered. Persistence at 3 months was assessed for 141 people, of which 93 (66%) were still using PrEP. There were no HIV diagnoses in people taking PrEP during the first 6 months. Twenty-nine people were diagnosed with 37 episodes of sexually transmissible infections (STIs) while on PrEP. STI incidence was 105.7 per 100 person-years. Conclusions: The early trend indicates that implementation of PrEP is progressing as planned, and the service has been utilised by clients. This analysis can help refine implementation, inform planning and research around uptake, use and effect in Wales and internationally. © 2019 CSIRO.	adherence; antiretrovirals; MSM; PrEP; STIs	English	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative

Changes in HIV preexposure prophylaxis awareness and use among men who have sex with men — 20 urban areas, 2014 and 2017	MMWR Recommendations and Reports	-	-	-	1492195	10.15585/MMWR.MM6827A1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069796315&doi=10.15585%2fMMWR.MM6827A1&partnerID=40&md5=6e061a1d88eb2138107064 6ed706c0fb	What is already known about this topic? Men who have sex with men (MSM) can reduce their risk for human immunodeficiency virus (HIV) infection by using preexposure prophylaxis (PrEP) consistently. Increasing PrEP use is a principal strategy of the Ending the HIV Epidemic initiative. What is added by this report? From 2014 to 2017, PrEP awareness among MSM in 20 urban areas increased from 60% to 90%, and PrEP use increased from 6% to 35%. PrEP use increased in almost all demographic subgroups but remains lower among black and Hispanic MSM. What are the implications for public health practice? By routinely testing patients for HIV, assessing HIV-negative patients for risk behaviors, and prescribing PrEP as needed, health care providers can play a critical role in ending the HIV epidemic. © 2019 Department of Health and Human Services. Theses and Dissertations	2019	Flores, Nicholas	PrEParing and Producing the Queer Medical Subject: An Ethnographic Account of Race, Ethnicity, Gender, Sexuality, and Class in Columbus, Ohio in the Time of Pre-Exposure Prophylaxis (PrEP)	-	-	The Ohio State University / OhioLINK	-	na	NA	http://rave.ohiolink.edu/etdc/view?acc_num=osu155715931433105	This dissertation examines the proliferation of the HIV pharmaceutical drug, Truvada, as an oral chemo pre-exposure prophylaxis, referred to as PrEP in central Ohio. I trace the social and cultural effects of PrEP on individuals and communities whose risks of HIV transmission are particularly elevated and cited in public health and medical literatures. My aim is to show how the distribution of PrEP in central Ohio elucidates meaning-making practices among key actors, stakeholders, structures, and institutional forces that claim efficacy of the drug through ethnic, racial, sexual, and class informed logics regarding the science and technology of PrEP. The objective of this project is to gain insight into how PrEP comes to matter as it moves from pharmaceutical laboratories, clinical sites, community-based organizations, and, finally, into a broader public sphere surrounding HIV/AIDS discourses and practices. As an ethnographer, I employ an interdisciplinary and collaborative research approach that draws from cultural and medical anthropology, literature on sex and sexuality, and critical literatures on race and ethnicity in the United States. I draw on ethnographic, discursive, and historical analysis to address the nature of minority communities' responses to PrEP by examining three independent yet interrelated moving parts: local community-based medical clinics and pharmacies, individual level knowledge and practices, and the broader HIV/AIDS context in the United States. I conducted sixteen months of ethnographic fieldwork and worked directly with medical providers, pharmacists, PrEP advocates, and minority populations to better understand the uptake and significance of PrEP in a local setting. I argue for expanded conceptualizations of structural racism and justice within the medical field in the United States, one oriented toward health equity, structural competency, and social and racial justice. My research expands upon how we think about social markers of difference in relationship to medical knowledge and practice. My research also highlights how medical mistrust, racism, shame, and stigma around sex practices continue to persist that affect medical encounters and PrEP use. The dissertation elucidates the material, political, and affective work that HIV prevention technologies are made to do in relation to our social and cultural contexts emerging out of contested histories of racialization and sexualization. While this dissertation is interested in PrEP's proliferation and the reconfiguration of what types of intimacy, pleasure, and affective registers are made available, it is equally invested in how these differential relationships are enacted in HIV prevention work. My project demonstrates that an understanding of HIV prevention must engage multiple convergences and how meanings are produced through the interaction of various phenomena, which include specific biomedical interventions like PrEP, as well as figurations of knowledge production found in multi-media campaigns, clinical practices, educational presentations about PrEP, and the bodies for whom the drug is intended. Each component and entity operates differently and creates their own space, as well as produce values to the practices, networks, and actors that are linked through racialization and sexualization.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Qualitative
Article	2019	Footer K.H.A.; Lim S.; Rael C.T.; Greene G.J.; Carballa-Diéguez A.; Giguere R.; Martinez M.; Bockting W.; D'Aquila R.; Sherman S.G.	Exploring new and existing PrEP modalities among female sex workers and women who inject drugs in a U.S. city	AIDS Care	-	-	-	9540121	10.1080/09540121.2019.1587352	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062439711&doi=10.1080%2f09540121.2019.1587352&partnerID=40&md5=d14f1bb5a2e83be4f67177 8af75edfe2	To address a shortage in research on Pre-Exposure Prophylaxis (PrEP) amongst women at high risk of HIV acquisition, this study explored the attitudes and preferences of female sex workers (FSW) (n = 15) and women who inject drugs (WWID) (n = 16) to existing (e.g., pill) and new (e.g., injection, implant) PrEP modalities, in Baltimore, Maryland, U.S.A. This study reports on seven focus groups conducted between December 2016 and April 2017 and aims to provide new insights into FSW and WWID attitudes and preferences towards three different PrEP delivery methods (i.e., PrEP pill, PrEP implant, PrEP injection). Results draw upon the PrEP care continuum framework and distill existing factors, including lack of control over side effects with new, longer lasting modalities, better privacy with injections, increased adherence with reduced dosing schedules from longer lasting PrEP and new factors such as perceptibility concerns with respect to the PrEP implant relevant to PrEP uptake and adherence among two important overlapping, at-risk populations. The study contributes to a better understanding of barriers and facilitators to uptake and adherence for FSW and WWID around both existing and new PrEP modalities, with implications for future clinical trials and PrEP interventions with at-risk populations. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group.	female injection drug user; female sex worker; HIV; Modes of delivery; PrEP	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Theses and Dissertations	2019	Force, Preventive Services Task; Owens, Douglas K; Davidson, Karina W; Krist, Alex H; Barry, Michael J; Cabana, Michael; Caughey, Aaron B; Curry, Susan J; Doubeni, Chyke A; Epling, John W; Kubik, Martha; Landefeld, C Seth; Mangione, Carol M; Pbert, Lori; Silverstein, Michael; Simon, Melissa A; Tseng, Chien-Wen	Preexposure Prophylaxis for the Prevention of HIV Infection: US Preventive Services Task Force Recommendation Statement	-	-	University of California	-	0098-7484	https://doi.org/10.1001/jama.2019.6390	https://escholarship.org/uc/item/9cb63897	ImportanceAn estimated 1.1 million individuals in the United States are currently living with HIV, and more than 700 000 persons have died of AIDS since the first cases were reported in 1981. In 2017, there were 38 281 new diagnoses of HIV infection reported in the United States; 81% of these new diagnoses were among males and 19% were among females. Although treatable, HIV infection has no cure and has significant health consequences.ObjectiveTo issue a new US Preventive Services Task Force (USPSTF) recommendation on preexposure prophylaxis (PrEP) for the prevention of HIV infection.Evidence reviewThe USPSTF reviewed the evidence on the benefits of PrEP for the prevention of HIV infection with oral tenofovir disoproxil fumarate monotherapy or combined tenofovir disoproxil fumarate and emtricitabine and whether the benefits vary by risk group, population subgroup, or regimen or dosing strategy; the diagnostic accuracy of risk assessment tools to identify persons at high risk of HIV acquisition; the rates of adherence to PrEP in primary care settings; the association between adherence and effectiveness of PrEP; and the harms of PrEP when used for HIV prevention.FindingsThe USPSTF found convincing evidence that PrEP is of substantial benefit in decreasing the risk of HIV infection in persons at high risk of HIV acquisition. The USPSTF also found convincing evidence that adherence to PrEP is highly associated with its efficacy in preventing the acquisition of HIV infection; thus, adherence to PrEP is central to realizing its benefit. The USPSTF found adequate evidence that PrEP is associated with small harms, including kidney and gastrointestinal adverse effects. The USPSTF concludes with high certainty that the magnitude of benefit of PrEP with oral tenofovir disoproxil fumarate-based therapy to reduce the risk of acquisition of HIV infection in persons at high risk is substantial.Conclusions and recommendationThe USPSTF recommends offering PrEP with effective antiretroviral therapy to persons at high risk of HIV acquisition. Article	2019	Frasca K.; Castillo-Mancilla J.; McNulty M.C.; Connors S.; Sweitzer E.; Zimmer S.; Madinger N.	A Mixed Methods Evaluation of an Inclusive Sexual History Taking and HIV Prevention Curriculum for Trainees	Journal of General Internal Medicine	-	-	-	8848734	10.1007/s11606-019-04958-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065167828&doi=10.1007%2fs11606-019-04958-z&partnerID=40&md5=aebac76d4f6248a2c2926d84f59792c2	Background: Health disparities exist in HIV risk in the USA among the lesbian-gay-bisexual-transgender-queer (LGBTQ) community. There is also scarce literature on curricula for HIV prevention and pre-exposure prophylaxis (PrEP) for trainees. Aim: To create a curriculum to train residents to perform inclusive sexual history taking and HIV prevention care. The curriculum covers sexual history, LGBTQ health, sexually transmitted infections, and HIV risk assessment and risk reduction counseling including use of PrEP. Setting: A dedicated PrEP Clinic was created within an Academic Medical Center Outpatient HIV Clinic. Patients were primarily LGBTQ identified, but also included HIV sero-discordant couples, cisgender individuals, heterosexual invididuals, and those with experience of homelessness, sex work, and substance abuse. Participants: Thirty-four internal medicine residents completed the course between November 2017 and May 2018. Program Description: The curriculum was delivered as Just in Time Teaching (JiTT) via online virtual patient cases followed by directly observed clinical care at a large urban PrEP clinic. Program Evaluation and Results: The effectiveness of the curriculum was assessed through paired pre/post-self-assessment surveys (n = 19), additional post-surveys on the online modules (n = 22), and interviews (n = 9). Many respondents reported no prior training or inadequate prior training in the course content. As a result of the course, participants reported statistically significant increased confidence and comfort in all seven HIV prevention topic areas, with the greatest gains in safe sex counseling for LGBTQ patients and in discussing PrEP (mean changes of 1.21, 1.58 on 5-point Likert scale, respectively, p < 0.0001). Six of nine interviewees post-course had applied what they learned to patient care; five indicated their learning would benefit patients. Discussion: An HIV prevention curriculum focused on cultural humility in care can improve trainee's skills in HIV risk reduction counseling, including PrEP, among all patients including those identifying as LGBTQ. © 2019, Society of General Internal Medicine.	disparities; HIV; medical education curriculum development/evaluation; preventative care; underserved populations	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
Article	2019	Fujimoto K.; Wang P.; Flash C.A.; Kuhns L.M.; Zhao Y.; Amith M.; Schneider J.A.	Network Modeling of PrEP Uptake on Referral Networks and Health Venue Utilization Among Young Men Who Have Sex with Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2327-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056784329&doi=10.1007%2fs10461-018-2327-7&partnerID=40&md5=9f53f1f35bd01bc8bd4dd2b935acea05	The objective of this study is to identify individual-level factors and health venue utilization patterns associated with uptake of pre-exposure prophylaxis (PrEP) and to evaluate whether PrEP uptake behavior is further diffused among young men who have sex with men (YMSM) through health venue referral networks. A sample of 543 HIV-seronegative YMSM aged 16–29 were recruited in 2014–2016 in Chicago, IL, and Houston, TX. Stochastic social network models were estimated to model PrEP uptake. PrEP uptake was associated with more utilization of health venues in Houston and higher levels of sexual risk behavior in Chicago. In Houston, both Hispanic and Black YMSM compared to White YMSM were less likely to take PrEP. No evidence was found to support the spread of PrEP uptake via referral networks, which highlights the need for more effective PrEP referral network systems to scale up PrEP implementation among at-risk YMSM. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Fulcher, Jennifer A; Li, Fan; Cook, Ryan R; Zabih, Sara; Louie, Alexander; Okochi, Hideaki; Tobin, Nicole H; Gandhi, Monica; Shoptaw, Steven; Gorbach, Pamina M	Rectal Microbiome Alterations Associated With Oral Human Immunodeficiency Virus Pre-Exposure Prophylaxis.	Open Forum Infectious Diseases	-	-	-	2328-8957	https://doi.org/10.1093/ofid/ofz463	https://escholarship.org/uc/item/43p9j71q	BackgroundOral daily tenofovir (TFV) disoproxil fumarate/emtricitabine (TDF/FTC) for human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) is highly effective for HIVprevention, yet long-term effects are not fully understood. We investigated the effects of PrEP on the rectal microbiome in a cohort of men who have sex with men (MSM).MethodsThis cross-sectional analysis included HIV-negative MSM either on PrEP (n = 37) or not (n = 37) selected from an ongoing cohort using propensity score matching. Rectal swabs were used to examine microbiome composition using 16S ribosomal ribonucleic acid gene sequencing, and associations between PrEP use and microbiota abundance were examined. Hair specimens were used to quantify TFV and FTC exposure over the past 6 weeks on a subset of participants (n = 15).ResultsPre-exposure prophylaxis use was associated with a significant increase in Streptococcus abundance (adjusted P = .015). Similar associations were identified using least absolute shrinkage and selection operator (LASSO) regression, confirming the increase in Streptococcus and also showing increased Mitsuokella, Fusobacterium, and decreased Escherichia/Shigella. Increased Fusobacterium was significantly associated with increasing TFV exposure.ConclusionsOral TDF/FTC for PrEP is associated with rectal microbiome changes compared to well matched controls, specifically increased Streptococcus and Fusobacterium abundance. This study highlights the need for future investigations of the role of microbiome changes on HIV susceptibility and effectiveness of PrEP.	men who have sex with men; pre-exposure prophylaxis; rectal microbiome	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

In this paper, we explore how PrEP use impacted existing sexual risk behaviours and risk reduction strategies using qualitative data from the PROUD study. From February 2014 to January 2016, we conducted 41 in-depth interviews with gay, bisexual and other men who have sex with men (GBMSM) enrolled in the PROUD PrEP study at sexual health clinics in England. The interviews were conducted in English and were audio-recorded. The recordings were transcribed, coded and analysed using framework analysis. In the interviews, we explored participants' sexual behaviour before joining the study and among those using or who had used PrEP, changes to sexual behaviour after starting PrEP. Participants described the risk behaviour and management strategies before using PrEP, which included irregular condom use, sero-sorting, and strategic positioning. Participants described their sexual risk taking before initiating PrEP in the context of the sexualised use of drugs, geographical spaces linked with higher risk sexual norms, and digitised sexual networking, as well as problematic psychological factors that exacerbated risk taking. The findings highlight that in the main, individuals who were already having frequent condomless sex, added PrEP to the existing range of risk management strategies, influencing the boundaries of the 'rules' for when not to use condoms. While approximately half the participants described some existing risk reduction strategies after starting PrEP, the other half did not alter their behaviours. PrEP provided an additional HIV prevention option to a cohort of GBMSM at high risk of HIV due to inconsistent use of other prevention options. In summary, PrEP provides a critical and necessary additional HIV prevention option that individuals can add to existing strategies in order to enhance protection, at least from HIV. As a daily pill, PrEP offers protection in the context of the sex cultures associated with sexualised drug use, digitised sexual applications and shifting social norms around sexual fulfilment and risk taking. PrEP can offer short or longer-term options for individuals as their sexual desires change over their life course offering protection from HIV during periods of heightened risk. PrEP should not be perceived or positioned in opposition to the existing HIV prevention toolkit, but rather as additive and as a tool that can and is having a substantial impact on HIV. Article	2019	Gaissad L.; Velter A.	"Getting high to get laid." Drugs and gay sex under influence.	Sexologies	-	-	-	-	11581360	10.1016/j.sexol.2019.06.007	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068969529&doi=10.1016%2fj.sexol.2019.06.007&partnerID=40&md5=a1a2b003bd666bcb054f81181460c5c4	The major studies on men who have sex with men (MSM) in France (which began with Michael Pollak and Marie-Ange Schiltz forty years ago in Gay Press) introduced the idea of drug use in 1997, just after highly effective antiretroviral treatment (HAART) combinations were made available for HIV, making AIDS a manageable chronic condition. Australian researcher Kane Race identifies this time as the beginning of a "lifetime of drugs", but the utility of surveys into the use of psychoactive substances among gay people was to emerge in the following decades, after it was discovered that ARV treatments could keep viral load at undetectable levels in HIV-positive people, who could therefore no longer infect others. In the early 2010s, the use of drugs became a major theme in surveys of gay sexuality, and in particular the use of drugs in a sexual setting, which was named "chemsex". Men who adopt this practice tend to have intense sex lives, with a very large number of sexual partners over the past 12 months, regular attendance at sexual meeting places, specific sexual practices and do not use condoms for anal penetration. The majority who are involved are HIV-positive MSM or HIV-negative MSM on PrEP. To date, the research and publications looking at chemsex have only investigated it through the prism of the associated risks linked to addiction and compulsive behaviour. In this article we intend to show how the emergence of a scientific literature of chemsex has contributed to a masking of the strictly sexual behaviours associated with it. We will draw upon two complementary types of material: several quantitative surveys of sexual and HIV prevention behaviours among gay men and other MSM (Prevagay 2015, the 2017 "Rapport au Sexe" survey, known as ERAS). and the initial results of the APACHES survey (Attentes et PArcours liés au CHEmSex/Expectations and Experiences of Chemsex), which used biographical interviews carried out on behalf of OFDT in 2018, focusing on sexual scripts as well as the role of pleasure and contemporary ways of socialising in this subculture. © 2019 Elsevier Masson SAS	Chemsex; HIV; Mental health; MSM; Pleasure; Sexual behaviour; Sexual health	English	France	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Qualitative
Article	2019	Gamarel K.E.; Golub S.A.	Closeness Discrepancies and Intimacy Interference: Motivations for HIV Prevention Behavior in Primary Romantic Relationships	Personality and Social Psychology Bulletin	-	-	-	-	1461672	10.1177/0146167218783196	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049851615&doi=10.1177%2f0146167218783196&partnerID=40&md5=c21d561a978c2ae42d875fe0cb4f3b1e	Relational closeness has been positively associated with relationship quality and mental health; however, desire for closeness and intimacy in a relationship may also motivate sexual risk-taking, that is, forgoing condom use. This study examined the impact of desiring more closeness with a primary partner (i.e., motivation for reducing closeness discrepancies) on HIV prevention behavior. Using pre-exposure prophylaxis (PrEP) as a case study, we examined the extent to which closeness discrepancies motivate behavioral intentions (Study 1) and actual behavior (Study 2). In both studies, desiring more closeness and believing that condoms interfere with intimacy were independently positively associated with PrEP adoption. Understanding the relational needs for closeness and intimacy in motivating prevention behavior is critical for social psychology, relationship science, and public health efforts to improve sexual health. © 2018 by the Society for Personality and Social Psychology, Inc.	closeness; discrepancies; HIV prevention; pre-exposure prophylaxis; relationships	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Gamarel, Kristi E.; Darbes, Lynae A.; Hightow-Weidman, Lisa; Sullivan, Patrick; Stephenson, Rob	The Development and Testing of a Relationship Skills Intervention to Improve HIV Prevention Uptake Among Young Gay, Bisexual, and Other Men Who Have Sex With Men and Their Primary Partners (We Prevent): Protocol for a Randomized Controlled Trial.	JMIR Research Protocols	-	-	-	-	1929-0748	10.2196/10370	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6746068/	BACKGROUND: Young gay, bisexual, and other men who have sex with men (YMSM) continue to be the group most heavily impacted by HIV in the United States. Substantial evidence indicates that up to two-thirds of new HIV infections occur in the context of a main partnership. Couples HIV testing and counseling (CHTC) has been shown to be a promising and effective strategy for increasing HIV prevention uptake among male couples; however, YMSM who are new to relationships may not have yet developed the efficacy, negotiation, and communication skills to navigate HIV testing in their relationship and communicate around developing a prevention plan. OBJECTIVE: This study aims to develop and test a relationship skills-focused HIV prevention intervention for YMSM and their partners. The intervention consists of two telehealth-delivered sessions: the first focuses on relationship skills and the second consists of CHTC and prevention planning. Both sessions are attended by both members of the dyad. METHODS: This protocol describes the development of the proposed intervention (We Prevent) and pilot test to examine its feasibility and preliminary efficacy. The intervention will include two motivational interviewing-based sessions: session one is a relationship skills-building session, focused on techniques to explore and build communication skills in a relationship, to help YMSM develop and enhance necessary skills for their current and future relationships; the second session is a CHTC session with YMSM and their partners, to help them develop an HIV prevention plan. Through qualitative data collection and a one-arm pilot with YMSM, we will develop and refine a developmentally appropriate relationship skills session as an addition to the current CHTC intervention. We will then conduct a pilot randomized controlled trial (RCT), comparing the acceptability, feasibility, and preliminary efficacy of the adapted two-session intervention for YMSM versus a control group receiving one session only-a CHTC session delivered via telehealth. RESULTS: The We Prevent intervention is designed to increase uptake of HIV prevention, shown through self-reported reductions in condomless sex and increases in knowledge and uptake of pre-exposure prophylaxis. In addition, the intervention is designed to increase HIV and sexually transmitted infection (STI) testing. STI incidence is examined as a secondary outcome. A cost-input analysis will examine the costs associated with intervention delivery to inform future scale-up of the intervention. CONCLUSIONS: Drawing on theory and existing CHTC protocols delivered with video-based counseling, this proposed intervention affords the opportunity to empower YMSM with the skills necessary to communicate with their partners and protect themselves from HIV in their current and future relationships. Article	2019	Gandhi, Monica; Bacchetti, Peter; Spinelli, Matthew A.; Okochi, Hideaki; Baeten, Jared M.; Siriprakaisil, Oraphan; Klinbuayaem, Virat; Rodrigues, Warren C.; Wang, Guohong; Vincent, Michael; Cressey, Tim R.; Drain, Paul K.	Validation of a Urine Tenofovir Immunoassay for Adherence Monitoring to PrEP and ART and Establishing the Cutoff for a Point-of-Care Test.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000001971	https://pubmed.ncbi.nlm.nih.gov/30664078/	BACKGROUND: Current pharmacologic adherence monitoring for antiretrovirals involves expensive, labor-intensive liquid chromatography/tandem mass spectrometry (LC-MS/MS)-based methods. Antibody-based assays can monitor and support adherence in real time. We developed a tenofovir (TFV)-based immunoassay and further validated it in a directly observed therapy (DOT) study. DESIGN: Pharmacologic DOT study of TFV disoproxil fumarate (TDF)/emtricitabine (FTC) administered to HIV-noninfected volunteers. METHODS: The TARGET study provided directly observed TDF 300 mg/FTC 200 mg 7 (high adherence), 4 (moderate), and 2 doses/week (low) to 30 volunteers (10/group) in Thailand, collecting a total of 637 urine samples over 6 weeks of administration and during washout. ELISA measured urine TFV levels by the immunoassay and LC-MS/MS measurements served as the gold standard. A mixed-effects regression model evaluated cutoffs for a point-of-care assay. Performance characteristics of the immunoassay were compared with LC-MS/MS at a chosen cutoff. RESULTS: Median TFV levels were 12,000 ng/mL by the immunoassay 1 day after dosing; 5000 ng/mL 2 days after dosing; 1500 ng/mL 3 days after dosing; and below the lower limit of quantification thereafter (≥4 days). An immunoassay cutoff of 1500 ng/mL accurately classified 98% of patients who took a dose 24 hours ago as adherent. The specificity and sensitivity of the immunoassay compared with LC-MS/MS at the 1500 ng/mL cutoff were 99% and 94%; the correlation between TFV levels by the 2 assays was high (0.92, P < 0.00001). CONCLUSIONS: We have developed a novel TFV immunoassay that is highly specific, sensitive, and correlates strongly with LC-MS/MS measurements in a large DOT study. Adherence benchmarks from this DOT study will guide the development of a low-cost rapid point-of-care test for pre-exposure prophylaxis and antiretroviral treatment adherence monitoring and interventions. Article	2019	Ganesh S.	A feasibility literature review, to explore the need to undertake a study, to assess the level of knowledge and awareness of HIV pre-exposure prophylaxis (PrEP) as an HIV prevention modality, among young adults attending institutes of higher learning in Durban, Kwa-Zulu Natal, South Africa	Indian Journal of Public Health Research and Development	-	-	-	-	9760245	10.37506/v10/i12/2019/ijphrd/192163	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85089761626&doi=10.37506%2fv10%2fi12%2f2019%2fijphrd%2f192163&partnerID=40&md5=dcc82b486071930f87d1a54b1dd26fe6	HIV-AIDS is an alarming health concern both globally and locally which continues to increase, despite efforts to curb the epidemic. The rate of new infections is the greatest in the younger age group between 18-35 years of age with women being more infected than men1. In the absence of a cure for the disease, the mainstay of clinical management involves adherence to lifelong anti-retro viral (ARV) therapy4. Another integral component in trying to decrease new HIV infections is enhancing HIV-AIDS prevention modalities. These approaches have grown through the years and range from local to systemic forms either singly or in combination with other therapies4. An emerging potentially viable option is Pre-exposure prophylaxis (PrEP) (5). This form of therapy is the ingestion of a type of ARV on a daily basis by an HIV-Negative individual to remain HIV free. There are several clinical trials ongoing and past that have shown efficacy for use in adults and primarily in young adults. The rollout of PrEP as prevention modality globally has commenced and South Africa stands on the brink of roll out for high risk and young adults through the South African Department of Health ARV treatment programme. It is thus imperative that a study to explore the level of knowledge and awareness of HIV pre-exposure prophylaxis (PrEP) as an HIV prevention modality among young adults occurs in order to assess readiness for implementation in order to identify potential challenges with recommendations for smart practices. © 2019, Indian Journal of Public Health Research and Development. Article	2019	Ganesh S.	Integrating pre-exposure prophylaxis into HIV-AIDS programme management	Indian Journal of Forensic Medicine and Toxicology	-	-	-	-	9739122	10.5958/0973-9130.2019.00151.8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066310072&doi=10.5958%2f0973-9130.2019.00151.8&partnerID=40&md5=53ac8c6f295b440b7889711019a981af	The global HIV-AIDS epidemic has grown and continues to grow to alarming rates. The rate of new infections continues to soar in developing nations1. A combination of prevention initiatives is needed to halt its spread. Pre-exposure prophylaxis (PrEP) is a daily course of antiretroviral drugs (ARVs) taken by HIV-negative people to protect themselves from infection5. Clinical data thus far has shown that PrEP reduces the chances of HIV infection to near-zero. PrEP is cost effective, and there is growing demand for it from people at higher risk of HIV-AIDS infection, but the scale and coverage remains extremely limited. This paper reviews the current landscape of integrating Pre-exposure prophylaxis in HIV-AIDS programmes and proposes smart practices toward optimal patient management. © 2019, Indian Journal of Forensic Medicine and Toxicology. Article	2019	García, Moctezuma; Saw, Guan	Socioeconomic disparities associated with awareness, access, and usage of Pre-Exposure Prophylaxis among Latino MSM ages 21–30 in San Antonio, TX	Journal of HIV/AIDS & Social Services	-	-	-	-	15381501	10.1080/15381501.2019.1607795	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065699719&doi=10.1080%2f15381501.2019.1607795&partnerID=40&md5=3a826d59c5180cee3968dee202531742	HIV continues to disproportionately affect Latino men who have sex with men (MSM) and disparities are even greater in the South. This study examines the implications of socioeconomic status (SES) associated with awareness, access, and usage of PrEP. Latino MSM (N = 154) from San Antonio, TX, completed a self-administered survey. Results revealed that PrEP uptake was significantly lower for low SES Latino MSM. PrEP related barriers included lack of awareness, stigmas, and side effects. Findings underscore the importance for a multisystemic approach to enhance awareness and access of PrEP for Latino MSM with varying levels of SES in the South. © 2019, © 2019 Taylor & Francis Group, LLC.	ethnic MSM; HIV prevention; Latino; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Gaspar M.; Marshall Z.; Rodrigues R.; Adam B.D.; Brennan D.J.; Hart T.A.; Grace D.	A tale of two epidemics: gay men's mental health and the biomedicalisation of HIV prevention and care in Toronto	Sociology of Health and Illness	-	-	-	-	1419889	10.1111/1467-9566.12884	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062533124&doi=10.1111%2f1467-9566.12884&partnerID=40&md5=06421a6656ab21fc9e844d09baa7702a	There is mounting urgency regarding the mental health of gay, bisexual and other men who have sex with men (GBM). We examined how GBM are understanding the relationship between HIV and their mental health given the increasing biomedicalisation of HIV prevention and care. Our Grounded Theory analysis derived from qualitative interviews with 24 GBM living in Toronto, Canada, including both HIV-negative and HIV-positive men. Participants understood biomedical advances, such as undetectable viral load and pre-exposure prophylaxis (PrEP), as providing some relief from HIV-related distress. However, they offered ambivalent perspectives on the biomedicalisation of HIV. Some considered non-HIV-specific stressors (e.g. unemployment, racial discrimination) more significant than HIV-related concerns. These men expressed HIV-related distress as being under control due to biomedical advances or as always negligible when compared to non-HIV-specific stressors. Others emphasised the ongoing mental health implications of HIV (e.g. enduring risk and stigma). We describe a tension between optimistic responses to biomedicine's ability to ease the psychosocial burdens associated with HIV and the inability for biomedicine to address the social and economic determinants driving the dual epidemics of HIV and mental distress amongst GBM. We argue for more socio-material analysis over further sexual behavioural analysis of GBM mental health disparities. © 2019 Foundation for the Sociology of Health & Illness	biomedicalisation; gay men; Grounded Theory; HIV; mental health and illness; PrEP (pre-exposure prophylaxis); qualitative methods; undetectable viral load	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Qualitative
Article	2019	Gee S.; Chum A.; Lim B.	Moving Metaphors: Shifting Institutional Responsibilities and Evidentiary Boundaries in the Commissioning of Pre-Exposure Prophylaxis for HIV	Qualitative Health Research	-	-	-	-	10497323	10.1177/1049732319831040	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062667340&doi=10.1177%2f1049732319831040&partnerID=40&md5=898481208f012554c51fc375c0798a13	In this article, we investigate how speakers in the U.K.'s House of Commons cited the same legislative context and medical research to arrive at contradictory conclusions regarding the Government's responsibility to fund pre-exposure prophylaxis (PrEP) as an HIV intervention. Because the Government had expressed that it would not comment on institutional responsibilities directly, given the likelihood of a legal challenge in response to the National Health Service withdrawing PrEP from the drug commissioning process, the Government's support of this decision could not be explicitly detailed. Our discourse analytic approach reveals how members of parliament adopted positions in the debate by using distinct metaphorical frames and lexical choices to linguistically encode assumptions that imply contrary interpretations of mutually agreed upon facts. This suggests that the concrete discursive practices used to cite evidence in policy-making discussions, regardless of the quality of the evidence, may have material consequences for evidence-based policy. © The Author(s) 2019.	discourse analysis; health policy; HIV; metaphor; pre-exposure prophylaxis; PrEP; qualitative; secondary data; stigma; UK	English	United States	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Qualitative
Article	2019	Gibas, Kevin M; van den Berg, Polly; Powell, Victoria E; Krakower, Douglas S	Drug Resistance During HIV Pre-Exposure Prophylaxis.	Drugs	-	-	-	-	1179-1950	10.1007/s40265-019-01108-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6606557	Clinical studies have demonstrated that use of tenofovir disoproxil fumarate with or without emtricitabine as antiretroviral pre-exposure prophylaxis (PrEP) can decrease the risk of human immunodeficiency virus (HIV) acquisition when medication adherence is high. However, the potential for PrEP to promote antiretroviral resistance remains an important public health consideration. We performed a search of the medical literature to identify studies that address HIV drug resistance during PrEP use. In this review, we summarize findings about emergent drug resistance during clinical trials of PrEP, case reports of seroconversions in patients adherent to PrEP, and animal studies of PrEP effectiveness against drug-resistant viral strains. We also discuss the potential utility of novel PrEP formulations for protection against drug-resistant HIV, the impact of drug resistance on HIV treatment options, and mathematical models that estimate the potential contribution of PrEP to population-level drug resistance. Evidence suggests that selection for HIV drug resistance with PrEP use is infrequent and most likely to occur when PrEP is used during undiagnosed acute HIV infection. Breakthrough infections during PrEP use with high adherence are possible, but appear to be rare. The prevalence of drug-resistant HIV strains needs to be monitored as PrEP is scaled up. However, the benefit of a decreased HIV incidence with wider PrEP use is likely to outweigh the risk of harms from possible increases in the prevalence of HIV drug resistance. Article	2019	Giguère K.; Béhanzin L.; Guédou F.A.; Talbot D.; Leblond F.A.; Goma-Matsétsé E.; Zannou D.M.; Affolabi D.; Kêkê R.K.; Gangbo F.; Bachabi M.; Alary M.	PrEP Use among Female Sex Workers: No Evidence for Risk Compensation	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002134	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073183179&doi=10.1097%2fQAI.0000000000002134&partnerID=40&md5=af797977dbbaa4701da4613f844376a3	Background:Little is known about risk compensation among female sex workers (FSW) on HIV pre-exposure prophylaxis (PrEP), and self-report of sexual behaviors is subject to bias.Setting:Prospective observational PrEP demonstration study conducted among FSW in Cotonou, Benin.Methods:Over a period of 24 months, we assessed and compared trends in unprotected sex as measured by self-report (last 2 or 14 days), by detection of sexually transmitted infections (STIs), and by vaginal detection of prostate-specific antigen and Y-chromosomal DNA, 2 biomarkers of semen exposure in the last 2 or 14 days, respectively. Trends were assessed and compared using a log-binomial regression that was simultaneously fit for all unprotected sex measures.Results:Of 255 participants, 120 (47.1%) completed their follow-up. Prevalence of STI decreased from 15.8% (95% confidence interval: 11.8% to 21.0%) at baseline to 2.1% (95% confidence interval: 0.4% to 10.2%) at 24 months of follow-up (P-trend = 0.04). However, we observed no trend in self-report of unprotected sex in the last 2 (P = 0.42) or 14 days (P = 0.49), nor in prostate-specific antigen (P = 0.53) or Y chromosomal DNA (P = 0.25) over the same period. We observed no statistically significant difference between trends in self-report of unprotected sex and trends in biomarkers of semen exposure in the last 2 days (P = 0.14) or in the last 14 days (P = 0.29).Conclusions:We observed no evidence of risk compensation, and a decrease in STI among FSW on PrEP. PrEP intervention may be an opportunity to control STI among FSW. Future studies should assess risk compensation with biomarkers of semen exposure when possible. © 2019 Wolters Kluwer Health, Inc. Article	2019	Gilbert H.N.; Wyatt M.A.; Pisarski E.E.; Muwonge T.R.; Heffron R.; Katabira E.T.; Celum C.L.; Baeten J.M.; Haberer J.E.; Ware N.C.	PrEP Discontinuation and Prevention-Effective Adherence: Experiences of PrEP Users in Ugandan HIV Serodiscordant Couples	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002139	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073174623&doi=10.1097%2fQAI.0000000000002139&partnerID=40&md5=1a00dd38c438f41f08abcee53b9a33a0	Background:Optimal adherence to oral pre-exposure prophylaxis (PrEP) for HIV prevention involves aligning consistent PrEP use with periods of risk to achieve prevention-effective adherence. Prevention-effective adherence is predicated on individuals discontinuing PrEP during periods without expected risk. For stable, serodiscordant couples, antiretroviral therapy (ART) adherence by the HIV-positive partner markedly decreases HIV transmission risk, potentially obviating the need for continued PrEP use; yet little is known about actual lived experiences of discontinuing PrEP.Methods:In-depth qualitative interviews were conducted with HIV-uninfected PrEP users in serodiscordant couples taking part in the Partners Demonstration Project at IDI-Kasangati, Kampala, Uganda. Open-ended interviews elicited information on the partnered relationship; understandings of PrEP; prevention strategies; and experiences of PrEP discontinuation. An inductive, thematic, content-analytic approach was used to analyze study data.Results:Uninfected partners experienced PrEP as a valued resource for preventing HIV acquisition. Despite ongoing ART use by HIV-positive partners for a period of time consistent with viral suppression, discontinuation of PrEP was experienced as a loss of protection and a corresponding increase in risk of HIV acquisition. Uninfected partners responded with strategies aimed at offsetting this subjective sense of increased risk, specifically: (1) changing sexual practices; (2) prioritizing fidelity in the relationship; (3) increasing reliance on condoms; and (4) seeking evidence of partners' ART adherence.Conclusions:These experiences highlight the challenges PrEP users in serodiscordant couples face in discontinuing PrEP for prevention-effective adherence. Flexible interventions that support individuals during this transition may increase comfort with discontinuing PrEP when alternative prevention strategies provide protection, such as a partner's consistent adherence to ART. © 2019 Wolters Kluwer Health, Inc. Article	2019	Gilbert, Mark; Michelow, Warren; Dulai, Joshun; Wexel, Daniel; Hart, Trevor; Young, Ingrid; Martin, Susan; Flowers, Paul; Donelle, Lorie; Ferlatte, Olivier	Provision of online HIV-related information to gay, bisexual and other men who have sex with men: a health literacy-informed critical appraisal of Canadian agency websites.	Sexual Health	-	-	-	-	1449-8987	10.1071/SH18092	https://dx.doi.org/10.1071/SH18092	Background HIV risk and prevention information is increasingly complex and poses challenges for gay, bisexual and other men who have sex with men (GBMSM) seeking to find, understand and apply this information. A directed content analysis of Canadian HIV websites to see what information is provided, how it is presented and experienced by users, was conducted. METHODS: Eligible sites provided information relevant for GBMSM on HIV risk or prevention, were from community or government agencies, and were aimed at the public. Sites were found by using a Google search using French and English search terms, from expert suggestions and a review of links. Eligibility and content for review was determined by two reviewers, and coded using a standardised form. Reading grade level and usability scores were assessed through Flesch-Kincaid and LIDA instruments. RESULTS: Of 50 eligible sites, 78% were from community agencies and 26% were focussed on GBMSM. Overall, fewer websites contained information on more recent biomedical advances (e.g. pre-exposure prophylaxis, 10%) or community-based prevention strategies (e.g. seroadaptive positioning, 10%). Many sites had high reading levels, used technical language and relied on text and prose. And 44% of websites had no interactive features and most had poor usability scores for engageability. CONCLUSIONS: Overall, less information about emerging topics and a reliance on text with high reading requirements was observed. Our study speaks to potential challenges for agency website operators to maintain information relevant to GBMSM which is up-to-date, understandable for a range of health literacy skills and optimises user experience. Article	2019	Gilkey, Melissa B; Marcus, Julia L; Garrell, Jacob M; Powell, Victoria E; Maloney, Kevin M; Krakower, Douglas S	Using HIV Risk Prediction Tools to Identify Candidates for Pre-Exposure Prophylaxis: Perspectives from Patients and Primary Care Providers.	AIDS Patient Care and STDs	-	-	-	-	1557-7449	10.1089/apc.2019.0056	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6661917	Clinical guidelines for HIV pre-exposure prophylaxis (PrEP) include risk prediction tools to identify appropriate candidates. We conducted a qualitative interview study to explore the potential acceptability, interpretation, and anticipated impact of such tools from the perspectives of men who have sex with men (MSM) and primary care providers (PCPs). Our purposive sample of English-speaking participants included: (1) MSM reporting HIV risk behaviors (n = 32; median age = 38 years; 53% non-Hispanic white; 22% high school degree or less education); (2) PCPs specializing in health care for MSM (n = 12); and (3) PCPs in general practice (n = 19). MSM participants questioned the ability of risk tools to predict HIV acquisition, and their perceptions of what might constitute a high HIV risk score varied widely. Many MSM participants believed that receiving a high score would prompt them to consider PrEP or other risk reduction strategies. Some believed that the data would be useful, particularly if discussed with their providers, whereas others anticipated feeling fear, anxiety, or mistrust. PCPs expressed more confidence in HIV risk prediction and imagined integrating tools with medical histories and their clinical judgment to assess risk. PCPs were most enthusiastic about adopting HIV risk prediction as a teaching tool to help patients visualize and reduce risk, their concerns about time constraints notwithstanding. In conclusion, our findings suggest that PCPs' views of HIV risk prediction tools are generally positive, whereas MSM participants' are more mixed. Given that both groups emphasized the value of contextualizing risk, shared decision making may be needed to implement HIV risk prediction tools effectively.	primary care, risk communication, decision making, HIV/AIDS, prevention	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2019	Giovenco D.; Pettifor A.; MacPhail C.; Kahn K.; Wagner R.; Piwowar-Manning E.; Wang J.; Hughes J.P.	Assessing risk for HIV infection among adolescent girls in South Africa: an evaluation of the VOICE risk score (HPTN 068)	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25359	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070838218&doi=10.1002%2fjia2.25359&partnerID=40&md5=a68d82c93af58a389e17b94f675739d5	Introduction: To maximize impact and minimize costs, antiretroviral pre-exposure prophylaxis (PrEP) interventions should be offered to those at highest risk for HIV infection. The risk score derived from the VOICE trial is one tool currently being utilized to determine eligibility in adolescent PrEP trials in sub-Saharan Africa. This study is aimed at evaluating the utility of the risk score in predicting HIV incidence among a cohort of adolescent girls in rural South Africa. Methods: We utilized data from HIV Prevention Trials Network (HPTN) 068, a phase III randomized controlled trial conducted in rural Mpumalanga province, South Africa. School-attending young women aged 13 to 20 years were enrolled into the trial from 2011 to 2012 and followed for up to three years. A risk score based on individual-level risk factors measured at enrolment was calculated for HPTN 068 participants who completed a one-year follow-up visit and were HIV seronegative at enrolment. Possible scores ranged from 0 to 10. A proportional hazards model was then used to determine if risk score at enrolment was predictive of incident HIV infection at follow-up and an area under the curve analysis was used to examine the predictive ability of the score. Results and Discussion: The risk score had limited variability in the HPTN 068 sample. Scores ≥5 identified 85% of incident infections from 94% of the sample, compared to the VOICE sample in which scores ≥5 identified 91% of incident infections from only 64% of participants. The risk score did not predict HIV incidence after one year of follow-up (hazard ratio = 1.029; 95% confidence interval (CI): 0.704, 1.503, p =.884) and showed poor predictive ability (area under the curve = 0.55; 95% CI: 0.44, 0.65). Certain individual risk factors that comprise the risk score may be context specific or not relevant for adolescent populations. Additional factors should be considered when assessing risk for the purposes of determining PrEP eligibility. Conclusions: The VOICE risk score demonstrated low utility to predict HIV incidence in the HPTN 068 sample. Findings highlight the need for an age and developmentally appropriate tool for assessing risk for HIV infection among adolescents. Use of the VOICE risk score for determining PrEP eligibility in younger populations should be carefully considered. © 2019 The Authors. Article	2019	Girard, Gabriel; Patten, San; LeBlanc, Marc-André; Adam, Barry D; Jackson, Edward	Is HIV prevention creating new biosocialities among gay men? Treatment as prevention and pre-exposure prophylaxis in Canada.	Sociology of Health & Illness	-	-	-	-	1467-9566	10.1111/1467-9566.12826	https://dx.doi.org/10.1111/1467-9566.12826	The advancements of "treatment as prevention" (TasP), "undetectable viral load" (UVL) and "pre-exposure prophylaxis" (PrEP) are redefining HIV prevention standards. Relying on the concept of biosociality, this article explores how gay men rally around, debate, and sometimes disagree about these emerging HIV prevention technologies. This article is based on data from the Resonance Project, a Canadian community-based research project. Twelve focus groups (totalling 86 gay and bisexual men) were held in three Canadian cities (Montreal, Toronto, Vancouver) in 2013-2014. Respondents view UVL and PrEP through the prism of their generational experience of HIV prevention. In this respect, biosocialities highlight an experiential dimension that is tied to the context of the HIV epidemic. The biosocialities of HIV prevention are also built around serological identities. However, our study shows the diversity of these positions. Analysis grounded in biosocialities is useful for better understanding how scientific information circulates, is made sense of, and generates debate among gay men.	gay men, HIV prevention, risk, biosociality, treatment as prevention, pre-exposureprophylaxis, Canada	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Qualitative
Article	2019	Glaubius, Robert; Ding, Yajun; Penrose, Kerri J.; Hood, Greg; Engquist, Erik; Mellors, John W.; Parikh, Urvi M.; Abbas, Ume L.	Dapivirine vaginal ring for HIV prevention: modelling health outcomes, drug resistance and cost-effectiveness.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25282	https://onlinelibrary.wiley.com/doi/full/10.1002/jia2.25282	INTRODUCTION: A vaginal ring containing dapivirine is effective for HIV prevention as pre-exposure prophylaxis (PrEP). We evaluated the potential epidemiological impact and cost-effectiveness of dapivirine vaginal ring PrEP among 22- to 45-year-old women in KwaZulu-Natal, South Africa. METHODS: Using mathematical modelling, we studied dapivirine vaginal ring PrEP implementation, either unprioritized, or prioritized based on HIV incidence (≥3% per year), age (22 to 29 years) or female sex worker status, alongside the implementation of voluntary medical male circumcision and antiretroviral therapy scaled-up to UNAIDS Fast-Track targets. Outcomes over the intervention (2019 to 2030) and lifetime horizons included cumulative HIV infections, life-years lived, costs and cost-effectiveness. We assessed the incremental cost-effectiveness ratios against the revealed willingness to pay ($500) and the standard (2017 per capita gross domestic product; $6161) cost-effectiveness thresholds for South Africa. RESULTS: Compared to a reference scenario without PrEP, implementation of dapivirine vaginal ring PrEP, assuming 56% effectiveness and covering 50% of 22 to 29-year-old or high-incidence women, prevented 10% or 11% of infections by 2030 respectively. Equivalent, unprioritized coverage (30%) prevented fewer infections (7%), whereas 50% coverage of female sex workers had the least impact (4%). Drug resistance attributable to PrEP was modest (2% to 4% of people living with drug-resistant HIV). Over the lifetime horizon, dapivirine PrEP implementation among female sex workers was cost-saving, whereas incidence-based PrEP cost $1898 per life-year gained, relative to PrEP among female sex workers and $989 versus the reference scenario. In a scenario of 37% PrEP effectiveness, PrEP had less impact, but prioritization to female sex workers remained cost-saving. In uncertainty analysis, female sex worker PrEP was consistently cost-saving; and over the lifetime horizon, PrEP cost less than $6161 per life-year gained in over 99% of simulations, whereas incidence- and age-based PrEP cost below $500 per life-year gained in 61% and 49% of simulations respectively. PrEP adherence and efficacy, and the effectiveness of antiretroviral therapy for HIV prevention, were the principal drivers of uncertainty in the cost-effectiveness of PrEP. CONCLUSIONS: Dapivirine vaginal ring PrEP would be cost-saving in KwaZulu-Natal if prioritized to female sex workers. PrEP's impact on HIV prevention would be increased, with potential affordability, if prioritized to women by age or incidence. Article	2019	Glidden D.V.; Mehrotra M.L.; Dunn D.T.; Geng E.H.	Mosaic effectiveness: measuring the impact of novel PrEP methods	The Lancet HIV	-	-	-	-	23523018	10.1016/S2352-3018(19)30227-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072645867&doi=10.1016%2fS2352-3018%2819%2930227-9&partnerID=40&md5=95f66686aa9596566f451605af04fc58	Various ongoing trials seek to evaluate long-acting pre-exposure prophylaxis (PrEP) agents by showing that they are non-inferior to daily oral tenofovir disoproxil fumarate and emtricitabine. Trials comparing oral PrEP to new methods examine effectiveness in a setting where only one or the other is provided; however, a new product will probably be delivered in a context where oral PrEP is also available. The effectiveness of a new PrEP product is best measured by its potential effect in a context that also includes oral tenofovir disoproxil fumarate and emtricitabine as an option. We offer an alternative standard for long-acting products—a measure of the effectiveness of the new product in addition to oral tenofovir disoproxil fumarate and emtricitabine as compared with oral PrEP alone. We term this measure mosaic effectiveness. We illustrate scenarios where a novel product can fail to show non-inferiority but show substantial mosaic effectiveness, thus implying the public health value of the novel product even if it is less effective than oral PrEP. Regulatory standards should consider mosaic effectiveness, not just comparative effectiveness. We assert that measurements that combine rigor with public health relevance can accelerate progress against the HIV epidemic. © 2019 Elsevier Ltd	NA	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Glidden, David V	Advancing Novel PrEP Products - Alternatives to Non-Inferiority.	Statistical Communications in Infectious Diseases	-	-	-	-	2194-6310	10.1515/scid-2019-0011	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6731035	With the scale-up of HIV pre-exposure prophylaxis (PrEP) with tenofovir (TDF) with or without emtricitabine (FTC), we have entered an era of highly effective HIV prevention with a growing pipeline of potential products to be studied. These studies are likely to be randomized trials with an oral TDF/FTC control arm. These studies require comparison of incident infections and can be time and resource intensive. Conventional approaches for design and analysis active controlled trial can lead to very large sample sizes. We demonstrate the important of assumptions about background infections for interpreting trial results and suggest alternative criteria for demonstrating the efficacy and effectiveness of potential PrEP agents.	active controlled, non-inferiority, hiv prevention, pre-exposure prophylaxis	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Goedel W.C.; Mayer K.H.; Mimiaga M.J.; Duncan D.	Considerable interest in pre-exposure prophylaxis uptake among men who have sex with men recruited from a popular geosocial-networking smartphone application in London	Global Public Health	-	-	-	-	17441692	10.1080/17441692.2017.1391859	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85031909754&doi=10.1080%2f17441692.2017.1391859&partnerID=40&md5=26b7f6e13594effa756560ca5b097408	Men who have sex with men (MSM) who use smartphone applications (apps) to meet sexual partners represent a high-risk subset of MSM. As such, the use of pre-exposure prophylaxis (PrEP) may be highly suitable. The purpose of the study was to evaluate awareness of and willingness to use PrEP among 179 HIV-uninfected MSM recruited in London who use these apps. Regression models were fit to assess the associations between perceived barriers and willingness to use PrEP in the future. Most (84.9%) had heard of PrEP and more than half (57.1%) were willing to use PrEP in the future if it were to become available. Low perceived risk for acquiring HIV (prevalence ratio (PR): 0.11; 95% confidence interval (CI): 0.04, 0.33) and concerns about PrEP-related side effects (PR: 0.01; 95% CI: 0.00, 0.04) were associated with being unwilling to use PrEP. Efforts to make PrEP widely available should be continued. Future efforts should focus on correcting self-perceptions of HIV risk and educate MSM about the potential side effects of PrEP use so that MSM can make more informed decisions about prevention options. © 2017, © 2017 Informa UK Limited, trading as Taylor & Francis Group.	geosocial-networking smartphone applications; Men who have sex with men; pre-exposure prophylaxis; United Kingdom	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Golub S.A.; Fikslin R.A.; Starbuck L.; Klein A.	High Rates of PrEP Eligibility but Low Rates of PrEP Access among a National Sample of Transmasculine Individuals	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002116	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071353482&doi=10.1097%2fQAI.0000000000002116&partnerID=40&md5=523c2cb1295427900e0ae03a28725c8f	Background:Transmasculine individuals have been largely ignored in HIV prevention research, and there is a lack of data regarding this population's eligibility for and utilization of HIV pre-exposure prophylaxis (PrEP).Setting:National online survey conducted in the United States.Methods:Between May and July 2017, we surveyed 1808 transmasculine individuals (aged 18-60 years; 30% people of color and/or Latinx), asking questions about sexual behavior and receipt of sexual health care, including PrEP. We examined the number of individuals who would meet eligibility criteria for PrEP and then used log-linked Poisson regression with robust variance estimation to examine predictors of PrEP eligibility.Results:Almost one-quarter of the sample (n = 439; 24.3%) met one or more criterion for PrEP eligibility. PrEP eligibility did not differ by age, race/ethnicity, education, or binary gender identity. PrEP eligibility was lower among heterosexual-identified and higher income participants, and was higher among participants who were in open relationships and reported substance use. Among PrEP-eligible individuals, 64.9% had received an HIV test in the past year, 33.9% had received PrEP information from a provider, and 10.9% (n = 48) had received a PrEP prescription. PrEP-eligible individuals who had received a PrEP prescription were more likely to have a binary gender identity, identify as gay, and be taking testosterone.Conclusions:A substantial proportion of transmasculine individuals meet PrEP eligibility criteria, but few are receiving adequate PrEP services. Enhanced efforts should be made by providers, programs, and systems to assess HIV-related risk in transmasculine patients and engage them in comprehensive sexual health care. Article	2019	Golub S.A.; Myers J.E.	Next-Wave HIV Pre-Exposure Prophylaxis Implementation for Gay and Bisexual Men	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2018.0290	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066939113&doi=10.1089%2fapc.2018.0290&partnerID=40&md5=a9e8851297660b0034d8e174bb6dde76	Data indicate that diffusion of pre-exposure prophylaxis (PrEP) programs for HIV prevention is increasing in the United States; however, persistent disparities in PrEP access remain. Earlier waves of PrEP implementation focused on development (2012-2015) and diffusion (2016-2018). To reduce disparities, the next wave of PrEP implementation should focus on integration; that is, the assimilation of PrEP service as an integral part of HIV prevention, sexual health, and primary care. This review analyzes PrEP implementation literature in the context of three "next-wave" challenges: increasing patient demand, enhancing provider investment and competency, and improving health systems capacity. Our review revealed five activities we consider critical to successful next-wave PrEP implementation efforts: (1) redefining PrEP eligibility assessment, (2) de-emphasizing risk perception as a strategy to increase demand, (3) rejecting risk compensation arguments, (4) altering guidelines to make PrEP follow-up less onerous, and (5) focusing directly on strategies to reduce the cost of PrEP medication. This article ends with a case study of a research-practice partnership designed to instantiate new approaches to integrative implementation efforts. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019.	implementation; MSM; pre-exposure prophylaxis; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Golub, Sarit A; Fikslin, Rachel A; Goldberg, Matthew H; Peña, Stephanie M; Radix, Asa	Predictors of PrEP Uptake Among Patients with Equivalent Access	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2376-y	https://www.proquest.com/scholarly-journals/predictors-prep-uptake-among-patients-with/docview/2162263526/se-2?accountid=8113	Increasing PrEP adoption for eligible individuals is critical, but limited research has examined individual-level factors that might be amenable to educational or behavioral intervention. Using data from a PrEP demonstration project conducted at a community health center, we examined differences in behavioral and psychosocial factors between patients offered PrEP who chose to accept it and those who declined. In a multivariable model, the odds of accepting PrEP were higher among those with an HIV-positive main partner, greater risk behavior in the past 3 months, and higher HIV risk perception. PrEP adoption was positively associated with PrEP adherence self-efficacy and negatively associated with perceived sensitivity to medicines. These psychological variables were associated with measures of PrEP- and HIV-related stigma. In the multivariable model, there were no differences in PrEP adoption by demographic factors or socioeconomic status. Data suggest that patients' decisions about PrEP uptake may be impacted not only by objective and subjective HIV risk, but also by psychological variables such as stigma beliefs, medication beliefs, and self-efficacy. Article	2019	Goodman-Meza, David; Beymer, Matthew R.; Kofron, Ryan M.; Amico, K. Rivet; Psaros, Christina; Bushman, Lane R.; Anderson, Peter L.; Bolan, Robert; Jordan, Wilbert C.; Rooney, James F.; Wohl, Amy R.; Landovitz, Raphael J.	Effective use of pre-exposure prophylaxis (PrEP) Among stimulant users with multiple condomless sex partners: a longitudinal study of men who have sex with men in Los Angeles.	AIDS Care	-	-	-	-	1360-0451 0954-0121	10.1080/09540121.2019.1595523	https://pubmed.ncbi.nlm.nih.gov/30894013/	PrEP's potential benefit for men who have sex with men (MSM) who use stimulants may be limited by adherence or prescriber willingness to recommend PrEP due to concerns of non-compliance. Using data from PATH-PrEP, a 48-week study evaluating PrEP for MSM in Los Angeles, we modeled an interaction between stimulant use and condomless sex with multiple partners (CAS-MP) on prevention-effective dried blood spot tenofovir-diphosphate concentrations. At week 4, participants reporting stimulant use and CAS-MP had a decreased odds of prevention-effective adherence compared to non-stimulant use and non-CAS-MP (AOR 0.15, 95% CI 0.04-0.57). From week 4-48, participants reporting stimulant use and CAS-MP had increased odds of prevention-effective adherence (AOR 1.06 per week, 95%CI 1.01-1.12). Participants reporting CAS-MP without stimulant use had no significant change in prevention-effective adherence (AOR 0.99 per week, 95%CI 0.96-1.02). Stimulant use moderated the association of CAS-MP on prevention-effective PrEP adherence over time. Article	2019	Grangeiro, Alexandre	Nonoccupational post-exposure prophylaxis for HIV after sexual intercourse among women in Brazil: risk profiles and predictors of loss to follow-up	Medicine	-	-	-	-	NA	10.1097/MD.0000000000017071	https://pubmed.ncbi.nlm.nih.gov/31574806/	Access to antiretroviral-based HIV prevention has been marked by sex asymmetries, and its effectiveness has been compromised by low clinical follow-up rates. We investigated risk profiles of women who received nonoccupational post-exposure prophylaxis (nPEP), as well as the rates and predictive factors of loss to follow-up after nPEP initiation.Retrospective study evaluating 501 women who received nPEP between 2014 and 2015 at 5 HIV centers (testing centers-VCT, outpatient clinics, and infectious diseases hospital). Risk profiles were drawn based on the characteristics of the women and their sexual partners, and then stratified by sociodemographic indicators and previous use of HIV prevention services. Loss to follow-up (LTFU) was defined as not presenting for follow-up visits or for HIV testing after nPEP initiation. Predictors of LTFU were analyzed by calculating adjusted prevalence ratios (aPRs).Approximately 90% of women had sexual encounters that met the criteria established in the Brazilian guidelines for nPEP. Those who declared to be sex workers (26.5%) or drug users (19.2%) had the highest social vulnerability indicators. In contrast, women who had intercourse with casual partners of unknown HIV risk (42.7%) had higher education and less experience with previous HIV testing (89.3%) or nPEP use (98.6%). Of the women who received nPEP after sexual intercourse with stable partners, 75.8% had HIV-infected partners. LTFU rate was 72.8% and predictors included being Black (aPR = 1.15, 95% confidence interval [CI]: 1.03-1.30), using drugs/alcohol (aPR = 1.15, 95% CI: 1.01-1.32) and having received nPEP at an HIV outpatient clinic (aPR = 1.35, 95% CI: 1.20-1.51) or at an infectious diseases hospital (aPR = 1.37, 95% CI: 1.11-1.69) compared with a VCT. The risk of LTFU declined as age increased (aPR 41-59 years = 0.80, 95% CI: 0.68-0.96).Most women who used nPEP had higher socioeconomic status and were not part of populations most affected by HIV. In contrast, factors that contribute to loss to follow-up were: having increased social vulnerability; increased vulnerability to HIV infection; and seeking nPEP at HIV treatment services as opposed to at a VCT.	combination prevention; HIV; post-exposure prophylaxis after sexual exposure; women	Portuguese	United States	Western and Central Europe and North America	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Quantitative
Theses and Dissertations	2019	Green, Keith Romell	Exploring the Implications of Shifting HIV Prevention Practice Ideologies on the Work of Community-Based Organizations: A Resource Dependence Perspective	-	-	University of Chicago	University of Chicago	-	NA	https://doi.org/10.6082/uchicago.1388	http://knowledge.uchicago.edu/record/1388	Antiretroviral (ARV)-based prevention approaches such as Treatment as Prevention (TasP) and Pre-Exposure Prophylaxis (PrEP), present unprecedented opportunities for stemming the HIV epidemic in the United States. However, current racial/ethnic disparities in both the PrEP and HIV Continuums of Care point to significant implementation problems and gaps in the diffusion and uptake of these interventions. Community-based organizations (CBOs) that offer HIV prevention programming are uniquely positioned to assist our nation's most vulnerable populations with accessing TasP and PrEP, which includes navigating their options under the Affordable Care Act (ACA). However, these prevention approaches represent a shift in HIV prevention practice ideologies, which requires significant change in the way that CBOs have historically approached HIV prevention. The U.S. Centers for Disease Control and Prevention (CDC), which is the largest funder of HIV prevention services in the country, has long recognized CBOs as important partners in the domestic fight against HIV/AIDS. In response to changing trends in the epidemic over time, the CDC's HIV prevention program with CBOs has grown in size, scope, and complexity. Little is known, however, about the capacity of CBOs to support the shift in practice ideology at the CDC that prioritizes ARV-based prevention, or about how local variations in ACA implementation impact the ability of organizational staff to integrate such approaches into their existing programming. Grounded in resource dependence and new institutional theories, this dissertation employed qualitative research methods and is organized around two primary aims. The first aim was to explore the impact of emerging ARV-based approaches on HIV prevention practice ideologies as they are communicated to CBOs from the CDC. To achieve this aim, I conducted a document analysis of Funding Opportunity Announcements (FOAs) and other reports issued by the CDC related to community-based HIV prevention between 2003 and 2013. The second aim was to examine—via semi-structured interviews with organizational leaders, frontline prevention workers, and public health officials in Atlanta, Baltimore, Memphis, and New Orleans—how a diverse mix of CBOs in four cities heavily impacted by HIV/AIDS and with differing ACA implementation strategies are responding to shifts in the CDC's program for community-based HIV prevention. Two primary shifts in HIV prevention practice ideologies communicated to CBOs from the CDC are revealed through this analysis. First, in accordance with the Advancing HIV Prevention initiative announced in 2003, funded organizations were required to implement standardized evidence-based behavioral interventions as determined by the CDC—in contrast to locally developed models. Then, as antiretroviral-based prevention emerged and evolved over time, the CDC's program for community-based HIV prevention shifted from a primary focus on behavioral interventions to the inclusion of these biomedical approaches. In addition to shifts…	community-based organizations; HIV/AIDS; HIV prevention; organizational theory; resource dependence; social services	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Qualitative

Article	2019	Greenwald Z.R.; Maheu-Giroux M.; Szabo J.; Robin J.A.B.; Boissonnault M.; Nguyen V.-K.; Thomas R.	Cohort profile: L'Actuel Pre-Exposure Prophylaxis (PrEP) Cohort study in Montreal, Canada	BMJ Open	-	-	-	-	20446055	10.1136/bmjopen-2018-028768	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068266590&doi=10.1136%2fbmjopen-2018-028768&partnerID=40&md5=9a54bdca9ba1aaf3818edd710ec7531b	Purpose The l'Actuel PrEP Cohort was established to monitor the uptake, effectiveness, safety and changes in sexual risk behaviours among individuals receiving pre-exposure prophylaxis (PrEP) for the prevention of HIV. This prospective dynamic cohort is based at Clinique médicale l'Actuel, a large sexual health clinic located in Montreal, Canada. Participants Since the cohort inception in January of 2013 through June 2018, 2156 individuals consulted for PrEP as participants in the l'Actuel PrEP Cohort. Median age was 35 years (IQR: 29-44 years) and the majority (96%) were men who have sex with men. Among 1551 individuals who initiated PrEP care, the median duration of follow-up was 9.2 months (IQR: 3.7-19.6), with substantial variation based on year of cohort entry. The l'Actuel PrEP Cohort contains both daily and intermittent 'on-demand' PrEP users and has the largest reported population of intermittent PrEP users (n=406) in North America. Findings to date No incident HIV infections have occurred among individuals using PrEP over 1637 person-years of follow-up. However, retention in PrEP care is essential as three individuals who discontinued PrEP subsequently acquired HIV, translating to an HIV incidence of 3.9 cases per 100 person-years (95% CI: 1.3 to 12.1). Among a sample of participants with 1 year of follow-up before and after PrEP initiation (n=109), a moderate increase in sexually transmitted infections was observed following PrEP start. Future plans The l'Actuel PrEP Cohort continues to grow with new participants starting PrEP monthly and extended follow-up for existing users. The cohort data will be used for ongoing monitoring of PrEP and for population-level modelling of the impact of PrEP on HIV incidence in Montreal. © Author(s) (or their employer(s)) 2019. Article	2019	Griffin, Jennifer B; Ridgeway, Kathleen; Montgomery, Elizabeth; Torjesen, Kristine; Clark, Rachel; Peterson, Jill; Baggaley, Rachel; van der Straten, Ariane	Vaginal ring acceptability and related preferences among women in low- And middle-income countries: A systematic review and narrative synthesis	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0224898	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074729664&doi=10.1371%2fjournal.pone.0224898&partnerID=40&md5=879a12910ad18e476cccb6e6c8983af1	The vaginal ring (VR) is a female-initiated drug-delivery platform used for different indications, including HIV pre-exposure prophylaxis (PrEP). We conducted a systematic review of VR acceptability, values and preferences among women in low- and middle-income countries (LMIC) to inform further investment and/or guidance on VR use for HIV prevention. Following PRISMA guidelines, we used structured methods to search, screen, and extract data from randomized controlled trials (RCTs) and observational studies reporting quantitative outcomes of acceptability of the VR for any indication published 1/1970-2/2019 (PROSPERO: CRD42019122220). Of 1,110 records identified, 68 met inclusion criteria. Studies included women 15–50+ years from 25 LMIC for indications including HIV prevention, contraception, abnormal bleeding, and menopause. Overall VR acceptability was high (71–98% across RCTs; 62–100% across observational studies), with 80–100% continuation rates in RCTs and favorable ease of insertion (greater than 85%) and removal 89–99%). Users reported concerns about the VR getting lost in the body (8–43%), although actual expulsions and adverse events were generally infrequent. Most women disclosed use to partners, with some worrying about partner anger/violence. The VR was not felt during intercourse by 70–92% of users and 48–97% of partners. Acceptability improved over time both within studies (as women gained VR experience and worries diminished), and over chronological time (as the device was popularized). Women expressed preferences for accessible, long-acting, partner-approved methods that prevent both HIV and pregnancy, can be used without partner knowledge, and have no impact on sex and few side effects. This review was limited by a lack of standardization of acceptability measures and study heterogeneity. This systematic review suggests that most LMIC women users have a positive view of the VR that increases with familiarity of use; and, that many would consider the VR an acceptable future delivery device for HIV prevention or other indications. © 2019 Griffin et al. Article	2019	Grimm, Josh; Schwartz, Joseph	"It's Like Birth Control for HIV": Communication and Stigma for Gay Men on PrEP.	Journal of Homosexuality	-	-	-	-	1540-3602 0091-8369	10.1080/00918369.2018.1495978	https://dx.doi.org/10.1080/00918369.2018.1495978	This study focuses on how gay men communicate about pre-exposure prophylaxis (PrEP), focusing on how they learned about PrEP, how they discussed adoption with health care providers, and to what extent they have encountered stigma on social networks. In this qualitative study, 39 gay PrEP users were interviewed about PrEP. A majority of the participants learned about PrEP via friends and potential sex partners, and a majority of the participants experienced stigma from their health care provider and from other gay men online, mainly referring to promiscuity and risks of STIs. The authors recommend that health care providers should be trained in minimizing the expression of stigmatizing attitudes and should increase their knowledge of PrEP.	*Homosexuality, Male; Adult; Humans; Male; HIV Infections/*prevention & control; Anti-HIV Agents/*administration & dosage; Truvada; HIV; Interviews as Topic; Sexual Partners; *Pre-Exposure Prophylaxis; PrEP; MSM; Sexual and Gender Minorities; Qualitative Research; Social Stigma; gay; *Social Networking; communication; stigma; interview	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2019	Grov C.; Flynn A.W.P.; D'Angelo A.B.; Lopez-Rios J.; Pantalone D.W.; Holloway I.W.; Parsons J.T.	Gay and Bisexual Men's Strategies to Maintain Daily Adherence to Their HIV Pre-exposure Prophylaxis (PrEP) Medication: Results from a Qualitative Study	Prevention Science	-	-	-	-	13894986	10.1007/s11121-019-0985-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060023030&doi=10.1007%2fs11121-019-0985-y&partnerID=40&md5=2f6fa18c7018b8c4e190217dd0afadfd	Since FDA approval in 2012, HIV pre-exposure prophylaxis (PrEP) has been adopted by key populations, including gay and bisexual men (GBM), to reduce their HIV transmission risk. Given that PrEP is optimally effective when taken as prescribed, it is critical to understand the adherence strategies GBM use. We conducted one-on-one, semi-structured interviews with GBM taking PrEP in 2015–2016 (n = 103). Using thematic analysis, we identified six adherence strategies, with most participants (84.3%) utilizing multiple strategies to maintain adequate adherence: (1) integrating PrEP into part of a daily routine, (2) using a pillbox, (3) cognitive strategies/visual cues, (4) setting recurring smartphone alarms or reminders, (5) keeping medication on oneself at all times, and (6) partner or peer support for reminders and/or pill sharing. Overall, participants reported high PrEP adherence (M = 1.6 missed doses in the prior 30 days), though nearly all described missing at least one dose unintentionally in the past. Participants credited their high levels of adherence in part to the strategies they adopted. Providers working with GBM prescribed PrEP, especially patients reporting difficulties with adherence, might consider recommending any or all of the six strategies described in this study. © 2019, Society for Prevention Research. Article	2019	Grov C.; Rendina H.J.; John S.A.; Parsons J.T.	Determining the Roles that Club Drugs, Marijuana, and Heavy Drinking Play in PrEP Medication Adherence Among Gay and Bisexual Men: Implications for Treatment and Research	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2309-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055266526&doi=10.1007%2fs10461-018-2309-9&partnerID=40&md5=52bfb8b2bd500421f65af477570b3426	Researchers have established that substance use interferes with anti-retroviral medication adherence among gay and bisexual men (GBM) living with HIV. There is limited parallel examination of pre-exposure prophylaxis (PrEP) adherence among HIV-negative GBM. We conducted retrospective 30-day timeline follow-back interviews and prospective semi-weekly diary data for 10 weeks with 104 PrEP-using GBM, half of whom engaged in club drug use (ketamine, ecstasy, GHB, cocaine, or methamphetamine)—generating 9532 days of data. Participants reported their day-by-day PrEP, club drug, marijuana, and heavy alcohol use (5 + drinks in one sitting). On average, club drug users were no more likely to miss a dose of PrEP than non-club drug users (M = 1.6 doses, SD = 3.0, past 30 days). However, we found that club drug use (at the event level) increased the odds of missing a dose on the same day by 55% and the next day (e.g., a "carryover effect") by 60%. Further, missing a dose on one day increased the odds of missing a dose the following day by eightfold. We did not identify an event-level effect of marijuana use or heavy drinking on PrEP adherence. Our data suggest club drug users could have greater protective effects from daily oral or long-acting injectable PrEP compared to a time-driven PrEP regimen because of the concurrence of club drug use and PrEP non-adherence. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Grov, Christian; Westmoreland, Drew; Rendina, H Jonathon; Nash, Denis	Seeing Is Believing? Unique Capabilities of Internet-Only Studies as a Tool for Implementation Research on HIV Prevention for Men Who Have Sex With Men: A Review of Studies and Methodological Considerations.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000002217	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6880799	BACKGROUND: In 2014, Grov et al published a comprehensive review cataloguing both men who have sex with men's (MSM's) sexual behavior transitions in online environments from the 1990s through 2013, as well as researchers' efforts in tandem to use the internet to engage MSM into research, treatment, and prevention. METHODS: In this article, we discuss historical events and research having occurred in the half decade since the Grov et al publication. RESULTS: Notable transitions include MSM's expanded use of geosocial networking apps, as well as other forms of social media accessed primarily through mobile devices, as well as the addition of biomedical prevention strategies (eg, pre-exposure prophylaxis and undetectable = untransmittable) to the proverbial HIV prevention toolkit. In tandem, researchers have rapidly expanded their employment of internet-mediated methods for the recruitment and engagement of key populations for HIV research, treatment, and prevention. In this article, we discuss methodological considerations for using the internet to conduct HIV prevention research with MSM: (1) sources of recruitment (eg, geosocial apps, Facebook, crowdsourced online panels); (2) design (eg, cross sectional, longitudinal, diaries); (3) incentives (including disincentivizing fraudulent participants and/or spam bots); (4) confidentiality; and (5) representativeness. CONCLUSION: We conclude by discussing future directions in HIV prevention research in light of forthcoming technologies such as fifth generation (5G) mobile networks, combined use of self-collected biological data alongside self-report, and the utility of metadata and metaresearch to document, evaluate, and inform best practices.	men who have sex with men, internet, smart phones, online cohorts	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Guinness R.R.; Volk J.E.; Hurley L.B.; Tobias T.T.; Marcus J.L.	Low-Intensity Outreach to Increase Uptake of HIV Preexposure Prophylaxis Among Patients with Sexually Transmitted Infections	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2245-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051851158&doi=10.1007%2fs10461-018-2245-8&partnerID=40&md5=5fcdcfa0b896e69c77bb36c7642a0650	We piloted a low-intensity outreach intervention to increase linkage to PrEP care among HIV-uninfected individuals with rectal sexually transmitted infections or syphilis. We sent a secure email message or letter with information about accessing PrEP. Of those sent an email, 12.4% were linked to PrEP care; linkage differed by race/ethnicity, ranging from 0% of Black individuals to 32% of Hispanic individuals (P = 0.019). No individuals sent letters were linked to PrEP care. A one-time secure email to high-risk patients is feasible to increase linkage to PrEP care. Studies are needed to evaluate scalable interventions to increase PrEP uptake in at-risk populations. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Gulick R.M.; Flexner C.	Long-acting HIV drugs for treatment and prevention	Annual Review of Medicine	-	-	-	-	664219	10.1146/annurev-med-041217-013717	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060583710&doi=10.1146%2fannurev-med-041217-013717&partnerID=40&md5=5b55e27594a8faf6b262cf97e54aa5d2	Antiretroviral drugs have revolutionized the treatment and prevention of HIV infection; however, adherence is critical for sustained efficacy. Current HIV treatment consists of three-drug regimens, and current HIV pre-exposure prophylaxis (PrEP) consists of a two-drug regimen; both generally require adherence to once-daily dosing. Long-acting formulations are useful in the treatment and prevention of other conditions (e.g., contraceptives, antipsychotics) and help promote adherence. Newer long-acting formulations of approved and investigational antiretroviral drugs in existing and newer mechanistic classes are under study for HIV treatment and prevention, including some phase III trials. Although long-acting antiretroviral drugs hold promise, some clinical challenges exist, including managing side effects, drug-drug interactions, pregnancy, and long-lasting drug concentrations that could lead to the development of drug resistance. This review aims to summarize currently available information on long-acting antiretroviral drugs for HIV treatment and prevention. © 2019 by Annual Reviews.	antiretroviral drugs; extended-release; HIV; implants; long-acting; monoclonal antibodies	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Gunn L.H.; Janson B.; Lorjuste I.; Summers L.; Burns P.; Bryant T., III	Healthcare providers' knowledge, readiness, prescribing behaviors, and perceived barriers regarding routine HIV testing and pre-exposure prophylaxis in DeLand, Florida	SAGE Open Medicine	-	-	-	-	20503121	10.1177/2050312119836030	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85084182100&doi=10.1177%2f2050312119836030&partnerID=40&md5=d8745606107c78c8fe51c2950ccfa6db	Objectives: Florida ranks highest in the United States among newly diagnosed HIV infections. This ranking reflects the need for investigation of healthcare providers' knowledge, readiness, prescribing behaviors, and perceived barriers to routine HIV testing and pre-exposure prophylaxis. Methods: We adapted national questionnaires with questions co-developed with Florida Department of Health to form a 25-item instrument. Questionnaires were distributed to the population of eligible healthcare providers in DeLand, Florida. Results: Results from an approximate 20% response rate that encompasses 12 providers demonstrate baseline findings to inform future studies. For example, 75% of respondents were aware of FL Administrative Code 64D-3.042 that pregnant women should receive HIV testing during first and third trimesters. However, 50% of respondents rarely or never offer tests to pregnant women according to practice guidelines. About 75% of respondents strongly agree or agree with willingness to prescribe pre-exposure prophylaxis to high-risk patients, yet 8.3% always or very often prescribe pre-exposure prophylaxis. Conclusions: Results convey the importance of and need for greater collaboration between providers and the Florida Department of Health to enhance providers' knowledge, readiness, and, ultimately, behaviors regarding routine HIV testing and pre-exposure prophylaxis prescription. © The Author(s) 2019. Theses and Dissertations	2019	Gutin, Sarah	Multiple Perspectives on Safer Conception for Women Living with HIV in Botswana: Implications for Service Delivery	-	-	University of Michigan	University of Michigan	-	NA	NA	http://hdl.handle.net/2027.42/153408	HIV-affected couples in sub-Saharan Africa continue to desire childbearing. With high repeat pregnancy rates among women living with HIV and HIV sero-discordance rates close to 50% among couples in sub-Saharan Africa, it is imperative to address the reproductive needs of women living with HIV. Low-cost safer conception (SC) methods to limit HIV transmission risks within HIV sero-discordant couples can be made available in resource-constrained settings. However, SC services are underutilized in many high HIV prevalence countries, including Botswana. In order to develop culturally appropriate programs, research is needed that identifies feasible and acceptable targets for SC interventions. Therefore, this dissertation explores issues around childbearing and pregnancy planning, perceptions of different SC methods, and the correlates of SC information, motivation, behavioral skills, and self-efficacy. The research for this dissertation was conducted in collaboration with local Batswana HIV activists, community-based organizations, and women living with HIV. In addition, the in-country research team was composed of Batswana women who collected data in the local language. Our team first conducted individual in-depth interviews with HIV healthcare providers (n=10) and women living with HIV (n=10) to develop a deeper understanding of attitudes surrounding childbearing and pregnancy planning. Interviews were qualitatively analyzed using an interpretive phenomenological approach. Providers reported it was a human right and normative for women living with HIV to have children but also expressed hesitancy about women living with HIV having children. Although providers believed pregnancies amongst women living with HIV were unplanned, women described discussing pregnancy desires with sexual partners. Participants shared that women living with HIV anticipated stigma from providers regarding childbearing. Following that study, our team conducted eight focus group discussions with women living with HIV (n=45) to gain an in-depth understanding of their perceptions regarding different SC methods, including perceived benefits and challenges of each. These qualitative data were analyzed using an interpretive phenomenological approach. Key factors influencing method perceptions reflected issues at the individual (knowledge of methods, personal motivation to protect partners from HIV transmission, and risks), interpersonal (partner support and communication, relationship intimacy, reducing partner transmission risks, provider stigma), health systems (access and availability, cost of methods, human resource shortages), policy (Ministry of Health policies), and socio-cultural levels (cultural acceptability of methods, norms of masculinity). Although a lack of prior SC knowledge and counseling was a noted challenge to uptake, women were interested in pre-exposure prophylaxis (PrEP) and vaginal insemination techniques for SC. Finally, our team conducted cross-sectional surveys amongst women living with HIV (n=356) to identify areas to target…	Safer conception; HIV; Botswana; Public Health; Health Sciences	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Qualitative
Article	2019	Gwokyalya V.; Beyeza-Kashesya J.; Bwanika J.B.; Matovu J.K.B.; Mugerwa S.; Arinaitwe J.; Kasozi D.; Bukenya J.; Kindyomunda R.; Wagner G.J.; Makumbi F.E.; Wanyenze R.K.	Knowledge and correlates of use of safer conception methods among HIV-infected women attending HIV care in Uganda	Reproductive Health	-	-	-	-	17424755	10.1186/s12978-019-0717-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066629928&doi=10.1186%2fs12978-019-0717-6&partnerID=40&md5=a93687cbedd745a29108778776b8f90d	Background: Many people living with HIV would like to have children but family planning (FP) services often focus on only contraception. Availability of safer conception services is still very low in most low income countries. In this study we assessed the knowledge and use of safer conception methods (SCM) among HIV infected women in HIV care in Uganda to inform integration of safer conception in existing FP services. Methods: Data were accrued from a nationally representative cross-sectional survey of 5198 HIV+ women aged 15-49 years from 245 HIV clinics in Uganda. Knowledge and use of safer conception methods and associated factors were determined. The measure of association was prevalence ratio (PR) with corresponding 95% confidence intervals, obtained using a modified Poisson regression via generalized linear models. All the analyses were conducted using STATA version 12.0. Results: Overall knowledge of any safer conception method was 74.1% (3852/5198). However only 13.2% knew 3 to 4 methods, 18.9% knew only 2 methods and 42% knew only one method. Knowledge of specific SCM was highest for timed unprotected intercourse (TUI) at 39% (n = 2027) followed by manual self-insemination (MSI) at 34.8% (n = 1809), and pre-exposure prophylaxis (PrEP) at 24.8% (n = 1289). Knowledge of SCM was higher in the Eastern region (84.8%, P < 0.001), among women in HIV-discordant relationships (76.7%, p < 0.017), and those on ART (74.5%, p < 0.034). Overall, 1796 (34.6%) women were pregnant or reported a birth in the past 2 years - overall use of SCM in this group was 11.6% (209/1796). The odds of use of SCM were significantly lower in Kampala adj. PR = 0.489(0.314, 0.764) or Eastern region adj.PR = 0.244; (0.147, 0.405) compared to Northern region. Higher odds of SCM use were associated with HIV status disclosure to partner adj.PR = 2.613(1.308, 5.221) and sero-discordant compared to HIV+ concordant relationship adj.PR = 1.637(1.236, 2.168). Pre-existing knowledge of any one SCM did not influence SCM use. Conclusions: Knowledge and use of SCM among HIV+ women in care is low. Efforts to improve HIV status disclosure, integration of safer conception into FP and HIV services and regional efforts to promote sensitization and access to safer conception can help to increase uptake of safer conception methods. © 2019 The Author(s). Article	2019	H Fisher Raymond; Snowden, Jonathan M; Guigayoma, John; McFarland, Willi; Chen, Yea-Hung	Community Levels of PrEP Use Among Men Who Have Sex with Men by Race/Ethnicity, San Francisco, 2017	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02428-5	https://www.proquest.com/scholarly-journals/community-levels-prep-use-among-men-who-have-sex/docview/2179176662/se-2?accountid=8113	Efforts in San Francisco are maximizing the use of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) where high levels of use are needed to maximize reducing new HIV infections. National HIV Behavioral Surveillance surveys MSM in San Francisco. Demographics, health care and risk behaviors are assessed. PrEP use is measured for 12 month, 6 month and 30 day periods. Of 399 HIV uninfected men sampled in 2017, 43.4% used PrEP in the past 12 months. Proportions of men using PrEP by race/ethnicity were not significant at any time point. Decreases between 6 month and 30 day use were highest among African American and Latino men. These men had the highest proportion of intermittent use in the past 30 days but not significantly. While our data suggest the disparity in PrEP use by race/ethnicity has narrowed in San Francisco, novel delivery of PrEP may narrow disparity further. Article	2019	Ha, Tran Viet; Chockalingam, L; Giang, L M; Krishnan, A; Bhadra, M; Miller, WC; Sripaipan, T; Go, V F	AWARENESS OF HIV PRE-EXPOSURE PROPHYLAXIS (PrEP) AMONG MEN WHO HAVE SEX WITH MEN IN HANOI, VIETNAM	Southeast Asian Journal of Tropical Medicine and Public Health	-	-	-	-	1251562	NA	https://www.proquest.com/scholarly-journals/awareness-hiv-pre-exposure-prophylaxis-prep-among/docview/2554643459/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) of human immunodeficiency virus (HIV) with medication is used to reduce the risk of contracting HIV infection. We investigated the awareness of PrEP among men who have sex with men (MSM) in Hanoi, Vietnam, in order to inform HIV-treatment programs promoting PrEP's use. Eligibility criteria for the study included: self-identified MSM; 18 years of age or older; sexual intercourse with one or more men in the previous 3 months; voluntary study participation. From February-May 2016, 190 study participants were recruited to complete an anonymous cross-sectional survey about their awareness of PrEP and willingness to use it. The mean age of study participants was 23 years, and 28% of study participants had ever heard of PrEP. On a multivariate regression analysis, disclosing MSM status to parents, using websites to find male sexual partners and ever being tested for HIV infection were all significantly associated with awareness of PrEP. Sixty percent of participants stated they would be willing to use oral PrEP and 55% stated they would be willing to use injectable PrEP. Our findings show awareness of PrEP in the study population was low, but PrEP promotion programs through mobile applications, websites, or HIV testing sites could raise awareness among at-risk MSM. Further research is needed to better understand the factors associated with increased PrEP awareness and acceptance. It should be noted at the time this paper was written, injectable PrEP is an experimental treatment. Article	2019	Haaland, Richard E.; Martin, Amy; Livermont, Tamee; Fountain, Jeffrey; Dinh, Chuong; Holder, Angela; Lupo, Lindsey D.; Hall, LaShonda; Conway-Washington, Christopher; Kelley, Colleen F.	Urine Emtricitabine and Tenofovir Concentrations Provide Markers of Recent Antiretroviral Drug Exposure Among HIV-Negative Men Who Have Sex With Men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000002133	https://pubmed.ncbi.nlm.nih.gov/31335590/	BACKGROUND: Urine provides a minimally invasive specimen that may allow for development of rapid tests to detect antiretroviral drugs and provide opportunities to improve individual adherence. This study sought to determine whether urine could provide a biomarker of adherence for currently approved pre-exposure prophylaxis and HIV treatment regimens. METHODS: Urine and blood were collected from 34 HIV-negative men who have sex with men aged 18-49 years, enrolled in a clinical trial comparing 2 antiretroviral regimens. Specimens were collected 4 and 24 hours after a single oral dose of tenofovir disoproxil fumarate (TDF)/emtricitabine (FTC) (n = 10) or tenofovir alafenamide (TAF)/FTC/cobicistat (COBI)/elvitegravir (EVG) (n = 8), or after 4 and 10 days of daily oral TDF/FTC (n = 9) or TAF/FTC/COBI/EVG (n = 7). Tenofovir (TFV), FTC, and EVG were measured by high-performance liquid chromatography-mass spectrometry. RESULTS: Median urine FTC concentrations at 4 and 24 hours were similar between men receiving TDF/FTC (4 hours 147 μg/mL; 24 hours 10 μg/mL) and men receiving TAF/FTC/COBI/EVG (4 hours 333 μg/mL, P = 0.173; 24 hours 13 μg/mL, P = 0.681). Median urine TFV concentrations were lower among men receiving TAF/FTC/COBI/EVG (4 hours 1.2 μg/mL; 24 hours 0.8 μg/mL) compared with men receiving TDF/FTC (4 hours 17 μg/mL, P < 0.001; 24 hours 7 μg/mL, P = 0.001). Urine TFV concentrations remained reduced among men receiving TAF/FTC/COBI/EVG compared with men receiving TDF/FTC after daily dosing. EVG was not consistently measurable in urine. CONCLUSIONS: High urine FTC and TFV concentrations could provide an indication of adherence to daily oral dosing with TDF or TAF-based regimens used for treatment and prevention.	*Homosexuality, Male; Administration, Oral; Adolescent; Adult; Humans; Male; Middle Aged; Young Adult; HIV Infections/*drug therapy; Time Factors; Adenine/analogs & derivatives; Alanine; Biomarkers/*urine; *Sexual and Gender Minorities; Anti-HIV Agents/administration & dosage/therapeutic use/urine; Anti-Retroviral Agents/administration & dosage/therapeutic use/*urine; Cobicistat/therapeutic use; Emtricitabine/administration & dosage/therapeutic use/*urine; Quinolones; Tenofovir/administration & dosage/therapeutic use/*urine	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Haberer, Jessica E; Mugo Nelly; Baeten, Jared M; Pyra, Maria; Bukusi, Elizabeth; Linda-Gail, Bekker	PrEP as a Lifestyle and Investment for Adolescent Girls and Young Women in Sub-Saharan Africa	Journal of the International Association of Physicians in AIDS Care	-	-	-	-	23259574	10.1177/2325958219831011	https://www.proquest.com/scholarly-journals/prep-as-lifestyle-investment-adolescent-girls/docview/2375780338/se-2?accountid=8113	Adolescent girls and young women (AGYW) are highly affected by the HIV epidemic, yet standard approaches to pre-exposure prophylaxis (PrEP) delivery will not meet their needs. This commentary highlights key characteristics of AGYW related to PrEP use and delivery, including typical neurocognitive development, lack of experience with sustained medication use, and the social and connected nature of AGYW's lives. We then suggest ways for programs to embrace these characteristics, such as presenting PrEP as a lifestyle choice and not a biomedical tool, making access to PrEP simple and easy, and recognizing the many influences AGYW face in taking PrEP. We also suggest ways for programs to identify AGYW at the highest risk of HIV acquisition. Adolescent girls and young women have an important role to play in ending the HIV epidemic and they deserve considerable, tailored investment. Article	2019	Hamilton D.T.; Rosenberg E.S.; Jenness S.M.; Sullivan P.S.; Wang L.Y.; Dunville R.L.; Barrios L.C.; Aslam M.; Goodreau S.M.	Modeling the joint effects of adolescent and adult PrEP for sexual minority males in the United States	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0217315	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066028011&doi=10.1371%2fjournal.pone.0217315&partnerID=40&md5=e65e303fb952ce33aa522d73bf2b75e8	Background Pre-exposure prophylaxis (PrEP) is an effective and safe intervention approved for use to prevent HIV transmission. PrEP scale-up strategies and clinical practice are currently being informed by modeling studies, which have estimated the impact of PrEP in adult and adolescent MSM populations separately. This partitioning may miss important effects or yield biased estimates by excluding dependencies between populations. Methods We combined two published models of HIV transmission among adults and adolescent MSM. We simulated an HIV epidemic among MSM aged 13–39 without PrEP, with PrEP for adult MSM ages (19–39) and with the addition of PrEP for adolescents ages (16–18), comparing percent of incident infections averted (impact), the number of person-years on PrEP per infection averted (efficiency), and changes in prevalence. Results PrEP use among eligible 19–39 year old MSM averted 29.0% of infections and reduced HIV prevalence from 23.2% to 17.0% over ten years in the population as a whole. Despite being ineligible for PrEP in this scenario, prevalence among sexually active 18 year-olds declined from 6.0% to 4.3% due to reduced transmissions across age cohorts. The addition of PrEP for adolescents ages 16–18 had a small impact on the overall epidemic, further reducing overall prevalence from 17.0% to 16.8%; however prevalence among the sexually active 18 year-olds further declined from 4.3% to 3.8%. Conclusions PrEP use among adults may significantly reduce HIV prevalence among MSM and may also have significant downstream effects on HIV incidence among adolescents; PrEP targeting adolescents remains an important intervention for HIV prevention. © This is an open access article, free of all copyright, and may be freely reproduced, distributed, transmitted, modified, built upon, or otherwise used by anyone for any lawful purpose. Article	2019	Hammack P.L.; Toolis E.E.; Wilson B.D.M.; Clark R.C.; Frost D.M.	Making Meaning of the Impact of Pre-Exposure Prophylaxis (PrEP) on Public Health and Sexual Culture: Narratives of Three Generations of Gay and Bisexual Men	Archives of Sexual Behavior	-	-	-	-	40002	10.1007/s10508-019-1417-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062954877&doi=10.1007%2fs10508-019-1417-6&partnerID=40&md5=0353773fd03c04e7b7cc37eb7b233ef5	Pre-exposure prophylaxis (PrEP) with Truvada has emerged as an increasingly common approach to HIV prevention among gay, bisexual, and other men who have sex with men. This study examined generational differences and similarities in narrative accounts of PrEP among a diverse sample of 89 gay and bisexual men in the U.S. Over 50% of men in the older (52–59 years) and younger (18–25 years) generations endorsed positive views, compared with 32% of men in the middle (34–41 years) generation. Men in the middle cohort expressed the most negative (21%) and ambivalent (47%) views of PrEP. Thematic analysis of men's narratives revealed three central stories about the perceived impact of PrEP: (1) PrEP has a positive impact on public health by preventing HIV transmission (endorsed more frequently by men in the older and younger cohorts); (2) PrEP has a positive effect on gay and bisexual men's sexual culture by decreasing anxiety and making sex more enjoyable (endorsed more frequently by men in the middle and younger cohorts); and (3) PrEP has a negative impact on public health and sexual culture by increasing condomless, multi-partner sex (endorsed more frequently by men in the middle and younger cohorts). Results are discussed in terms of the significance of generation cohort in meanings of sexual health and culture and implications for public health approaches to PrEP promotion among gay and bisexual men. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Hammoud M.A.; Vaccher S.; Jin F.; Bourne A.; Maher L.; Holt M.; Bavinton B.R.; Haire B.; Degenhardt L.; Grulich A.; Prestage G.P.	HIV Pre-exposure Prophylaxis (PrEP) Uptake among Gay and Bisexual Men in Australia and Factors Associated with the Nonuse of PrEP among Eligible Men: Results from a Prospective Cohort Study	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002047	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068197251&doi=10.1097%2fQAI.0000000000002047&partnerID=40&md5=d36952c02b285e10d0bc1807ee31036c	Background:HIV pre-exposure prophylaxis (PrEP) is a highly effective biomedical HIV prevention strategy, yet some gay and bisexual men (GBM) who are eligible to access PrEP are not using it. We report the incidence of PrEP uptake, factors predicting its initiation, and identify characteristics associated with nonuptake of PrEP among Australian GBM who meet the eligibility criteria.Methods:The Following Lives Undergoing Change (Flux) Study is a national, online, prospective observational study among GBM focusing on licit and illicit drug use. Participants (N = 1257) responded to baseline and 6-monthly follow-up questionnaires. Incidence per 100 person-years and incidence rate ratios of PrEP initiation are presented. Multivariate Poisson regression was used to examine associations with PrEP initiation and logistic regression to examine associations with nonuptake of PrEP among GBM.Results:Among GBM who met the eligibility criteria, 69.8% of men did not commence PrEP. Factors independently associated with nonuptake of PrEP were younger age, living in an Australian state without a PrEP trial, lower social engagement with other gay men, less use of illicit party drugs or use of illicit party drugs for sex, and less likely to have engaged in HIV sexual risk behaviors such as group sex or any condomless anal intercourse.Conclusions:Despite meeting formal eligibility criteria for PrEP, men who were relatively less sexually active or less socially connected were less likely to initiate PrEP. Men who did not initiate PrEP may assess their risk as insufficient relative to others to warrant using PrEP because they engaged in less frequent "risky" behaviors. © 2019 The Author(s). Theses and Dissertations	2019	Hammoud, Mohamed	Adherence to HIV pre-exposure prophylaxis in New South Wales, Australia	-	-	University of New South Wales	University of New South Wales	-	NA	https://doi.org/10.26190/unsworks/21408	http://hdl.handle.net/1959.4/63345 https://unsworks.unsw.edu.au/bitstreams/3f576730-f504-4758-931f-2bd4047884ff/download https://doi.org/10.26190/unsworks/21408	Pre-exposure prophylaxis (PrEP) is a highly efficacious HIV prevention strategy. The caveat, however, is that PrEP requires high adherence to antiretroviral medications during periods when a person is at risk of acquiring HIV. Identifying who is at risk of HIV and ensuring adequate coverage during these risk periods is a key challenge of PrEP implementation. The overarching objective of this thesis was to examine adherence to PrEP among gay and bisexual men (GBM) in New South Wales, Australia. This body of research comprises four projects. Data for three projects came from the PrELUDE Demonstration Project (2014 – 2017), while data for the fourth project was drawn from SIN-PrEP (2015 – 2018). The first project assessed the NSW PrEP guidelines and found that individuals at high risk of HIV could be identified and enrolled into a PrEP demonstration project. The second project investigated PrEP dosing preferences and found that one-third of GBM expressed a preference for non-daily PrEP. A preference for taking daily PrEP was associated with lower levels of education, having an HIV-positive partner, and rating oneself better at taking medications. The third project compared four different adherence measures and found that in our setting, facilitated recall to clinicians was as good as biological measures in identifying adherent individuals. Over 90% of participants remaining under follow-up after 12 months reported taking seven PrEP pills per week throughout the year. A generalised estimating equation model identified that practices such as group sex were associated with taking daily PrEP. The fourth project used qualitative data from interviews with current and previous PrEP users to explore in-depth issues relating to PrEP adherence. Although most participants reported encountering barriers to PrEP use, they had developed effective strategies to ensure that high levels of adherence to PrEP could be maintained. This thesis assesses the interplay between social, behavioural, and biomedical factors that impact PrEP adherence, and how the influence of each of these factors may fluctuate during PrEP use. The high level of adherence in this cohort I have described through this thesis underpins the success of PrEP as an HIV prevention intervention in GBM in Australia. Article	2019	Han J.; Bouey J.Z.H.; Wang L.; Mi G.; Chen Z.; He Y.; Viviani T.; Zhang F.	PrEP uptake preferences among men who have sex with men in China: results from a National Internet Survey	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25242	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061124731&doi=10.1002%2fjia2.25242&partnerID=40&md5=e446221ebfb8897fcf055bf27866b7d3	Introduction: HIV incidence among men who have sex with men (MSM) is high in China. Pre-exposure prophylaxis (PrEP) is a promising mean to prevent HIV transmission but it is not widely available in China. We conducted a large Internet-based online survey to assess the willingness of Chinese MSM to take PrEP and associated factors to their uptake preferences. Methods: Between 19 January and 6 February, 2017, 4581 MSM aged over 15 years were recruited via a social networking app to take an online PrEP survey. HIV status at the time of the survey being conducted was not one of recruitment criteria. Participants were asked if they had heard of PrEP, if they had concerns about PrEP, and if they would be ready to uptake PrEP should it be provided. When asked if participants were willing to take PrEP, they were asked to select from the following responses: "definitely not," "probably not," "not sure," "probably yes," and "definitely yes." In the final analysis, we grouped these five-level Likert scale responses into three-level responses as "definitely yes," "probably yes," and "no (definitely not/probably not/not sure)." Descriptive analysis and multinomial logistic regressions were conducted to assess the associations of PrEP adoption readiness and uptake concerns with HIV risk behaviours and demographic characteristics. Results: MSM from 33 geographical regions of China participated in the survey. The majority were younger than 25 (65.2%) and had attended college (68.6%). HIV prevalence was high (6.8%) and 43.3% reported a history of unprotected anal sex. Only 22.4% of participants had heard of PrEP. When asked if they would uptake PrEP, 26.0% said "definitely yes," 49.6% were "probably yes," and 24.4% said "no." PrEP adoption readiness was associated with having previously heard of PrEP and expressing concerns about accessibility and cost. Worries about side effects, low perceived HIV risk, preference for condoms, and never having received HIV testing were negatively associated with PrEP uptake willingness. Conclusion: Young and well-educated Chinese MSM reported a low willingness to uptake PrEP despite being high-risk for HIV. Effective education, especially through online mediums, will be critical to optimize this group's PrEP uptake. © 2019 The Authors. Article	2019	Hanscom, Brett; Hughes, James P; Williamson, Brian D; Donnell, Deborah	Adaptive non-inferiority margins under observable non-constancy	Statistical Methods in Medical Research	-	-	-	-	9622802	10.1177/0962280218801134	https://pubmed.ncbi.nlm.nih.gov/30293490/	A central assumption in the design and conduct of non-inferiority trials is that the active-control therapy will have the same degree of effectiveness in the planned non-inferiority trial as in the prior placebo-controlled trials used to define the non-inferiority margin. This is referred to as the 'constancy' assumption. If the constancy assumption fails, decisions based on the chosen non-inferiority margin may be incorrect, and the study runs the risk of approving an inferior product or failing to approve a beneficial product. The constancy assumption cannot be validated in a trial without a placebo arm, and it is unlikely ever to be met completely. When there are strong, observable predictors of constancy, such as dosing and adherence to the active-control product, we can specify conditions where the constancy assumption will likely fail. We propose a method for using measurable predictors of active-control effectiveness to specify non-inferiority margins targeted to the planned study population characteristics. We describe a pre-specified method, using baseline characteristics or post-baseline predictors in the active-control arm, to adapt the non-inferiority margin at the end of the study if constancy is violated. Adaptive margins can help adjust for constancy violations that will inevitably occur in real clinical trials, while maintaining pre-specified levels of Type I error and power. Article	2019	Hargreaves, James; Dalal, Shona; Rice, Brian; Anderegg, Nanina; Bhattacharjee, Parinita; Gafos, Mitzy; Hensen, Bernadette; Mangenah, Collin; Quaife, Matthew; Padian, Nancy	Repositioning Implementation Science in the HIV Response: Looking Ahead From AIDS 2018.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000002209	https://dx.doi.org/10.1097/QAI.0000000000002209	BACKGROUND: Implementation science (IS) occupies a critical place in HIV/AIDS research, reflected by a scientific track ("Track E") at the biannual International AIDS Conference. IS seeks to identify health delivery strategies that cost-effectively translate the efficacy of evidence-based interventions for HIV prevention, testing, and treatment into impact on HIV incidence, quality of life, and mortality. METHOD: We reviewed the content of Track E, and other presentations relevant to IS, at the 22nd International AIDS Conference held in Amsterdam in 2018. We identified key findings and themes and made recommendations for areas where the field can be strengthened by the 2020 meeting. RESULTS: Trials of "treat all" strategies in Africa showed mixed evidence of effect. Innovations in HIV testing included expanding self-testing and index testing, which are reaching groups, such as men, where previously testing rates have been low. Adherence clubs and other innovations are being trialed to improve retention in care, with mixed findings. The implementation of pre-exposure prophylaxis for HIV prevention continues but with many challenges remaining in identifying implementation strategies that strengthen demand and support continuation. DISCUSSION: IS for HIV/AIDS treatment and prevention continues to expand. IS for primary HIV prevention must be prioritized with a dearth of rigorous, intersectoral studies in this area. The weakness of routine data must be addressed. Costing and financing studies should form a stronger component of the conference agenda. Implementation scientists must continue to grapple with the methodological challenges posed by the real-world context for their research. Article	2019	Harling G.; Muya A.; Ortblad K.F.; Mashasi I.; Dambach P.; Ulenga N.; Barnhart D.; Mboggo E.; Oldenburg C.E.; Bärnighausen T.; Spiegelman D.	HIV risk and pre-exposure prophylaxis interest among female bar workers in Dar es Salaam: Cross-sectional survey	BMJ Open	-	-	-	-	20446055	10.1136/bmjopen-2018-023272	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063324704&doi=10.1136%2fbmjopen-2018-023272&partnerID=40&md5=decb2be561254fa0980d7e0646da5afb	Objective Female bar workers (FBW) in East Africa often conduct sex work to supplement their incomes, and may be vulnerable to HIV acquisition. Pre-exposure prophylaxis (PrEP) offers protection against HIV acquisition. However, there is little research on FBW's sexual health. Our objective was to determine HIV risk behaviours and interest in PrEP among FBW in the largest city in East Africa. Design Cross-sectional survey covering respondents' work and personal lives, including social and behavioural risk factors for HIV. The survey aimed to determine the feasibility of working with FBW and HIV prevalence estimates. Those who did not report being HIV positive were asked about their knowledge of and interest in PrEP. All women were offered free on-site HIV testing and counselling (HTC). Setting Eight randomly selected workplaces, that is, bars, in Kinondoni district, Dar es Salaam (DSM). Participants 66 FBW (≥18 years) selected at random from all women working in selected bars on the day of visit. Results Half of respondents reported having had sex for money: 20% with bar clients only, 15% with other men only and 15% with both. Almost all (98%) reported ≥1 non-commercial partners in the past 12 months; only 30% reported using condoms with these partners. 85% of respondents had ever been pregnant; 44% had had an unintended pregnancy. Only 5% of respondents had ever heard of PrEP. However, 54% were somewhat/very interested in daily-pill PrEP and 79% were somewhat/very interested in long-acting injectable PrEP. When asked to rank modalities, long-acting injectable PrEP was the most preferred. Seven per cent of the 56 respondents who completed HTC tested HIV positive. Conclusions FBW in DSM have elevated risk factors for HIV acquisition, and PrEP appears highly acceptable. Studies developing PrEP delivery models and assessing PrEP initiation and adherence in FBW appear warranted. © Author(s) (or their employer(s)) 2019. Re-use permitted under CC BY-NC. Article	2019	Harris N.S.; Johnson A.S.; Huang Y.-L.A.; Kern D.; Fulton P.; Smith D.K.; Valleroy L.A.; Hall H.I.	Vital signs: Status of human immunodeficiency virus testing, viral suppression, and HIV preexposure prophylaxis — United States, 2013–2018	MMWR Recommendations and Reports	-	-	-	-	1492195	10.15585/mmwr.mm6848e1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076305701&doi=10.15585%2fmmwr.mm6848e1&partnerID=40&md5=7385a711a5d2433f7645252e84c3d852	Background: Approximately 38,000 new human immunodeficiency virus (HIV) infections occur in the United States each year; these infections can be prevented. A proposed national initiative, Ending the HIV Epidemic: A Plan for America, incorporates three strategies (diagnose, treat, and prevent HIV infection) and seeks to leverage testing, treatment, and preexposure prophylaxis (PrEP) to reduce new HIV infections in the United States by at least 90% by 2030. Targets to reach this goal include that at least 95% of persons with HIV have a diagnosis, 95% of persons with diagnosed HIV infection have a suppressed viral load, and 50% of those at increased risk for acquiring HIV are prescribed PrEP. Using surveillance, pharmacy, and other data, CDC determined the current status of these three initiative strategies. Methods: CDC analyzed HIV surveillance data to estimate annual number of new HIV infections (2013–2017); estimate the percentage of infections that were diagnosed (2017); and determine the percentage of persons with diagnosed HIV infection with viral load suppression (2017). CDC analyzed surveillance, pharmacy, and other data to estimate PrEP coverage, reported as a percentage and calculated as the number of persons who were prescribed PrEP divided by the estimated number of persons with indications for PrEP. Results: The number of new HIV infections remained stable from 2013 (38,500) to 2017 (37,500) (p = 0.448). In 2017, an estimated 85.8% of infections were diagnosed. Among 854,206 persons with diagnosed HIV infection in 42 jurisdictions with complete reporting of laboratory data, 62.7% had a suppressed viral load. Among an estimated 1.2 million persons with indications for use of PrEP, 18.1% had been prescribed PrEP in 2018. Conclusion: Accelerated efforts to diagnose, treat, and prevent HIV infection are needed to achieve the U.S. goal of at least 90% reduction in the number of new HIV infections by 2030. © 2019 Department of Health and Human Services. Generating charisma: Development of an intervention to help women build agency and safety in their relationships while using prep for HIV prevention	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2019.31.5.433	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072608638&doi=10.1521%2faeap.2019.31.5.433&partnerID=40&md5=2dd66f712a0ab7e7d2bb102ac4540988	This article describes the development of the Community Health clinic model for Agency in Relationships and Safer Microbicide Adherence intervention (CHARISMA), an intervention designed to address the ways in which gender norms and power differentials within relationships affect women's ability to safely and consistently use HIV pre-exposure prophylaxis (PrEP). CHARISMA development involved three main activities: (1) a literature review to identify appropriate evidence-based relationship dynamic scales and interventions; (2) the analysis of primary and secondary data collected from completed PrEP studies, surveys and cognitive interviews with PrEP-experienced and naïve women, and in-depth interviews with former vaginal ring trial participants and male partners; and (3) the conduct of workshops to test and refine key intervention activities prior to pilot testing. These steps are described along with the final clinic and community-based intervention, which was tested for feasibility, acceptability, and preliminary effectiveness in Johannesburg, South Africa. © 2019 The Guilford Press. Article	2019	Hassan, A; Wertheim, JO; Blumenthal, JS; Ellorin, E; Dube, MP; Corado, K; Moore, DJ; Morris, SR	Characteristics of a cohort of high-risk men who have sex with men on pre-exposure prophylaxis reporting transgender sexual partners	Medicine (United States)	-	-	-	-	NA	10.1097/MD.0000000000018232	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-02012186/full	Transgender people continue to be at high-risk for HIV acquisition, but little is known about the characteristics of their sexual partners. To address this gap, we examined sociodemographic and sexual characteristics of cisgender men who have sex with men (MSM) on pre-exposure prophylaxis (PrEP) reporting transgender sexual partners.A cohort of 392 MSM in southern California in a randomized clinical trial for PrEP adherence were followed from 2013 to 2016. Multivariable generalized estimating equation and logistic models identified characteristics of MSM reporting transgender sexual partners and PrEP adherence.Only 14 (4%) MSM reported having transgender sexual partners. MSM were more likely to report transgender partners if they were African American, had incident chlamydia, reported injection drug-using sexual partners, or received items for sex. Most associations remained significant in the multivariable model: African American (adjusted odds ratio AOR 11.20, P=.01), incident chlamydia (AOR 3.71, P=.04), and receiving items for sex (AOR 5.29, P=.04). There were no significant differences in PrEP adherence between MSM reporting transgender partners and their counterpart.MSM who report transgender sexual partners share characteristics associated with individuals with high HIV prevalence. Identifying this group distinct from larger cohorts of MSM could offer new HIV prevention opportunities for this group of MSM and the transgender community. Article	2019	Havens J.P.; Scarsi K.K.; Sayles H.; Klepser D.G.; Swindells S.; Bares S.H.	Acceptability and Feasibility of a Pharmacist-Led Human Immunodeficiency Virus Pre-Exposure Prophylaxis Program in the Midwestern United States	Open Forum Infectious Diseases	-	-	-	-	23288957	10.1093/ofid/ofz365	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073526252&doi=10.1093%2fofid%2fofz365&partnerID=40&md5=13e25d961307f29443129542df8b7ef7	Background: Human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) substantially reduces the risk of HIV acquisition, yet significant barriers exist to its prescription and use. Incorporating pharmacists in the PrEP care process may help increase access to PrEP services. Methods: Our pharmacist-led PrEP program (P-PrEP) included pharmacists from a university-based HIV clinic, a community pharmacy, and 2 community-based clinics. Through a collaborative practice agreement, pharmacists conducted PrEP visits with potential candidates for PrEP, according to the recommended Centers for Disease Control and Prevention guidelines, and authorized emtricitabine-tenofovir disoproxil fumarate prescriptions. Demographics and retention in care over 12 months were summarized, and participant satisfaction and pharmacist acceptability with the P-PrEP program were assessed by Likert-scale questionnaires. Results: Sixty patients enrolled in the P-PrEP program between January and June 2017 completing 139 visits. The mean age was 34 years (range, 20-61 years), and 88% identified as men who have sex with men, 91.7% were men, 83.3% were white, 80% were commercially insured, and 89.8% had completed some college education or higher. Participant retention at 3, 6, 9, and 12 months was 73%, 58%, 43%, and 28%, respectively. To date, no participant has seroconverted. One hundred percent of the participants who completed the patient satisfaction questionnaire would recommend the P-PrEP program. Pharmacists reported feeling comfortable performing point-of-care testing and rarely reported feeling uncomfortable during PrEP visits (3 occasions, 2.2%) or experiencing workflow disruption (1 occasion, 0.7%). Conclusions: Implementation of a pharmacist-led PrEP program is feasible and associated with high rates of patient satisfaction and pharmacist acceptability. © 2019 The Author(s) 2019. Article	2019	Havens, PL; Tamhane, A; Stephensen, CB; Schuster, GU; Gordon, CM; Liu, N; Wilson, CM; Hosek, SG; Anderson, PL; Kapogiannis, BG; Mulligan, K; Adolescent Trials Network HIV AIDS	Association of Vitamin D Insufficiency and Protective Tenofovir Diphosphate Concentrations with Bone Toxicity in Adolescent Boys and Young Men Using Tenofovir Disoproxil Fumarate/Emtricitabine for HIV Pre-Exposure Prophylaxis	AIDS Research and Human Retroviruses	-	-	-	-	0889-2229	10.1089/aid.2018.0096	https://pubmed.ncbi.nlm.nih.gov/30280906/	We examined associations of 25-hydroxy vitamin D (25-OHD), tenofovir disoproxil fumarate (TDF), and bone toxicity. We studied TDF/emtricitabine (FTC) HIV pre-exposure prophylaxis (PrEP) in young men who have sex with men (YMSM). Bone toxicity was predefined using bone mineral density/content change from baseline to week 48. Baseline serum 25-OHD was dichotomized as <20ng/mL (insufficient/deficient) versus 20 (sufficient), and week 48 dried blood spot tenofovir diphosphate (TFV-DP) as >700fmol/punch (protective against HIV acquisition) versus 700. Associations were examined by univariate and multivariable logistic regression, reporting crude and adjusted odds ratios (ORs), with 95% confidence intervals (CIs). Of 101 enrolled, 69 had complete bone assessments and 25-OHD; of these, 59 had week 48 TFV-DP data. Median (Q1-Q3) age was 20 (18-21) years; 54% were black/African American. In univariate analysis, participants with baseline 25-OHD <20ng/mL (OR=5.4; 95% CI=1.9-16.5) and blacks (OR=4.9; 95% CI=1.7-15.2) had greater odds of bone toxicity than those with 25-OHD 20 or other races. TFV-DP was not associated with bone toxicity (OR=1.6; 95% CI=0.5-5.5). In multivariable analysis, compared with those with 25-OHD 20 and TFV-DP 700, those with 25-OHD 20 and TFV-DP >700 (OR=11.5; 95% CI=1.4-169.6), 25-OHD <20 and TFV-DP 700 (OR=19.4; 95% CI=3.0-228.7), and 25-OHD <20 and TFV-DP >700 (OR=32.3; 95% CI=3.3-653.6) had greater odds of bone toxicity after adjusting for race. In multivariable models, 25-OHD insufficiency, protective TFV-DP concentrations, and black race were significantly associated with bone toxicity after 48 weeks of TDF/FTC PrEP in YMSM. Clinical Trials Registration: NCT01769469.	tenofovir disoproxil fumarate; HIV pre-exposure prophylaxis; EMTRICITABINE; SEX; ANTIRETROVIRAL THERAPY; bone mineral density; MINERAL DENSITY; PARATHYROID-HORMONE; 25-hydroxy vitamin D; D DEFICIENCY	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Estimating the 'PrEP Gap': How implementation and access to PrEP differ between countries in Europe and Central Asia in 2019	Eurosurveillance	-	-	-	-	1025496X	10.2807/1560-7917.ES.2019.24.41.1900598	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073474764&doi=10.2807%2f1560-7917.ES.2019.24.41.1900598&partnerID=40&md5=67dafc22b1aea96903daee115866fabe	In 2019, only 14 European and Central Asian countries provided reimbursed HIV pre-exposure prophylaxis (PrEP). Using EMIS-2017 data, we present the difference between self-reported use and expressed need for PrEP in individual countries and the European Union (EU). We estimate that 500,000 men who have sex with men in the EU cannot access PrEP, although they would be very likely to use it. PrEP's potential to eliminate HIV is currently unrealised by national healthcare systems. © 2019 European Centre for Disease Prevention and Control (ECDC). All rights reserved. Article	2019	Heendeniya A.; Bogoch I.I.	Antiretroviral Medications for the Prevention of HIV Infection: A Clinical Approach to Preexposure Prophylaxis, Postexposure Prophylaxis, and Treatment as Prevention	Infectious Disease Clinics of North America	-	-	-	-	8915520	10.1016/j.idc.2019.04.002	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067564302&doi=10.1016%2fj.idc.2019.04.002&partnerID=40&md5=d728868561c102f301857dfff4590afc	Preventing new human immunodeficiency virus (HIV) infections is essential to halting the global pandemic. HIV prevention strategies include integrating both nonpharmacologic (eg, safe sexual counseling, circumcision) and pharmacologic approaches. Several pharmacologic HIV prevention strategies are increasingly used globally and include postexposure prophylaxis, preexposure prophylaxis, and treatment as prevention. These prevention modalities have enormous clinical and public health appeal, as they effectively reduce HIV acquisition in individuals and also may lower HIV incidence in communities when integrated and implemented broadly. Efforts are now underway to scale HIV prevention programs using these techniques in both high- and low-resource settings. © 2019 Elsevier Inc. Article	2019	Heendeniya, Amila; Bogoch, Isaac I	HIV prevention with post-exposure prophylaxis-in-pocket.	The Lancet Public Health	-	-	-	-	2468-2667	10.1016/S2468-2667(19)30152-5	https://dx.doi.org/10.1016/S2468-2667(19)30152-5	HIV continues to be a major global heath threat and pharmacological prevention measures are important components of the multipronged approach focused on eliminating the disease by 2030.1 HIV pre-exposure prophylaxis (PrEP)2 and post-exposure prophylaxis (PEP) are two effective pharmacological prevention tools available, and are best integrated with non-pharmacological prevention strategies such as safe-sex counselling and addressing other syndemic health issues. Although these preventative interventions can reduce transmission at individual and community levels,2 gaps in HIV prevention still exist, especially for those who have a low frequency of HIV exposures. For such individuals, daily PrEP with co-formulated tenofovir disoproxil fumarate and emtricitabine might be highly effective2 but the large pill burden and expense might be disproportionate to a very low HIV exposure frequency. On-demand PrEP might be of benefit as well, but the only data demonstrating efficacy with infrequent use of this approach is with 15 tablets of tenofovir disoproxil fumarate and emtricitabine per month, and it is unclear how effective on-demand PrEP would be for individuals with lower usage because of less frequent HIV exposures.3 On-demand PrEP is also not helpful for people who do not proactively anticipate a potential HIV exposure. PEP is a retroactive approach to HIV prevention and is helpful if accessed within a 72-h window, but there are substantial issues with timely access to medications, adherence to clinic appointments, and adherence to the 28-day course of medication.4 So, how can these gaps in HIV prevention be narrowed and care be improved for individuals who have a lower frequency (eg, up to four) of HIV exposures per year? A PEP-in-pocket (PIP) approach might be helpful in these situations.5 This approach involves providing selected patients with a 28-day prescription for PEP before an exposure occurs. Patients are counselled to obtain the medications and keep them accessible in case of an exposure. Should there be an exposure, patients are advised to initiate medications as soon as possible (and within a 72-h window) and to come to the clinic within the first week of initiating medications for clinical assessment and baseline HIV screening. Patients are typically followed at 6-month intervals for routine screening for HIV and sexually transmitted infections, or sooner based on their exposure history. PIP enables immediate access to antiretroviral medications and might reduce the need for time-sensitive emergency department or clinic visits. PIP empowers patients by providing a degree of autonomy over their care and might also alleviate anxiety associated with potential HIV exposures. Although daily or on-demand PrEP might be appropriate for those with more frequent HIV exposures, PIP is a valuable HIV prevention modality for those who have infrequent exposures. As public health units increasingly provide HIV prevention services, PIP may be integrated into the prevention modalities offered to deliver more targeted care to those at risk of HIV infection. We declare no competing interests. Article	2019	Heendeniya, Amila; Tumarkin, Ethan; Bogoch, Isaac I	HIV preexposure prophylaxis in Canadian primary care and community settings	Canadian Family Physician	-	-	-	-	0008350X	NA	https://www.proquest.com/scholarly-journals/hiv-preexposure-prophylaxis-canadian-primary-care/docview/2213126663/se-2?accountid=8113	In Canada HIV continues to be a challenge, with more than 2500 new cases reported per year despite the considerable resources available compared with other countries that bear the brunt of this pandemic. Approximately 21% of HIV-infected individuals are unaware of their HIV-positive status and might be contributing to further disease transmission. Here, Heendeniya et al outline several aspects of the implementation of the human immunodeficiency virus preexposure prophylaxis (PrEP), an HIV prevention approach that protects individuals from infection. The use of PrEP in Canada and worldwide has increased over the past few years. Canadians at elevated risk of HIV acquisition are approaching their family physicians for PrEP care in greater numbers. Implementation of a comprehensive safer conception intervention for HIV-serodiscordant couples in Kenya: uptake, use and effectiveness	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25261	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064508584&doi=10.1002%2fjia2.25261&partnerID=40&md5=e5c0ce22baa6d1a8577a041732c9fbd4	Introduction: Safer conception strategies minimize HIV risk during condomless sex to become pregnant. Gaps remain in understanding the acceptability, feasibility and choices HIV-serodiscordant couples make when multiple safer conception options are available. Methods: We conducted a pilot study of a comprehensive safer conception package for HIV-serodiscordant couples with immediate fertility desires in Kenya from March 2016 to April 2018. The intervention package included antiretroviral therapy (ART) for HIV-positive partners, oral pre-exposure prophylaxis (PrEP) for HIV-negative partners, daily fertility and sexual behaviour tracking via short message service (SMS) surveys, counselling on self-insemination, and referrals for voluntary medical male circumcision and fertility care. Couples attended monthly visits until pregnancy with HIV testing for negative partners at each visit. We estimated the number of expected HIV seroconversions using a counterfactual cohort simulated from gender-matched couples in the placebo arm of a previous PrEP clinical trial. We used bootstrap methods to compare expected and observed seroconversions. Results: Of the 74 enrolled couples, 54% were HIV-negative female/HIV-positive male couples. The 6 and 12-month cumulative pregnancy rates were 45.3% and 61.9% respectively. In the month preceding pregnancy, 80.9% of HIV-positive partners were virally suppressed, 81.4% of HIV-negative partners were highly adherent to PrEP, and SMS surveys indicated potential timing of condomless sex to peak fertility (median of sex acts = 10, interquartile range (IQR) 7 to 12; median condomless sex acts = 3.5, IQR 1 to 7). Most (95.7%) pregnancies were protected by ≥2 strategies: 57.4% were protected by high PrEP and ART adherence, male circumcision with or without timed condomless sex; 10 (21.3%) were protected by viral suppression in the HIV-positive partner and male circumcision with or without timed condomless sex; 8 (17.0%) were protected by high PrEP adherence and male circumcision with or without timed condomless sex. We observed 0 HIV seroconversions (95% CI 0.0 to 6.0 per 100 person years), indicating a 100% reduction in HIV risk (p = 0.04). Conclusions: The use of multiple safer conception strategies, primarily PrEP, ART, male circumcision and/or tracking fertility, was acceptable and feasible for African HIV-serodiscordant couples and significantly reduced HIV transmission risk. It is important to increase the availability of and counselling about safer conception services in regions with HIV epidemics involving heterosexual transmission and high fertility. © 2019 The Authors. Article	2019	Henny K.D.; Duke C.C.; Geter A.; Gaul Z.; Frazier C.; Peterson J.; Buchacz K.; Sutton M.Y.	HIV-Related Training and Correlates of Knowledge, HIV Screening and Prescribing of nPEP and PrEP Among Primary Care Providers in Southeast United States, 2017	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02545-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067264714&doi=10.1007%2fs10461-019-02545-1&partnerID=40&md5=9069294854183635ab654f1a106ecf3b	The Southeast accounted for most HIV diagnoses (52%) in the United States in 2015. Primary care providers (PCPs) play a vital role in HIV prevention for at-risk persons and treatment of persons living with HIV. We studied HIV-related training, knowledge, and clinical practices among PCPs in the Southeast to address knowledge gaps to inform HIV prevention strategies. Between April and August 2017, we conducted an on-line survey of a representative sample of PCPs in six Southeast jurisdictions with high rates of HIV diagnoses (Atlanta; Baltimore; Baton Rouge; District of Columbia; Miami; New Orleans). We defined HIV-related training as self-reported completion of any certified HIV/STD course or continuing education in past 24 months (prior to survey completion). We assessed associations between training and HIV testing practices, familiarity with nonoccupational post-exposure prophylaxis (nPEP) and pre-exposure prophylaxis (PrEP), and ever prescribing nPEP or PrEP. There were 820 participants after fielding 4595 surveys (29.6% adjusted response rate). In weighted analyses, 36.3% reported HIV-related training. Using adjusted prevalence ratio (aPR) and confidence intervals (CI), we found that PCPs with HIV-related training (compared to those with no training) were more likely to be familiar with nPEP (aPR = 1.32, 95% CI 1.05, 1.67) and PrEP (aPR = 1.67, 95% CI 1.19, 2.38); and to have ever prescribed PrEP to patients (aPR = 1.75, 95% CI 1.10, 2.78). Increased HIV-related trainings among PCPs in high HIV prevalence Southeast jurisdictions may be warranted. Strengthening nPEP and PrEP familiarity among PCPs in Southeast may advance national HIV prevention goals. © 2019, This is a U.S. Government work and not under copyright protection in the US; foreign copyright protection may apply. Article	2019	Hershow R.B.; Gonzalez M.; Costenbader E.; Zule W.; Golin C.; Brinkley-Rubinstein L.	Medical providers and harm reduction views on pre-exposure prophylaxis for hiv prevention among people who inject drugs	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2019.31.4.363	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070834772&doi=10.1521%2faeap.2019.31.4.363&partnerID=40&md5=dfb195457cd354a2210e2cdf8cb54282	Despite high pre-exposure prophylaxis (PrEP) acceptability among people who inject drugs (PWID) and PrEP providers, PrEP uptake is low and little is known about how to promote PrEP among PWID. This qualitative study with providers in North Carolina explored views on PrEP delivery approaches for PWID. Interviewers conducted semistructured interviews with 10 PrEP providers and 10 harm reduction (HR) providers. Interviews were transcribed and analyzed. Many participants expressed acceptability for providing PrEP referrals at syringe exchange sites, stationing PrEP providers at syringe exchange sites to provide PrEP prescriptions, and providing standing orders for PrEP at syringe exchange sites. Barriers were identified, including low PrEP awareness and limited resources. Many advocated for co-location of HR and PrEP services and scaled-up outreach services. PrEP providers emphasized maintenance of clinical requirements, while HR providers emphasized flexibility when treating PWID. Promoting PrEP uptake and adherence among PWID likely requires integration of HR and PrEP services. © 2019 The Guilford Press. Article	2019	Hess K.M.; Crawford J.; Eanes A.; Felner J.K.; Mittal M.L.; Smith L.R.; Hoenigl M.; Amico K.R.	Reasons Why Young Men Who Have Sex with Men Report Not Using HIV Pre-Exposure Prophylaxis: Perceptions of Burden, Need, and Safety	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2019.0150	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072938415&doi=10.1089%2fapc.2019.0150&partnerID=40&md5=49733e9e848e92207c54ab951c38ce60	Uptake of pre-exposure prophylaxis (PrEP) has dramatically increased but remains well below the estimated number of individuals who could benefit from PrEP in the United States, and uptake remains limited among young men who have sex with men (YMSM) and MSM of color. Reasons for not adopting PrEP as a prevention strategy among those at elevated risk for HIV is an important area of inquiry that could advise efforts to better position PrEP as an active part of prevention programs. As part of a mixed methods study investigating experiences with repeat HIV testing, we identified main themes emerging from in-depth interview data pertaining to reasons why YMSM report not using PrEP, among YMSM with frequent access to HIV testing services. Themes from 14 in-depth interviews with predominantly Latino MSM for not using PrEP included perceived burden of daily dosing, feeling that risk was not high enough to warrant PrEP, and beliefs that PrEP would have severe adverse events affecting the kidneys and bones. Less prominent but noteworthy themes included stigma as a PrEP user, social or provider influence on decisions not to use PrEP, and preference for current prevention strategy. No differences in PrEP discourse were noted across those at different levels of HIV risk. Results suggest that efforts are needed to engage communities and individuals around PrEP-related education, facilitate risk evaluation, and reduce PrEP stigma. New formulations and nondaily regimens may also be of particular interest to YMSM who may perceive daily PrEP regimens as highly burdensome. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019.	barriers; PrEP; risk; uptake; young MSM	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
Article	2019	Hightow-Weidman L.B.; Magnus M.; Beauchamp G.; Hurt C.B.; Shoptaw S.; Emel L.; Piwowar-Manning E.; Mayer K.H.; Nelson L.E.; Wilton L.; Watkins P.; Whitfield D.; Fields S.D.; Wheeler D.	Incidence and Correlates of Sexually Transmitted Infections among Black Men Who Have Sex with Men Participating in the HIV Prevention Trials Network 073 Preexposure Prophylaxis Study	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciy1141	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073183981&doi=10.1093%2fcid%2fciy1141&partnerID=40&md5=e652838ea7afebc9e724202a7651ed6	The HIV Prevention Trials Network (HPTN) Study 073 (HPTN 073) assessed the feasibility, acceptability, and safety of preexposure prophylaxis (PrEP) for black men who have sex with men (BMSM). The purpose of this analysis was to characterize the relationship between PrEP uptake and use and incident sexually transmitted infections (STIs) among participants enrolled in HPTN 073. Methods: A total of 226 human immunodeficiency virus (HIV)-uninfected BMSM were enrolled in 3 US cities; all participants received client-centered care coordination (C4) and were offered daily oral PrEP. Participants were followed for 12 months with STI testing (rectal and urine nucleic acid amplification test for gonorrhea and chlamydia, rapid plasma reagin for syphilis) conducted at baseline, week 26, and week 52. Logistic regression was used to examine associations between STI incidence and PrEP uptake. Generalized estimating equations were used to evaluate associations between age, PrEP acceptance, sexual behaviors, and incident STIs. Results: Baseline STI prevalence was 14.2%. Men aged <25 years were more likely to have a baseline STI (25.3% vs 6.7%; odds ratio OR, 4.39; 95% confidence interval CI, 1.91, 10.11). Sixty participants (26.5%) acquired ≥1 STI during follow-up; the incidence rate was 34.2 cases per 100 person-years (95% CI, 27.4, 42.9). In adjusted analyses, baseline STI diagnosis (OR, 4.23; 95% CI, 1.82, 9.87; P <. 001) and additional C4 time (OR, 1.03; 95% CI, 1.00, 1.06; P =. 027) were associated with having an incident STI. STI incidence was not associated with PrEP acceptance or adherence. Conclusions: While we found higher rates of STIs in younger BMSM, overall rates of STI were lower than in prior PrEP trials, with no increase over time. BMSM with STIs at PrEP initiation may require additional interventions that target STI acquisition risk. Clinical Trials Registration: NCT01808352. © 2019 The Author(s). Article	2019	Hildebrandt, Timothy; Bode, Leticia; Ng, Jessica S C	Effect of 'lifestyle stigma' on public support for NHS-provisioned pre-exposure prophylaxis (PrEP) and preventative interventions for HPV and type 2 diabetes: a nationwide UK survey.	BMJ Open	-	-	-	-	2044-6055	10.1136/bmjopen-2019-029747	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6707679	OBJECTIVES: This study examines how the perceived role of poor lifestyle and irresponsible behaviour in contracting HIV, human papilloma virus (HPV) and diabetes affects public support for government-provisioned prevention efforts in Britain. It assesses whether public attitudes on healthcare spending are broadly sensitive to 'lifestyle stigmas'. METHODS: We conducted an online survey of 738 respondents in Britain and embedded three separate survey experiments to measure support for government-provisioned interventions for HIV, HPV and type 2 diabetes. In each experiment, we manipulated language used to describe the extent to which the diseases are caused by lifestyle choices. Most respondents participated in all three experiments, but assignment was randomised within each condition. Analysis compared support among respondents exposed to 'lifestyle' treatment (information emphasising the disease's lifestyle causes) versus control treatment. We estimated three separate t-tests in which support for government provision of interventions is the dependent variable. RESULTS: Support for government-provisioned prevention was high for all three diseases. There was no statistical difference between treatment and control conditions for HIV (treatment mean=3.73, control mean=3.86, p=0.38). But in both HPV (treatment mean=3.96, control mean=4.43, p<0.01) and type 2 diabetes (treatment mean=3.53, control mean=4.03, p<0.01) experiments, support for government-provisioned interventions was significantly lower under lifestyle treatment conditions. CONCLUSIONS: Public opinion on healthcare expenditures in Britain is unexpected and uneven. Consistent participant support for pre-exposure prophylaxis (PrEP) shows public attitudes are not always sensitive to lifestyle stigmas-but for other diseases, perceived relationships between individual behaviour and poor health can still shape public opinion about health expenditures. Policymakers and practitioners should remain attentive to how health problems are framed and discussed to ensure broad public support, and take advantage of policy windows like with PrEP as they may close.	pre-exposure prophylaxis (PrEP), HIV, HPV, diabetes, public opinion	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2019	Hill, Lucas A; Ballard, Craig; Cachay, Edward R	The role of the clinical pharmacist in the management of people living with hiv in the modern antiretroviral era	AIDS Reviews	-	-	-	-	11396121	10.24875/AIDSRev.19000089	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076320507&doi=10.24875%2fAIDSRev.19000089&partnerID=40&md5=21cf7f6073eb53384c812dcdf6346b46	As the HIV epidemic has evolved, so too has the role of the clinical pharmacist (CP) in the management of people living with HIV (PLWH). The modern antiretroviral therapy (ART) era has resulted in PLWH living normal life spans with resulting increased comorbidities. CPs have long been a part of the multidisciplinary management of ART. However, with the changing demographics of PLWH and health-care system dynamics, CPs have had the opportunity to expand their role. This includes involvement in managing increasing comorbidities with expanding and more complicated medication regimens, drug interaction monitoring, and optimizing transitions of care, all while recognizing and addressing barriers to successful HIV and hepatitis C virus (HCV) treatment. In addition, with the expansion of HIV prevention and pre-exposure prophylaxis (PrEP) services, CPs have the opportunity to be involved in HIV prevention. This study summarizes the literature evaluating the impact of CPs in the management of PLWH in the era of modern ART. We conducted a literature search to identify studies that assessed the CP role in HIV clinical practice since 2006. The identified studies were grouped into two categories. The first was HIV related outcomes, including interventions on regimen selection, adherence, regimen optimization, and management of treatment failure. The second group of studies pertained to aging and vulnerable populations, including management of comorbidities, transitions of care, medication-assisted treatment, hepatitis C, and HIV screening and PrEP. We concluded that the evidence supports the expanding role of CPs to positively impact a variety of aspects related to the care of PLWH. © Permanyer 2019. Article	2019	Hiransuthikul A.; Janamnuaysook R.; Himmad K.; Kerr S.J.; Thammajaruk N.; Pankam T.; Phanjaroen K.; Mills S.; Vannakit R.; Phanuphak P.; Phanuphak N.	Drug-drug interactions between feminizing hormone therapy and pre-exposure prophylaxis among transgender women: the iFACT study	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25338	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069775657&doi=10.1002%2fjia2.25338&partnerID=40&md5=6cdd36cdcda83f234ad4ecf792bce99c	Introduction: Concerns over potential drug-drug interactions (DDI) between feminizing hormone therapy (FHT) and pre-exposure prophylaxis (PrEP) have hampered uptake and adherence of PrEP among transgender women (TGW). To determine DDI between FHT and PrEP, we measured the pharmacokinetic (PK) parameters of blood plasma estradiol (E2) and tenofovir (TFV) in Thai TGW. Methods: Twenty TGW who never underwent orchiectomy and had not received injectable FHT within six months were enrolled between January and March 2018. FHT (E2 valerate and cyproterone acetate) were prescribed to participants at baseline until week 5, and then from week 8 until the end of study. Daily PrEP (tenofovir disoproxil fumarate/emtricitabine) was initiated at week 3 and continued without interruption. Intensive E2 PK parameters and testosterone concentration at 24 hours (C24) were measured at weeks 3 (without PrEP) and 5 (with PrEP), and intensive TFV PK parameters were measured at weeks 5 (with FHT) and 8 (without FHT). Results: Median (interquartile range) age, body mass index, and creatinine clearance were 21.5 (21–26) years, 20.6 (19.0-22.4) kg/m2, and 116 (101-126.5) mL/min, respectively. The geometric mean (%CV) of area under curve from time zero to 24 hours (AUC0-24), maximum concentration (Cmax), and C24 of E2 at weeks 3 and 5 were 775.13 (26.2) pg h/mL, 51.47 (26.9) pg/mL, and 15.15 (42.0) pg/mL; and 782.84 (39.6), 55.76 (32.9), and 14.32 (67.4), respectively. The geometric mean (%CV) of TFV AUC0-24, Cmax, and C24 at weeks 5 and 8 were 2242.1 (26.5) ng h/mL, 353.9 (34.0) ng/mL, and 40.9 (31.4) ng/mL; and 2530.2 (31.3), 311.4 (30.0), and 49.8 (29.6), respectively. The geometric mean of TFV AUC0-24 and C24 at week 5 were significantly less than that at week 8 by 12% (p = 0.03) and 18% (p < 0.001), respectively. There were no significant changes in E2 PK parameters and median C24 of bioavailable testosterone between week 3 and week 5. Conclusions: Our study demonstrated lower blood plasma TFV exposure in the presence of FHT, suggesting that FHT may potentially affect PrEP efficacy among TGW; but E2 exposure was not affected by PrEP. Further studies are warranted to determine whether these reductions in TFV are clinically significant. Clinical Trial Number: NCT03620734. © 2019 The Authors. Article	2019	Hoang T.; Date A.A.; Ortiz J.O.; Young T.-W.; Bensouda S.; Xiao P.; Marzinke M.; Rohan L.; Fuchs E.J.; Hendrix C.; Gumber S.; Villinger F.; Cone R.A.; Hanes J.; Ensign L.M.	Development of rectal enema as microbicide (DREAM): Preclinical progressive selection of a tenofovir prodrug enema	European Journal of Pharmaceutics and Biopharmaceutics	-	-	-	-	9396411	10.1016/j.ejpb.2018.05.030	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047833359&doi=10.1016%2fj.ejpb.2018.05.030&partnerID=40&md5=440ed9f6c564fb1c22411235d0a998d2	HIV pre-exposure prophylaxis (PrEP) strategies have the potential to prevent millions of incident HIV infections each year. However, the efficacy of PrEP strategies has been plagued by issues of non-adherence, likely because of the difficulty in motivating otherwise healthy people to adhere to treatment regimens that require significant behavioral changes and daily discipline. An alternative approach to PrEP is to focus on strategies that fit in to normal, and even desirable, sexual behaviors, such as the use of cleansing enemas by men who have sex with men (MSM) prior to receptive anal intercourse (RAI). Here, we describe preclinical efforts toward optimizing a tenofovir (TFV)-based enema formulation for rectal PrEP. Using a murine model, we compared the plasma and tissue pharmacokinetics of TFV and various TFV prodrugs, including tenofovir disoproxil fumarate (TDF), tenofovir alafenamide (TAF), and hexadecyloxypropyl tenofovir (CMX157), after dosing as enema formulations with varying osmolality and ion content. We observed that the enema vehicle composition played a more important role than the TFV prodrug properties in achieving rapid and therapeutically relevant tenofovir diphosphate (TFV-DP) concentrations in mouse colorectal tissue. Our results support the next steps, which are further preclinical (non-human primate) and clinical development of a hypo-osmolar TDF enema product for rectal PrEP. © 2018 Elsevier B.V. Theses and Dissertations	2019	Hobbs, Richard	An exploration of PrEP-stigma and viewpoints on testing for HIV amongst men who have sex with men	-	-	Cardiff University	Cardiff University	-	NA	NA	https://orca.cardiff.ac.uk/id/eprint/125480/	This thesis aimed to address gaps in the psychosocial aspects of Human Immunodeficiency Viruses (HIV) prevention ad testing literature as biomedical prevention methods have advanced. It is explored through three papers: a systematic review, an empirical study and a reflective critique. The systematic literature review utilised a narrative synthesis approach to explore and aggregate qualitative literature, which considered a newly reported phenomenon of Pre-Exposure Prophylaxis (PrEP) stigma as experienced by men who have sex with men taking PrEP. Eight studies were included in the final review. The studies were heterogeneous in the types of Men who have Sex with Men (MSM) they recruited and their methods. However, across the studies, it was demonstrated that PrEP-stigma was present at multiple levels. Five key themes identified were: 1. Stigma directly associated with PrEP; 2. Imposed stigma from others; 3. Internalised stigma; 4. Acts to mitigate stigma; 5. Sex-related stigma. The review concluded by arguing that PrEP-stigma can be imposed on the individual by others. PrEP-stigma can be internalised by PrEP users. There are various strategies that could be developed to overcome PrEP-stigma experienced by MSM who are PrEP users at the different levels within the system. The application of the findings to policy and clinical practice are considered alongside recommendations for further research. The empirical study utilised Q methodology to explore gay men's view on testing for HIV in Wales. Three distinct perspectives were identified: "testing for PrEP and shame/stigma", "the psychological distress of testing and the search for certainty" and "HIV Testing a prosocial act and self-learning". The findings highlight that some aspects of HIV testing for gay men are consistent with previous research. The findings also describe how PrEP relates to the psychosocial context of HIV testing in Wales for gay men. That some PrEP users regularly test for HIV in order to gain long-term certainty over HIV status, but that this process can be stigmatising and shaming. The findings highlight the need for considerations of psychosocial context as HIV prevention methods develop. The implication of the findings for clinical practice and future research are considered. The third paper is a critique and reflection on the research undertaken and its process. This consists of: an extended discussion of the decisions made in the research process; plans of dissemination; strengths and weaknesses of the studies; specific implications for theory; clinical practice and policy and further research. Reflection and critique are also given on the thesis as a whole. Article	2019	Hodges-Mameletzis I.; Fonner V.A.; Dalal S.; Mugo N.; Msimanga-Radebe B.; Baggaley R.	Pre-Exposure Prophylaxis for HIV Prevention in Women: Current Status and Future Directions	Drugs	-	-	-	-	126667	10.1007/s40265-019-01143-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068990677&doi=10.1007%2fs40265-019-01143-8&partnerID=40&md5=167da3beb1a0862e758359f06e02e65d	Pre-exposure prophylaxis (PrEP) is a promising intervention to prevent HIV acquisition, with benefits both to the individual and to population-level health. PrEP is an opportunity to complement ongoing public health efforts to eliminate HIV. For women, PrEP can also serve as a gateway to access sexual and reproductive health (SRH) services. Clinical efficacy of PrEP was initially reported in women using a 1% tenofovir vaginal gel in 2010, followed by an efficacy trial of oral PrEP using TDF/FTC in men who have sex with men (MSM). Since then, further trials have reported efficacy in oral PrEP containing tenofovir in women and heterosexual men, while the subsequent trials for women using tenofovir gel reported no efficacy, stemming from difficulties in achieving adequate adherence. In an effort to offer women additional choices to oral PrEP, alternative modalities are being tested in clinical research, including long-acting injectable formulations and intra-vaginal rings. In 2015, a meta-analysis of clinic trials and open-label extension studies led to the World Health Organization (WHO) strongly recommending the provision of oral PrEP containing tenofovir for any person at substantial risk of HIV infection, irrespective of gender or population group. Currently, PrEP services for women around the world, including those who are either pregnant or breastfeeding, remain limited. Outside sub-Saharan Africa, most PrEP programmes are focused on MSM. South Africa, Kenya, and the USA have the greatest utilization of oral PrEP by women. Yet, since 2012, of the estimated > 300,000 people globally who have initiated PrEP, a minority are women. In this narrative review, we examine the most recent literature on clinical and implementation PrEP research among women. We highlight the high burden of disease related to common sexually transmitted infections (STIs) in women, and the opportunity to integrate PrEP and other HIV prevention services, STI case management, and family planning services, as part of a more robust package of SRH services. Raising awareness on PrEP amongst women and their healthcare providers, minimizing gaps in access, and ensuring adherence and persistence of PrEP during periods of risk are critical issues if PrEP can have a meaningful impact on reducing HIV incidence in women globally. © 2019, Springer Nature Switzerland AG. Article	2019	Hoenigl M.; Morgan E.; Franklin D.; Anderson P.L.; Pasipanodya E.; Dawson M.; Hanashiro M.; Ellorin E.E.; Blumenthal J.; Heaton R.; Moore D.J.; Morris S.R.	Self-initiated continuation of and adherence to HIV pre-exposure prophylaxis (PrEP) after PrEP demonstration project roll-off in men who have sex with men: associations with risky decision making, impulsivity/disinhibition, and sensation seeking	Journal of Neurology	-	-	-	-	13550284	10.1007/s13365-018-0716-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059691192&doi=10.1007%2fs13365-018-0716-3&partnerID=40&md5=8a3e53a80a4b04f3f40f6cd1240794f4	The objective of this study was to examine differences in the levels of risky decision making and other frontal system behavior constructs in relation to self-initiated continuance of HIV pre-exposure prophylaxis (PrEP) and PrEP adherence outcomes among men who have sex with men (MSM) following completion of a clinical PrEP trial. At the last PrEP trial visit, study provided PrEP was discontinued and participants were navigated to the community for PrEP continuation. In this cross-sectional analysis, 84/187 (45%) MSM who completed a prospective observational post-PrEP trial follow-up visit at the University of California San Diego were included. PrEP adherence was measured using dried blood spot tenofovir diphosphate (TFV-DP) levels. Risky decision making was assessed using the Iowa Gambling Task (IGT) and the Balloon Analogue Risk Task (BART), while impulsivity/disinhibition, sensation seeking, and substance use were assessed via standardized self-report questionnaires. A total of 58/84 (69%) of MSM who completed the 12-month post-study visit continued PrEP. Of those, n = 46 (79%) reached TFV-DP levels associated with adequate adherence. Individuals who elected to continue PrEP 12 months post-trial had riskier decision making on BART, but less impulsivity/disinhibition compared to individuals who did not continue PrEP. Neither risky decision making nor impulsivity/disinhibition/sensation seeking nor substance use correlated with PrEP adherence. Our findings suggest that those with risky decision making may have greater insight into their HIV risks, and therefore be more likely to continue to use PrEP. However, elevated impulsivity/disinhibition, indicative of greater neurobehavioral alterations, was negatively associated with PrEP continuance and is a potential target for future interventions to help people link to PrEP. © 2019, Journal of NeuroVirology, Inc. Article	2019	Hoenigl, Martin; Hassan, Adiba; Moore, David J; Anderson, Peter L; Corado, Katya; Dubé, Michael P; Ellorin, Eric E; Blumenthal, Jill; Morris, Sheldon R	Predictors of Long-Term HIV Pre-exposure Prophylaxis Adherence After Study Participation in Men Who Have Sex With Men.	JAIDS Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1525-4135	https://doi.org/10.1097/qai.0000000000002003	https://escholarship.org/uc/item/8b12z6p2	BackgroundEfficacy of HIV pre-exposure prophylaxis (PrEP) among men who have sex with men is well documented in randomized trials. After trial completion, participants are challenged with acquiring PrEP on their own and remaining adherent.MethodsThis was a follow-up study of the TAPIR randomized controlled multicenter PrEP trial. Participants were contacted after their last TAPIR visit (ie, after study-provided PrEP was discontinued) to attend observational posttrial visits 24 and 48 weeks later. Adherence during TAPIR and posttrial visits was estimated by dried blood spot intracellular tenofovir diphosphate levels (adequate adherence defined as tenofovir diphosphate levels >719 fmol/punch). Binary logistic regression analysis assessed predictors of completing posttrial visits and PrEP adherence among participants completing ≥1 visit.ResultsOf 395 TAPIR participants who were on PrEP as part of the TAPIR trial for a median of 597 days (range 3-757 days), 122 (31%) completed ≥1 posttrial visit (57% of University of California San Diego participants completed posttrial visits, whereas this was 13% or lower for other study sites). Among participants who completed ≥1 posttrial visit, 57% had adequate adherence posttrial. Significant predictors of adequate adherence posttrial were less problematic substance use, higher risk behavior, and adequate adherence in year 1 of TAPIR.ConclusionMore than half of PrEP users followed after trial completion had successfully acquired PrEP and showed adequate adherence. Additional adherence monitoring and intervention measures may be needed for those with low PrEP adherence and problematic substance use during the first year of trial. Article	2019	Hojilla J.C.; Satre D.D.; Glidden D.V.; McMahan V.M.; Gandhi M.; Defechereux P.; Guanira J.V.; Mehrotra M.; Grant R.M.; Carrico A.W.	Cocaine Use and Pre-exposure Prophylaxis: Adherence, Care Engagement, and Kidney Function	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001972	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064721751&doi=10.1097%2fQAI.0000000000001972&partnerID=40&md5=386ed60845f9c3e92395c0bb0cde80bf	Background:Concomitant use of cocaine and HIV pre-exposure prophylaxis (PrEP) raises important clinical questions around adherence, retention in care, and renal toxicity.Methods:We assessed the associations of confirmed cocaine use with PrEP adherence (both ascertained through objective measures), care engagement, and renal function in the iPrEx open-label extension. Cocaine use was measured in scalp hair samples and categorized as light (500-3000 pg/mg) and moderate to heavy (>3000 pg/mg). PrEP adherence in the first 3 months was measured through plasma tenofovir concentrations. Disengagement from PrEP care was defined as a gap in follow-up greater than 4 months. Serum creatinine was assessed at baseline and quarterly thereafter.Results:Of the 400 participants included in this analysis, 90% were men who have sex with men, 10% transgender women, 74% Hispanic/Latino; 21% tested positive for cocaine use in the last 3 months. In adjusted analysis, light cocaine use adjusted odds ratio 2.10 (95% confidence interval: 1.07 to 4.14) and moderate to heavy use adjusted odds ratio 2.32 (1.08 to 5.00) were associated with greater odds of having plasma tenofovir concentrations below the level of quantitation. Participants with moderate to heavy use had a nearly 3-fold higher rate of disengagement from PrEP care compared with nonusers (adjusted hazard ratio 2.90 1.48 to 5.66). We found no statistically or clinically significant differences in creatinine clearance and serum creatinine between participants who tested positive for cocaine and those who did not.Conclusions:Cocaine use decreases PrEP adherence and care engagement. Comprehensive approaches are needed to reduce cocaine use and enhance engagement along the PrEP care continuum. Copyright © 2019 Wolters Kluwer Health, Inc. Article	2019	Holder, Cheryl L; Perez-Gilbe, Hector R; Fajardo, Francisco J; Garcia, Stephanie; Cyrus, Elena	Disparities of HIV risk and PrEP use among transgender women of color in South Florida	Journal of the National Medical Association	-	-	-	-	279684	10.1016/j.jnma.2019.08.001	https://www.proquest.com/scholarly-journals/disparities-hiv-risk-prep-use-among-transgender/docview/2327892598/se-2?accountid=8113	BackgroundThe majority of the transgender female population in South Florida are Latina and Black, and are at greatest risk for acquiring HIV, yet there is limited research focused on South Florida transgender women of color. The study objective was to describe the disparities among racial/ethnic minority transgender women regarding HIV screening, pre-exposure prophylaxis (PrEP) knowledge and PrEP utilization.MethodsSixty transgender women, recruited from South Florida community-based organizations, completed a questionnaire on HIV prevention and PrEP awareness and use. Univariate statistics were generated to describe sexual risk behavior, PrEP awareness and use, and HIV screening by race/ethnicity.ResultsOf the 60 participants, 50.0% were Latina, 35.0% African American/non-Hispanic Black (AA/NHB), 11.7% white and 3.3% other race/ethnicity. 75.0% reported being screened for HIV in the last 12 months, 15.3% of the participants reported living with HIV (PLWH), while 18.6% reported an unknown status. Compared to Latinas, AA/NHB demonstrated more risk (≥2 sexual partners: 76.2% vs 53.3%; transactional sex: 47.6% vs. 26.7%; unprotected receptive anal sex: 42.9% v. 26.7%), and more engagement in routine care (81.0% vs. 76.7%) at least once a year. PrEP knowledge was 76.7% among Latinas, 71.4% among whites, 47.6% among Blacks, and 50.0% among other race/ethnicity. 65.0% of participants knew about PrEP. Of the 8.2% with current or previous PrEP use, none were AA/NHB.ConclusionFindings suggest that education and public health campaigns in South Florida that promote HIV prevention should focus on increasing awareness and utilization of PrEP among racial/ethnic minority transgender, particularly among AA/NHB transgender women who are most at risk and had the lowest knowledge and use of PrEP. Article	2019	Holt, M; Newman, CE; Lancaster, K; Smith, AK; Hughes, S; Truong, HHM	HIV pre-exposure prophylaxis and the 'problems' of reduced condom use and sexually transmitted infections in Australia: a critical analysis from an evidence-making intervention perspective	Sociology of Health and Illness	-	-	-	-	0141-9889	10.1111/1467-9566.12967	https://onlinelibrary.wiley.com/doi/full/10.1111/1467-9566.12967	HIV pre-exposure prophylaxis (PrEP) has been embraced in Australia, making PrEP available with public funding to people at risk of HIV. Here, we consider the associated 'problems' of reduced condom use and sexually transmissible infections (STIs), as seen by HIV professionals. Twenty-one interviews were conducted during May-August 2017. All agreed that PrEP was a valuable addition to HIV prevention, but their views about reduced condom use and STIs were variable. Using poststructural policy analysis, three main stances were identified: (1) Concerned/alarmed. PrEP was seen as causing reduced condom use, STIs and antibiotic resistance, posing threats to the general population; (2) Neutral/normalising. Stakeholders emphasised that condom use was declining and STIs increasing independently of PrEP, and that PrEP was simply a new tool to be accommodated; (3) Optimistic/critical. PrEP was seen as diminishing fear of HIV and engaging users in more frequent testing and treatment that could lead to declining STI rates. What linked all three stances was the selective performance of evidence, deploying a mixture of personal experience, clinical observations, behavioural data and epidemiology. Anticipating possible futures through evidence-making suggested practical, political and moral consequences for what PrEP could become. We encourage others to consider these consequences with care. Article	2019	Holt, Martin; Lea, Toby; Bear, Brandon; Halliday, Dale; Ellard, Jeanne; Murphy, Dean; Kolstee, Johann; de Wit, John	Trends in Attitudes to and the Use of HIV Pre-exposure Prophylaxis by Australian Gay and Bisexual Men, 2011-2017: Implications for Further Implementation from a Diffusion of Innovations Perspective.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-018-2368-y	https://dx.doi.org/10.1007/s10461-018-2368-y	Using repeated, national, online, cross-sectional surveys of Australian gay and bisexual men (GBM), we analysed trends related to HIV pre-exposure prophylaxis (PrEP). Specifically, we analysed trends in PrEP use, willingness to use PrEP, and concern about using PrEP during 2011-2017. We assessed support for GBM using PrEP and willingness to have sex with men taking PrEP between 2015 and 2017. For time-based analyses, we used multivariate logistic regression, controlling for sampling variations over time. We constructed new scales assessing reduced concern about HIV among PrEP users and non-users in 2017, and used multivariate logistic regression to identify independent correlates of PrEP use (vs. non-use). The analyses included 4567 HIV-negative and untested participants (2011-2017). PrEP use increased from 0.5% in 2011 to 25.5% in 2017 (p < 0.001). Willingness to use PrEP increased from 27.9% in 2011 to 36.5% in 2017 (p < 0.001) while concern about using PrEP fell (52.1-36.1%, p < 0.001). Support for GBM using PrEP remained stable (52.5% in 2015, 51.9% in 2017, p = 0.62), and willingness to have sex with men taking PrEP increased from 34.9% in 2015 to 49.0% in 2017 (p < 0.001). In 2017, 22.8% of non-PrEP-users had reduced HIV concern because of PrEP, while 73.6% of PrEP users had reduced HIV concern and greater sexual pleasure because of PrEP. The analysis of PrEP users vs. non-users in 2017 indicated that PrEP users were more sexually active and reported higher risk sexual practices, were more likely to live in New South Wales and Victoria, and to be in full-time employment. They were also more likely to know HIV-positive people and other PrEP users. Diffusion of Innovations theory suggests that future PrEP users in Australia may be less adventurous and require greater reassurance about PrEP's efficacy and legitimacy, to sustain rollout and address current disparities in uptake. Article	2019	Holtz T.H.; Chitwarakorn A.; Hughes J.P.; Curlin M.E.; Varangrat A.; Li M.; Amico K.R.; Mock P.A.; Grant R.M.	HPTN 067/ADAPT: Correlates of Sex-Related Pre-exposure Prophylaxis Adherence, Thai Men Who Have Sex with Men, and Transgender Women, 2012-2013	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002131	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072134470&doi=10.1097%2fQAI.0000000000002131&partnerID=40&md5=a4216057c2b32a9ad86cc0b7be4fd2f1	Background: We identified correlates of sex-related pre-exposure prophylaxis (PrEP) adherence in HPTN067/ADAPT, a phase 2, open-label feasibility study of daily and nondaily regimens of emtricitabine/tenofovir disoproxil fumarate (FTC/TDF)-based PrEP, among Thai men who have sex with men (MSM), and transgender women (TGW), Bangkok. Methods: Participants were randomly assigned to one of three self-administered dosing regimens for 24 weeks: daily, time-driven, or event-driven. Demographic and behavioral information was obtained at screening. Pill-container opening was recorded with electronic dose monitoring, and self-reported information on PrEP use, sex events, and substance use was obtained during weekly interviews to confirm dose data. Sex-related PrEP adherence was calculated as the proportion of sex events covered by PrEP use (at least one tablet taken within 4 days before sex and at least one tablet taken within 24 hours after sex) to total sex events. We used multivariate modeling with sex event as the unit of analysis to evaluate correlates associated with sex-related PrEP adherence. Results: Among 178 MSM and TGW, sex-related PrEP adherence was similar in the daily and time-driven arms (P = 0.79), both significantly greater than the event-driven arm (P = 0.02 compared to daily). Sex-related PrEP adherence by those reporting stimulant use (74.2%) was similar to those reporting other nonalcohol drug use (76.3%, P = 0.80), but lower than those reporting no substance use (84.6%, P = 0.04). In a multivariable model, randomization to the event-driven arm, a higher prestudy number of reported sex events, and use of stimulant drugs were associated with significantly lower sex-related PrEP adherence.Conclusion: Adherence was influenced by treatment schedule and adversely affected by nonalcoholic substance use. Regardless of these factors, Thai MSM and TGW maintained high adherence levels to oral PrEP dosing regimens and coverage of sexual exposures. © 2019 Wolters Kluwer Health, Inc. Article	2019	Holtz, T H; Wimonsate, W; Mock, P A; Pattanasin, S; Chonwattana, W; Thienkrua, W; Sukwicha, W; Curlin, M E; Chitwarakorn, A; Dunne, E F	Why we need pre-exposure prophylaxis: incident HIV and syphilis among men, and transgender women, who have sex with men, Bangkok, Thailand, 2005-2015.	International Journal of STD & AIDS	-	-	-	-	1758-1052	10.1177/0956462418814994	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6474786	We describe incident human immunodeficiency virus (HIV) and syphilis trends in men who have sex with men (MSM) and transgender women (TGW) presenting for HIV voluntary counseling and testing (VCT) services and sexually transmitted infection (STI) management at the Silom Community Clinic, Bangkok, Thailand. Clients underwent rapid HIV testing and syphilis rapid plasma reagin (RPR) testing. For incidence analysis, we included clients with >1 follow-up visit. Initial negative HIV with subsequent positive HIV defined incident HIV infection; incident syphilis infection was defined as negative RPR followed by positive RPR (titer ≥1:8) and confirmatory anti- Treponema pallidum antibodies. Calculation of incidence using Poisson regression assumed a uniform probability distribution throughout the seroconversion interval. From 15 September 2005 to 31 December 2015, we tested 10,158 clients for HIV and 10,324 for syphilis. Overall, 7109 clients tested HIV-seronegative and contributed 7157 person-years (PY). Three-hundred forty-seven incident HIV infections resulted in an incidence rate of 4.8 per 100 PY (95% confidence interval CI 4.4-5.4). We found an inverted U-shape trend of HIV incidence over time with a peak of 6.4 per 100 PY in quarter 2/2011 (p < 0.01) (Poisson with RCS function, p = 0.001). Overall, 8713 clients tested seronegative for syphilis and contributed 8623 PY. The incidence of syphilis infection was 4.4 per 100 PY (95% CI 3.9-4.8). Despite an apparent decline in HIV incidence among MSM and TGW attending VCT services, syphilis incidence rose and remained high. Evaluating temporal trends of HIV and syphilis incidence provides an opportunity to evaluate epidemic trajectories and target limited program funding. We recommend focused HIV and STI prevention interventions for MSM in Bangkok. Article	2019	Hoornenborg, Elske; Coyer, Liza; Achterbergh, Roel C A; Matser, Amy; Schim van der Loeff, Maarten F; Boyd, Anders; van Duijnhoven, Yvonne T H P; Bruisten, Sylvia; Oostvogel, Paul; Davidovich, Udi; Hogewoning, Arjan; Prins, Maria; de Vries, Henry J C	Sexual behaviour and incidence of HIV and sexually transmitted infections among men who have sex with men using daily and event-driven pre-exposure prophylaxis in AMPrEP: 2 year results from a demonstration study	The Lancet HIV	-	-	-	-	23523018	10.1016/S2352-3018(19)30136-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068082386&doi=10.1016%2fS2352-3018%2819%2930136-5&partnerID=40&md5=ac16fadb6b9de44e35c7ed046681d161	Background: Pre-exposure prophylaxis (PrEP) for HIV might induce risk compensation, defined as increased sexual risk behaviour leading to increased incidence of bacterial sexually transmitted infections (STIs). We examined the incidence of HIV, STIs, and sexual behaviour after initiating daily and event-driven PrEP. Methods: AMPrEP is a demonstration study that assessed the incidence of HIV and bacterial STIs and sexual behaviour among PrEP users at the STI clinic of the Public Health Service of Amsterdam (Amsterdam, the Netherlands). Eligible adults (aged ≥18 years) were HIV-negative men who have sex with men (MSM) and transgender people who had reported one or more of the following in the previous 6 months: condomless anal sex with casual partners, at least one bacterial STI, use of post-exposure prophylaxis after a sexual risk incident, or an HIV-positive sexual partner with detectable viral load. Participants were given a choice of daily PrEP or event-driven PrEP regimens. Participants were seen every 3 months for HIV and STI testing. Participants also completed self-administered questionnaires about sexual behaviour at each visit. Over the first 2 years, we assessed the number and incidence rate of HIV and chlamydia, gonorrhoea, and syphilis, including STIs diagnosed in between study visits and assessed changes in incidence over time using piecewise exponential survival models. The number of sexual acts and sexual partners were also analysed and changes over time were assessed using negative binomial regression models. This study is ongoing; the data cutoff for this analysis was June 30, 2018. Findings: Between Aug 3, 2015, and May 31, 2016, 376 participants were recruited, of whom nine participants were lost to follow-up, thus 367 participants were included in the analysis. Overall, 365 MSM and two transgender women were included, contributing 681·7 person-years of follow-up. At enrolment, 269 (73%) of 367 participants chose daily PrEP and 98 (27%) participants chose event-driven PrEP. Two individuals in the daily PrEP group became HIV-positive; overall HIV incidence rate was 0·30 per 100 person-years (95% CI 0·07–1·19). 253 participants were diagnosed with one or more STI during the first 2 years (incidence rate 90·4 per 100 person-years). STI incidence did not change over time (adjusted incidence rate ratio aIRR 1·00 per 3 month follow-up, 95% CI 0·93–1·07). More than a quarter of all STIs were diagnosed from tests done in between study visits. STI incidence was lower in the event-driven PrEP group than the daily PrEP group (aIRR 0·59, 95% CI 0·46–0·75). The number of condomless anal sex acts with casual partners per 3 months increased, but the number of partners and sex acts remained stable. Interpretation: Although the overall incidence of STIs did not change during 2 years of PrEP use, the incidence of STIs was higher among participants using daily PrEP than those using event-driven PrEP, which is likely a result of differences in sexual behaviour. This finding suggests the need to tailor STI prevention interventions according to behavioural profiles. Article	2019	Hoover, Karen W; Hu, Xiaohong; Porter, Sarah E; Buchacz, Kate; Bond, Martha D; Siddiqi, Azfar-E-Alam; Haynes, Suzanne G	HIV Diagnoses and the HIV Care Continuum Among Women and Girls Aged ≥13 Years-39 States and the District of Columbia, 2015-2016.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000002023	https://dx.doi.org/10.1097/QAI.0000000000002023	BACKGROUND: In 2017, 19% of new HIV diagnoses in the United States were in women. HIV acquisition can be prevented with pre-exposure prophylaxis, and HIV transmission with viral suppression. HIV viral suppression is achieved by linking women to care and supporting adherence to antiretroviral medications. The national HIV prevention goal for viral suppression is 80%. SETTING: United States. METHODS: We analyzed data reported by 40 US jurisdictions to the Centers for Disease Control and Prevention's National HIV Surveillance System to determine the number and rate of HIV diagnoses per 100,000 women in 2016. We also determined the percentages of women with diagnosed HIV who were linked to care within 1 and 3 months, received HIV care, were retained in HIV care, and were virally suppressed in 2015. Findings were stratified by demographic characteristics and HIV transmission category. RESULTS: In 2016, 6407 women were diagnosed with HIV. Black women had a rate of 783.7 per 100,000, Hispanic/Latino women 182.7, and white women 43.6. In 2015, 190,735 women were living with diagnosed HIV. Viral suppression increased with age, ranging from 46.5% among women aged 13-24 years to 62.3% among women aged ≥45 years. Black women had the lowest rate of viral suppression (55.5%). No age group of women achieved 80% viral suppression. CONCLUSIONS: Pre-exposure prophylaxis implementation for women at high risk for HIV infection can help to decrease new infections. Women living with HIV would benefit from interventions that support linkage to HIV care and antiretroviral medication adherence to increase viral suppression. Article	2019	Hope, A; Haire, B	"No-one's driving this bus" - qualitative analysis of PrEP health promotion for Aboriginal and Torres Strait Islander gay and bisexual men	Australian and New Zealand Journal of Public Health	-	-	-	-	1326-0200	10.1111/1753-6405.12852	https://pubmed.ncbi.nlm.nih.gov/30516311/	Objective: HIV prevention tools such as pre-exposure prophylaxis require equitable access and uptake to protect all at-risk populations. This project assessed the perceived barriers to accessible HIV prevention for Aboriginal and Torres Strait Islander gay and bisexual men (GBM) and evaluated the presence of health promotion for pre-exposure prophylaxis (PrEP) for this population from the perspective of service providers. Methods: Eighteen semi-structured interviews with healthcare providers, researchers and AIDS Council employees were qualitatively analysed for themes and concepts related to PrEP-specific health promotion. Results: Respondents noted AIDS Councils and affiliated sexual health clinics had been instrumental in promoting PrEP to at-risk GBM. However, many Aboriginal gay and bisexual men who are not well connected with these communities and services may not have been exposed to this health promotion and therefore have not accessed PrEP effectively. Conclusions: Aboriginal community and gay community controlled health organisations need to collaborate to ensure they deliver effective and tailored health promotion to Aboriginal communities. Implications for public health: The rising HIV notification rates in Aboriginal Australians is an example of the health gap experienced by First Nation people. Effective HIV prevention is required to ensure this gap does not widen further, and that Australia meets its goal of preventing all new HIV infections. However, these efforts will be hampered by ineffective health promotion of HIV prevention tools, such as PrEP, for Aboriginal Australians. Article	2019	Horgan L.; Blyth C.C.; Bowen A.C.; Nolan D.A.; McLean-Tooke A.P.	Pre-exposure prophylaxis for HIV prevention during pregnancy and lactation: forget not the women and children	Medical Journal of Australia	-	-	-	-	0025729X	10.5694/mja2.50052	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062531863&doi=10.5694%2fmja2.50052&partnerID=40&md5=f860d70b44fe811ac1f6a88cf394b179	Pregnancy is known to be a time of increased susceptibility to acquiring to human immunodeficiency virus (HIV) infection and this increased maternal risk places the unborn child at risk of vertical transmission. Pre-exposure prophylaxis (PrEP) involves the provision of antiretroviral therapy to an HIV-negative individual with ongoing risk of HIV exposure to limit the likelihood of HIV transmission. The inclusion of PrEP as part of a comprehensive strategy is recognised as an effective and safe means of reducing HIV infection in serodiscordant couples, thereby reducing the risk of vertical transmission of HIV. Current data suggest that PrEP is safe to continue during pregnancy and breastfeeding in HIV-negative women who remain vulnerable to acquiring HIV. The recent Pharmaceutical Benefits Scheme subsidisation of PrEP has reduced the financial and practical obstacles of PrEP provision, and a subsequent increase in patient awareness and acceptance of PrEP is expected. The framework for appropriately identifying and managing at-risk pregnant and lactating women requiring PrEP is poorly defined and warrants further clarification to better support clinicians and this patient group. This review discusses the current recommendations highlighting the gaps in the guidelines and makes some recommendations for future guideline development. © 2019 AMPCo Pty Ltd	Acquired immunodeficiency syndrome; Breastfeeding; Immunologic deficiency syndromes; Immunology; Infectious diseases; Obstetrics; Pregnancy; Prescribing	English	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review
Article	2019	Horridge, Danielle N.; Oh, Timothy S.; Alonzo, Jorge; Mann-Jackson, Lilli; Tanner, Amanda E.; Song, Eunyoung Y.; Smart, Benjamin D.; Van Dam, Cornelius N.; Baker, Logan S.; Rhodes, Scott D.	Barriers to HIV Testing Within a Sample of Spanish-speaking Latinx Gay, Bisexual, and Other Men Who Have Sex with Men: Implications for HIV Prevention and Care.	Health Behavior Research	-	-	-	-	2572-1836	https://doi.org/10.4148/2572-1836.1069	https://pmc.ncbi.nlm.nih.gov/articles/PMC6889883/	Gay, bisexual, and other men who have sex with men (GBMSM) have higher rates of HIV infection compared to the general population in the United States, and the infection rate is growing among Latinx GBMSM, compared to a decline in most other demographic subgroups. Uptake of pre-exposure prophylaxis (PrEP), a biomedical strategy designed to reduce HIV transmission, is very low among Latinx GBMSM. HIV testing is a critical first step in the HIV prevention and care continua. We analyzed data from a community-based sample of Latinx GBMSM in the southeastern United States to identify the most common HIV testing barriers and the factors associated with barriers. The five most commonly reported HIV testing barriers included not knowing where to get tested, not having health insurance, fear of being HIV positive, practicing safer sex and perceiving not needing to be tested, and not being recommended to get tested. Using multivariable logistic regression modeling, speaking only Spanish, being unemployed, and adhering to traditional notions of masculinity were associated with increased barriers to HIV testing. We recommend that interventions to increase HIV testing among Latinx GBMSM be in Spanish and use culturally congruent messaging, be accessible to those who are unemployed, and incorporate positive risk-reducing aspects of masculinity. Essay	2019	Horvath, Keith J; Todd, Kieran; Arayasirikul, Sean; Cotta, Nicholas W; Stephenson, Rob	Underutilization of Pre-Exposure Prophylaxis Services Among Transgender and Nonbinary Youth: Findings from Project Moxie and TechStep.	Transgender Health	-	-	-	-	2688-4887	10.1089/trgh.2019.0027	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6778317	We use quantitative and qualitative data from two ongoing studies to describe pre-exposure prophylaxis (PrEP) awareness, willingness to use PrEP, barriers to facilitators of PrEP uptake, and PrEP use among 15- to 24-year-old transgender and gender nonbinary (TGNB) youth. Most youth were aware of PrEP, but only one participant across both studies reported current use. Uncertainty about willingness to take PrEP may be related to general (e.g., medication cost) and trans-specific (e.g., PrEP-hormone interactions) concerns. Intensified and sustained efforts are needed to engage TGNB youth along the PrEP continuum and the impact of new PrEP administration and dosing options should be examined for TGNB youth.	adolescents, barriers to care, HIV/AIDS, PrEP, prevention, transgender	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Other
Article	2019	Hosek, Sybil; Pettifor, Audrey	HIV Prevention Interventions for Adolescents.	Current HIV/AIDS Reports	-	-	-	-	1548-3576	10.1007/s11904-019-00431-y	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6703904	PURPOSE OF REVIEW: The goal of this paper is to review recent data on biomedical, behavioral, and structural HIV prevention interventions for adolescents and young adults. RECENT FINDINGS: While it is accepted that HIV prevention interventions must take an integrated approach to achieve maximum effectiveness, to date, there have been limited, rigorously evaluated combination prevention interventions for adolescents. There are currently a range of effective biomedical, behavioral, and structural approaches that can be integrated into prevention packages to address the prevention needs of adolescents, including oral PrEP, male circumcision, rapid HIV testing, numerous behavioral interventions, and structural interventions such as cash transfers and community mobilization to address gender-based violence. There is still a need for rigorously evaluated, innovative combination prevention packages for adolescents. Prevention approaches must take into account the context of young people's lives and address the multiple levels of influence on their lives including parents, partners, and communities. Article	2019	Hoth, Angela B; Shafer, Cody; Dillon, Dena Behm; Mayer, Randy; Walton, George; Ohl, Michael E	Iowa TelePrEP: A Public-Health-Partnered Telehealth Model for Human Immunodeficiency Virus Preexposure Prophylaxis Delivery in a Rural State.	Sexually Transmitted Diseases	-	-	-	-	1537-4521	10.1097/OLQ.0000000000001017	https://dx.doi.org/10.1097/OLQ.0000000000001017	BACKGROUND: Access to human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP) is often poor in small urban and rural areas because of stigma and long distances to providers. The Iowa Department of Public Health and The University of Iowa created a regional telehealth program to address these barriers ("Iowa TelePrEP"). We describe initial TelePrEP results and share lessons learned. METHODS: Iowa Department of Public Health personnel in sexually transmitted infection (STI) clinics, disease intervention specialist and partner services, and HIV testing programs referred clients to pharmacists at University of Iowa. Clients could also self-refer via a website. Pharmacists completed video visits with clients in the community on smartphones and other devices, arranged local laboratory studies, and mailed medications. We performed a retrospective record review to quantify rates of PrEP referral, initiation, retention, guideline-concordant laboratory monitoring, and STI identification and treatment. RESULTS: Between February 2017 and October 2018, TelePrEP received 186 referrals (37% from public health) and completed 127 (68%) initial video visits with clients. Median client age was 32; 91% were men who have sex with men. Most clients with video visits (91%) started PrEP. Retention in TelePrEP at 6 months was 61%, and 96% of indicated laboratory monitoring tests were completed. Screening identified 37 STIs (8 syphilis, 10 gonorrhea, 19 chlamydia). Disease intervention specialist and partner services linked all clients with STIs to local treatment within 14 days (80% in 3 days). CONCLUSIONS: Using widely available technology and infrastructure, public health departments and health care systems can collaborate to develop regional telehealth programs to deliver PrEP in small urban and rural settings. Article	2019	Hu Q.-H.; Meyers K.; Xu J.-J.; Chu Z.-X.; Zhang J.; Ding H.-B.; Han X.-X.; Jiang Y.-J.; Geng W.-Q.; Shang H.	Efficacy and cost-effectiveness of early antiretroviral therapy and partners' pre-exposure prophylaxis among men who have sex with men in Shenyang, China: A prospective cohort and costing study	BMC Infectious Diseases	-	-	-	-	14712334	10.1186/s12879-019-4275-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069753052&doi=10.1186%2fs12879-019-4275-x&partnerID=40&md5=4896d8fe7f4dccf27fd71255f0b9ddcd	Background: Biomedical interventions such as antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) are highly effective for prevention of human immunodeficiency virus (HIV) infection. However, China has not released national PrEP guidelines, and HIV incidence among men who have sex with men (MSM) is unchanged despite substantial scale-up of ART. We evaluated reductions in HIV transmission that may be achieved through early initiation of ART plus partners' PrEP. Methods: Six intervention scenarios were evaluated in terms of their impact on HIV transmission and their cost-effectiveness for 36 months post-infection. Three scenarios were based on observed data: non-ART, standard-ART, and early-ART. Another three scenarios were based on observed and hypothetical data: non-ART plus partners' PrEP, standard-ART plus partners' PrEP, and early-ART plus partners' PrEP. The number of onward transmissions was calculated according to viral load and self-reported sexual behaviors, and calibrated by the prevalence and incidence of HIV among Chinese MSM. Cost-effectiveness outcomes were quality-adjusted life-years (QALYs) and cost-utility ratio (CUR). Results: The estimated number of onward transmissions by every 100 HIV-positive cases 36 months post-infection was 41.83 (95% credible interval: 30.75-57.69) in the non-ART scenario, 7.95 (5.85-10.95) in the early-ART scenario, and 0.79 (0.58-1.09) in the early-ART plus partners' PrEP scenario. Compared with non-ART, the early-ART and early-ART plus partners' PrEP scenarios were associated with an 81.0 and 98.1% reduction in HIV transmission, and had a CUR of $12,864/QALY and $16,817/QALY, respectively. Conclusions: Integrated delivery of early ART and sexual partners' PrEP could nearly eliminate HIV transmission and reduce costs during the first 36 months of HIV infection. Our results suggest a feasible and cost-effective strategy for reversing the HIV epidemic among MSM in China. © 2019 The Author(s). Article	2019	Hu, Xiaotong; Wang, Liming; Xu, Fujie	Guides concerning tenofovir exposure via breastfeeding: A comparison of drug dosages by developmental stage.	International Journal of Infectious Diseases	-	-	-	-	1878-3511	10.1016/j.ijid.2019.07.023	https://dx.doi.org/10.1016/j.ijid.2019.07.023	Tenofovir disoproxil fumarate (TDF) is a prodrug of tenofovir, and after being administered orally, it converts to tenofovir in the blood. With the increasing use of TDF in women for treatment and prevention of mother-to-child transmission (MTCT) of both human immunodeficiency virus (HIV) and hepatitis B virus (HBV), or the pre-exposure prophylaxis (PrEP) for HIV, many nursing mothers have to understand the risk of exposure to tenofovir via breastmilk and make the decision about breastfeeding while on TDF treatment. Despite the safety record of TDF in pregnancy, some guidelines recommend against its use during breastfeeding. In this paper, we compared the dosage levels of tenofovir exposure in fetuses, breastfed infants, and children receiving tenofovir treatment. We found that breastfed infants were exposed to only 0.5%-16% of the tenofovir dosage that fetuses experienced via placental transfer, and 0.01-0.04% of the recommended weight-adjusted therapeutic dose. The assessment of toxicity risk from the dose perspective is an important and natural way of addressing safety concerns about exposure to tenofovir via breastfeeding. Based on the safety data from fetuses and children with tenofovir exposure, and the comparatively negligible exposure dosage from breastfeeding, our study supports mothers on TDF treatment should be encouraged to breastfeed. Article	2019	Huang, Poyao; Wu, Huei-Jiuan; Strong, Carol; Jan, Feng-Ming; Mao, Ling-Wen; Ko, Nai-Ying; Li, Chia-Wen; Cheng, Chien-Yu; Ku, Stephane Wen-Wei	Unspeakable PrEP: a qualitative study of sexual communication, problematic integration, and uncertainty management among men who have sex with men in Taiwan	Journal of Applied Communication Research	-	-	-	-	909882	10.1080/00909882.2019.1693608	https://www.proquest.com/scholarly-journals/unspeakable-prep-qualitative-study-sexual/docview/2325199176/se-2?accountid=8113	This study explored how men who have sex with men (MSM) communicated their use of pre-exposure prophylaxis (PrEP) on smartphone applications. Informed by the theory of problematic integration and uncertainty management, we asked if revealing 'HIV negative, on PrEP' status on smartphone applications might increase one's uncertainty in communicating about safe sex with others. We conducted interviews with 31 Taiwanese MSM currently taking PrEP who participated in a national demonstration project. We identified three types of PrEP-related uncertainty: condition, information, and stigma uncertainty. Applied implications of our findings indicate the importance of the feasibility of medical infrastructure in implementing PrEP, the complication in translating scientific and medical jargon into everyday language, and dynamics of negotiating stigmas associated with HIV and AIDS in the context of HIV prevention. Article	2019	Huang, Wenting; Wu, Dan; Ong, Jason J; Smith, M Kumi; Pan, Stephen; Yang, Fan; Fu, Hongyun; Tang, Weiming; Tucker, Joseph D	Prepared for PrEP: preferences for HIV pre-exposure prophylaxis among Chinese men who have sex with men in an online national survey.	BMC Infectious Diseases	-	-	-	-	1471-2334	10.1186/s12879-019-4692-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6916236	BACKGROUND: Pre-exposure prophylaxis (PrEP) is not widely available in China. Previous studies reported low awareness and inconclusive findings on the acceptability of PrEP among Chinese men who have sex with men (MSM). METHODS: We conducted a secondary analysis of an online national survey comparing preferences for oral and long-acting injectable PrEP among MSM and identifying correlates of preferences. The study did not collect detailed information about partner types that may influence negotiated safety and PrEP uptake. RESULTS: Nine-hundred and seventy-nine men from the larger sample of 1045 men responded to the PrEP survey questions. Most men (81.9%) had never heard of PrEP, but reported interest in using PrEP. More participants chose injectable PrEP (36.3%) as their preferred formulation than oral PrEP (24.6%). Men who had at least two HIV tests (adjusted OR = 1.36, 95%CI 1.04, 1.78) more commonly preferred injectable PrEP. CONCLUSION: Our findings may help inform PrEP messaging in areas where PrEP has yet to be scaled up. Article	2019	Hunt, Travis; Lalley-Chareczko, Linden; Daughtridge, Giffin; Swyryn, Meghan; Koenig, Helen	Challenges to PrEP use and perceptions of urine tenofovir adherence monitoring reported by individuals on PrEP.	AIDS Care	-	-	-	-	1360-0451	10.1080/09540121.2019.1587369	https://dx.doi.org/10.1080/09540121.2019.1587369	Maximizing the impact of HIV pre-exposure prophylaxis (PrEP) requires optimizing access and adherence for those at risk of contracting HIV. This study examined challenges to the processes of accessing and adhering to PrEP encountered by participants from a large, U.S. urban clinical center and assessed the utility of objectively monitoring PrEP adherence via urine. Most participants (65%) reported starting PrEP within 1-3 months of hearing about it, although 35% of participants encountered a provider unwilling to prescribe PrEP. Self-reported adherence was high among this population, with remembering to take the medication reported as the major barrier to adherence (44%) rather than cost or stigma. Urine tenofovir (TFV) monitoring was highly acceptable to this population, and participants indicated greater willingness to undergo urine monitoring every 3 months compared to finger prick (dried blood spot), phlebotomy, or hair follicle testing. These findings highlight the importance of focusing efforts toward reducing obstacles to PrEP use and support the use of urine TFV adherence monitoring as a marker of PrEP adherence. Article	2019	Hurley, Ciara Frances	Prevention is Better than Cure, But who Foots the Bill? R (National AIDS Trust) v NHS England.	Medical Law Review	-	-	-	-	1464-3790	10.1093/medlaw/fwy018	https://dx.doi.org/10.1093/medlaw/fwy018	This case note discusses R (on the Application of National Aids Trust) v The National Health Service Commissioning Board (NHS England), The Local Government Association, The Secretary of State For Health 2016 EWCA Civ 1100. The case is an appeal on an earlier finding by the High Court that the power to commission pre-exposure prophylaxis (PrEP) lies within National Health Service (NHS) England's competence, instead of being within the realm of local authorities' responsibilities. It now forms the sole piece of judicial guidance on NHS England's duties under the National Health Service Act 2006 and is significant for the process by which the Court of Appeal reached its decision. Rather than adhere to the literal meaning of relevant legislation, the judges engaged in a holistic examination of the issue to reach a functional and sensible decision. Examining this case under the lens of both legal theory and pragmatism, comment is made on the soundness of the judges' approach and it is argued that the decision reached was the correct one. This case now forms binding precedent on this issue and the clear process by which the judges reached their conclusion may form instructive guidance for similar such problems in the future. Article	2019	Iliyasu, Zubairu; Galadanci, Hadiza S; Oladimeji, Alfa I; Babashani, Musa; Gajida, Auwalu U; Aliyu, Muktar H	Predictors of Safer Conception Practices Among HIV-Infected Women in Northern Nigeria.	International Journal of Health Policy and Management	-	-	-	-	2322-5939	10.15171/ijhpm.2019.27	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6706964	BACKGROUND: Persons living with HIV often face discrimination in safe sex and reproductive choices, especially in lowresource settings. This study assessed fertility desires and intentions, risk perception and correlates of ever use of at least one safer conception method among HIV-infected women attending a tertiary health facility in Kano, Nigeria. METHODS: Structured questionnaires were administered to a cross section of 328 of 427 eligible HIV-infected women. Fertility desires and intentions, risk perception and safer conception practice were analyzed. Logistic regression was employed to assess for predictors. RESULTS: Of the 328 respondents, 150 respondents (45.7%) wanted more children. The proportions of respondents aware of their transmission risk during pregnancy, delivery, and breastfeeding were 69.5%, 75.3%, and 78.9%, respectively. Further, 68.9% of respondents were aware of the prospects of bearing HIV-negative children without infecting their partners. About 64.8% of women were aware of at least one safer conception method. Safer conception methods everused by the participants include: antiretroviral therapy (ART) (36.7%), timed unprotected intercourse with (10.9%), and without pre-exposure prophylaxis (PrEP) (17.2%), intravaginal insemination (7.3%) and intrauterine insemination (4.7%). Safer conception practice was predicted by marital status (married versus single, adjusted odds ratio AOR=1.50, 95% CI =1.10-3.55), parity (2-4 versus 0, AOR=12.1, 95% CI=3.7-39.8), occupation (civil servants versus traders, AOR=0.37, 95% CI=0.16-0.86), husband's serostatus (seroconcordant versus serodiscordant) (AOR=1.51, 95% CI=1.13-4.64), couple contraceptive use (users versus non-users) (AOR=1.62, 95% CI=1.16-5.83) and transmission risk perception (high risk versus low/no risk) (AOR=2.14, 95% CI=1.18-3.90). CONCLUSION: We found high levels of fertility desires and intentions and moderate risk perception among a cohort of HIV-infected women in urban Kano, Nigeria. The use of safer conception practices was not common. Our findings underscore the need for healthcare provider capacity building to enhance safer conception counseling and service delivery. Article	2019	Iliyasu, Zubairu; Galadanci, Hadiza S; Zubairu, Ahmad A; Amole, Taiwo G; Sam-Agudu, Nadia A; Aliyu, Muktar H	Health workers' knowledge of safer conception and attitudes toward reproductive rights of HIV-infected couples in Kano, Nigeria.	International Health	-	-	-	-	1876-3405	10.1093/inthealth/ihz016	https://dx.doi.org/10.1093/inthealth/ihz016	BACKGROUND: The restriction of reproductive rights of HIV-positive couples in low-resource settings could be related to the attitudes and skills of health workers. We assessed health workers' knowledge of safer conception and their attitudes toward the reproductive rights of HIV-positive couples in a tertiary hospital in Nigeria. METHODS: A cross-section of health workers (n=294) was interviewed using structured questionnaires. Knowledge and attitude scores were analyzed. Logistic regression was employed to generate adjusted odds ratios (AORs) for predictors of attitude. RESULTS: Safer conception methods mentioned by respondents included timed unprotected intercourse with (27.9%) and without antiretroviral pre-exposure prophylaxis (37.4%), in vitro fertilization plus intracytoplasmic sperm injection (26.5%), and sperm washing and intrauterine insemination (24.8%). The majority (94.2%) of health workers acknowledged the reproductive rights of HIV-infected persons, although (64.6%) strongly felt that HIV-infected couples should have fewer children. Health workers reported always/nearly always counseling their patients on HIV transmission risks (64.1%) and safer conception (59.2% and 48.3% for females and males, respectively) (p<0.05). Among health workers, being older (30-39 vs <30 y) (AOR=1.33, 95% CI=1.13-2.47), married (AOR=2.15, 95% CI=1.17-5.58) and having a larger HIV-positive daily caseload (20-49 vs <20) (AOR=1.98, 95% CI=1.07-3.64) predicted positive attitude towards reproductive rights of HIV-affected couples. CONCLUSIONS: Health workers had limited knowledge of safer conception methods, but were supportive of the reproductive rights of HIV-positive couples. Health workers in Nigeria require training to effectively counsel couples on their reproductive rights, risks and options	: HIV/AIDS, PMTCT, safer conception knowledge, health workers, reproductive rights, Nigeria	English	United Kingdom	Western and Central Europe and North America	Nigeria	Western and Central Africa	Nigeria	Western and Central Africa	Clinical
Article	2019	Irungu, Elizabeth M; Ngure, Kenneth; Mugwanya, Kenneth; Mugo, Nelly; Bukusi, Elizabeth; Wamoni, Elizabeth; Odoyo, Josephine; Morton, Jennifer F; Bernabee, Gena; Mambo, Barbara; Masyuko, Sarah; Mukui, Irene; O'Malley, Gabrielle; Baeten, Jared M	Training health care providers to provide PrEP for HIV serodiscordant couples attending public health facilities in Kenya	Global Public Health	-	-	-	-	17441692	10.1080/17441692.2019.1588908	https://www.proquest.com/scholarly-journals/training-health-care-providers-provide-prep-hiv/docview/2275896917/se-2?accountid=8113	To catalyse national scale up of PrEP for HIV serodiscordant couples in public health facilities in Kenya, the Partners Scale-Up Project, using a two-day case-based interactive curriculum, trained health care providers working in 24 high volume facilities in central and western Kenya on PrEP service delivery. Using a standardised test with questions about PrEP and antiretroviral-based HIV prevention we assessed gain in knowledge and confidence gain by comparing pre-and post-training test scores. We explored experiences of the training through key informant interviews after clinics started delivering PrEP. Of 716 health care providers trained, 235 (32.9%) were nurses, 144 (20.2%) were clinical officers and 155 (21.7%) were HIV counsellors. There was a significant improvement between the means of pre-test and post-test scores (61.7% (SD 17.4) vs 86.4% (SD 12.7) p < 0.001). The proportion of those who reported being 'very comfortable' providing care to HIV serodiscordant couples increased from 22.8% to 67.3% (p < 0.001). Key themes that training increasing both knowledge of PrEP and confidence to deliver PrEP to HIV serodiscordant couples emerged from interviews. This short, standardised training resulted in a substantial increase in knowledge of PrEP and in the confidence of the health providers to provide PrEP to HIV serodiscordant couples.Trial registration ClinicalTrials.gov NCT03052010	Antiretroviral therapy; Kenya; Prevention; Health services; Health care; Public health; HIV serodiscordant couples; Prep; Trust; Registration; Training; Preventive medicine; Nurses; health care providers; Couples; training; PrEP scale up; public HIV care clinics; Human immunodeficiency virus--HIV; Clinics; Medical Sciences; Prevention programs; Medical personnel; Health care industry; Health facilities; Curricula; Health care facilities; Public health clinics; Counselors; Test scores	English	United Kingdom	Western and Central Europe and North America	Kenya	Eastern and Southern Africa	Kenya	Eastern and Southern Africa	Quantitative
Article	2019	Jadwin-Cakmak, Laura; Reisner, Sari L; Hughto, Jaclyn M W; Salomon, Liz; Martinez, Miguel; Popoff, Elliot; Rivera, Bré Anne; Harper, Gary W	HIV prevention and HIV care among transgender and gender diverse youth: design and implementation of a multisite mixed-methods study protocol in the U.S.	BMC Public Health	-	-	-	-	1471-2458	10.1186/s12889-019-7605-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6858737	BACKGROUND: In the U.S., transgender and gender diverse (TGD) populations face structural, interpersonal, and individual barriers to healthcare. Less is known, however, about the HIV prevention and treatment experiences of TGD youth in the U.S. The current study was developed to fill this research gap. METHODS: This article describes the research protocol for a multi-site, U.S.-based mixed-methods study that sought to identify the multi-level facilitators and barriers that influence participation of TGD youth in various stages of the HIV prevention (e.g., pre-exposure prophylaxis uptake) and care continua. A sample of diverse TGD youth ages 16-24 was recruited from 14 U.S. sites. TGD youth participants completed a one-time, in-person visit that included an informed consent process, computer-based quantitative survey, and in-depth qualitative interview assessing experiences accessing HIV prevention and/or care services. Providers serving TGD youth were recruited from the same 14 sites and completed a one-time visit via phone that included informed consent, demographic questionnaire, and in-depth qualitative interview assessing their experiences providing HIV prevention or treatment services to TGD youth. RESULTS: Overall, 186 TGD youth ages 16-24 and 59 providers serving TGD youth were recruited and enrolled from across the 14 U.S. sites. TGD youth participants had a mean age of 20.69; 77.3% youth of color; 59.7% trans-feminine; 15.5% trans-masculine; 24.9% non-binary; 53.6% family income under poverty level. Providers included medical and mental health providers as well as case manager/care coordinators, HIV test counselors, and health educators/outreach workers. Providers were 81.3% cisgender and 30.5% people of color. Successes with community-engagement strategies and gender-affirming research methods are reported. CONCLUSIONS: This study addresses critical gaps in current knowledge about the HIV prevention and care experiences of TGD youth. Findings have implications for the development of HIV interventions across levels to support the health and well-being of TGD youth. Future research is warranted to replicate and expand on lessons learned regarding recruitment and engagement of communities of TGD youth, including longitudinal designs to assess engagement across their developmental stages. Lessons learned working with TGD youth through developing and implementing the study protocol are shared. TRIAL REGISTRATION: Registered on ClinicalTrials.gov on 05/20/2015 (NCT02449629). Article	2019	Jaiswal, Jessica	Whose Responsibility Is It to Dismantle Medical Mistrust? Future Directions for Researchers and Health Care Providers.	Behavioral Medicine	-	-	-	-	0896-4289	10.1080/08964289.2019.1630357	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7808309	Medical mistrust persists and appears to be growing. The public health literature on medical mistrust has largely focused on mistrust among Black and African American populations due to legacies of abuse and mistreatment, such as the infamous Tuskegee Syphilis Study. However, research is now emerging that explores mistrust among various populations and in varying contexts, and the literature now largely emphasizes the role of ongoing, present-day social and economic inequalities in shaping and sustaining mistrust, particularly among populations who experience staggering health disparities. This special issue showcased nine articles exploring medical mistrust among diverse populations, exploring a wide array of topics and spanning myriad methodologies. In addition to a rigorous systematic review of the literature, this issue covers several critical subareas of the health disparities literature, including preventative health screenings among Black men, discrimination and cultural factors among rural Latinx communities, health care satisfaction among Latina immigrant women, the complex relationship between HIV testing and "conspiracy beliefs" among Black populations, pre-exposure prophylaxis use among transgender women, the impacts of mass incarceration on HIV care, eHealth interventions to address chronic diseases among sexual minority men of color, and participatory research to engage underserved populations as co-researchers. The purpose of this article is to provide a brief summary of the nine manuscripts in this special issue and to outline some recommendations and future directions for research on medical mistrust.	health disparities, health care providers, HIV, medical mistrust, research	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Jaiswal, Jessica; Halkitis, Perry N	Towards a More Inclusive and Dynamic Understanding of Medical Mistrust Informed by Science.	Behavioral Medicine	-	-	-	-	0896-4289	10.1080/08964289.2019.1619511	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7808310	Mistrust of medical advances and the medical professions continues to persist, and is perhaps increasing. The popular press has documented the growing number of parents globally whose concerns around childhood vaccination, albeit based on faulty scientific information, has led to the anti-vax movement which has already resulted in outbreaks of measles in various parts of the U.S. In recent years, the AIDS Healthcare Foundation has increased speculation and mistrust with regard to the denialism of the effectiveness of pre-exposure prophylaxis (PrEP) to avert HIV infections, again based on misinformation. However, in other cases, medical mistrust reflects the very real historical and ongoing injustices experienced by socially and economically marginalized groups. Whether the genesis of the mistrust is based on fact or fallacy, the results may be similar. There are myriad negative consequences associated with medical mistrust, including lower utilization of healthcare and poorer management of health conditions. Mistrust is thought to provide a partial explanation for staggering health disparities, particularly among Black and African American people, and much of the public health and medical literature cites the infamous Tuskegee Study as a main catalyst for this persistent health-related mistrust among people of color and other groups who experience social and economic vulnerability. While mistrust is often referred to as a phenomenon existing within an individual or community, we must rethink this conceptualization and instead locate mistrust as a phenomenon created by and existing within a system that creates, sustains and reinforces racism, classism, homophobia and transphobia, and stigma. The purpose of this article is to briefly address the state of the medical mistrust literature, and to provide a summary of the articles included in this special issue on medical mistrust. Although the scholarship in this issue addresses diverse methodologies, outcomes and populations, they share a message: social inequality drives mistrust. Article	2019	Janes H.; Brown M.D.; Glidden D.V.; Mayer K.H.; Buchbinder S.P.; McMahan V.M.; Schechter M.; Guanira J.; Casapia M.	Evaluating the impact of policies recommending PrEP to subpopulations of men and transgender women who have sex with men based on demographic and behavioral risk factors	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0222183	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072340939&doi=10.1371%2fjournal.pone.0222183&partnerID=40&md5=3512238b7b3916631d77c4e7d6471719	Introduction Developing guidelines to inform the use of antiretroviral pre-exposure prophylaxis (PrEP) for HIV prevention in resource-limited settings must necessarily be informed by considering the resources and infrastructure needed for PrEP delivery. We describe an approach that identifies subpopulations of cisgender men who have sex with men (MSM) and transgender women (TGW) to prioritize for the rollout of PrEP in resource-limited settings. Methods We use data from the iPrEx study, a multi-national phase III study of PrEP for HIV prevention in MSM/TGW, to build statistical models that identify subpopulations at high risk of HIV acquisition without PrEP, and with high expected PrEP benefit. We then evaluate empirically the population impact of policies recommending PrEP to these subpopulations, and contrast these with existing policies. Results A policy recommending PrEP to a high risk subpopulation of MSM/TGW reporting condomless receptive anal intercourse over the last 3 months (estimated 3.3% 1-year HIV incidence) yields an estimated 1.95% absolute reduction in 1-year HIV incidence at the population level, and 3.83% reduction over 2 years. Importantly, such a policy requires rolling PrEP out to just 59.7% of MSM/TGW in the iPrEx population. We find that this policy is identical to that which prioritizes MSM/TGW with high expected PrEP benefit. It is estimated to achieve nearly the same reduction in HIV incidence as the PrEP guideline put forth by the US Centers for Disease Control, which relies on the measurement of more behavioral risk factors and which would recommend PrEP to a larger subset of the MSM/TGW population (86% vs. 60%). Conclusions These findings may be used to focus future mathematical modelling studies of PrEP in resource-limited settings on prioritizing PrEP for high-risk subpopulations of MSM/TGW. The statistical approach we took could be employed to develop PrEP policies for other at-risk populations and resource-limited settings. © 2019 Janes et al. Article	2019	Jarrin, Inmaculada	Durability of first-line antiretroviral regimens in the era of integrase inhibitors: a cohort of HIV-positive individuals in Spain, 2014-2015	Antiviral Therapy	-	-	-	-	NA	https://doi.org/10.3851/IMP3297	https://journals.sagepub.com/doi/10.3851/IMP3297	Background: We compared time to treatment change (TC), viral suppression (VS) and change in CD4+ T-cell counts of first-line antiretroviral regimens (ART). Methods: We analysed HIV treatment-naive adults from the Cohort of the Spanish HIV/AIDS Research Network (CoRIS) initiating the most commonly used ART regimens from September 2014 to November 2015. We used proportional hazards models on the sub-distribution hazard to estimate sub-distribution hazard ratios (sHR) for time to TC, logistic regression to estimate odds ratios (ORs) for VS (viral load <50 copies/ml), and linear regression to assess mean differences in CD4+ T-cell changes from ART initiation. Results: Among 960 individuals, tenofovir (TDF)/emtricitabine (FTC)/rilpivirine (RPV) was the most frequently prescribed regimen (24.2%), followed by elvitegravir (EVG)/cobicistat (COBI)/TDF/FTC (22.8%), abacavir (ABC)/lamivudine (3TC)/dolutegravir (DTG; 17.4%), TDF/FTC+darunavir/ritonavir (DRV/r) or darunavir/cobicistat (DRV/c; 12.1%), TDF/FTC/efavirenz (EFV; 8.8%), TDF/FTC+raltegravir (RAL; 7.7%) and TDF/FTC+DTG (7.0%). Initiating ART with TDF/FTC+DRV/r or DRV/c (adjusted sHR: 2.96; 95% CI: 1.44, 6.08), TDF/FTC/EFV (2.18; 0.98, 4.82), TDF/FTC+RAL (2.37; 1.08, 5.22) and TDF/FTC+DTG (6.34; 3.18, 12.64) was associated with a higher risk of TC compared to ABC/3TC/DTG. At 24 weeks, VS was lower in TDF/FTC+DRV/r or DRV/c (adjusted OR: 0.37, 95% CI: 0.18, 0.74) compared with ABC/3TC/DTG, and CD4+ T-cell increase was lower in patients initiating with TDF/FTC/RPV (adjusted mean difference: -75.9, 95% CI: -130.6, -21.2) compared with those who did with ABC/3TC/DTG. Conclusions: Time to TC, VS and change in CD4+ T-cell counts varies by initial regimen. These differences may be useful for making decision when initiating ART. Article	2019	Jaspal R.; Lopes B.; Maatouk I.	The Attitudes toward Pre-Exposure Prophylaxis (PrEP) Scale: Development and validation	Journal of HIV/AIDS & Social Services	-	-	-	-	15381501	10.1080/15381501.2019.1596861	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064560759&doi=10.1080%2f15381501.2019.1596861&partnerID=40&md5=e47148f5de21ed4a07cbc20e846631ff	Pre-exposure prophylaxis (PrEP) is a novel, clinically effective biomedical HIV prevention tool but it has not met with widespread public acceptance. In this article, the results of a study designed to develop a scale for measuring attitudes toward PrEP is presented. The psychometric properties of the scale are described for use in both the general population and in-patient samples. Two hundred twenty-two university students completed the Attitudes toward PrEP Scale (APS) and additional measures of attitudes toward gay men, Black Africans, and condom use. The APS comprised three factors (Attitudes toward the Science of PrEP, Perception of Sexual Health Risks of PrEP, and Perception of Dangerous Effects of PrEP), which explained 49.31% of the variance. The 14-item APS had a good internal consistency, α =.72, and satisfactory concurrent validity with measures of condom use, and attitudes toward social groups associated with PrEP. Additional studies in other nonstudent samples are required to assess the external validity of the scale. © 2019, © 2019 Taylor & Francis Group, LLC.	attitudes; gay men; HIV; PrEP; sexual health	English	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2019	Jaspal, R; Lopes, B; Bayley, J; Papaloukas, P	A structural equation model to predict pre-exposure prophylaxis acceptability in men who have sex with men in Leicester, UK.	HIV Medicine	-	-	-	-	1468-1293	10.1111/hiv.12667	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6585773	OBJECTIVES: Pre-exposure prophylaxis (PrEP) is an effective HIV prevention tool for high-risk men who have sex with men (MSM). However, acceptability and uptake have been variable. This study explored the factors that predict PrEP acceptability in MSM in Leicester, where HIV prevalence is double the national average. METHODS: A total of 191 HIV-negative MSM completed a cross-sectional survey. Participants provided demographic information, and completed measures of HIV knowledge, perceived HIV risk, engagement in sexual risk behaviour, acquisition of a sexually transmitted infection (STI) in the last 12 months, frequency of HIV testing and PrEP acceptability. RESULTS: Kruskal-Wallis tests showed statistically significant effects of sexual orientation, education level and income, respectively, on HIV knowledge. Gay-identified individuals possessed greater HIV knowledge than bisexuals. Respondents with General Certificate of Secondary Education (GCSE)-level education had significantly less HIV knowledge than those educated to postgraduate level. Respondents with income of < £10 000 possessed significantly less HIV knowledge than higher income groups. Structural equation modelling showed that the relationship between HIV knowledge and PrEP acceptability was mediated by perceived HIV risk, engagement in sexual risk behaviour, acquisition of an STI in the past 12 months and frequency of HIV testing. CONCLUSIONS: The results reveal socio-economic inequalities in HIV knowledge and HIV testing, and suggest that MSM who have high levels of HIV knowledge and perceived HIV risk and who regularly test for HIV are most likely to endorse PrEP as personally beneficial. HIV knowledge and accurate risk appraisal should be promoted in MSM. The HIV testing context constitutes an ideal context for promoting PrEP to high-risk MSM.	acceptability, HIV prevention, men who have sex with men, pre-exposure prophylaxis	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2019	Jayawardene, Wasantha; Carter, Gregory; Agley, Jon; Meyerson, Beth; Garcia, Justin R; Miller, Wendy	HIV pre-exposure prophylaxis uptake by advanced practice nurses: Interplay of agency, community and attitudinal factors.	Journal of Advanced Nursing	-	-	-	-	1365-2648	10.1111/jan.14019	https://dx.doi.org/10.1111/jan.14019	AIMS: To identify associations among agency, community, personal and attitudinal factors that affect advanced practice nurses' uptake of HIV pre-exposure prophylaxis, an intervention consists of emtricitabine/tenofovir once-daily pill, along with sexual risk reduction education. DESIGN: Cross-sectional. METHODS: During March-May 2017, randomly selected Indiana advanced practice nurses were invited to complete an online survey, consisted of several validated self-rating measures (N = 1,358; response = 32.3%). Final sample (N = 369) was predominantly White, non-Hispanic, female advanced practice nurses in urban practices (mean age = 46). Conceptual model for structural equation model included 29 original/composite variables and five latent factors. RESULTS: Final model consisted of 11 variables and four factors: agency, community, HIV prevention practices (including screening) and motivation to adopt evidence-based practices overall. Community had direct effects on HIV prevention practices (estimate = 0.28) and agency (estimate = 0.29). Agency had direct effects on HIV prevention practices (estimate = 0.74) and motivation to adopt evidence-based practices (estimate = 0.24). Community had indirect effects, through agency, on the two remaining factors. CONCLUSION: Barriers exist against pre-exposure prophylaxis implementation, although practice guidelines are available. HIV prevention practices must be integrated across organizational structures, especially in high-risk communities, whereas practice change is more effective when focused on changing providers' attitudes towards intervention. When planning a pre-exposure prophylaxis intervention, advancing inputs from healthcare professionals, organizational leadership and community members, is crucial to success. IMPACT: In settings where advanced practice nurses are primary contact points for health care, they may be best positioned to have an impact on implementation of HIV risk reduction strategies. Further research is needed to optimize their contributions to pre-exposure prophylaxis implementation. Article	2019	Jenness S.M.; Maloney K.M.; Smith D.K.; Hoover K.W.; Goodreau S.M.; Rosenberg E.S.; Weiss K.M.; Liu A.Y.; Rao D.W.; Sullivan P.S.	Addressing Gaps in HIV Preexposure Prophylaxis Care to Reduce Racial Disparities in HIV Incidence in the United States	American Journal of Epidemiology	-	-	-	-	29262	10.1093/aje/kwy230	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061110003&doi=10.1093%2faje%2fkwy230&partnerID=40&md5=8462cfe21abfb327851fb6954cb80bf3	The potential for human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP) to reduce the racial disparities in HIV incidence in the United States might be limited by racial gaps in PrEP care. We used a network-based mathematical model of HIV transmission for younger black and white men who have sex with men (BMSM and WMSM) in the Atlanta, Georgia, area to evaluate how race-stratified transitions through the PrEP care continuum from initiation to adherence and retention could affect HIV incidence overall and disparities in incidence between races, using current empirical estimates of BMSM continuum parameters. Relative to a no-PrEP scenario, implementing PrEP according to observed BMSM parameters was projected to yield a 23% decline in HIV incidence (hazard ratio = 0.77) among BMSM at year 10. The racial disparity in incidence in this observed scenario was 4.95 per 100 person-years at risk (PYAR), a 19% decline from the 6.08 per 100 PYAR disparity in the no-PrEP scenario. If BMSM parameters were increased to WMSM values, incidence would decline by 47% (hazard ratio = 0.53), with an associated disparity of 3.30 per 100 PYAR (a 46% decline in the disparity). PrEP could simultaneously lower HIV incidence overall and reduce racial disparities despite current gaps in PrEP care. Interventions addressing these gaps will be needed to substantially decrease disparities. © 2018 The Author(s).	human immunodeficiency virus; mathematical model; men who have sex with men; preexposure prophylaxis; racial disparities	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Theses and Dissertations	2019	Jhunjhunwala, Kunal	Rectal Suppository as a Versatile Platform for Delivering Physicochemically Diverse Antiretrovirals for HIV Prevention	-	-	University of Pittsburgh	-	NA	NA	http://d-scholarship.pitt.edu/37930/1/Dissertation_KJ_12032019.pdf	When reflecting on new Human Immunodeficiency Virus (HIV-1) infections across the globe, we find that men who have sex with men (MSM) are disproportionally impacted, especially in developed nations. Several studies have now shown that the chances of HIV-1 transmission through receptive anal intercourse (RAI) is about 10 times higher compared to vaginal intercourse. Therefore, new strategies are needed to combat rectal transmission of HIV-1. However, the rectal anatomy and physiology, limit dosage form options for drug delivery to this compartment. Suppositories offer several advantages over other rectally administered dosage forms, from a formulation as well as user acceptability perspective. Considering these advantages, this dissertation aims to explore application of the rectal suppository platform to deliver antiretroviral (ARV) drugs as pre-exposure prophylaxis (PrEP) for HIV prevention. In addition, since HIV-1 treatment and products typically utilize more than one ARV, we also explored the potential of developing a suppository product which co-delivered multiple ARV candidates. Several suppository bases were screened to obtain a desired set of suppository characteristics. From this analysis, two bases (Witepsol H15 and PEG 3350:1000:400 at ratio 60:30:10) were chosen for further evaluation. Additionally, based on factors such as the mechanism of action, physicochemical properties, and drug-resistance profile, tenofovir (TFV), tenofovir alafenamide fumarate (TAF) and elvitegravir (EVG) were selected as the lead ARV candidates. The suppositories were manufactured, characterized and tested for stability as per ICH guidelines. Combination suppositories (TFV and EVG) were manufactured and their pharmacokinetics following a single dose administration was evaluated in a non-human primate (NHP) model. Rectal fluid, tissues (biopsies) and plasma samples were collected to determine the drug exposure achieved using each test suppository dosage form. Furthermore, to evaluate whether there was any pharmacokinetic advantage gained by replacing tenofovir with its prodrug TAF, combination suppositories (TAF and EVG) were manufactured and evaluated in the same NHP model. The results from both these studies confirmed comparable or in some cases better drug exposure achieved in vivo using a suppository dosage form as compared to other dosage forms such as gels and enemas. The studies presented in this dissertation provide a proof of concept that suppositories can be used as potential ARV drug delivery platform for PrEP from HIV. Article	2019	Jiang T.; Su B.; Song T.; Zhu Z.; Xia W.; Dai L.; Wang W.; Zhang T.; Wu H.	Immunological efficacy of tenofovir disproxil fumarate-containing regimens in patients with HIV-HBV coinfection: A systematic review and meta-analysis	Frontiers in Pharmacology	-	-	-	16639812	10.3389/fphar.2019.01023	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072939111&doi=10.3389%2ffphar.2019.01023&partnerID=40&md5=7b280619dc7d16e2147d7aa5e8ef12df	Background: Hepatitis B virus (HBV) coinfection is common in HIV-positive patients. HIV infection modifies the natural course of HBV infection, leading to a faster progression of liver-related morbidity and mortality than is observed in HBV mono-infected patients. This systematic review and meta-analysis evaluates the current clinical evidence regarding the use of oral tenofovir disproxil fumarate (TDF)-based treatments in patients coinfected with HIV and HBV. Methods: We performed a comprehensive literature search in PubMed and Web of Science. Supplementary searches were conducted in Google Scholar and Clinicaltrials. gov. We conducted a random effects meta-analysis using the event rate (ER) to estimate the incidence of HBV seroconversion. A subgroup meta-analysis was performed to assess the moderate effects of demographic and disease-related variables on HBsAg loss. This review is registered in the PROSPERO database (CRD42018092379). Results: We included 11 studies in the review. The immunological effects of oral TDF-based Pre-exposure prophylaxis (PrEP) treatment in patients with HIV-HBV coinfection were 0.249 for HBeAg loss, 0.237 for HBeAg conversion, 0.073 for HBsAg loss, and 0.055 for HBsAg conversion. The factors associated with HBsAg loss were the baseline HBV viral load, participant's location, and a history of exposure to lamivudine/emtricitabine (3TC/FTC) (all p < 0.05). A trend toward a negative relationship between the baseline CD4+ T-cell count and HBsAg loss was observed (p = 0.078). Conclusion: This systematic review and meta-analysis demonstrated that TDF-containing regimens are effective at stimulating HBeAg loss (24.9%), HBeAg conversion (23.7%), HBsAg loss (7.3%), and HBsAg conversion (5.5%) in HIV-HBV coinfected patients. The moderator analysis showed that HBV viral load, the location of participants, and prior exposure to 3TC/FTC are factors associated with HBsAg loss. Asian ethnicity, prior exposure to 3TC, and a nondetectable baseline HBV viral load are associated with lower odds of HBsAg loss. Well-designed prospective cohort studies and randomized controlled trials (RCTs) with large sample sizes are required for the investigation of potential predictors and biological markers associated with strategies for achieving HBV remission in patients with HIV-HBV coinfection, which is a matter of considerable importance to clinicians and those responsible for health policies. © 2019 Jiang, Su, Song, Zhu, Xia, Dai, Wang, Zhang and Wu. Article	2019	John, Steven A; Parsons, Jeffrey T; Rendina, H Jonathon; Grov, Christian	Club drug users had higher odds of reporting a bacterial STI compared with non-club drug users: results from a cross-sectional analysis of gay and bisexual men on HIV pre-exposure prophylaxis.	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2018-053591	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6383506	OBJECTIVES: Pre-exposure prophylaxis (PrEP) can reduce HIV transmission risk for many gay, bisexual and other men who have sex with men. However, bacterial STI (BSTI) associated with decreasing condom use among HIV PrEP users is a growing concern. Determining the characteristics of current PrEP users at highest BSTI risk fills a critical gap in the literature. METHODS: Gay and bisexual men (GBM) in New York City on HIV PrEP for 6 or more months (n=65) were asked about chlamydia, gonorrhoea and syphilis diagnoses in the past 6 months. By design, half (51%) of the sample were club drug users. We examined the associations of length of time on PrEP, type of PrEP care provider, PrEP adherence, number of sexual partners, number of condomless anal sex acts and club drug use on self-reported BSTI using multivariable, binary logistic regressions, adjusting for age, race/ethnicity, education and income. RESULTS: Twenty-six per cent of GBM on HIV PrEP reported a diagnosis of BSTI in the past 6 months. Men who reported club drug use (adjusted OR (AOR)=6.60, p<0.05) and more frequent condomless anal sex in the past 30 days (AOR=1.13, p<0.05) had higher odds of reporting a BSTI. No other variables were significantly associated with self-reported BSTI in the multivariable models. CONCLUSIONS: Club drug users could be at a unique BSTI risk, perhaps because of higher risk sexual networks. Findings should be considered preliminary, but suggest the importance of ongoing BSTI screening and risk-reduction counselling for GBM on HIV PrEP.	hiv pre-exposure prophylaxis; club drug use; chemsex; men who have sex with men; gay and bisexual men; sexually transmitted infections	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	John, Steven A; Rendina, H Jonathon; Starks, Tyrel J; Grov, Christian; Parsons, Jeffrey T	Decisional Balance and Contemplation Ladder to Support Interventions for HIV Pre-Exposure Prophylaxis Uptake and Persistence	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0136	https://www.proquest.com/scholarly-journals/decisional-balance-contemplation-ladder-support/docview/2235053534/se-2?accountid=8113	Fewer than 60,000 males—inclusive of all sexual identities—were prescribed HIV pre-exposure prophylaxis (PrEP) by mid-2017 in the United States. Efforts to increase PrEP uptake among gay, bisexual, and other men who have sex with men (GBM), in particular, are ongoing in research and practice settings, but few tools exist to support interventions. We aimed to develop and validate tools to support motivational interviewing interventions for PrEP. In 2017, a national sample of HIV-negative GBM of relatively high socioeconomic status (n = 786) was asked about sexual behaviors that encompass Centers for Disease Control and Prevention guidelines for PrEP use, a 35-item decisional-balance scale (i.e., PrEP-DB) assessing benefits and consequences of PrEP use, and questions assessing location on the motivational PrEP cascade and derivative—the PrEP contemplation ladder. Principal axis factoring with oblique promax rotation was used for PrEP-DB construct identification and item reduction. The final 20-item PrEP-DB performed well; eigenvalues indicating a 4-factor solution provided an adequate fit to the data. Factors included the following: health benefits (α = 0.91), health consequences (α = 0.82), social benefits (α = 0.72), and social consequences (α = 0.86). Ladder scores increased across the cascade (ρ = 0.89, p < 0.001), and health benefits (β = 0.50, p < 0.001) and health consequences (β = −0.37, p < 0.001) were more strongly associated with ladder location than social benefits (β = 0.05, p > 0.05) and social consequences (β = −0.05, p > 0.05) in the fully adjusted regression model. The PrEP-DB demonstrated good reliability and predictive validity, and the ladder had strong construct validity with the motivational PrEP cascade. PrEP uptake and persistence interventions and additional empirical work could benefit from the utility of these measures. Article	2019	John, Steven A; Robles, Gabriel; Starks, Tyrel J; Rendina, H Jonathon	Differences Between Groups of Pre-exposure Prophylaxis (PrEP) Using Couples in HIV-Negative/Unknown Relationships.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000002058	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6594889	BACKGROUND: Epidemiology research is limited on the characteristics of HIV pre-exposure prophylaxis (PrEP) using couples. SETTING: US nationwide sample recruited online in 2017. METHODS: HIV negative/unknown gay, bisexual, and other men who have sex with men with HIV negative/unknown partners (n = 3140) were asked about individual and main partner PrEP uptake. Men were coded into the following 5 groups: (1) neither participant nor partner on PrEP, (2) partner only on PrEP, (3) participant only on PrEP, (4) both on PrEP, and (5) unknown partner PrEP use. We examined associations of demographics, relationship factors, condomless anal sex (CAS) with main and causal partners, bacterial sexually transmitted infection diagnoses, and sexual positioning with reported dyadic PrEP use using fully adjusted multinomial logistic regressions. RESULTS: PrEP use was 3.2% for the partner only, 5.7% for the participant only, and 4.9% for both the participant and partner; 5.6% reported not knowing their partner's PrEP use status. Men who reported any CAS with their main partner or any CAS with male causal partners were both more likely to be classified in the dyadic PrEP use group compared with the neither on PrEP group. Compared with monogamous, men in open arrangements were more likely to be classified in each of the 3 PrEP groups compared with the neither on PrEP group. Six-month bacterial sexually transmitted infection prevalence was 2.8%, 8.1%, 8.3%, 15.6%, and 4.0% for the 5 groups, respectively. CONCLUSIONS: PrEP use occurred during times of higher risk behavior engagement, but further efforts are needed to expand PrEP use to more partnered gay, bisexual, and other men who have sex with men. Article	2019	Johnson, Kelly A; Hessol, Nancy A; Kohn, Robert; Nguyen, Trang Q; Mara, Elise S; Hsu, Ling; Scheer, Susan; Cohen, Stephanie E	HIV Seroconversion in the Era of Pharmacologic Prevention: A Case-Control Study at a San Francisco STD Clinic	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000002107	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072134234&doi=10.1097%2fQAI.0000000000002107&partnerID=40&md5=89112d2d9b4bad58f3b998ea80d6ffa3	Background: The comparative effectiveness of pre- and post-exposure prophylaxis (PrEP and PEP) for men who have sex with men (MSM) is unclear.Setting: We conducted a case-control study of MSM who were initially HIV-uninfected during September 1, 2012-June 30, 2016 at San Francisco's only municipal sexually transmitted diseases (STDs) clinic. Methods: Each case was matched with up to 3 controls based on age, baseline visit date, and follow-up time. The primary dependent variable was HIV seroconversion; the primary independent variable was exposure to PrEP, PEP, or neither. Conditional logistic regression was used to calculate odds ratios and 95% confidence intervals. Results: Of 638 MSM (161 cases and 477 controls), 137 reported ever taking PrEP, 98 reported taking PEP-only, and 403 took neither. PrEP takers had more non-HIV sexually transmitted diseases during the analysis (72.3% vs. 55.1% vs. 42.4% P < 0.01) and were more likely to report receptive anal sex in the past 3 months (86.5% vs. 80.4% vs. 73.0%; P < 0.01). In the adjusted model, PrEP was associated with lower odds of HIV seroconversion (odds ratio 0.24; 95% confidence interval: 0.13 to 0.46) while PEP use had no effect on HIV acquisition compared with taking neither. Conclusions: MSM who ever used PrEP demonstrated equal or higher sexual risk compared with those using neither PrEP nor PEP but had 76% lower odds of HIV seroconversion. MSM who used PEP but never PrEP were no less likely to seroconvert than those using neither. MSM should be offered PrEP. PEP users with ongoing risk of HIV infection should be connected to PrEP after PEP. © 2019 Wolters Kluwer Health, Inc. All rights reserved. Article	2019	Johnson, Leah M; Krovi, Sai Archana; Li, Linying; Girouard, Natalie; Demkovich, Zach R; Myers, Daniel; Creelman, Ben; van der Straten, Ariane	Characterization of a Reservoir-Style Implant for Sustained Release of Tenofovir Alafenamide (TAF) for HIV Pre-Exposure Prophylaxis (PrEP)	Pharmaceutics	-	-	-	1999-4923	10.3390/pharmaceutics11070315.	https://pubmed.ncbi.nlm.nih.gov/31277461/	Long-acting (LA) HIV pre-exposure prophylaxis (PrEP) offers the potential to improve adherence by lowering the burden of daily or on-demand regimens of antiretroviral (ARV) drugs. This paper details the fabrication and in vitro performance of a subcutaneous and trocar-compatible implant for the LA delivery of tenofovir alafenamide (TAF). The reservoir-style implant comprises an extruded tube of a biodegradable polymer, poly(ε-caprolactone) (PCL), filled with a formulation of TAF and castor oil excipient. Parameters that affect the daily release rates of TAF are described, including the surface area of the implant, the thickness of the PCL tube walls (between 45 and 200 μm), and the properties of the PCL (e.g., crystallinity). In vitro studies show a linear relationship between daily release rates and surface area, demonstrating a membrane-controlled release mechanism from extruded PCL tubes. Release rates of TAF from the implant are inversely proportional to the wall thickness, with release rates between approximately 0.91 and 0.15 mg/day for 45 and 200 μm, respectively. The sustained release of TAF at 0.28 ± 0.06 mg/day over the course of 180 days in vitro was achieved. Progress in the development of this implant platform addresses the need for new biomedical approaches to the LA delivery of ARV drugs. Article	2019	Jones, Christopher M; Byrd, Danielle J; Clarke, Thomas J; Campbell, Tony B; Ohuoha, Chideha; McCance-Katz, Elinore F	Characteristics and current clinical practices of opioid treatment programs in the United States.	Drug and Alcohol Dependence	-	-	-	1879-0046	10.1016/j.drugalcdep.2019.107616	https://dx.doi.org/10.1016/j.drugalcdep.2019.107616	BACKGROUND: Given rising rates of opioid use disorder (OUD) and related consequences, opioid treatment programs (OTPs) can play a pivotal role in the U.S. opioid crisis. There is a paucity of recent research to guide how best to leverage OTPs in the opioid response. METHODS: We conducted a national survey of U.S. OTPs using a 46-question electronic survey instrument covering three domains: 1) OTP characteristics; 2) services offered; and 3) current clinical practices. Descriptive statistics and multivariable logistic regression examined variables in these domains. RESULTS: Among responding OTPs, 32.4% reported using all three medications for OUD treatment; 95.8% used methadone, 61.8% used buprenorphine, and 43.9% used naltrexone. The mean (SD) number of patients currently receiving methadone was 383 (20.4), buprenorphine 51 (7.0), extended-release naltrexone 6 (1.0). Viral hepatitis testing was provided by 60.9% of OTPs, 15.3% provided hepatitis B vaccination, 14.9% provided hepatitis A vaccination, and 12.6% provided medication treatment for hepatitis C virus infection. HIV testing was provided by 60.7% of OTPs, 9.5% provided pre-exposure prophylaxis, and 8.4% provided medication treatment for HIV. OTP characteristics associated with using all three forms of medications for OUD included: providing medication for alcohol use disorder (aORâ¯=â¯5.24, 95% CI:2.99-9.16), providing telemedicine services (aORâ¯=â¯3.82, 95% CI:2.14-6.84), and directly providing naloxone to patients (aORâ¯=â¯2.57, 95% CI:1.53-4.29). Multiple barriers to providing buprenorphine and extended-release naltrexone were identified. CONCLUSIONS: Efforts are needed to increase availability of all medications approved to treat OUD in OTPs, integrate infectious disease-related services, and expand the reach of OTPs in the U.S.	NA	English	Netherlands	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Theses and Dissertations	2019	JUNIOR, FERNANDO JOAQUIM DA SILVA	NARRATIVAS, MEMÓRIAS E PRÁTICAS SOCIOPOLÍTICA: UMA ETNOGRAFIA DA MOBILIZAÇÃO SOCIAL E DA RESPOSTA COLETIVA À EPIDEMIA DO HIV/AIDS NO RIO GRANDE DO NORTE'	-	-	Universidade Federal do rio grande do norte	-	-	NA	https://sucupira.capes.gov.br/sucupira/public/consultas/coleta/trabalhoConclusao/viewTrabalhoConclusao.jsf?popup=true&id_trabalho=7899070	Este texto apresenta uma pesquisa de mestrado que oferece uma análise etnográfica da mobilização sociopolítica de resposta ao HIV e AIDS no contexto urbano de Natal e Mossoró, as duas maiores cidade do Rio Grande do Norte. A dissertação objetivou compreender as narrativas, práticas, e sentidos de resposta à epidemia entre ativistas, grupos de pacientes, gestores e profissionais de saúde diante de desigualdades e desafios na adesão à Terapia Antirretroviral (TARV) e de prevenção ao HIV. Busquei atentar como os projetos coletivos e individuais dos meus interlocutores eram elaborados e as suas razões internas ao ponto de enfrentarem a fofoca, cooperarem ou divergirem com gestores e demais participantes da mobilização, além de dedicarem tempo, investimento econômico, esforço físico e emocional. Na pesquisa etnográfica, realizei observação participante em diferentes ambientes, como: cerimônias, audiências e manifestações públicas, festejos, hospitais e serviços de atendimento especializado, dando ênfase aos usos dos espaços pelos interlocutores. Simultaneamente, foram produzidas entrevistas em profundidade com ativistas, profissionais de saúde, pacientes e gestores públicos, além de análise da imprensa local e uso de fotografias para ampliar as percepções sobre o campo pesquisado. Dessa forma, apresento um panorama da mobilização sociopolítica HIV e AIDS, sem deixar de perceber as particularidades desses diferentes coletivos e atores sociais. Pude constatar um mundo social fortemente disputado, cheio de projetos coletivos e individuais no enfrentamento da epidemia e atravessado por múltiplas desigualdades sociais que afetam decisivamente a vida de milhares de pessoas dessa região vivendo e convivendo com HIV. Percebi também a comunicação, a narrativa, a memória e o testemunho do trauma como poderosos instrumentos de ação política. Portanto, esta pesquisa busca contribuir para a discussão antropológica sobre a HIV e AIDS no contexto do Rio Grande do Norte, num momento crítico para o enfrentamento da epidemia no Estado, afetada pelo crescimento exponencial de pessoas diagnosticadas com HIV e de pessoas morrendo em decorrência da AIDS. Article	2019	Kakalou, Christine; Lazarus, Jeffrey V; Koutkias, Vassilis	Mining Social Media for Perceptions and Trends on HIV Pre-Exposure Prophylaxis.	Studies in Health Technology and Informatics	-	-	-	1879-8365	10.3233/SHTI190366	https://dx.doi.org/10.3233/SHTI190366	Pre-Exposure Prophylaxis (PrEP) is an approach for preventing the human immunodeficiency virus (HIV), which entails the administration of antiretroviral medication to high-risk seronegative persons. If taken correctly, PrEP can reduce HIV infection risk by more than 90%. The aim of this study was to identify and examine PrEP-related perceptions and trends discussed on Twitter. Using open-source technologies, text-mining and interactive visualisation techniques, a comprehensive data gathering and analytics Web-based platform was developed to facilitate the study objectives. Our results demonstrate that monitoring of PrEP-related discussions on Twitter can be detected over time and valuable insights can be obtained concerning issues of PrEP awareness, expressed opinions, perceived barriers and key discussion points on its adoption. The proposed platform could support public-health professionals and policy makers in PrEP monitoring, facilitating informed decision making and strategy planning for efficient HIV combination prevention. Article	2019	Kamaara E.; Oketch D.; Chesire I.; Coats C.S.; Thomas G.; Ransome Y.; Willie T.C.; Nunn A.	Faith and healthcare providers' perspectives about enhancing HIV biomedical interventions in Western Kenya	Global Public Health	-	-	-	17441692	10.1080/17441692.2019.1647263	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070500786&doi=10.1080%2f17441692.2019.1647263&partnerID=40&md5=be4da2626f65cb411cf6aa84f7734d52	Adult HIV prevalence in Kenya was 5.9% in 2017. However, in the counties of Kisumu, Siaya, and Homa Bay, HIV prevalence was over 15%. Biomedical interventions, including home-based testing and counselling (HBTC), HIV treatment and pre-exposure prophylaxis (PrEP) provide opportunities to reduce HIV transmission, particularly in rural communities with limited access to health services. Faith-based institutions play an important role in the Kenyan social fabric, providing over 40% of all health care services in Kenya, but have played limited roles in promoting HIV prevention interventions. We conducted qualitative interviews with 45 medical professionals and focus groups with 93 faith leaders in Kisumu and Busia Counties, Kenya. We explored their knowledge, opinions, and experiences in promoting biomedical HIV prevention modalities, including HBTC and PrEP. Knowledge about and engagement in efforts to promote HIV prevention modalities varied; few health providers had partnered with faith leaders on HIV prevention programmes. Faith leaders and health providers agreed about the importance of increasing faith leaders' participation in HIV prevention and were positive about increasing their HIV prevention partnerships. Most faith leaders requested capacity building to better understand biomedical HIV prevention modalities and expressed interest in collaborating with clinical partners to spread awareness about HIV prevention modalities. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group.	beliefs; faith leaders; HBTC; HIV; intervention	English	United Kingdom	Western and Central Europe and North America	Kenya	Eastern and Southern Africa	Kenya	Eastern and Southern Africa	Qualitative
Article	2019	Kamis K.F.; Marx G.E.; Scott K.A.; Gardner E.M.; Wendel K.A.; Scott M.L.; Montgomery A.E.; Rowan S.E.	Same-Day HIV Pre-Exposure Prophylaxis (PrEP) Initiation during Drop-in Sexually Transmitted Diseases Clinic Appointments Is a Highly Acceptable, Feasible, and Safe Model that Engages Individuals at Risk for HIV into PrEP Care	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/ofid/ofz310	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074977475&doi=10.1093%2fofid%2fofz310&partnerID=40&md5=20f4d9f100f004e22674ca81f7a1e0a0	Objective: Strategies to increase pre-exposure prophylaxis (PrEP) uptake are needed. We hypothesized that same-day PrEP initiation in a sexually transmitted diseases (STD) clinic would be acceptable, feasible, and safe, and that individuals would engage in ongoing PrEP care. Method: Individuals aged ≥ 18 years were evaluated for PrEP. Exclusion criteria were HIV, history of renal dysfunction or chronic hepatitis B infection, pregnancy, indications for HIV post-exposure prophylaxis, or positive screen for acute HIV symptoms. One hundred individuals received a free 30-day PrEP starter pack and met with a patient navigator to establish ongoing care. Bivariate analysis and multivariable logistic regression were used to compare individuals who did and did not attend at least 1 PrEP follow-up appointment within 180 days of enrollment. Client satisfaction surveys were given 3 months after enrollment. Results: The majority (78%) of participants completed at least 1 PrEP follow-up appointment, and 57% attended at least 2 follow-up appointments. After adjusting for race and ethnicity, age, health insurance status, and annual income, only income was associated with follow-up appointment attendance. Each additional $10,000 increase in income was associated with a 1.7-fold increase in the odds of attending a PrEP follow-up appointment (95% confidence interval, 1.07-2.66, P =. 02). The majority (54%) of individuals completed the satisfaction survey and all respondents liked the option of same-day PrEP initiation. Conclusions: Our study suggests STD clinic-based, same-day PrEP initiation is acceptable, feasible, safe, and links a high proportion of individuals into ongoing PrEP care. Additional resources may be needed to support low-income individuals' retention in care. © 2019 The Author(s) 2019. Article	2019	Kamitani E.; Johnson A.H.; Wichser M.; Mizuno Y.; Deluca J.B.; Higa D.H.	Mapping the study topics and characteristics of HIV pre-exposure prophylaxis research literature: A protocol for a scoping review	BMJ Open	-	-	-	20446055	10.1136/bmjopen-2018-024212	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066862712&doi=10.1136%2fbmjopen-2018-024212&partnerID=40&md5=fdf71eb21d0f28d632269982b1591cea	Introduction The research literature addressing pre-exposure prophylaxis (PrEP) has increased considerably over the last decade. To better understand the research areas and explore research gaps, we will conduct a scoping review to map study topics and describe study characteristics and populations in publications focused on PrEP. The purpose of this protocol is to describe planned methods for the scoping review. Methods and analysis We will implement a comprehensive systematic literature search to identify PrEP citations in the United States Centres for Disease Control and Prevention HIV/AIDS Prevention Research Synthesis Project database that is unique and extensively focuses on HIV/sexually transmitted infections/hepatitis. We will screen and include studies that are (1) focused on HIV PrEP, (2) primary research with human participants and (3) published in English. Two reviewers will independently abstract data on authors' names, study years, countries, population characteristics and design. To describe and summarise study topics, we will use 19 codes and five categories that were developed from a preliminary study. The five categories are category 1: potential PrEP user/prescriber (behaviours/issues for potential PrEP takers/healthcare professionals), category 2: considerations while on PrEP (experiences of and problems related to staying on or prescribing PrEP), category 3: PrEP efficacy and safety (biomedical aspects and medication efficacy), category 4: methods of and experiences with PrEP clinical trials (possesses/experiences of clinical trials) and category 5: cost-effectiveness or economic evaluation (cost studies). Data will be analysed with descriptive statistics. Ethics and dissemination The findings will be presented at HIV-related conferences and published in peer-review journals. © Author(s) (or their employer(s)) 2019. Re-use permitted under CC BY-NC. Article	2019	Kamitani E.; Mizuno Y.; Wichser M.; Adegbite A.H.; Deluca J.B.; Higa D.H.	Mapping the study characteristics and topics of hiv pre-exposure prophylaxis research literature: A scoping review	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2019.31.6.505	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076266456&doi=10.1521%2faeap.2019.31.6.505&partnerID=40&md5=637dffc24e03c90633ce53f0f6252b4b	Since WHO released the first PrEP guidance in 2012, the PrEP research literature has rapidly increased, but PrEP uptake is still low. To identify research gaps, this scoping review describes study characteristics, identifies populations, and maps study topics in PrEP publications. We identified 561 PrEP primary studies published in English between 2006 and 2018. The most commonly used study design was cross-sectional. Almost half of studies were conducted in non-U.S. countries and focused on men who have sex with men. We mapped study topics using five categories. The most studied category was Potential PrEP user/prescriber (41.3%) followed by Considerations while on PrEP (28.2%), PrEP efficacy and safety (20.9%), Cost-effectiveness or economic evaluation (5.2%), and Methods of and experiences with PrEP clinical trials (4.2%). Although the PrEP literature has dramatically increased, some research areas (e.g., PrEP awareness in non-U.S. countries, intervention studies to promote PrEP use) and populations (e.g., Black women) are still understudied. © 2019 The Guilford Press. Article	2019	Kanny D.; Jeffries W.L., IV; Chapin-Bardales J.; Denning P.; Cha S.; Finlayson T.; Wejnert C.	Racial/ethnic disparities in HIV preexposure prophylaxis among men who have sex with men — 23 urban areas, 2017	MMWR Recommendations and Reports	-	-	-	1492195	10.15585/MMWR.MM6837A2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072409517&doi=10.15585%2fMMWR.MM6837A2&partnerID=40&md5=43a34cee466c794c3f42abcf33039ad8	What is already known about this topic? Preexposure prophylaxis (PrEP) reduces the risk for sexual human immunodeficiency virus transmission by approximately 99%. In 2017, approximately one third of gay, bisexual, and other men who have sex with men (MSM) reported using PrEP. What is added by this report? Although PrEP awareness was high for all racial/ethnic groups, a lower percentage of black and Hispanic MSM than white MSM had discussed PrEP with health care provider or had used PrEP within the past year. What are the implications for public health practice? To expand PrEP use, interventions to increase PrEP awareness, encourage health care providers to discuss PrEP, destigmatize PrEP use, and promote racial/ethnic equity in PrEP access are needed.. © 2019 Department of Health and Human Services. Article	2019	Kasaie P.; Schumacher C.M.; Jennings J.M.; Berry S.A.; Tuddenham S.A.; Shah M.S.; Rosenberg E.S.; Hoover K.W.; Gift T.L.; Chesson H.; German D.; Dowdy D.W.	Gonorrhoea and chlamydia diagnosis as an entry point for HIV pre-exposure prophylaxis: A modelling study	BMJ Open	-	-	-	20446055	10.1136/bmjopen-2018-023453	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062586848&doi=10.1136%2fbmjopen-2018-023453&partnerID=40&md5=5a1b4280be771bba6d101d0367d3bdad	Objectives Neisseria gonorrhoeae (NG) and Chlamydia trachomatis (CT) increase the risk of HIV transmission among men who have sex with men (MSM). Diagnosis of NG/CT may provide an efficient entry point for prevention of HIV through the delivery of pre-exposure prophylaxis (PrEP); however, the additional population-level impact of targeting PrEP to MSM diagnosed with NG/CT is unknown. Design An agent-based simulation model of NG/CT and HIV cocirculation among MSM calibrated against census data, disease surveillance reports and the US National HIV Behavioral Surveillance study. Setting Baltimore City, Maryland, USA. Interventions PrEP implementation was modelled under three alternative scenarios: (1) PrEP delivery at NG/CT diagnosis (targeted delivery), (2) PrEP evaluation at NG/CT screening/testing and (3) PrEP evaluation in the general community (untargeted). Main outcome The projected incidence of HIV after 20 years of PrEP delivery under two alternatives: when equal numbers of MSM are (1) screened for PrEP or (2) receive PrEP in each year. Results Assuming 60% uptake and 60% adherence, targeting PrEP to MSM diagnosed with NG/CT could reduce HIV incidence among MSM in Baltimore City by 12.4% (95% uncertainty range (UR) 10.3% to 14.4%) in 20 years, relative to no PrEP. Expanding the coverage of NG/CT screening (such that individuals experience a 50% annual probability of NG/CT screening and evaluation for PrEP on NG/CT diagnosis) can further increase the impact of targeted PrEP to generate a 22.0% (95% UR 20.1% to 23.9%) reduction in HIV incidence within 20 years. When compared with alternative implementation scenarios, PrEP evaluation at NG/CT diagnosis increased impact of PrEP on HIV incidence by 1.5(95% UR 1.1 to 1.9) times relative to a scenario in which PrEP evaluation happened at the time of NG/CT screening/testing and by 1.6 (95% UR 1.2 to 2.2) times relative to evaluating random MSM from the community. Conclusions Targeting MSM infected with NG/CT increases the efficiency and effectiveness of PrEP delivery. If high levels of sexually transmitted infection screening can be achieved at the community level, NG/CT diagnosis may be a highly effective entry point for PrEP initialisation. © Author(s) (or their employer(s)) 2019. Article	2019	Katz D.A.; Dombrowski J.C.; Barry M.; Spellman D.; Bell T.R.; Golden M.R.	STD Partner Services to Monitor and Promote HIV Pre-exposure Prophylaxis Use among Men Who Have Sex with Men	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001952	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062833575&doi=10.1097%2fQAI.0000000000001952&partnerID=40&md5=ca4123306a9dfacaeefa21ceb8578918	Background:Men who have sex with men (MSM) with bacterial sexually transmitted diseases (STDs) are at elevated risk of HIV. We evaluated the integration of pre-exposure prophylaxis (PrEP) referrals into STD partner services (PS) for MSM.Setting:King County, Washington.Methods:Disease Intervention Specialists (DIS) in King County attempt to provide PS to all MSM with early syphilis and, as resources allow, MSM with gonorrhea or chlamydia. Our health department defines MSM with any of the following as at high HIV risk: early syphilis, rectal gonorrhea, methamphetamine/poppers use, sex work, or an HIV-unsuppressed partner. DIS offer high-risk MSM referral to our STD Clinic for PrEP and other MSM referral to community providers. In 2017, we interviewed a random sample of MSM offered referrals in 2016 to assess PrEP initiation after PS.Results:From August 2014 to August 2017, 7546 cases of bacterial STDs were reported among HIV-negative MSM. DIS provided PS to 3739 MSM, of whom 2055 (55%) were at high risk. DIS assessed PrEP use in 1840 (90%) of these men, 895 (49%) of whom reported already using PrEP. DIS offered referrals to 693 (73%) of 945 MSM not on PrEP; 372 (54%) accepted. Among 132 interviewed for the random sample, men who accepted referrals at initial interview were more likely to report using PrEP at follow-up (32/68 = 47%) than those who did not (12/64 = 19%) (P = 0.0006). An estimated 10.4% of all interviewed MSM initiated PrEP following PS-based referral.Conclusions:Integrating PrEP referrals into STD PS is an effective population-based strategy to link MSM at high HIV risk to PrEP. © 2019 Wolters Kluwer Health, Inc. Article	2019	Katz, AWK; Mensch, BS; Woeber, K; Musara, P; Etima, J; Van Der Straten, A	Understanding women's motivations to participate in MTN-003/VOICE, a phase 2b HIV prevention trial with low adherence	BMC Women's Health	-	-	-	NA	10.1186/s12905-019-0713-6	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01966529/full	Background: In biomedical prevention trials, correct and consistent use of the investigational product is crucial to determine efficacy. Product adherence in VOICE, a phase 2B randomized trial of a vaginal gel and oral tablets for HIV prevention, was low (34%), yet self-reported adherence and retention was high (> 90%). This analysis from VOICE-D, a post-trial qualitative ancillary study, explores motivations to participate in VOICE, and possible sources of misalignment between the stated priorities of the trial and the participants. Methods: VOICE-D enrolled 171 former VOICE participants to investigate, among other things, reasons for joining and remaining in the trial. Local language in-depth interviews and focus groups were transcribed and translated into English and coded and analyzed using NVivo. Data on motivation to join obtained from a VOICE termination visit survey of 106 participants were also analyzed to corroborate the VOICE-D findings. Results: Participants primarily participated for personal health benefits (e.g. free healthcare and HIV testing) and reported remaining enrolled from a sense of commitment to the trial. Altruistic motivations were the most commonly stated motivation on the termination visit survey; qualitatively, many of those stating altruistic reasons also desired personal health benefits. Joining for financial reimbursement was not commonly mentioned. Social networks influenced recruitment and spread therapeutic misconception. Conclusions: Women's participation for personal health benefits highlighted their desire to monitor their HIV risk and overall health. Helping participants view use of investigational products as improving social capital and reminding participants of their study responsibilities may improve trial outcomes. Understanding the reasons for participating in studies will help to ensure alignment between priorities of researchers and participants. Article	2019	Keller, Marla J; Wood, Lianna; Billingsley, James M; Ray, Laurie L; Goymer, Jessica; Sinclair, Shada; McGinn, Aileen P; Marzinke, Mark A; Frank, Bruce; Srinivasan, Sujatha; Liu, Congzhou; Atrio, Jessica M; Espinoza, Lilia; Mugo, Nelly; Spiegel, Hans M L; Anderson, Peter L; Fredricks, David N; Hendrix, Craig W; Marrazzo, Jeanne; Bosinger, Steven E; Herold, Betsy C	Tenofovir disoproxil fumarate intravaginal ring for HIV pre-exposure prophylaxis in sexually active women: a phase 1, single-blind, randomised, controlled trial.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(19)30145-6	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6719300	BACKGROUND: An intravaginal ring that releases the tenofovir prodrug, tenofovir disoproxil fumarate, provided 100% protection in macaques against simian HIV and was safe in a 14-day clinical trial in sexually abstinent women. We aimed to assess the safety and pharmacokinetics of this intravaginal ring over 90 days in sexually active women. METHODS: We did a phase 1, single-blind, randomised, placebo-controlled trial to assess safety, pharmacokinetics, and acceptability of a tenofovir disoproxil fumarate intravaginal ring used continuously with monthly ring changes for 3 months. Sexually active women who were HIV negative were randomly assigned (3:1) to a tenofovir disoproxil fumarate ring or placebo ring. Primary safety endpoint was the proportion of women who had grade 2 or higher genitourinary adverse events judged related to study product and any grade 2 or higher adverse event as defined by the Division of AIDS Table for Grading the Severity of Adult and Pediatric Adverse Events. We quantified tenofovir disoproxil fumarate and tenofovir concentrations in cervicovaginal fluid, tenofovir in plasma, and tenofovir diphosphate, the active metabolite, in cervical tissue and dried blood spots 1 month after each ring insertion. We compared changes over time in cervicovaginal fluid cytokine and chemokine concentrations and vaginal microbiota. The study was electively stopped early and is registered with ClinicalTrials.gov, number NCT02762617. FINDINGS: Between Feb 24 and July 20, 2017, 17 women were enrolled before study termination. 12 were assigned to receive the tenofovir disoproxil fumarate ring and five were assigned to receive the placebo ring. Two participants in the tenofovir disoproxil fumarate ring group completed 3 months of continuous ring use; eight were asked to discontinue ring use early because of ulcerations (grade 1) near the ring; in the remaining two women, rings were electively removed by study staff on day 20 and day 23. Ulcers were detected a mean of 32 days after ring use (range 23-56). Four of eight participants with ulcers were symptomatic with vaginal discharge; four had ulcers identified when examined; three had two ulcers; all ulcers resolved after ring removal. No participants in the placebo group developed ulcers. No grade 2 product-related adverse events were reported in either group and four non-product-related grade 2 adverse events were reported in the tenofovir disoproxil fumarate ring group. Cervicovaginal fluid tenofovir concentrations did not differ at day 14 (p=0·14) comparing the eight patients who did (median 1·0â×â105 ng/mL IQR 9·1â×â104-1·1â×â105) with the four who did not (6·0â×â104 ng/mL 5·6â×â104-1·1â×â105) develop ulcers. No significant changes in vaginal microbiota were detected in either group. Concentrations of multiple inflammatory cytokines and chemokines were significantly higher at days 14 and 28 compared with baseline in the tenofovir disoproxil fumarate ring group but not the placebo group. INTERPRETATION: Future studies are needed to establish whether the unanticipated finding of ulcerations is specific to this tenofovir disoproxil fumarate ring or generalisable to other sustained topical release formulations of tenofovir or its prodrugs. FUNDING: National Institutes of Health. Article	2019	Kelly J.A.	Ten Things We Need to Do to Achieve the Goals of the End the HIV Epidemic Plan for America	Journal of Acquired Immune Deficiency Syndromes	-	-	-	19447884	10.1097/QAI.0000000000002166	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074225693&doi=10.1097%2fQAI.0000000000002166&partnerID=40&md5=0da22953837e5772c374a6bd5a6e38ed	PROBLEM: DHHS announced a plan for Ending the HIV Epidemic (EtHE) by reducing new HIV infections in the United States by 75% within 5 years and 90% within 10 years through early diagnosis of all individuals with HIV, immediate treatment to achieve viral suppression, protection of high-risk but uninfected individuals including with pre-exposure prophylaxis (PrEP), and quickly responding to emerging HIV clusters. APPROACH: Ten steps are outlined that will help the field achieve EtHE Plan goals. FINDINGS: Steps needed to reach EtHE goals are: (1) better reaching, understanding, and meeting the HIV prevention and care needs of Black men who have sex with men; (2) deployment of interventions that address social, cultural, behavioral, and structural determinants of HIV disparities; (3) improving uptake in biomedical HIV-prevention strategies in mid-sized cities across the country's center; (4) addressing with long-term commitment the urgent HIV-prevention needs in the US Southeast; (5) encouraging more frequent and regular HIV testing; (6) developing better strategies to not only encourage initiation but also the long-term and sustained use of PrEP by persons at high risk for contracting HIV infection; (7) improving the comfort and capacity of primary care providers to prescribe PrEP; (8) increasing HIV medical care retention and care re-engagement, especially among persons with competing life stressors; (9) developing sustainable implementation efforts; and (10) addressing policies that can facilitate or impede success in eliminating the HIV epidemic in the United States. CONCLUSION: EtHE goals are achievable but will require concerted, sustained effort. Article	2019	Kenyon, Chris	Toward a Set of Criteria to Decide Which STIs to Screen for in PrEP Cohorts.	Frontiers in Public Health	-	-	-	2296-2565	10.3389/fpubh.2019.00154	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6582697	Contemporary HIV preexposure prophylaxis (PrEP) cohorts are characterized by high rates of partner change and as a result have high and fairly stable prevalences of N. gonorrhoeae and C. trachomatis. The available evidence suggests that intensive 3-monthly screening in this setting does not have a large effect on the prevalence of these infections but results in high antimicrobial exposures. Gonorrhea/chlamydia screening may thus be doing more harm than good. Compelling arguments can, however, be made to screen for HIV, hepatitis C, and syphilis in PrEP cohorts. In this perspective piece, we explore the logical basis for deciding which STIs to screen for in PrEP cohorts. We propose that a Delphi consensus methodology is used to derive, assess, and apply a broadly accepted set of criteria to evaluate which STIs to screen for in these cohorts. Finally, to illustrate the utility of the process, we derive and apply our own list of criteria as to which STIs to screen for. This process leads to a controversial conclusion, namely that stopping gonorrhea/chlamydia screening in a controlled and phased manner may offer net health benefits to PrEP cohorts. Article	2019	Kenyon, Chris	We need to consider collateral damage to resistomes when we decide how frequently to screen for chlamydia/gonorrhoea in preexposure prophylaxis cohorts.	AIDS	-	-	-	1473-5571	10.1097/QAD.0000000000002020	https://dx.doi.org/10.1097/QAD.0000000000002020	Numerous preexposure prophylaxis (PrEP) guidelines recommend three-monthly screening for gonorrhoea and chlamydia. To quantify the risk of antimicrobial resistance this may induce, we conducted a literature review of the incidence of gonorrhoea and chlamydia in PrEP studies that conducted 3-site, 3-monthly screening. We found that screening could result in macrolide consumption rates that exceed those in high macrolide consumption populations where consumption has been strongly associated with macrolide resistance. Article	2019	Khanna A.S.; Schneider J.A.; Collier N.; Ozik J.; Issema R.; Di Paola A.; Skwara A.; Ramachandran A.; Webb J.; Brewer R.; Cunningham W.; Hilliard C.; Ramani S.; Fujimoto K.; Harawa N.	A modeling framework to inform preexposure prophylaxis initiation and retention scale-up in the context of 'Getting to Zero' initiatives	AIDS	-	-	-	2699370	10.1097/QAD.0000000000002290	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071755956&doi=10.1097%2fQAD.0000000000002290&partnerID=40&md5=d1d24e18ec446c8a18bac4df0c97156d	Objective(s): 'Getting to Zero' (GTZ) initiatives aim to eliminate new HIV infections over a projected time frame. Increased preexposure prophylaxis (PrEP) uptake among populations with the highest HIV incidence, such as young Black MSM, is necessary to accomplish this aim. Agent-based network models (ABNMs) can help guide policymakers on strategies to increase PrEP uptake. Design: Effective PrEP implementation requires a model that incorporates the dynamics of interventions and dynamic feedbacks across multiple levels including virus, host, behavior, networks, and population. ABNMs are a powerful tool to incorporate these processes. Methods: An ABNM, designed for and parameterized using data for young Black MSM in Illinois, was used to compare the impact of PrEP initiation and retention interventions on HIV incidence after 10 years, consistent with GTZ timelines. Initiation interventions selected individuals in serodiscordant partnerships, or in critical sexual network positions, and compared with a controlled setting where PrEP initiators were randomly selected. Retention interventions increased the mean duration of PrEP use. A combination intervention modeled concurrent increases in PrEP initiation and retention. Results: Selecting HIV-negative individuals for PrEP initiation in serodiscordant partnerships resulted in the largest HIV incidence declines, relative to other interventions. For a given PrEP uptake level, distributing effort between increasing PrEP initiation and retention in combination was approximately as effective as increasing only one exclusively. Conclusion: Simulation results indicate that expanded PrEP interventions alone may not accomplish GTZ goals within a decade, and integrated scale-up of PrEP, antiretroviral therapy, and other interventions might be necessary. Article	2019	Kim B.; Callander D.; DiClemente R.; Trinh-Shevrin C.; Thorpe L.E.; Duncan D.T.	Location of Pre-exposure Prophylaxis Services Across New York City Neighborhoods: Do Neighborhood Socio-demographic Characteristics and HIV Incidence Matter?	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02609-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069459312&doi=10.1007%2fs10461-019-02609-2&partnerID=40&md5=ff9cc1ef4a90f23dedacd50ba188182c	Despite an increasing pre-exposure prophylaxis (PrEP) use among populations at highest risk of HIV acquisition, comprehensive and easy access to PrEP is limited among racial/ethnic minorities and low-income populations. The present study analyzed the geographic distribution of PrEP providers and the relationship between their location, neighborhood characteristics, and HIV incidence using spatial analytic methods. PrEP provider density, socio-demographics, healthcare availability, and HIV incidence data were collected by ZIP-code tabulation area in New York City (NYC). Neighborhood socio-demographic measures of race/ethnicity, income, insurance coverage, or same-sex couple household, were not associated with PrEP provider density, after adjusting for spatial autocorrelation, and PrEP providers were located in high HIV incidence neighborhoods (P < 0.01). These findings validate the need for ongoing policy interventions (e.g. public health detailing) vis-à-vis PrEP provider locations in NYC and inform the design of future PrEP implementation strategies, such as public health campaigns and navigation assistance for low-cost insurance. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Kimani M.; van der Elst E.M.; Chiro O.; Oduor C.; Wahome E.; Kazungu W.; Shally M.; Rinke de Wit T.F.; Graham S.M.; Operario D.; Sanders E.J.	PrEP interest and HIV-1 incidence among MSM and transgender women in coastal Kenya	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25323	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068190558&doi=10.1002%2fjia2.25323&partnerID=40&md5=ea392957e22934b66204c6484bfbcbe9	Introduction: There is emerging data on HIV-1 incidence among MSM in sub-Saharan Africa (SSA), but no known estimate of HIV-1 incidence among transgender women (TGW) in the region has yet been reported. We assessed HIV-1 incidence and pre-exposure prophylaxis (PrEP) interest in men who have sex with men exclusively (MSME), men who have sex with men and women (MSMW) and TGW in coastal Kenya. Methods: HIV-1-seronegative individuals who had participated in an HIV testing study in 2016 were traced and retested in 2017 according to Kenyan guidelines. All participants were assigned male sex at birth and had male sex partners; additional data on gender identity and sexual orientation were obtained. We assessed the factors associated with HIV-1 acquisition using Poisson regression and calculated HIV-1 incidence in MSME, MSMW and TGW. PrEP interest was assessed through focus group discussions to characterize subcategories' perceived PrEP needs. Results: Of the 168 cohort participants, 42 were classified as MSME, 112 as MSMW and 14 as TGW. Overall, HIV-1 incidence was 5.1 (95% confidence interval (CI): 2.6 to 9.8) per 100 person-years (PY): 4.5 (95% CI: 1.1 to 17.8 per 100 PY among MSME, 3.4 (95% CI: 1.3 to 9.1) per 100 PY among MSMW and 20.6 (95% CI: 6.6 to 63.8 per 100 PY among TGW. HIV-1 acquisition was associated with exclusive receptive anal intercourse (aIRR 13.0, 95% CI 1.9 to 88.6), history of an STI in preceding six months (aIRR 10.3, 95% CI 2.2 to 49.4) and separated/divorced marital status (aIRR 8.2 (95%: 1.1 to 62.2). Almost all (98.8%) participants were interested in initiating PrEP. MSME and TGW felt that PrEP would lead to increases in condomless anal or group sex. Conclusions: TGW had a very high HIV-1 incidence compared with MSME and MSMW. Subcategories of MSM anticipated different PrEP needs and post-PrEP risk behaviour. Further studies should assess if TGW may have been wrongly categorized as MSM in other HIV-1 incidence studies in the region. © 2019 The Authors. Theses and Dissertations	2019	Kimmel, Allison	Implementation of pre-exposure prophylaxis (PrEP) for HIV prevention: three case studies from the PrEP for women initiative in Washington, D.C.	-	-	Boston University	-	NA	na	https://hdl.handle.net/2144/39287	BACKGROUND: Women account for 19% of new HIV diagnoses in the United States, with women of color (WOC) comprising 83% of this group. Pre-exposure prophylaxis (PrEP) is a safe and effective method of HIV prevention for women. Yet, prescribing to WOC remains disproportionately low, leaving a major gap in HIV prevention options for this population. The purpose of this study was to examine PrEP implementation barriers and facilitators in a high HIV incidence setting in order to identify strategies to better provide comprehensive HIV prevention options for WOC. METHODS: This study used a case study approach with qualitative data collection to examine PrEP implementation for WOC as it happened in the "real world" in three clinical settings: a community-based clinic, a pediatric emergency department, and a Federally Qualified Health Center. Guided by the integrated-Promoting Action on Research Implementation in Health Services (i-PARIHS) implementation science framework, two rounds of semi-structured interviews were conducted with clinical staff and providers. Data analysis was completed according to the five steps of the Framework Method. RESULTS: By the end of the one-year implementation period, only three WOC had been prescribed PrEP out of the targeted 387. Staff cited support of PrEP provision among staff and leadership, PrEP alignment with their clinics' missions, having a centralized PrEP coordinator, and relationships with other implementing sites and within the local community as implementation facilitators. Despite these supportive factors, staff reported time limitations, resistance to PrEP prescribing, discomfort with PrEP counseling, and managing different and changing priorities across clinic departments as implementation barriers. CONCLUSION: Though the clinics seemed well-positioned for PrEP implementation, significant challenges impeded their success. To successfully provide PrEP to women, implementation should include clarifying staff roles and responsibilities, engaging staff and providers through ongoing and targeted feedback, and ensuring care is focused on women's needs and experiences. The HIV epidemic can only be fought by utilizing all available HIV prevention tools in combination with HIV treatment, delivered with consideration of the local context and population. Specific practice recommendations identified will support clinics as they provide PrEP to WOC. Article	2019	Kipke M.D.; Kubicek K.; Wong C.F.; Robinson Y.A.; Akinyemi I.C.; Beyer W.J.; Hawkins W.; Rice C.E.; Layland E.; Bray B.C.; Belzer M.	A focus on the HIV care continuum through the healthy young men's cohort study: Protocol for a mixed-methods study	JMIR Research Protocols	-	-	-	19290748	10.2196/10738	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067217460&doi=10.2196%2f10738&partnerID=40&md5=156ff4692d7a81bb84c49e134c1d2702	Background: No group is at greater risk for acquiring HIV than young men who have sex with men (YMSM), particularly black or African American (AA) and Hispanic or Latino (L) YMSM living in inner cities, who account for the largest number of new HIV infections each year. Although pre-exposure prophylaxis (PrEP), postexposure prophylaxis (PEP), and treatment as prevention hold enormous promise for changing the course of the epidemic, AA/L-YMSM are the least likely population to be receiving primary health care and HIV prevention/care and are the least likely to be using PrEP and PEP. Objective: The overarching aim of the Healthy Young Men's (HYM) cohort study is to conduct longitudinal research with a cohort of AA/L-YMSM to prevent new HIV infections, reduce transmission, and reduce HIV/AIDS-related disparities by focusing on successful engagement in care. Findings from this research will be used to inform the development of new interventions designed to engage AA/L-YMSM in the HIV prevention and care continua. Methods: Longitudinal research (baseline and follow-up assessments every 6 months for a total of 8 waves of data collection) is ongoing with a cohort of 450 high-risk AA/L-YMSM in Los Angeles. Participants were recruited using a venue-based and social media sampling design. In addition to self-report surveys, the study protocol includes the collection of urine to assess recent use of illicit drugs and the collection of blood and rectal/throat swabs to test for current sexually transmitted infection (STI)/HIV infection. An additional sample of blood/plasma (10 mL for 4 aliquots and 1 pellet) is also collected and stored in the HYM cohort study biorepository for future research. By design, we recruited 400 HIV-negative participants and 50 HIV-positive (HIV+) participants. This mixed-methods study design includes collection and triangulated analysis of quantitative, qualitative, and biological measures (ie, drug use, STI/HIV testing, and adherence to antiretroviral therapy among HIV+ participants) at baseline and every 6 months. The HYM cohort study will provide a platform from which new and emerging biomedical prevention strategies (eg, PrEP, rectal microbicides, and PEP) and other HIV prevention and care engagement interventions can be developed and evaluated with AA/L-YMSM. Results: To date, all participants in the HYM cohort study have been recruited and baseline assessment has been conducted. Conclusions: The findings from this research will be used to inform the development of new and/or adaptation of existing evidence-based HIV prevention interventions and interventions designed to engage this population in the HIV prevention and care continua. © Michele D Kipke, Katrina Kubicek, Carolyn F Wong, Yolo Akili Robinson, Ifedayo C Akinyemi, William J Beyer, Wendy Hawkins, Cara E Rice, Eric Layland, Bethany C Bray, Marvin Belzer. Article	2019	Klein A.; Golub S.A.	Increasing Access to Pre-Exposure Prophylaxis among Transgender Women and Transfeminine Nonbinary Individuals	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2019.0049	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066955254&doi=10.1089%2fapc.2019.0049&partnerID=40&md5=36401826d4e5906f841c548c745bb8a9	In the United States, transgender women and transfeminine nonbinary individuals (TGWNBI) are a highly vulnerable and marginalized population at high risk for HIV. Despite disproportionate rates of HIV, a striking lack of research exists on pre-exposure prophylaxis (PrEP) use among TGWNBI. We conducted 30 semi-structured interviews with TGWNBI both on PrEP and those not on PrEP. Questions explored PrEP access, initiation, and factors to increase broad interest and participation in PrEP. Qualitative data were coded and analyzed using thematic analysis. Participants identified five components to increase PrEP use among TGWNBI: (1) eliminating the practice of conflating TGWNBI with cisgender men who have sex with men, (2) recognition of and support for the contextual factors associated with HIV risk among TGWNBI, (3) ensuring the design and development of transgender-inclusive and gender-affirming sexual health programs that include PrEP, (4) active provider engagement and assistance around PrEP, and (5) identification and implementation of strategies to bolster existing community mobilization/activism around PrEP. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019.	biomedical prevention; HIV; pre-exposure prophylaxis; PrEP; transgender women	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	
Article	2019	Klein, Hugh; Washington, Thomas Alex	The Pre-Exposure Prophylaxis (PrEP) Stigma Scale: Preliminary findings from a pilot study.	International Public Health Journal	-	-	-	1947-4989	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7034943	Despite being at the cornerstone of current initiatives to curtail the spread of HIV, Pre-Exposure Prophylaxis (PrEP) medication has been slow to proliferate among many "at risk" populations. This is true for men who have sex with other men (MSM), who account for the largest number of new HIV diagnoses in the United States. To try to understand why MSM are not adopting PrEP in greater numbers, the present authors have created a 22-item PrEP Stigma Scale. This paper reports findings for that scale. METHODS: Purposive sampling was used to derive a sample of 273 diverse MSM. Men completed a brief questionnaire inquiring about their awareness of PrEP, willingness to avail themselves of various sources of information about PrEP, perceptions about PrEP-related stigma, and perceptions about obstacles to PrEP use. Cronbach's alpha reliability coefficients were computed for the PrEP Stigma Scale, for the full sample and for key subgroups. Factor analysis was performed to determine whether or not subscales exist. RESULTS: The PrEP Stigma Scale was found to be highly reliable, both in its full version (alpha=0.96) and in its shortened version (alpha=0.95). Reliability estimates were strong for all subgroups based on age, race, sexual orientation, educational attainment, relationship status, and HIV serostatus. Two subscales were identified, each with excellent reliability (alpha=0.95 and 0.94), again for the sample as a whole and for all key subgroups. CONCLUSIONS: The PrEP Stigma Scale shows great promise for aiding our understanding of why more MSM are not adopting PrEP. It was found to be reliable for all key subgroups under examination, and that is true both for the 22-item and the 11-item version of the scale. Article	2019	Koppe U.; Marcus U.; Albrecht S.; Jansen K.; Jessen H.; Gunsenheimer-Bartmeyer B.; Bremer V.	Factors associated with the informal use of HIV pre-exposure prophylaxis in Germany: a cross-sectional study	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25395	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072915692&doi=10.1002%2fjia2.25395&partnerID=40&md5=430324836edc001b084dc5884c60d00c	Introduction: Until September 2019, pre-exposure prophylaxis (PrEP) with tenofovir disoproxil/emtricitabine for HIV prevention was not covered by health insurance plans in Germany, and was only available through private prescriptions with self-pay or through informal non-prescription sources. The objective of this study was to investigate the proportion of informal PrEP use among PrEP users and to identify factors of public health relevance that might be associated with informal PrEP use. Methods: We conducted a cross-sectional study recruiting PrEP users independent of their PrEP source. Clients from anonymous community testing checkpoints, users of three dating apps for men who have sex with men residing in Germany and users of a PrEP community website, were recruited to complete a short anonymous online survey. Participants were recruited between 24 July and 3 September 2018. The results were analysed using univariable and multivariable logistic regressions. Results: We recruited 2005 participants currently using PrEP. The median age was 38 years, and 80.3% of the participants identified themselves as male (missing: 19.1%). Overall, 71.6% obtained PrEP through medical services with a private prescription or a clinical trial, and 17.4% obtained PrEP through informal sources (missing: 11.0%). The most common informal sources were ordering online from another country (8.8%), travel abroad (3.6%), and friends (2.5%). Factors associated with informal PrEP use were on demand/intermittent dosing (adjusted OR: 3.5, 95% CI 2.5 to 5.0) and not receiving medical tests during PrEP use (adjusted OR: 3.2, 95% CI 2.0 to 5.2). In addition, informal PrEP users who did not take PrEP daily had a strongly increased risk of taking PrEP without prior medical tests (adjusted stratum-specific OR = 31.7, 95% CI 4.6 to 219.5). Conclusions: Informal PrEP use was associated with a higher risk of not getting tested before and during PrEP use, which could lead to HIV infections resistant to tenofovir and emtricitabine if people with undiagnosed HIV use PrEP. Health insurance plans that cover PrEP and the accompanying routine tests could ensure adequate medical supervision of PrEP users and reduce barriers to PrEP use. Our findings strongly support the implementation of PrEP programmes in countries with similar patterns of informal PrEP use. © 2019 The Authors. Journal of the International AIDS Society published by John Wiley & Sons Ltd on behalf of the International AIDS Society.	affordability; informal PrEP; men who have sex with men; non-daily use; PrEP; testing	English	United States	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Quantitative
Article	2019	Krakower D.; Maloney K.M.; Powell V.E.; Levine K.; Grasso C.; Melbourne K.; Marcus J.L.; Mayer K.H.	Patterns and clinical consequences of discontinuing HIV preexposure prophylaxis during primary care	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25250	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061601371&doi=10.1002%2fjia2.25250&partnerID=40&md5=c476a4f0d8228b95b12deb2c58f7c502	Introduction: Discontinuations of HIV preexposure prophylaxis (PrEP) by at-risk individuals could decrease the effectiveness of PrEP. Our objective was to characterize patterns of, reasons for, and clinical outcomes associated with PrEP discontinuations in primary care. Methods: We conducted medical chart reviews for patients prescribed PrEP during 2011 to 2014 at a Boston community health centre specializing in healthcare for sexual and gender minorities. Patients were followed through 2015. We characterized patients' sociodemographics, relationship status, behavioural health conditions, patterns of and reasons for PrEP discontinuations, and HIV seroconversions. Cox proportional hazards models were used to assess patient factors associated with PrEP discontinuations. Results: Of the 663 patients prescribed PrEP, the median age was 33 years, 96% were men who have sex with men (MSM) and 73% were non-Hispanic white; 40% were in committed relationships and 15% had HIV-infected partners. Patients either used PrEP continuously (60%), had 1 or more discontinuations (36%), or did not initiate PrEP (4%). Discontinuations were most often due to a decrease in HIV risk perception (33%), non-adherence to care plans (16%), or insurance barriers (12%). Of the 7 (1.1%) PrEP patients diagnosed with HIV, 1 was HIV-infected at baseline, 2 seroconverted while using PrEP, and 4 seroconverted after discontinuations. In a multivariable model adjusted for race/ethnicity, relationship status, substance use disorders, and insurance status, those who were less than 30 years old (aHR 2.0, 95% CI 1.4 to 2.9 for ages 18 to 24, aHR 2.2, 95% CI 1.6 to 3.1 for ages 25 to 29, vs. ages 30 to 39 years), who identified as transgender women (aHR 2.0, 95% CI 1.2 to 3.4, vs. cisgender men), and who had mental health disorders (aHR 1.2, 95% CI 1.1 to 1.4 for each additional disorder) were more likely to have discontinuations. Conclusions: Discontinuations of PrEP use among this American sample of predominately MSM were common, particularly among patients who were younger, identified as transgender women, or had behavioural health issues. As HIV seroconversions occurred after discontinuations of PrEP, strategies to prevent inappropriate discontinuations are needed. © 2019 The Authors. Article	2019	Krakower, Douglas S; Gruber, Susan; Hsu, Katherine; Menchaca, John T; Maro, Judith C; Kruskal, Benjamin A; Wilson, Ira B; Mayer, Kenneth H; Klompas, Michael	Development and validation of an automated HIV prediction algorithm to identify candidates for pre-exposure prophylaxis: a modelling study.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(19)30139-0	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7522919	BACKGROUND: HIV pre-exposure prophylaxis (PrEP) is effective but underused, in part because clinicians do not have the tools to identify PrEP candidates. We developed and validated an automated prediction algorithm that uses electronic health record (EHR) data to identify individuals at increased risk for HIV acquisition. METHODS: We used machine learning algorithms to predict incident HIV infections with 180 potential predictors of HIV risk drawn from EHR data from 2007-15 at Atrius Health, an ambulatory group practice in Massachusetts, USA. We included EHRs of all patients aged 15 years or older with at least one clinical encounter during 2007-15. We used ten-fold cross-validated area under the receiver operating characteristic curve (cv-AUC) with 95% CIs to assess the model's performance at identifying individuals with incident HIV and patients independently prescribed PrEP by clinicians. The best-performing model was validated prospectively with 2016 data from Atrius Health and externally with 2011-16 data from Fenway Health, a community health centre specialising in sexual health care in Boston (MA, USA). We calculated HIV risk scores (ie, probability of an incident HIV diagnosis) for every HIV-uninfected patient not on PrEP during 2007-15 at Atrius Health and assessed the distribution of scores for thresholds to determine possible candidates for PrEP in the three study cohorts. FINDINGS: We included 1ä155ä966 Atrius Health patients from 2007-15 (150 <0·1% patients with incident HIV) in our development cohort, 537ä257 Atrius Health patients in 2016 (16 <0·1% with incident HIV) in our prospective validation cohort, and 33ä404 Fenway Health patients from 2011-16 (423 1·3% with incident HIV) in our external validation cohort. The best-performing algorithm was obtained with least absolute shrinkage and selection operator (LASSO) and had a cv-AUC of 0·86 (95% CI 0·82-0·90) for identification of incident HIV infections in the development cohort, 0·91 (0·81-1·00) on prospective validation, and 0·77 (0·74-0·79) on external validation. The LASSO model successfully identified patients independently prescribed PrEP by clinicians at Atrius Health in 2016 (cv-AUC 0·93, 95% CI 0·90-0·96) or Fenway Health (0·79, 0·78-0·80). HIV risk scores increased steeply at the 98th percentile. Using this score as a threshold, we prospectively identified 9515 (1·8%) of 536ä384 patients at Atrius Health in 2016 and 4385 (15·3%) of 28ä702 Fenway Health patients as potential PrEP candidates. INTERPRETATION: Automated algorithms can efficiently identify patients at increased risk for HIV acquisition. Integrating these models into EHRs to alert providers about patients who might benefit from PrEP could improve prescribing and prevent new HIV infections. FUNDING: Harvard University Center for AIDS Research, Providence/Boston Center for AIDS Research, Rhode Island IDeA-CTR, the National Institute of Mental Health, and the US Centers for Disease Control and Prevention. Article	2019	Krogstad E.A.; Montgomery E.T.; Atujuna M.; Minnis A.M.; O'Rourke S.; Ahmed K.; Bekker L.-G.; Van Der Straten A.	Design of an Implant for Long-Acting HIV Pre-Exposure Prophylaxis: Input from South African Health Care Providers	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0177	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063986053&doi=10.1089%2fapc.2018.0177&partnerID=40&md5=7d54677a8e08c90fb751bf8b9e84a606	Implants are in the pre-clinical stage for long-acting HIV pre-exposure prophylaxis (PrEP), with an opportunity to solicit end-users' feedback early in development. Health care providers (HCPs) have been key gatekeepers for contraceptive implant uptake, and uniquely understand both technical considerations and the social context of use. Given their influential role, we gathered South African HCP perspectives on contraceptive implant implementation and features of PrEP implant prototypes that may influence future provider and patient acceptability. We conducted in-depth interviews with 30 HCPs (20 nurses and 10 doctors) in Cape Town and Soshanguve, South Africa. Interviews were conducted by a bioengineer and later transcribed, coded, and analyzed for key themes. HCPs described health system barriers such as understaffed clinics and inadequate training on contraceptive implant removal as major influences to their PrEP implant design preferences. They preferred a PrEP implant that is long lasting (>6 months) to minimize patient-clinic interactions, biodegradable to avoid need for removal, and flexible (but still palpable in case of removal). Commenting on negative experiences with contraceptive implant rollout, they recommended prioritizing both HCP and community education on the PrEP implant, with emphasis on expected side effects, and planning ahead for adequate training of HCPs before rollout. Challenges experienced with past contraceptive implant rollout may taint perspectives on future PrEP implants and must be carefully considered during product development and planning for clinical studies. Particular consideration should be given to the health system context of future distribution, including staff who would be providing and monitoring implants. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019.	contraceptive; health care providers; HIV pre-exposure prophylaxis; implant; product development; South Africa	English	United States	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Qualitative
Theses and Dissertations	2019	Kuipa, Michael	Antiretroviral drugs differentially modulate glucocorticoid activity via the glucocorticoid receptor in vitro	-	-	University of Cape Town	-	NA	NA	http://hdl.handle.net/11427/31426	Concurrent use of anti-retroviral drugs (ARVs) and progestin-based hormonal contraceptives is widespread. During times of stress and during glucocorticoid (GC) therapy, intracellular ARVs are in the presence of high concentrations of GCs, which regulate all aspects of immunity and inflammation via the glucocorticoid receptor (GR). However, the reciprocal modulation of ARV and steroid intracellular functions is relatively unexplored. In this study, the effects of the ARVs tenofovir disoproxil fumarate (TDF), dapivirine (DPV), and maraviroc (MVC) on activation of the GR and GR-regulated mRNA expression were investigated, in the absence and presence of select GR ligands. The effects of TDF and DPV on GR protein levels and phosphorylation were also determined. The inhibitory activity of these ARVs on HIV-1 infection in the presence of the progestins medroxyprogesterone acetate (MPA) and levonorgestrel (LNG), and a GR agonist, dexamethasone (DEX) was also assessed. This study shows that (0.01 nM-10 μM) TDF, DPV and MVC do not transactivate reporter gene expression via the unliganded GR exogenously expressed in the steroid receptor-deficient U2OS human osteosarcoma cell line, or alter the reporter gene transcriptional activity of (100 nM) MPA or LNG via the GR in these cells. However, (1 μM) TDF and DPV modulate the reporter gene transcriptional efficacy of (0.01 nM-10 μM) DEX via the GR. In the U2OS cell line model, (1 μM) TDF, but not DPV significantly decreased (1μM and 10μM) DEX-induced mRNA expression of the anti-inflammatory glucocorticoid-induced leucine zipper (GILZ) gene. TDF also appeared to decrease (1 μM) cortisol (CORT)- and MPA-induced GILZ mRNA expression. This may be mediated by the apparent increase in (100 nM and 1μM) DEXinduced phosphorylation at Serine 226 on the GR, observed in the presence of (1μM) TDF in this study. DPV and TDF (at 1μM) did not significantly alter GR protein levels, or cell-viability in the absence and presence of (100 nM) DEX, CORT or MPA in U2OS cells. However, (1 μM) DPV and TDF alone, significantly altered cell viability in peripheral blood mononuclear cells (PBMCs). In PBMCs, (1 μM) TDF, MVC and DPV alone altered basal GILZ mRNA expression and had variable, donor-specific effects on interleukin (IL)-6, IL-8, and interferon (IFN)-γ gene expression. In PBMCs from some of the nine donors tested, these ARVs had proinflammatory effects which may undermine their efficacy at preventing HIV-1 acquisition in pre-exposure prophylaxis products. Moreover, the ARVs proinflammatory effects may negatively impact HIV-1 disease progression and increase the risk of non-AIDS mortality in individuals using the ARVs therapeutically. Neither (1 μM) DPV, TDF nor MVC significantly altered the effects of (100 nM) DEX on the immunomodulatory genes assessed in PBMCs. DEX, MPA and LNG (at 100 nM) did not affect the anti-HIV-1 activity of the ARVs (at 1 μM) in PBMCs from the majority of the three donors tested in this study. Taken together, the results show that ARVs can modulate GR activity in an ARV-, steroid-, gene- and cell-specific manner, while the steroids investigated did not modulate ARV anti-HIV-1 activity. Article	2019	Kundu, Iman; Martinez-Donate, Ana; Karkada, Navya; Roth, Alexis; Felsher, Marisa; Sandling, Marcus; Szep, Zsofia	Attitudes and referral practices for pre-exposure prophylaxis (PrEP) among HIV rapid testers and case managers in Philadelphia: A mixed methods study.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0223486	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6779237	OBJECTIVE: Adoption of pre-exposure prophylaxis (PrEP) to prevent HIV infection has been slow. The purpose of this study was to evaluate knowledge, attitudes and referral practices for PrEP among non-prescribing providers, who may play key role. METHODS: We performed a cross-sectional survey on PrEP knowledge, attitudes, and referral practices among 66 non-prescribing HIV prevention providers (1st August to 31st December, 2016), in Philadelphia, followed by qualitative interviews with 12 of them (5th April to 10th May, 2017). RESULTS: Participants had a mean age of 36 years, with 62% females. Majority were HIV case managers and rapid testers. For half of the respondents, PrEP eligibility screening was part of rapid HIV testing at their organization, 40% never had PrEP training and only 27% indicated personally screening clients for eligibility. Qualitative data revealed that participants held positive attitudes about PrEP and perceived organizational support, but had concerns about potential negative impacts and barriers to routine HIV screening. CONCLUSION: Results highlight the importance of training non-prescribing HIV prevention providers about PrEP, addressing their concerns, and incorporating PrEP screening and referral into routine HIV testing. Article	2019	Kuteesa M.O.; Quaife M.; Biraro S.; Katumba K.R.; Seeley J.; Kamali A.; Nakanjako D.	Acceptability and Predictors of Uptake of Anti-retroviral Pre-exposure Prophylaxis (PrEP) Among Fishing Communities in Uganda: A Cross-Sectional Discrete Choice Experiment Survey	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02418-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061261311&doi=10.1007%2fs10461-019-02418-7&partnerID=40&md5=8dcff3ffefdb24728379fca3b4f8ce39	We used a discrete choice experiment to assess the acceptability and potential uptake of HIV pre-exposure prophylaxis (PrEP) among 713 HIV-negative members of fishing communities in Uganda. Participants were asked to choose between oral pill, injection, implant, condoms, vaginal ring (women), and men circumcision. Product attributes were HIV prevention effectiveness, sexually transmitted infection (STI) prevention, contraception, waiting time, and secrecy of use. Data were analysed using mixed multinomial logit and latent class models. HIV prevention effectiveness was viewed as the most important attribute. Both genders preferred oral PrEP. Women least preferred the vaginal ring and men the implant. Condom use was predicted to decrease by one third among men, and not to change amongst women. Oral PrEP and other new prevention technologies are acceptable among fishing communities and may have substantial demand. Future work should explore utility of multiple product technologies that combine contraception with HIV and other STI prevention. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Kwan T.H.; Lee S.S.	Bridging awareness and acceptance of pre-exposure prophylaxis among men who have sex with men and the need for targeting chemsex and HIV testing: Cross-sectional survey	Journal of Medical Internet Research	-	-	-	14388871	10.2196/13083	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85097200181&doi=10.2196%2f13083&partnerID=40&md5=6f41c6ae16ff483bfc713b0ed77d6d6b	Background: Pre-exposure prophylaxis (PrEP) is currently an important tool for HIV prevention, especially in communities with higher risk of infection, notably men who have sex with men (MSM). To date, PrEP has remained generally unavailable in many cities around the world. In the planning of strategies for PrEP targeting MSM, community assessment is crucial to understand members' responses to the new intervention. Objective: Awareness and acceptance are 2 different but intricately linked contexts of PrEP. The aim of this study was to identify the determinants of awareness and acceptance of PrEP among MSM and to delineate their interrelationships in Hong Kong where PrEP services have not been developed. Methods: A Web-based questionnaire survey was administered in light of the popularity of the internet as a platform for information and networking in the MSM community. Factors associated with PrEP acceptance and awareness were separately analyzed, and their predictors were subsequently tested by multivariate logistic regression. Associations between acceptance and awareness of PrEP were examined by factor network analysis. Results: Between August and September 2016, results from a total of 453 HIV-negative MSM were analyzed. Half (49.7%, 225/453) of the respondents were aware of PrEP, and 78.3% (355/453) would consider using PrEP when it becomes available. Awareness of PrEP was associated with recent (P=.01) and ongoing (P=.04) use of psychotropic drugs for sex (chemsex). MSM who used online forums to seek sex partners had lower awareness (P=.04) than those visiting physical venues for sex networking. MSM who accepted PrEP were more likely users of internet channels for sex networking (P=.049), especially location-based social network apps (P=.04). MSM accepting PrEP were more concerned about their partners' HIV status (P=.002), history of sexually transmitted infections (P=.01), condom use (P=.02), and HIV testing behavior (P=.02). Multivariate logistic regressions revealed that PrEP awareness was related to one's networking pattern, whereas its acceptance was associated with inclination to self-protect from HIV. Factor network analysis highlighted the importance of chemsex, which was linked by over half of the edges, whereas the rest were contributed by HIV testing behaviors. Conclusions: In Hong Kong, the overall awareness among MSM toward PrEP was only moderate but their acceptance was higher. Targeting MSM with chemsex behaviors through Web-based platforms and parallel development of tailored HIV testing services are important when introducing PrEP in the community. © 2019 Journal of Medical Internet Research. Article	2019	Kwena Z.A.; Njuguna S.W.; Ssetala A.; Seeley J.; Nielsen L.; De Bont J.; Bukusi E.A.	HIV prevalence, spatial distribution and risk factors for HIV infection in the Kenyan fishing communities of Lake Victoria	PLOS One	-	-	-	19326203	10.1371/journal.pone.0214360	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063584088&doi=10.1371%2fjournal.pone.0214360&partnerID=40&md5=17f4980687a1be99a6d50ce5f7f260c7	Introduction Global efforts to end HIV by 2030 focus on reducing and eventually eliminating new infections in priority populations. Identifying these populations and characterizing their vulnerability factors helps in guiding investment of scarce HIV prevention resources to achieve maximum impact. We sought to establish HIV prevalence, spatial distribution and risk factors for HIV infection in the Kenyan fishing communities of Lake Victoria. Methods We conducted a cross-sectional survey of 2637 people from all the 308 fish-landing beaches on the Kenyan shore of Lake Victoria. The number of participants enrolled at each beach were weighted based on the size of the beach, determined by the number of functional registered boats. We used simple random sampling to select those to be approached for study participation. Consenting participants were privately interviewed about their socioeconomic and demographic characteristics and sexual behavior, and were invited for HIV test using the Kenya rapid HIV testing protocol. We used descriptive statistics and multivariate logistic and linear regression for analysis. Results We found high HIV prevalence of 32% with significant differences between men (29%) and women (38%). Among men, having an HIV negative sexual partner, being circumcised, increasing number of condom protected sex acts in the preceding month, being younger and being a resident of Homa Bay, Kisumu, Siaya and Busia counties compared to Migori County reduced the risk of HIV infection. For women, being married, having more children with the current spouse, having an HIV negative sexual partner and being a resident of Busia compared to Migori County reduced the risk of HIV infection. We also found that longer distance from the beaches to the nearest public health facilities was associated with increasing cumulative HIV prevalence at the beaches. Conclusion Fishing communities have high HIV prevalence and may greatly benefit from interventions such as wider ART coverage, couple HIV risk reduction counseling, PrEP use for HIV negative partner at substantial continuous risk, alongside other HIV prevention services that the Kenyan government is currently rolling out. This will additionally require adequate plans to synchronize the provision of these services with the population's routine schedules for all these options to be reasonably accessible to them. © 2019 Kwena et al. Article	2019	Lachowsky, Nathan J; Lawson Tattersall, Tessa; Sereda, Paul; Wang, Clara; Edwards, Joshua; Hull, Mark	Community awareness of, use of and attitudes towards HIV pre-exposure prophylaxis (PrEP) among men who have sex with men in Vancouver, Canada: preparing health promotion for a publicly funded PrEP program.	Sexual Health	-	-	-	1449-8987	10.1071/SH18115	https://dx.doi.org/10.1071/SH18115	Background HIV rates are persistently disproportionate among men who have sex with men (MSM). Pre-exposure prophylaxis (PrEP) is an effective HIV prevention method, now publicly funded in British Columbia. This study assessed PrEP-related attitudes, sexual behaviour and self-reported use before public funding. METHODS: Adult MSM were recruited from January to June 2017 through a local community-based organisation's PrEP campaign website (www.getpreped.ca). Participants self-completed an anonymous online questionnaire, and were stratified into three groups: (i) HIV-positive participants; (ii) HIV-negative participants not using PrEP; and (iii) HIV-negative participants using PrEP. Descriptive, bivariate and univariate regression analyses were conducted. RESULTS: Of 249 participants, 191 (77%) were HIV-negative not using PrEP, 41 (17%) were HIV-negative using PrEP and 17 (7%) were HIV-positive. Among PrEP users, 90% used PrEP daily and all reported having recommended medical follow-up care. Among HIV-negative, non-PrEP-users, 44% said they would reduce condom use if they used PrEP and 28% were uncomfortable asking their doctor for PrEP. Interest in PrEP among non-users was associated with higher objective risk scores (i.e. HIV Incidence Risk Index for MSM), higher self-perceived risk, greater perceived PrEP effectiveness, no prescription medications insurance, open or single relationship status (vs closed) and not always using condoms (vs always). Among HIV-positive participants, 53% agreed PrEP reduced stigma for people living with HIV. All study groups perceived a greater percentage of MSM on PrEP (10%, 15%, 18%) than in their own social networks (5%, 4%, 6%). CONCLUSIONS: PrEP health promotion must consider comprehensive PrEP education; accuracy of self-perceived HIV risk and PrEP social norms; and barriers to culturally safe primary care for MSM. Frontiers in Pharmacology	-	-	-	1663-9812	10.3389/fphar.2019.01269	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6854879	Background: In Australia, clinical trial drugs are conventionally dispensed through clinical trial pharmacies only, while community pharmacies dispense drugs approved by Australia's regulatory body. A large HIV pre-exposure prophylaxis study aimed to deliver clinical trial drug through community pharmacies to improve convenience and mimic real world prescribing. This paper describes the process of making community trials compliant with good clinical practice and reports outcomes of delivering clinical trial drug through community pharmacies. Methods: Eight community and four clinical trial pharmacies across three Australian states were approached to participate. A good clinical practice checklist was generated and pharmacies underwent a number of changes to meet clinical trial pharmacy requirements prior to study opening. Changes were made to community pharmacies to make them compliant with good clinical trial practice including; staff training, structural changes, and implementing monitoring of study drug and prescribing practices. Study drug was ordered through standard clinical trial processes and dispensed through study pharmacies by accredited pharmacists. Throughout the trial, record logs for training, prescriber signature and delegation, temperature, participant, and drug accountability were maintained at each pharmacy. The study team monitored each log and delivered on-site training to correct protocol variations. Results: Each pharmacy that was approached agreed to participate. All community pharmacies achieved good clinical practice compliance prior to dispensing study drug. Over the course of the study, 20,152 dispensations of study drug occurred, 83% of these occurred at community pharmacies. Only 2.0% of dispensations had an error, and errors were predominantly minor. On five occasions a pharmacist who was not accredited dispensed study drug. Conclusions: Community based pharmacies can undergo training and modifications to achieve good clinical practice compliance and dispense clinical trial study drug. Community based pharmacies recorded few variations from study protocol. Community based pharmacies offer a useful alternative to clinical trial pharmacies to increase convenience for study participants and expanded use of these pharmacies should be considered for large clinical trials, including HIV prevention trials.	pre-exposure prophylaxis, pre-exposure prophylaxis expanded, pharmacy, clinical trials, human immunodeficiency virus prevention, prophylaxis	English	Switzerland	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Clinical
Article	2019	Lama, Javier R; Mayer, Kenneth H; Perez-Brumer, Amaya G; Huerta, Leyla; Sanchez, Hugo; Clark, Jesse L; Sanchez, Jorge; Reisner, Sari L	Integration of Gender-Affirming Primary Care and Peer Navigation With HIV Prevention and Treatment Services to Improve the Health of Transgender Women: Protocol for a Prospective Longitudinal Cohort Study.	JMIR Research Protocols	-	-	-	1929-0748	10.2196/14091	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6620883	BACKGROUND: Public health strategies are urgently needed to improve HIV disparities among transgender women, including holistic intervention approaches that address those health needs prioritized by the community. Hormone therapy is the primary method by which many transgender women medically achieve gender affirmation. Peer navigation has been shown to be effective to engage and retain underserved populations living with HIV in stable primary medical care. OBJECTIVE: This study aims to assess the feasibility and acceptability of an integrated innovative HIV service delivery model designed to improve HIV prevention and care by combining gender-affirming primary care and peer navigation with HIV prevention and treatment services. METHODS: A 12-month, nonrandomized, single-arm cohort study was implemented in Lima, Peru, among adult individuals, assigned a male sex at birth, who identified themselves as transgender women, regardless of initiation or completion of medical gender affirmation, and who were unaware of their HIV serostatus or were living with HIV but not engaged in HIV treatment. HIV-negative participants received quarterly HIV testing and were offered to initiate pre-exposure prophylaxis. HIV-positive participants were offered to initiate antiretroviral treatment and underwent quarterly plasma HIV-1 RNA and peripheral CD4+ lymphocyte cell count monitoring. All participants received feminizing hormone therapy and adherence counseling and education on their use. Peer health navigation facilitated retention in care by visiting participants at home, work, or socialization venues, or by contacting them by social media and phone. RESULTS: Patient recruitment started in October 2016 and finished in March 2017. The cohort ended follow-up on March 2018. Data analysis is currently underway. CONCLUSIONS: Innovative and culturally sensitive strategies to improve access to HIV prevention and treatment services for transgender women are vital to curb the burden of HIV epidemic for this key population. Findings of this intervention will inform future policies and research, including evaluation of its efficacy in a randomized controlled trial. Article	2019	Lane W.; Heal C.; Banks J.	HIV pre-exposure prophylaxis: Knowledge and attitudes among general practitioners	Australian Journal of General Practice	-	-	-	22087958	10.31128/AJGP-02-19-4860	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85077028335&doi=10.31128%2fAJGP-02-19-4860&partnerID=40&md5=37d4825a4b68e7c7c671bedea3a6da61	BACKGROUND AND OBJECTIVES: Human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) was accepted on the Australian Pharmaceutical Benefits Scheme on 1 April 2018, allowing general practitioners (GPs) to prescribe to patients in general practice. This study provides a timely assessment of GP knowledge and attitudes towards HIV PrEP. METHOD: An explanatory mixed method approach was used. A content-validated questionnaire was distributed to GPs in the Mackay region to assess knowledge and attitudes towards PrEP, followed by individual in-depth interviews. RESULTS: Forty-five of 109 GPs (41.1%) responded. One-third (15 of 45) had previously heard of PrEP; 71.4% (30 of 42) indicated a lack of comfort with its prescription while 60% (27 of 45) reported that provision of formalised guidelines was likely to increase prescription confidence. Ten GPs were interviewed until data saturation was achieved. Results supported the quantitative findings. DISCUSSION: GPs expressed positive attitudes towards HIV PrEP. Limited knowledge could be overcome through formalised guidelines and education. Article	2019	Lankowski, Alexander J; Bien-Gund, Cedric H; Patel, Viraj V; Felsen, Uriel R; Silvera, Richard; Blackstock, Oni J	PrEP in the Real World: Predictors of 6-Month Retention in a Diverse Urban Cohort	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2296-x	https://www.proquest.com/scholarly-journals/prep-real-world-predictors-6-month-retention/docview/2122920119/se-2?accountid=8113	The effectiveness of HIV pre-exposure prophylaxis (PrEP) depends on adherence, which requires retention in PrEP care. We sought to examine factors associated with six-month retention in PrEP care among individuals prescribed PrEP between 2011 and 2015 in a large, academic health system in the Bronx, New York. We used multivariable logistic regression to identify factors independently associated with six-month retention. Among 107 patients, retention at 6 months was 42%. In the multivariable analysis, heterosexual individuals were less likely to be retained in PrEP care at 6 months, but individuals who received prescriptions from attending physicians were more likely to be retained in care. Larger prospective studies are needed to better evaluate the individual and health system factors associated with long-term engagement in PrEP care.Resumo alternativo:La efectividad de la Profilaxis de Pre-Exposición para el VIH (PrEP) depende de la adherencia, la cual requiere retención en el cuidado de PrEP. Buscamos examinar los factores asociados con la retención durante seis meses en el cuidado de PrEP, entre las personas a las cuales se les recetó PrEP entre los años 2011 y 2015 en un amplio sistema académico de salud en el Bronx, Nueva York. Utilizamos análisis de regresión logística multivariada para identificar los factores independientemente asociados con seis meses de retención. Entre 107 pacientes, la retención a los seis meses fue del 42%. En el análisis multivariado, las personas que se identificaron como heterosexuales fueron menos propensas a estar recibiendo el cuidado de PrEP a los seis meses, pero las que recibieron su receta de parte de los médicos asistentes tuvieron más probabilidad de retención en el cuidado de PrEP. Se necesitan estudios prospectivos más amplios para evaluar mejor los factores individuales y del sistema de salud asociados con la participación a largo plazo en el cuidado de PrEP. Theses and Dissertations	2019	Lazarus, Lisa	In search of success: the politics of care and responsibility in a PrEP demonstration project among sex workers in India	-	-	University of Manitoba	-	NA	NA	http://hdl.handle.net/1993/34178	Pre-exposure prophylaxis (PrEP), which contains a combination of tenofovir and emtricitabine, has emerged as a new biomedical HIV prevention option. Multilateral groups and health policy makers have called for demonstration projects to better understand PrEP's everyday use and effectiveness. Funded by the Bill & Melinda Gates Foundation and in partnership with the University of Manitoba, Ashodaya Samithi, a sex worker collective, initiated a PrEP demonstration project in Mysore and Mandya, Karnataka State, South India. Drawing on qualitative ethnographic methods, a study of the PrEP demonstration project took place between January 2015 and April 2018 and included field visits, participant observation, and in-depth interviews with demonstration project participants and the implementation team. Community researchers and I conducted 167 interviews over the course of the study. Following a community validation and contextualization (or "member checking") session, I coded the data for key themes and emergent categories. According to the biomedical indicators of retention and adherence, the demonstration project proved immensely successful, with 640/647 participants retained for the 16-month project and participants reporting high adherence confirmed by blood-level tenofovir testing. Attempting to more fully account for how this "success" arrived, however, I go beyond these biomedical interpretations of retention and adherence, pointing instead toward Ashodaya's history of collectivization around sexual health—a history of community action that has given rise to forms of health citizenship and new spaces of belonging for sex workers. In what I call the "search for success", a particular attention is placed on the role that care plays among Ashodaya sex workers over the life course of the demonstration project. This care is tied not only to the community of sex workers Ashodaya seeks to serve, but also to the careful production of evidence that demonstrates accountability to funders, which is, furthermore, tied to caring for the very survival and future of the organization. Article	2019	Leddy A.M.; Weiss E.; Yam E.; Pulerwitz J.	Gender-based violence and engagement in biomedical HIV prevention, care and treatment: A scoping review	BMC Public Health	-	-	-	14712458	10.1186/s12889-019-7192-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068836852&doi=10.1186%2fs12889-019-7192-4&partnerID=40&md5=db053ad6f931cf23e19085a8375ecbe6	Background: While gender-based violence (GBV) has been shown to increase women's risk of HIV acquisition, the role of GBV in the HIV testing to care continuum is less clear. Clarifying how GBV may act as a barrier to accessing HIV services, treatment and care - such as anti-retroviral treatment (ART) or pre-exposure prophylaxis (PrEP) - will not only provide insights into how to best meet individual women's HIV care needs, but also inform public health oriented HIV epidemic control strategies. Methods: Through a comprehensive scoping review, we synthesized and analyzed existing evidence regarding the influence of GBV on engagement in PrEP and the HIV care continuum among women living with HIV, including members of key populations (female sex workers, transgender women and women who use drugs). We explored PubMed, Scopus and Web of Science for peer-reviewed studies published in 2003-2017. Of the 279 sources identified, a subset of 51 sources met the criteria and were included in the scoping review. Results: Studies were identified from 17 countries. The majority of studies utilized quantitative cross-sectional designs (n = 33), with the rest using longitudinal (n = 4), qualitative (n = 10) or mixed methods (n = 4) designs. Taken together, findings suggest that GBV impedes women's uptake of HIV testing, care, and treatment, yet this can vary across different geographic and epidemic settings. Substantial gaps in the literature do still exist, including studies on the impact of GBV on engagement in PrEP, and research among key populations. Conclusions: This scoping review contributes to our knowledge regarding the role GBV plays in women's engagement in PrEP and the HIV care continuum. Findings reveal the need for more longitudinal research to provide insights into the causal pathways linking GBV and HIV care and treatment outcomes. Research is also needed to illuminate the impact of GBV on PrEP use and adherence as well as the impact of GBV on engagement along the HIV care continuum among key populations. It is critical that programs and research keep pace with these findings in order to reduce the global burden of GBV and HIV among women. © 2019 The Author(s). Article	2019	Leduc J.-M.; Fortin C.; Rouleau D.; Martel-Laferrière V.	Measuring the impact of an hiv rotation on trainees' knowledge and confidence level: The importance of inviting recent graduates	Journal of the Association of Medical Microbiology and Infectious Disease Canada (JAMMI)	-	-	-	23710888	10.3138/jammi.2018-0041	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072154930&doi=10.3138%2fjammi.2018-0041&partnerID=40&md5=3e25167a467d47159a31c651ba5792ba	BACKGROUND: The new Canadian Residency Accreditation Consortium (CanRAC) standards recommend surveying recently graduated trainees to target improvements in training programs. The goal of this study was to estimate the impact of a rotation in an HIV clinic on trainees' related knowledge, confidence, and practice profile at the Université de Montréal. METHODS: An electronic survey was sent to practising physicians who completed the rotation between 2006 and 2016. Participants were asked to rate their agreement and level of confidence toward HIV-and HCV-related topics using 5-point Likert scales (0 to 4). Descriptive statistics and mean comparisons were calculated. RESULTS: Among invited participants, 27 of 45 (60%) completed the questionnaire. The majority of respondents were infectious diseases physicians (48%) or family physicians (37%) and had an outpatient caseload of <10 HIV patients/ year (80%). For 37% of the respondents, the rotation had a large or very large impact on their career path. They considered that the rotation had increased their knowledge on the overall management of HIV (mean 3.2/4 95% CI 2.9 to 3.4), but less on pre-exposure prophylaxis (PrEP) (mean 1.5/4 95% CI 1.1 to 2.0) or HCV care (mean 1.9/4 95% CI 1.4 to 2.3). Participants felt less confident with genotyping interpretation (mean 2.6/4 95% CI 2.2 to 2.9) and PrEP (mean 2.4/4 95% CI 2.0 to 2.8). CONCLUSIONS: These results suggest that a rotation in an HIV clinic improves knowledge related to HIV care. Feedback from past graduates helped us identify gaps in knowledge or level of confidence in PrEP and HCV care, which will feed curriculum improvement. © 2019, University of Toronto Press Inc.. Article	2019	Lee S.S.; Kwan T.H.; Wong N.S.; Lee K.C.K.; Chan D.P.C.; Lam T.T.N.; Lui G.C.Y.	Piloting a partially self-financed mode of human immunodeficiency virus pre-exposure prophylaxis delivery for men who have sex with men in hong kong	Hong Kong Medical Journal	-	-	-	10242708	10.12809/hkmj198030	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074578879&doi=10.12809%2fhkmj198030&partnerID=40&md5=69d27dc1cdd4d5ec37d303dfb53c8e24	Introduction: Pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate (TDF) 300 mg/ emtricitabine (FTC) 200 mg is a proven strategy for preventing human immunodeficiency virus (HIV) transmission in men who have sex with men (MSM). This study aimed to test the feasibility and acceptability of PrEP delivered at a pilot clinic for MSM in Hong Kong, where PrEP service is currently unavailable. Methods: Partially self-financed PrEP was provided to HIV-negative adult MSM with high behavioural risk of HIV transmission after excluding hepatitis B infection and renal insufficiency. Participants received daily TDF/FTC for 30 weeks at 13.3% of the drug cost. Adherence and behaviours were monitored through questionnaires while creatinine and HIV/ STI (sexually transmitted infection) incidence were monitored with point-of-care and laboratory tests. Preference for continuing with PrEP was evaluated at the end of the prescription period. Results: Seventy-one PrEP-naïve MSM were included in the study, of whom 57 (80%) were retained at the end of 28 weeks. Satisfactory adherence and self-limiting adverse events were reported, while one of the participants contracted HIV. Risk compensation was observed, with an STI incidence of 3.17 per 100 person-years. At the end of the prescription period, a majority (89%) indicated interest in continuing with PrEP. Preference for PrEP was associated with age ≥28 years and peer influence (P=0.04), while stigma was a concern. Price was a deterrent to self-financed PrEP, and only half (51%) considered a monthly cost of ≤HK$500 (US$1=HK$7.8) as reasonable. Conclusions: A partially self-financed mode of PrEP delivery is feasible with good retention in MSM in Hong Kong. © 2019, Hong Kong Academy of Medicine Press. All rights reserved. Article	2019	Lelièvre J.-D.	Preexposure Prophylaxis for Mitigating Risk of HIV Transmission during HIV Cure-Related Clinical Trials with a Treatment Interruption	Journal of Infectious Diseases	-	-	-	221899	10.1093/infdis/jiz036	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069293337&doi=10.1093%2finfdis%2fjiz036&partnerID=40&md5=d719475f42573f20bf3b20f66a429741	Analytical treatment interruption performed during human immunodeficiency virus (HIV) cure-related clinical trials exposes sex partners of participants in these trials to a risk of HIV transmission. Preexposure prophylaxis (PrEP), which emerged in recent years as a key strategy for preventing HIV transmission, is often considered a useful tool to prevent this risk. This article supports offering PrEP to the stable sex partners of participants in these trials but also notes limitations that must be addressed. It concludes that PrEP cannot on its own eliminate the risk of secondary transmission in this context. © 2019 The Author(s).	analytical treatment interruption; HIV; HIV transmission; PrEP	English	United States	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Clinical
Article	2019	Leluţiu-Weinberger C.; Rendina H.J.; Mirandola M.; Gios L.; Folch C.; Rafila A.; Pachankis J.E.	The Role of Gay-Related Stigma in HIV-Risk Behavior Among Sexual Minority Men in Europe	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2306-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054918637&doi=10.1007%2fs10461-018-2306-z&partnerID=40&md5=9e0e579ed8b72b33f742afecbc95a0c2	Sexual orientation stigma stems from discriminatory social contexts and may ultimately impact the behavioral health of stigmatized individuals through stress-related pathways. Sexual minority stigma is of particular concern in Europe given the diversity of social contexts on the continent and sexual minority men's rapidly increasing risk of HIV infection, especially in Central and Eastern Europe, potentially rooted in stigma. This study assesses whether stigma in the ubiquitous social contexts surrounding sexual minority men (e.g., family, workplace, government) may place them at higher risk for HIV contraction across six countries. We utilized a large cross-sectional survey sample of HIV-negative sexual minority men (N = 2087; mean age = 31.6, SD = 9.7) from six European countries to test whether those who reported sexual orientation stigma also engaged in more HIV risk-related behaviors, including condomless sex with casual partners (in the absence of PrEP) and substance use before and during sex. Regression analyses were performed in Mplus. We found that a one standard deviation increase in reported sexual orientation stigma was significantly associated with the following during the last sexual encounter: a 19% increase in odds of sex under the influence of alcohol, 27% increase in odds of sex under the influence of cannabis, 49% increase in odds of sex under the influence of illicit drugs, an 11% increase in odds of condomless sex with casual partners in the past 6 months, and a 26% increase in odds of knowing where to receive an HIV test. Sexual minority men who reported perceiving greater sexual orientation-related stigma within their ubiquitous social contexts were significantly more likely to report sexual risk and alcohol and drug use during their last sexual encounter, yet reported more knowledge of preventive services. Contextual stigma might serve as a precursor to behavioral risks of HIV infection, generating maladaptive stress responses capable of being modified through individually-focused interventions. Structural interventions are also needed to ultimately reduce stigma at its source. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Leporati, Anita; Gupta, Suresh; Bolotin, Elijah; Castillo, Gerardo; Alfaro, Joshua; Gottikh, Marina B; Bogdanov, Alexei A	Antiretroviral Hydrophobic Core Graft-Copolymer Nanoparticles: The Effectiveness against Mutant HIV-1 Strains and in Vivo Distribution after Topical Application.	Pharmaceutical Research	-	-	-	1573-904X	10.1007/s11095-019-2604-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6822620	PURPOSE: Developing and testing of microbicides for pre-exposure prophylaxis and post-exposure protection from HIV are on the list of major HIV/AIDS research priorities. To improve solubility and bioavailability of highly potent anti-retroviral drugs, we explored the use of a nanoparticle (NP) for formulating a combination of two water-insoluble HIV inhibitors. METHODS: The combination of a non-nucleoside HIV reverse transcriptase inhibitor (NNRTI), Efavirenz (EFV), and an inhibitor of HIV integrase, Elvitegravir (ELV) was stabilized with a graft copolymer of methoxypolyethylene glycol-polylysine with a hydrophobic core (HC) composed of fatty acids (HC-PGC). Formulations were tested in TZM-bl cells infected either with wild-type HIV-1IIIB, or drug-resistant HIV-1 strains. In vivo testing of double-labeled NP formulations was performed in female rats after a topical intravaginal administration using SPECT/CT imaging and fluorescence microscopy. RESULTS: We observed a formation of stable 23-30 nm NP with very low cytotoxicity when EFV and ELV were combined with HC-PGC at a 1:10 weight ratio. For NP containing ELV and EFV (at 1:1 by weight) we observed a remarkable improvement of EC50 of EFV by 20 times in the case of A17 strain. In vivo imaging and biodistribution showed in vivo presence of NP components at 24 and 48 h after administration, respectively. CONCLUSIONS: insoluble orthogonal inhibitors of HIV-1 life cycle may be formulated into the non-aggregating ultrasmall NP which are highly efficient against NNRTI-resistant HIV-1 variant. Article	2019	Lessard D.; Aslan A.; Zeggagh J.; Morel S.; Michels D.; Lebouché B.	Acceptability of a digital patient notification and linkage-to-care tool for French PrEPers (WeFLASH©): Key stakeholders' perspectives	International journal of STD & AIDS	-	-	-	9564624	10.1177/0956462419878043	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075382697&doi=10.1177%2f0956462419878043&partnerID=40&md5=01692078146cce117fcc03333c88d000	The objective of this study was to describe stakeholders' perspectives on the acceptability of WeFLASH© (AADISS, Paris, France), a digital smartphone sexually transmitted infection (STI) patient notification (PN) tool to be launched among French HIV pre-exposure prophylaxis users (PrEPers). In Paris, Lyon, and Nice, we conducted 2-hour focus group discussions with PrEPers (n = 21) and community mediators (n = 10), and one-on-one interviews with PrEP-prescribing physicians (n = 5) and HIV/STI management decision-makers (n = 4). Recordings were transcribed. The analysis focused on perceived benefits and risks. Concerning benefits, participants mentioned that WeFLASH© could provide: improved PN and STI screening, by refining the notification of anonymous partners; customized linkage-to-care, by providing users with tailored information on care; and transferable epidemiological data, by filling a need for real-time data. Participants anticipated risks for: privacy and confidentiality and suggested specific security settings to protect users' identity; sexual behavior and suggested game-like functions to improve the integration of the tool in sexual contexts; and fairness and emphasized the importance of making WeFLASH© accessible to all men who have sex with men. WeFLASH© could facilitate PN for an increasing proportion of anonymous partners met online, and empower users, including notified partners, on questions of confidentiality and consent, access to STI prevention and screening services, and access to data. © The Author(s) 2019. Article	2019	Li J.; Berg C.J.; Kramer M.R.; Haardörfer R.; Zlotorzynska M.; Sanchez T.H.	An Integrated Examination of County- and Individual-Level Factors in Relation to HIV Pre-exposure Prophylaxis Awareness, Willingness to Use, and Uptake Among Men Who Have Sex with Men in the US	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2334-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056756614&doi=10.1007%2fs10461-018-2334-8&partnerID=40&md5=204815ef68152a676edccefee8a010c3	This study explored the extent to which county- and individual-level factors were associated with awareness, willingness to use, and use of pre-exposure prophylaxis (PrEP) among US men who have sex with men (MSM). We conducted multilevel analyses using a sample of 8338 MSM residing in 1257 US counties drawn from the 2014–2015 American Men's Internet Survey to examine these associations, with focuses on variation in PrEP outcomes across counties and proportion variation explained by county-level factors (HIV prevalence, racial composition, median household income, income inequality, health insurance coverage). Results showed that PrEP awareness varied moderately across counties (intraclass correlation coefficients ICC = 7.7%), willingness to use did not vary; however, the actual use varied substantially (ICC = 20.7%). Half of the variation in awareness and use was explained by county-level factors. Higher median household income was associated with greater likelihood of awareness and use. Higher income inequality was associated with greater likelihood of PrEP awareness. Findings can inform the development of multilevel interventions to address PrEP uptake among MSM and identify communities where structural intervention is most needed. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Theses and Dissertations	2019	Lima Neto, João Marinho de	Riscos, vulnerabilidades e HIV/Aids entre homens que fazem sexo com homens: uma análise verbal	-	-	Pontifícia Universidade Católica de São Paulo	-	NA	NA	https://sapientia.pucsp.br/handle/handle/22411	Statistical data indicate that the majority of cases of HIV infection in Brazil occur among men (over 68%) and are related to homosexual exposure (about 50%), with a significant concentration in the age group 20-29 (over 40%). The pattern is reproduced in the city of São Paulo, where there is an estimate of 85,000 people living with HIV/AIDS, suggesting that prevention campaigns may have become less effective. Therefore, this study conducted a behavioral analysis of discourse (BAD) based on a questionnaire applied to eight men who have sex with men (MSM) aged 20 to 29 years, who attend the district of República Republic, in order to identify possible discursive variables that were socially reinforced. The results indicated a medium-low risk of exposure to HIV for most participants, and discourses that reinforce perception of AIDS as a chronic disease; inconsistent condom use, especially with regular partners; knowledge about PrEP and PEP as preventive methods; and use of apps in search for sexual partnerships. Reinforcing, antecedent and countercontrolling variables may be involved in the maintenance of condomless sex, referred as pleasure, contact, intensity, and freedom, among others. The study also presents a definition of risk based on the concept of operant behavior and concludes that condomless anal intercourse is maintained mainly by reinforcement contingencies, and immediate and potent reinforcers	AIDS (Doença) Comportamento verbal Homossexuais masculinos	Portuguese	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	-	-	Qualitative
Article	2019	Liu A.; Coleman K.; Bojan K.; Serrano P.A.; Oyedele T.; Garcia A.; Enriquez-Bruce E.; Emmanuel P.; Jones J.; Sullivan P.; Hightow-Weidman L.; Buchbinder S.; Scott H.	Developing a mobile app (LYNX) to support linkage to HIV/sexually transmitted infection testing and pre-exposure prophylaxis for young men who have sex with men: Protocol for a randomized controlled trial	JMIR Research Protocols	-	-	-	19290748	10.2196/10659	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067293819&doi=10.2196%2f10659&partnerID=40&md5=db6c072db92daf137cda4b23e724d386	Background: Young men who have sex with men (YMSM) in the United States have among the highest incidence of HIV and sexually transmitted infection (STI) and the lowest uptake of HIV and STI testing and pre-exposure prophylaxis (PrEP). Nearly universal mobile phone ownership among youth provides an opportunity to leverage mobile health apps to increase HIV/STI testing and PrEP uptake among YMSM. Objective: The goals of this project are to develop and refine LYNX, a novel mobile app to support linkage to HIV/STIs testing and PrEP services among YMSM in the United States, and to evaluate the acceptability and feasibility of LYNX in a pilot randomized controlled trial (RCT). Methods: This research protocol will be conducted in 3 phases: an iterative development phase with a series of 3 focus groups among 20 YMSM to refine the LYNX app; an open technical pilot among 15 YMSM to optimize usability of the app; and then a 6-month pilot RCT among 60 HIV-uninfected YMSM at risk for HIV acquisition. Developed using the Information, Motivation, and Behavioral skills theoretical model, the LYNX app includes an electronic diary to track sexual behaviors (information), a personalized risk score to promote accurate risk perception (information/motivation), testing reminders (motivation/behavioral skills), and access to home-based HIV/STI testing options and geospatial-based HIV/STI testing care sites (behavioral skills). Feasibility and acceptability will be assessed through app analytics of usage patterns and acceptability scales administered via computer-assisted self-interview at 3 and 6 months. We will also evaluate preliminary efficacy by comparing the proportion of YMSM who test at least once during the 6-month pilot and the proportion who successfully link to a PrEP provider in the intervention versus control groups. Results: Formative work is currently underway. The LYNX pilot RCT will begin enrollment in October 2018, with study results available in 2019. Conclusions: The LYNX app is one of the first mobile apps designed to increase HIV/STI testing and PrEP uptake among YMSM. As low-perceived risk is a barrier to HIV/STI testing and PrEP use among youth, the personalized risk assessment and interactive sexual diary in LYNX could assist YMSM in better understanding their HIV and STI risk, and encourage them to test for HIV/STIs and initiate PrEP. Coupled with community-based recruitment, this novel mobile app has great potential to reach and engage YMSM not currently involved in care and increase rates of HIV/STI testing and PrEP uptake in this vulnerable population. © Albert Liu, Kenneth Coleman, Kelly Bojan, Pedro Alonso Serrano, Temitope Oyedele, Amayvis Garcia, Elizabeth Enriquez-Bruce, Patricia Emmanuel, Jeb Jones, Patrick Sullivan, Lisa Hightow-Weidman, Susan Buchbinder, Hyman Scott. Article	2019	Liu, Albert Y; Vittinghoff, Eric; von Felten, Patricia; Rivet Amico, K; Anderson, Peter L; Lester, Richard; Andrew, Erin; Estes, Ixchell; Serrano, Pedro; Brothers, Jennifer; Buchbinder, Susan; Hosek, Sybil; Fuchs, Jonathan D	Randomized Controlled Trial of a Mobile Health Intervention to Promote Retention and Adherence to Preexposure Prophylaxis among Young People at Risk for Human Immunodeficiency Virus: The EPIC Study	Clinical Infectious Diseases	-	-	-	10584838	10.1093/cid/ciy810	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066778170&doi=10.1093%2fcid%2fciy810&partnerID=40&md5=b4ac8cae2f8f425b2bc2976d82d2591c	Background: Young men who have sex with men are among the most vulnerable to human immunodeficiency virus (HIV) infection. Although preexposure prophylaxis (PrEP) has demonstrated effectiveness, adherence and retention have been low among youth. Methods: We conducted a randomized controlled trial to evaluate the impact of a youth-tailored, bidirectional text-messaging intervention (PrEPmate) on study retention and PrEP adherence. Young individuals at risk for HIV initiating PrEP within Chicago's safety-net system were randomized 2:1 to receive PrEPmate or standard of care (SoC) for 36 weeks. The primary retention outcome was study-visit completion, and the primary adherence outcome was tenofovir diphosphate (TFV-DP) concentrations ≥700 fmol/punch (consistent with ≥4 doses/week) assessed at 4, 12, 24, and 36 weeks. The impact of PrEPmate on retention and adherence was evaluated using generalized estimating equation logistic models with robust standard errors. Results: From April 2015 to March 2016, 121 participants enrolled (mean age 24; 27% black, 36% Latino). Participants who received PrEPmate were more likely to attend study visits (86% PrEPmate vs. 71% SoC, odds ratio OR = 2.62, 95% confidence interval CI 1.24-5.54) and have TFV-DP levels consistent with ≥4 doses/week (72% PrEPmate vs. 57% SoC, OR = 2.05, 95% CI 1.06-3.94). PrEPmate efficacy did not differ significantly by age, race/ethnicity, education, or insurance. Overall, 88% reported PrEPmate to be very/somewhat helpful, and 92% would recommend PrEPmate to others. Conclusions: An interactive text-messaging intervention had high acceptability and significantly increased study-visit retention and PrEP adherence among young individuals at risk for HIV acquisition. Article	2019	Liu, AY; Norwood, A; Gundacker, H; Carballo-Diéguez, A; Johnson, S; Patterson, K; Bekker, LG; Chariyalertsak, S; Chitwarakorn, A; Gonzales, P; Holtz, TH; Mayer, KH; Zorrilla, C; Buchbinder, S; Piper, JM; Lama, JR; Cranston, RD; Microbicide Trials Network 017	Routine Use of Oral PrEP in a Phase 2 Rectal Microbicide Study of Tenofovir Reduced-Glycerin 1% Gel (MTN-017)	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	10.1097/QAI.0000000000002066	https://pubmed.ncbi.nlm.nih.gov/31299013/	Background: As daily oral preexposure prophylaxis (PrEP) becomes standard for HIV prevention, routine use of PrEP is likely to increase within clinical trials of novel preventive agents. We describe the prevalence and characteristics of participants reporting nonstudy oral PrEP use within Microbicide Trials Network-017 (MTN-017), a phase 2 trial of a rectal microbicide. Setting and Methods: One hundred ninety-five HIV-uninfected men who have sex with men and transgender women were enrolled and followed in MTN-017 across 8 sites in the United States, Thailand, South Africa, and Peru from 2013 to 2015. Nonstudy oral PrEP use was recorded on case report forms and progress notes. Characteristics of PrEP users and non-PrEP users were compared using tests of statistical significance. Results: Overall, 11% of participants reported nonstudy oral PrEP use, all from the San Francisco (SF) site, accounting for 58% (22/38) of participants enrolled in SF. There was a higher median number of sex partners reported in the past 8 weeks before enrollment among oral PrEP users vs. nonusers (7 vs. 2, P = 0.02). Most PrEP users (18/22, 82%) began PrEP treatment during screening/after enrollment, and most (19/22, 86%) decided to continue oral PrEP after study completion. Conclusion: Nonstudy oral PrEP use was high at a single site in SF where community PrEP availability and use was expanding. Investigators should consider the evolving context of nonstudy oral PrEP use across trial sites when designing and interpreting trials of novel biomedical prevention modalities. Article	2019	Liu, SN; Lu, J; Gupta, SK; Desta, Z; Gufford, BT	Effects of probenecid on the pharmacokinetics of tenofovir disoproxil fumarate and emtricitabine for on-demand HIV PrEP	Clinical Pharmacology and Therapeutics	-	-	-	0009-9236	10.1002/(ISSN)1532-6535	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01916952/full	Background: Prevention of HIV transmission is a worldwide imperative. The antiretroviral combination tablet tenofovir disoproxil fumarate (TDF)/emtricitabine (FTC) is highly efficacious in preventing HIV, but adherence is limited by the need for dosing both before after HIV exposure. We hypothesized that probenecid (PRO), an OAT inhibitor, would reduce renal clearance of TDF, an OAT1/3 substrate, and thereby boost its systemic concentrations to allow a single-dose HIV PrEP dosing regimen. Methods: A randomized, cross-over pharmacokinetic study was designed in healthy volunteers (N = 14) to compare PRO-boosted TDF/FTC (treatment group) to current TDF/FTC (control) on-demand HIV PrEP. In the control phase, participants received a 600 mg TDF/400 mg FTC on the Day 1 and then 300 mg TDF/200 mg FTC on Days 2 and 3. In the treatment phase, participants received a 600 mg TDF/400 mg FTC with 2 g of PRO on Day 1 only. After a 6-week washout period, all participants received the opposite phase. Plasma and urine samples were collected to compare the exposure of TDF and FTC with and without PRO. Results: PII-009 Table Conclusion: PRO significantly alters the pharmacokinetics of TDF and FTC. The TDF and PRO interaction is novel based on current knowledge as FTC was supposed to be a substrate of OCTs and PRO does not inhibit these transporters. PRO-boosted TDF/FTC may allow simpler dosing and improved adherence to HIV PrEP.	*Human immunodeficiency virus; Adult; Clinical article; Conference abstract; Controlled study; Drug therapy; Female; Human; Human experiment; Human tissue; Male; Nonhuman; Pharmacokinetics; Plasma; Randomized controlled trial; Renal clearance; Urine sampling; Volunteer	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Lockard A.; Rosenberg E.S.; Sullivan P.S.; Kelley C.F.; Serota D.P.; Rolle C.-P.M.; Luisi N.; Pingel E.; Siegler A.J.	Contrasting self-perceived need and guideline-based indication for HIV pre-exposure prophylaxis among young, black men who have sex with men offered pre-exposure prophylaxis in Atlanta, Georgia	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0135	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062605901&doi=10.1089%2fapc.2018.0135&partnerID=40&md5=a235c153c548e78dea2d3c9471469291	Despite high HIV incidence among young black men who have sex with men (YBMSM), pre-exposure prophylaxis (PrEP) uptake in this group is low. In a cohort of HIV-negative YBMSM in Atlanta, GA, all participants were offered PrEP as standard of care with free clinician visits and laboratory testing. We explored self-perceived need for PrEP among 29 in-depth interview participants by asking about reasons for PrEP uptake or refusal and factors that may lead to future reconsideration. Self-perceived need was compared to US Center for Disease Control and Prevention guidance for clinical PrEP indication using behavioral data and laboratory testing data. Self-perceived need for PrEP consistently underestimated clinical indication, primarily due to optimism for choosing other HIV prevention strategies, such as condom use, abstinence, or monogamy. Many participants cited consistent condom use and lack of sexual activity as reasons for not starting PrEP; however, follow-up survey data frequently demonstrated low condom use and high levels of sexual activity in the period after the interview. Study participants endorsed perceptions that PrEP is only for people with very high levels of sexual activity. Only one participant perceived incident sexually transmitted infection (STI) to be an indication for PrEP, despite the fact that several of the participants had a history of an STI diagnosis. These findings point to an opportunity for clinician intervention at diagnosis. Disconnect between self-perceived and guidance-based PrEP indications, as well as other factors such as medical mistrust or difficulty with access, may contribute to low PrEP uptake among YBMSM. A better understanding of the ways in which these issues manifest may be one tool for clinicians to support PrEP uptake. © Mary Ann Liebert, Inc., publishers 2019. Article	2019	Lockart, Ian; Matthews, Gail V.; Danta, Mark	Sexually transmitted hepatitis C infection: the evolving epidemic in HIV-positive and HIV-negative MSM.	Current Opinion in Infectious Diseases	-	-	-	1473-6527 0951-7375	10.1097/QCO.0000000000000515	https://pubmed.ncbi.nlm.nih.gov/30531370/	PURPOSE OF REVIEW: The scale-up of direct-acting antiviral (DAA) therapy and introduction of preexposure prophylaxis (PrEP) has changed the epidemiology of sexually acquired hepatitis C virus (HCV) amongst HIV-positive and HIV-negative MSM. RECENT FINDINGS: Sexually acquired HCV continues to occur predominantly amongst HIV-positive MSM. Despite an increased uptake of DAA therapy the incidence of acute HCV has not declined consistently amongst HIV-positive MSM, likely a result of high infection and reinfection rates. Increasing cases of sexually acquired HCV have been reported amongst HIV-negative MSM accessing PrEP. Despite a lower prevalence of HCV at baseline, HIV-negative MSM accessing PrEP have an equally high overall incidence of HCV compared with HIV-positive MSM during follow-up. Behavioural factors (high-risk sexual behaviours and sexualized drug use) appear to be driving this HCV epidemic amongst MSM and effective behavioural interventions and early identification of reinfections are essential to control the HCV epidemic amongst MSM. SUMMARY: An improved understanding of the epidemiology of sexually acquired HCV will allow implementation of more effective public health interventions to control the transmission of HCV amongst HIV-positive and HIV-negative MSM.	*Homosexuality, Male; Humans; Male; Antiviral Agents/therapeutic use; HIV Infections/*complications; *Epidemics; Hepatitis C/*complications/*transmission; Sexually Transmitted Diseases, Viral	English	United Kingdom	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review
Article	2019	Logan L.; Fakoya I.; Howarth A.; Murphy G.; Johnson A.M.; Rodger A.J.; Burns F.; Nardone A.	Combination prevention and HIV: A cross-sectional community survey of gay and bisexual men in London, october to december 2016	Eurosurveillance	-	-	-	1025496X	10.2807/1560-7917.ES.2019.24.25.1800312	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068872255&doi=10.2807%2f1560-7917.ES.2019.24.25.1800312&partnerID=40&md5=533e5cbbfdf3cc72fe731cbb5943d3e3	Background: Men who have sex with men (MSM) are at risk of HIV and are an important population to monitor and ameliorate combination prevention efforts. Aim: To estimate HIV prevalence and identify factors associated with frequent HIV testing (= 2 HIV tests in the last year) and pre-exposure prophylaxis (PrEP) use among MSM in London. Methods: For this cross-sectional study, MSM recruited from 22 social venues provided oral-fluid samples for anonymous HIV antibody (Ab) testing and completed a questionnaire. Factors associated with frequent HIV testing and PrEP use were identified through logistic regression. Results: Of 767 men recruited, 545 provided an eligible oral specimen. Among these, 38 MSM (7.0%) were anti-HIV positive including five (13.2%; 5/38) who reported their status as negative. Condomless anal sex within the previous 3 months was reported by 60.1% (412/685) men. Frequent HIV testing was associated with, in the past year, a reported sexually transmitted infection (adjusted odds ratio (AOR): 5.05; 95% confidence interval (CI): 2.66-9.58) or = 2 casual condomless partners (AOR 2-4 partners: 3.65 (95% CI: 1.87-7.10); AOR 5-10 partners: 3.34 (95% CI: 1.32-8.49). Age = 35 years was related to less frequent HIV testing (AOR 35-44 years: 0.34 (95% CI: 0.16-0.72); AOR = 45 years: 0.29 (95% CI: 0.12-0.69). PrEP use in the past year was reported by 6.2% (46/744) of MSM and associated with = 2 casual condomless sex partners (AOR: 2.86; 95% CI: 1.17-6.98) or chemsex (AOR: 2.31; 95% CI: 1.09-4.91). Conclusion: This bio-behavioural study of MSM found high rates of behaviours associated with increased risk of HIV transmission. Combination prevention, including frequent HIV testing and use of PrEP, remains crucial in London. © 2019, European Centre for Disease Prevention and Control (ECDC). All rights reserved. Article	2019	Loriato, Cécile	Les figures sociales de l'usager de la PrEP au prisme de l'analyse de témoignages en ligne	Revista Brasileira de Pesquisa (Auto)Biográfica	-	-	-	2525-426X	https://doi.org/10.31892/rbpab2525-426X.2019.v4.n11.p463-481	https://revistas.uneb.br/index.php/rbpab/article/view/5965	En prenant pour objet d'analyse le témoignage en ligne, cette contribution propose d'éclairer les figures sociales de l'usager de la PrEP, nouvel outil de prévention du VIH, afin de questionner les représentations de la sexualité gay, telles qu'elles apparaissent dans les interactions entre les participants à un groupe de discussion Facebook dédié à la PrEP. Les témoignages ont été analysés dans une perspective diachronique dans le cadre d'une ethnographie en ligne pour laquelle ont été mobilisées plusieurs méthodes : l'observation et l'analyse du dispositif sociotechnique, des entretiens semi-directifs, une analyse qualitative des interactions, ainsi qu'une analyse quantitative de la participation. L'analyse des récits de soi, en tant qu'objets contraints par un dispositif sociotechnique institutionnalisé et mouvants dans l'interaction, a permis de mettre en évidence des figures sociales de l'usager de la PrEP, qui se constituent par le croisement de la nature du comportement (conforme ou non-conforme à la norme) avec les réactions qu'il suscite (c'est-à-dire en fonction de la perception qu'en ont les participants au groupe). Ainsi, ont émergé la figure du "prepeur raisonnable", celle du "bon prepeur" en opposition à la figure du "mauvais prepeur", puis celle du "prepeur responsable". Article	2019	Luehring-Jones, Peter; Palfai, Tibor P; Tahaney, Kelli D; Maisto, Stephen A; Simons, Jeffrey	Pre-Exposure Prophylaxis (PrEP) Use is Associated With Health Risk Behaviors Among Moderate- and Heavy-Drinking MSM	AIDS Education and Prevention	-	-	-	08999546	10.1521/aeap.2019.31.5.452	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-prep-use-is-associated/docview/2300159929/se-2?accountid=8113	Among men who have sex with men (MSM), acute alcohol consumption is associated with higher rates of condomless anal intercourse, which is linked with a greater likelihood of exposure to HIV and other sexually transmitted infections. While pre-exposure prophylaxis (PrEP) to prevent HIV infection has become more widespread in this population in recent years, so too have concerns that PrEP uptake may be associated with health risk behaviors. This study investigated differences in sexual behaviors and drug use habits between PrEP users and nonusers in a sample of moderate- and heavy-drinking MSM. Results indicated that PrEP use was associated with riskier sexual practices, weaker self-regulatory cognitions related to condom use, and more frequent illicit drug use. These findings suggest that moderate-and heavy-drinking MSM who use PrEP may comprise a unique risk group that could benefit from targeted counseling or other interventions to reduce their risk of negative health consequences. Article	2019	Luo, T.; Gulisiya, Hailili; Chen, Z.; Tuo, X. Q.; Cai, A. J.; Zhang, Z.; Dai, J. H.	The confidence affects willingness to use pre-exposure prophylaxis among MSM, based on Path analysis.	Zhonghua Liu Xing Bing Xue Za Zhi (Chinese Journal of Epidemiology)	-	-	-	0254-6450	10.3760/cma.j.issn.0254-6450.2019.10.020	https://pubmed.ncbi.nlm.nih.gov/31658531/	Objective: To analyze the influence of the confidence to pre-exposure prophylaxis (PrEP) on the willingness to use PrEP in men who have sex with men (MSM) by using the path analysis model based on structural equation model approach. Methods: A total of 550 MSM were recruited in Urumqi by snowball method and a questionnaire survey was conducted among them. According to the professional knowledge and analysis results of the confidence and willingness to use PrEP, structural equation model (SEM) analysis method was used to construct a path analysis model. Results: A total of 513 MSM participated in the survey. The modified path equation model was well fitted, with the modified fitting index as: GFI=0.993, RMSEA<0.001, and AGFI=0.984. The confidence to PrEP had direct influence on the willingness; the degree of influence from sex partners, the attitude of sex partner to PrEP and the positive emotions not only had direct effects on willingness of PrEP use, but also had indirect effects on willingness of PrEP use by affecting the confidence to it; the role in sexual behavior, AIDS severity, HIV positive behavior had direct effects on willingness of PrEP use. The proportion of HIV infection in the population had no direct effects on willingness of PrEP use, but had indirect effects on willingness of PrEP use by affecting the confidence to it. Conclusions: The confidence to PrEP had influence on willingness of PrEP use in MSM, therefore targeted activities can be conducted to improve the confidence and willingness of MSM in taking the PrEP and reducing the risk of HIV infection in MSM. Compared with the traditional multiple regression analysis, the path analysis using the structural equation model could better reveal the mediating effect between the independent variables and dependent variables. Article	2019	Luz, Paula M; Veloso, Valdilea G; Grinsztejn, Beatriz	The HIV epidemic in Latin America: accomplishments and challenges on treatment and prevention.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0000000000000564	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6688714	PURPOSE OF REVIEW: To describe how countries in Latin America and the Caribbean are (or are not) meeting 2016 WHO guidelines on the use of antiretroviral drugs for treating and preventing HIV infection, that is, their progress on the adoption of 'Treat All' and of preexposure prophylaxis (PrEP) as an additional prevention tool for people at substantial risk of HIV infection. RECENT FINDINGS: The HIV epidemic in the region continues largely concentrated in vulnerable populations with MSM and transgender women (TGW) suffering the highest burden. On treatment, the challenges of late initiation as well as suboptimal adherence persist. On prevention, recent studies on PrEP in key populations show promising results, meanwhile PrEP implementation projects as well as actual PrEP adoption by national health systems is expanding. A glimpse of real-world PrEP uptake is shown through Brazil's first-year experience of offering PrEP in multiple cities in all regions of the country. SUMMARY: In conclusion, accomplishments have been made though challenges for fully addressing the HIV epidemic persist. The impact of both treatment and PrEP will be limited by the availability and prompt use of all services, including HIV testing.	epidemiology, HIV/AIDS, Latin America, preexposure prophylaxis, treatment as prevention	English	United Kingdom	Western and Central Europe and North America	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Review
Article	2019	M Reuel Friedman; Sang, Jordan M; Bukowski, Leigh A; Chandler, Cristian J; Egan, James E; Eaton, Lisa A; Matthews, Derrick D; Ho, Ken; Raymond, Henry F; Stall, Ron	Prevalence and Correlates of PrEP Awareness and Use Among Black Men Who Have Sex with Men and Women (MSMW) in the United States	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02446-3	https://www.proquest.com/scholarly-journals/prevalence-correlates-prep-awareness-use-among/docview/2186929131/se-2?accountid=8113	Men who have sex with men and women (MSMW), including those who are Black, experience HIV-related disparities compared to men who have sex with men only (MSMO). Few studies have assessed the prevalence and correlates of pre-exposure prophylaxis (PrEP) awareness and use among Black MSMW. We recruited MSM ≥ 18 attending Black Gay Pride events between 2014–2017. We conducted multivariable logistic regressions to assess differences in PrEP awareness and use among HIV-negative Black MSMW (n = 2398) and within Black MSMW (n = 419). MSMW were less likely than MSMO to report PrEP awareness (p < 0.001). Among PrEP-aware MSM, MSMW were more likely than MSMO to report PrEP use (p < 0.05). MSMW receiving gay community support were more likely to be PrEP-aware (p < 0.01). MSMW reporting any past-year STI diagnoses were more likely to report PrEP use (p < 0.01). Findings suggest that PrEP awareness campaigns tailored for Black MSMW, concomitant with STI-to-PrEP interventions, will facilitate greater PrEP uptake in this population.Resumo alternativo:Los hombres que tienen sexo con hombres y mujeres (MSMW, siglas en Inglés), incluyendo los que son Negros, experimentan disparidades relacionadas con el VIH en comparación con los hombres que tienen sexo con hombres solamente (MSMO, siglas en Inglés). Pocos estudios han evaluado la prevalencia y los correlatos de conocimiento y uso de la profilaxis pre-exposición (PrEP, siglas en Inglés) entre los MSMW Negros. Reclutamos a hombres que tienen sexo con hombres (MSM, siglas en Inglés) ≥18 que asistieron a eventos del Orgullo Gay Negro entre 2014—2017. Realizamos regresiones logísticas multivariables para evaluar las diferencias en el conocimiento y uso de PrEP entre los MSM Negros VIH-negativos (n=2398) y dentro de los MSMW Negros (n=419). Los MSMW fueron menos probables que los MSMO a reportar sobre el conocimiento de la PrEP (p<.001). Entre los MSM con reconocimiento de PrEP, los MSMW fueron más probables que los MSMO a reportar el uso de PrEP (p<.05). Los MSMW que recibieron apoyo de la comunidad gay tenían más probabilidades de ser conscientes de la PrEP (p<.01). Los MSMW que informaron sobre cualquier diagnóstico de ITS el año anterior tenían más probabilidades de informar el uso de PrEP (p <.01). Los hallazgos sugieren que las campañas de concientización sobre la PrEP adaptadas para los MSMW Negros, concomitantes con las intervenciones de ITS-a-PrEP, facilitarán una mayor captación de PrEP en esta población. Article	2019	Mabire Xavier; Puppo Costanza; Morel Stéphane; Mora, Marion; Rojas Castro Daniela; Chas, Julie; Cua, Eric; Pintado, Claire; Suzan-Monti, Marie; Spire Bruno; Molina, Jean-Michel; Préau Marie	Pleasure and PrEP: Pleasure-Seeking Plays a Role in Prevention Choices and Could Lead to PrEP Initiation	American Journal of Men's Health	-	-	-	15579883	10.1177/1557988319827396	https://www.proquest.com/scholarly-journals/pleasure-prep-seeking-plays-role-prevention/docview/2313774969/se-2?accountid=8113	Pleasure-seeking plays a role in prevention (means choices and use), and in the sexual quality of life of men who have sex with men (MSM). Since HIV is a major threat to MSM health, new means of prevention, like pre-exposure prophylaxis (PrEP), must meet the needs of MSM to be fully efficient. Using a psychosocial approach, we examined how pleasure-seeking plays a role in participation of MSM in "ANRS-IPERGAY," a community-based trial on sexual health which included sexual on-demand PrEP. Thirteen semistructured collective interviews were conducted with 45 participants. First, we analyzed participants' search for new prevention means due to previous failures in condom use. We found that participants perceived condoms as a barrier—both materially and symbolically—to pleasure and desire, causing anxiety and stress considering sexual intercourse. Second, we explored representations and attitudes concerning pleasure within the context of PrEP. We found that PrEP allowed participants to freely choose their desired sexual positions and to better enjoy intimacy. Third, we studied the sexual quality of life for PrEP users in ANRS-IPERGAY and found an improvement. Thanks to the community-based design of the trial, this new prevention tool became a means to develop agency and empowerment for participants, not only in negotiating individual prevention but also in opposing the normative and stigmatizing discourse on sexuality and HIV. In conclusion, pleasure-seeking appears to be an essential element of sexual fulfillment that needs to be integrated as a positive notion in the study of HIV prevention. Theses and Dissertations	2019	Macgregor, Louis W.	Eliminating hepatitis C in the UK among men who have sex with men during the era of pre-exposure prophylaxis	-	-	University of Bristol	-	NA	NA	https://research-information.bris.ac.uk/en/studentTheses/eliminating-hepatitis-c-in-the-uk-among-men-who-have-sex-with-men	Globally, over 70 million people are infected with hepatitis C virus (HCV), leading to an estimated 400,000 deaths per year. Co-infection with HIV poses even greater risks due to accelerated rates of HCV related liver damage. Within men who have sex with men (MSM) HCV is more concentrated in those with HIV: in the UK 10% of MSM with HIV are co-infected, whereas HCV prevalence is 1% in HIV negative MSM. Yet reasons for this disparity are not fully clear. To tackle this global epidemic, in 2015 the World Health Organisation (WHO) and the UK National Health Service (NHS) announced their targets to eliminate HCV; by reducing HCV incidence by 90% by 2030 and 2025 respectively. In this thesis we utilise a compartmental transmission model, parameterized with UK behavioural data and biological factors associated with HIV and HCV co-infection to explore the feasibility of these HCV elimination targets and determine the key factors which may influence their success. This analysis was undertaken accounting for the changing landscape of (1) HCV treatment and prevention initiatives, such as the scale up of direct acting antivirals (DAAs) and (2) the evolution of HIV prevention through the introduction of pre-exposure prophylaxis (PrEP). PrEP use offers individuals an 86% reduced risk of HIV acquisition, but with PrEP's growing uptake, data is increasingly pointing to the rise of risk compensatory behaviours, including reducing condom usage or changes in sexual mixing. Our results indicate behavioural and not biological factors are largely accountable for the pattern of HCV infection; specifically preferential mixing by HIV status and heterogeneity in the number of sexual partners between MSM. We projected that HCV elimination in UK MSM is possible by both 2030 and 2025, requiring enhanced HCV screening in all MSM and faster initiation of treatment than in the pre-DAA era. Furthermore, by incorporating this extra screening into routine sexual health appointments, our proposed elimination strategies, for both the 2025 and 2030 targets, are also cost-effective at the willingness to pay threshold of < £20,000 per quality adjusted life-year (QALY) set by the NHS. In conclusion, HCV elimination within UK MSM is possible whilst being cost-effective, but requires a scale up of HCV screening over all MSM, not just those with HIV co-infection. It is also important to mitigate risk compensatory behaviours associated with PrEP use, as our projections have shown these behaviours to be both drivers of the UK HCV epidemic pattern in MSM, as well as highly influential to the overall cost-effectiveness of implementing our HCV elimination strategies. Article	2019	Magno L.; Dourado I.; Sutten Coats C.; Wilhite D.; da Silva L.A.V.; Oni-Orisan O.; Brown J.; Soares F.; Kerr L.; Ransome Y.; Chan P.A.; Nunn A.	Knowledge and willingness to use pre-exposure prophylaxis among men who have sex with men in Northeastern Brazil	Global Public Health	-	-	-	17441692	10.1080/17441692.2019.1571090	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061045003&doi=10.1080%2f17441692.2019.1571090&partnerID=40&md5=5332eda1c60b7f6a49860ade01b41a5c	Few studies evaluate knowledge and willingness to use pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) in middle-income countries. Brazil added PrEP to public drug formularies in December 2017, but little is known about local knowledge and attitudes about PrEP among MSM outside metropolitan areas in Southern Brazil. The cross-sectional HIV Surveillance Survey Project in Brazil estimates HIV and STD prevalence among MSM in 12 state capitals. Among 32 participants at the Salvador, Bahia study site, we used qualitative interviews to assess knowledge, willingness, and barriers to PrEP use among MSM; few MSM had previous knowledge of PrEP and were willing to use PrEP. Clinical, behavioural, social, and structural factors influencing participants' knowledge and willingness to take PrEP included concerns about efficacy and side effects, access to culturally congruent services for MSM, and stigma. Some participants reported that learning about PrEP online positively influenced their willingness to use PrEP. Participants' opinions about PrEP's contribution to risk compensation varied. Interventions to provide culturally congruent care and destigmatise PrEP for MSM at high risk for HIV acquisition, particularly those conducted collaboratively with Brazil's civil society movement, may enhance the public health effort to expand access to PrEP in Brazil. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group. Article	2019	Mahroum, Naim; Bragazzi, Nicola Luigi; Brigo, Francesco; Waknin, Roy; Sharif, Kassem; Mahagna, Hussein; Amital, Howard; Watad, Abdulla	Capturing public interest toward new tools for controlling human immunodeficiency virus (HIV) infection exploiting data from Google Trends.	Health Informatics Journal	-	-	-	1741-2811 1460-4582	10.1177/1460458218766573	https://pubmed.ncbi.nlm.nih.gov/29638172/	Human immunodeficiency virus vaccination and pre-exposure prophylaxis represent two different emerging preventive tools. Google Trends was used to assess the public interest toward these tools in terms of digital activities. Worldwide web searches concerning the human immunodeficiency virus represented 0.34 percent, 0.03 percent, and 46.97 percent of human immunodeficiency virus, acquired immune deficiency syndrome, and human immunodeficiency virus/acquired immune deficiency syndrome treatment-related Google Trends queries, respectively. Concerning temporal trends, digital activities were shown to increase from 0 percent as of 1 January 2004 percent to 46 percent as of 8 October 2017 with two spikes observed in May and July 2012, coinciding with the US Food and Drug Administration approval. Bursts in search number and volume were noticed as human immunodeficiency virus vaccine trials emerged. This search topic has decreased in the past decade in parallel to the increase in Truvada-related topics. Concentrated searches were noticed among African countries with high human immunodeficiency virus/acquired immune deficiency syndrome prevalence. Stakeholders should take advantage of public interest especially in preventive medicine in high disease burden countries. Theses and Dissertations	2019	MAIA, ELIZABETE BATISTA REZENDE	ACEITABILIDADE À PROFILAXIA PRÉ-EXPOSIÇÃO AO HIV PELAS TRAVESTIS E PELAS MULHERES TRANSEXUAIS: UMA REVISÃO SISTEMÁTICA Rio	-	-	UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO	-	-	NA	https://sucupira.capes.gov.br/sucupira/public/consultas/coleta/trabalhoConclusao/viewTrabalhoConclusao.jsf?popup=true&id_trabalho=8270324	A profilaxia pré-exposição ao HIV (PrEP) consiste no uso diário dos antirretrovirais (ARV) tenofovir e emtricitabina por indivíduo não infectado pelo HIV, sob risco de adquirir a infecção. Um dos alvos prioritários são as travestis e as mulheres transexuais. O sucesso da PrEP depende do interesse delas em usar de forma regular os ARV. Objetivo: conhecer a aceitabilidade à PrEP pelas travestis e mulheres transexuais descrita na literatura. Metodologia: revisão sistemática. Os descritores utilizados foram "pessoas transgênero", transexualismo, "profilaxia pré-exposição", "combinação emtricitabina e tenofovir", HIV, "aceitação pelo paciente de cuidados de saúde" (em português, inglês e espanhol). Resultados: 802 artigos foram recuperados. Após aplicação dos critérios de elegibilidade, incluíram-se 14. Todos foram publicados em inglês e provenientes dos continentes Americano, Africano e Asiático. A faixa etária predominante foi de 18 a 35 anos de idade e a escolaridade acima de 8 anos. 52% das participantes relataram sexo comercial, 59% uso do preservativo com parceiro eventual ou comercial e 52% uso de hormônios femininos. A aceitabilidade à PrEP concentrou-se entre 60 e 80%. Fatores associados: estigma pela utilização de ARV, preocupação com efeitos colaterais e interação hormonal, dificuldade de acesso aos serviços de saúde e não percepção de risco de adquirir o HIV. Conclusão: a aceitabilidade à PrEP pelas travestis e mulheres transexuais sofre influência de múltiplos fatores. Sugere-se publicidade que valorize suas preocupações e vulnerabilidades, discussões sobre gênero e sexualidade nas salas de aula e cursos de extensão universitária aos profissionais formados. Article	2019	Maier M.M.; Gylys-Colwell I.; Lowy E.; Van Epps P.; Ohl M.; Chartier M.; Beste L.A.	Health Care Facility Characteristics are Associated with Variation in Human Immunodeficiency Virus Pre-exposure Prophylaxis Initiation in Veteran's Health Administration	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2360-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058616455&doi=10.1007%2fs10461-018-2360-6&partnerID=40&md5=ccd4303538091434e9d8038daab19eea	To quantify health care facility-level variation in pre-exposure prophylaxis (PrEP) use in the Veteran's Health Administration (VHA); to identify facility characteristics associated with PrEP use. Retrospective analysis of the health care facility-level rate of PrEP initiation in VHA through June 30, 2017. Standardized PrEP initiation rates were used to rank facilities. Characteristics of facilities, prescribers, and PrEP recipients were examined within quartiles. Multiple linear regression was used to identify associations between facility characteristics and PrEP use. We identified 1600 PrEP recipients. Mean PrEP initiation rate was 20.0/100,000 (SD 22.8), ranging from 3.0/100,000 (SD 2.0) in the lowest quartile to 48.1/100,000 (SD 29.1) in the highest. PrEP prescribing was positively associated with proportions of urban dwellers and individuals < 45, tertiary care status, and location. Variability in PrEP uptake across a national health care system highlights opportunities to expand access in non-tertiary care facilities and underserved areas. © 2018, This is a U.S. Government work and not under copyright protection in the US; foreign copyright protection may apply. Article	2019	Mallayasamy S.; Chaturvedula A.; Fossler M.J.; Sale M.; Goti V.; Bumpus N.N.; Marzinke M.A.; Hendrix C.W.; Haberer J.E.	Tenofovir plasma concentration from preexposure prophylaxis at the time of potential HIV exposure: A population pharmacokinetic modeling and simulation study involving serodiscordant couples in east Africa	Antimicrobial Agents and Chemotherapy	-	-	-	664804	10.1128/AAC.00446-19	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070658182&doi=10.1128%2fAAC.00446-19&partnerID=40&md5=148aa22b1077692b06b7985d32454a8e	The Partners Demonstration Project was a prospective, open-label, implementation science-driven study of preexposure prophylaxis (PrEP) among heterosexual HIV serodiscordant couples in Kenya and Uganda. Adherence data were collected using the Medication Event Monitoring System (MEMS), and time of sexual activity was collected using the mobile phone short message service (SMS). Two plasma samples were collected at a single study visit. We integrated adherence, pharmacokinetics, and SMS data using a population pharmacokinetic (PopPK) model to simulate tenofovir plasma concentrations from PrEP at the time of sexual activity. In the first stage of this analysis, we used data from the current study to update a prior PopPK model of tenofovir (TFV) developed with data from the Partners PrEP Study (a phase III clinical trial). The second stage involved simulating plasma concentrations at the time of sexual activity using empirical Bayes estimates (EBEs) derived from the final model. In addition, EBEs from a previously published parent metabolite model of TFV (MTN-001, an open-label 3-way crossover study in healthy women) was used to simulate tenofovir diphosphate (TFV-DP) concentrations. We estimated percent PrEP "coverage" as the number of reported sexual events during which simulated concentrations were above an a priori threshold associated with a high degree of protection from HIV infection: Plasma TFV of >40 ng/ml and peripheral blood mononuclear cell (PBMC) TFV-DP concentration of >36 fmol/million cells. The levels of coverage were 72% for TFV and 81% for TFV-DP. These levels are consistent with a high degree of protection against HIV acquisition in this study of a pragmatic delivery model for antiretroviral-based HIV prevention. © 2019 American Society for Microbiology. Article	2019	Mallayasamy S.; Chaturvedula A.; Fossler M.J.; Sale M.E.; Hendrix C.W.; Haberer J.E.	Assessment of Demographic and Socio-Behavioral Factors on Adherence to HIV Pre-Exposure Prophylaxis Using a Markov Modeling Approach	Frontiers in Pharmacology	-	-	-	16639812	10.3389/fphar.2019.00785	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85093363438&doi=10.3389%2ffphar.2019.00785&partnerID=40&md5=b5851b9dbce83a84f466e5a2db58f36c	Purpose: Adherence is important for the effectiveness of human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP). The objective of the current work is to assess the impact of multiple demographic and socio-behavioral factors on the adherence to tenofovir-based PrEP among HIV serodiscordant couples in East Africa using Markov mixed-effects modeling approach. Methods: The Partners Demonstration Project was a prospective, open-label, implementation science-driven study of HIV PrEP among heterosexual HIV serodiscordant couples in Kenya and Uganda. The uninfected partner received oral PrEP according to the "bridge to antiretroviral therapy ART" strategy (i.e., until the infected partner had been on ART for ≥6 months). Adherence was monitored electronically; demographic and socio-behavioral data were collected during study visits. Analyzed data reflect 12 months of follow-up per participant. A two-state, first-order, discrete time Markov model was developed with longitudinal adherence data characterized by "dose taking (1)" and "dose missing (0)." Covariate effects were linearly added in the logit domain of transition probability parameters (P01 and P10) in the model. The full covariate model was initially developed, followed by backward elimination process to reduce the model. All significant covariates reported by a prior primary statistical analysis of the same data were included in the full covariate model. Results: The model included data from 920 participants, who were predominantly male (65%). Significant covariates associated with higher adherence were 25 years or older odds ratio (OR) for P10, 0.61, female sex (OR for P10, 0.67), participant wanting the relationship with the partner to succeed (OR for P10, 0.79; OR for P01, 1.45), and sex with partner either with 100% or <100% condom use compared to those reported no sex (OR for P10, 0.84; OR for P01, 1.21). Significant covariates associated with lower adherence were partner on ART >6 months (OR for P01, 0.86; OR for P10, 1.34), subject in the study for >6 months (OR for P01, 0.8; OR for P10, 1.25), and problematic alcohol use (OR for P01, 0.63; OR for P10, 1.16). Conclusion: The developed Markov model provides a mechanistic understanding of relationship between demographic, socio-behavioral covariates, and PrEP adherence, by indicating the pattern of adherence influenced by each factor over time. Such data can be used for further intervention development to promote PrEP adherence. © Copyright © 2019 Mallayasamy, Chaturvedula, Fossler, Sale, Hendrix and Haberer.	adherence; covariates; HIV; Markov model; preexposure prophylaxis	English	Switzerland	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Mandal S.; Kang G.; Prathipati P.K.; Zhou Y.; Fan W.; Li Q.; Destache C.J.	Nanoencapsulation introduces long-acting phenomenon to tenofovir alafenamide and emtricitabine drug combination: A comparative pre-exposure prophylaxis efficacy study against HIV-1 vaginal transmission	Journal of Controlled Release	-	-	-	1683659	10.1016/j.jconrel.2018.12.027	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058950216&doi=10.1016%2fj.jconrel.2018.12.027&partnerID=40&md5=73d84ce4fc76b06a4fbeccf0c84fcb73	Daily oral antiretroviral (ARV) drugs for pre-exposure prophylaxis (PrEP) has proven efficacy for diverse groups of high-risk individuals. However, daily dosing regimen has augmented non-adherence. These experiments comparatively investigated the long-acting (LA) PrEP potency of subcutaneous (SubQ) administrated tenofovir alafenamide (TAF) and emtricitabine (FTC) loaded nanoparticles (NPs) to solution in humanized (hu) mice. TAF + FTC NPs and TAF + FTC solution (each drug at 200 mg/kg) were administered to hu-CD34-NSG mice (n = 3/time point) for plasma and tissue pharmacokinetic parameter estimation using LC-MS/MS. NP enhanced tissue ARV assimilation compared to plasma. The same dose was administered for PrEP efficacy in HIV-1 challenged hu-BLT mice (n = 5/group). The hu-BLT mice were vaginally challenged with a transmission-founder (T/F) virus at 5 × 105 TCID50 inoculation, on day 4, 7 and 14 post-SubQ treatments (PT) and were compared to infected-untreated-control hu-BLT mice. By 21 days PT, 100% TAF + FTC solution-treated and control-untreated mice were infected. However, TAF + FTC NPs resulted in significant (p =.0002) protection from HIV-1 (day 4: 80%, day 7 and 14: 60%, respectively) compared to control mice. This proof-of-concept study demonstrated detectable TAF/FTC vaginal levels among TAF + FTC NP-treated hu-BLT mice correlating with prolonged PrEP efficacy, thus establishing long-acting TAF + FTC NPs as a potential PrEP modality. © 2018	Emtricitabine; HIV-1 prevention; Long-acting; Nanoparticles; Tenofovir alafenamide	English	Netherlands	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Factors Associated with Sex-Related Pre-exposure Prophylaxis Adherence among Men Who Have Sex with Men in New York City in HPTN 067	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001965	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062857874&doi=10.1097%2fQAI.0000000000001965&partnerID=40&md5=f5a13de317f2d780356f16320ab7ae16	Background:HPTN 067 assessed the feasibility of daily and non-daily dosing of open-label emtricitabine/tenofovir disoproxil fumarate (FTC/TDF)-based pre-exposure prophylaxis (PrEP).Methods:Factors associated with sex-related PrEP adherence were assessed among men who have sex with men (MSM) randomized to one of 3 PrEP dosing arms in HPTN 067 in New York City. Sex-related PrEP adherence was defined per protocol as at least 1 PrEP tablet taken within 4 days pre-sex and at least 1 additional PrEP tablet taken within 24 hours post-sex, assessed via electronic drug monitoring and weekly interviews. Demographic data and behavioral measures were evaluated for association with sex-related PrEP adherence. Logistic regression for clustered data was used to estimate the unadjusted and adjusted odds ratios.Results:Of 176 randomized MSM participants, 59% were Black, 10% White, 25% Hispanic, and 6% other; median age was 31 years. In the multivariable analyses, higher sex-related PrEP adherence was significantly associated with daily dosing arm, older age, employment, and higher PrEP adherence behavioral skills. Lower sex-related PrEP adherence was significantly associated with identifying as Black or Hispanic (compared with White), opiate use, and reporting "I forgot" as an adherence barrier.Conclusions:This analysis identified populations of MSM who might benefit from additional support to optimize PrEP adherence, including those who are younger, unemployed, or opiate users. MSM with lower PrEP behavioral skills may benefit from targeted interventions. Further study is needed to assess racial and ethnic disparities in PrEP adherence, which may reflect broader social and economic inequalities not captured in this study. © 2019 Wolters Kluwer Health, Inc.	adherence; Black MSM; Hispanic; HIV prevention; MSM; PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Mansergh G.; Baack B.N.; Holman J.; Mimiaga M.J.; Landers S.; Herbst J.H.	Quantitative Assessment of Brief Messages about HIV Pre-exposure Prophylaxis among HIV-Infected and HIV-Uninfected Black/African American and Hispanic/Latino MSM	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001869	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058436259&doi=10.1097%2fQAI.0000000000001869&partnerID=40&md5=1557e4130f96018a84b03fd7827c9658	Background:HIV pre-exposure prophylaxis (PrEP) is efficacious; however, many men who have sex with men (MSM) (especially racial/ethnic minorities) are still unaware of and underuse it.Methods:The 2014 Messages4Men Study focuses on black and Hispanic/Latino MSM in Chicago, Fort Lauderdale, and Kansas City (n = 937). Brief (2-3 sentence) messages were tested: a PrEP message tailored for HIV-uninfected MSM (n = 607) and a PrEP message tailored for HIV-infected MSM (n = 330). After reading the message, participants reported believability and awareness, and intent to use PrEP and condoms. Analyses consisted of bivariate and multivariable approaches.Results:Among HIV-uninfected MSM, black (vs Hispanic/Latino) MSM indicated greater intentions to use PrEP (81% vs 70% respectively, P < 0.05); 72% overall had similar intentions to use condoms after hearing a PrEP message. PrEP information was new (63%) and believable (80%), with no racial/ethnic differences (P > 0.05). In multivariable analysis, men who reported recent condomless anal sex were less likely to report that the PrEP message enhanced their intent to use condoms in the future.Discussion:Several years into the availability of PrEP, black and Hispanic/Latino MSM continue to be unaware of PrEP and its benefits, although information is largely believable once provided. The HIV prevention field should be prepared to incorporate new information about HIV prevention options into brief messages delivered through technology and social media. © 2018 Wolters Kluwer Health, Inc. Article	2019	Mansoor L.E.; Yende-Zuma N.; Baxter C.; Mngadi K.T.; Dawood H.; Gengiah T.N.; Samsunder N.; Schwartz J.L.; Doncel G.F.; Abdool Karim Q.	Integrated provision of topical pre-exposure prophylaxis in routine family planning services in South Africa: a non-inferiority randomized controlled trial	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25381	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072051423&doi=10.1002%2fjia2.25381&partnerID=40&md5=9c054cbf2027cf383b9aa16d76bfb5ee	Introduction: Tenofovir-containing oral pre-exposure prophylaxis (PrEP) is recommended for those at substantial risk as part of combination HIV prevention. However, there are limited data, beyond clinical trial settings, to guide the introduction of PrEP in healthcare services with adequate levels of adherence. Since young women in Africa are at high risk of HIV and likely to utilize family planning (FP) services, the feasibility, acceptability and effectiveness of integrating topical PrEP provision into routine FP services was assessed. Methods: This two-arm, randomized controlled, non-inferiority, open-label extension trial was undertaken in urban and rural KwaZulu-Natal, South Africa. HIV-negative eligible women (n = 372) from the parent trial (Centre for the AIDS Programme of Research in South Africa (CAPRISA) 004) were randomized to receive tenofovir gel either through intervention (FP clinics, n = 189) or control clinics (CAPRISA research clinics, n = 183). Non-inferiority was predefined as gel use in the intervention clinics would be no more than 20% lower than in the control clinics. Adherence, retention and HIV incidence rates were assessed. Results: Women were enrolled between November 2012 and October 2014, and followed up for 682.3 women-years (mean = 22 months). Baseline characteristics of women in intervention and control clinics were comparable and retention rates were 92.1% and 92.3% respectively. Women in intervention clinics and control clinics returned on average 5.2 (95% confidence interval (CI): 4.7 to 5.7) and 5.7 (CI: 5.2 to 6.2) used gel applicators per month respectively, with a mean difference of −0.47 (CI: −1.16 to 0.21). Per-protocol estimates were on average 5.5 (CI: 5.0 to 6.1) and 5.8 (CI: 5.3 to 6.3) respectively, with a mean difference of −0.25 (CI: −0.98 to 0.48), meeting the non-inferiority criteria. Adherence, based on proportion of reported sex acts covered by two gel doses, was 79.9% (CI: 76.7 to 83.2) in intervention compared with 73.9% (CI: 70.7 to 77.1) in control clinics; mean difference 6.0% (CI: 1.5 to 10.6) (p = 0.009). HIV incidence rates were 3.5 (CI: 1.8 to 6.0) and 3.6 (CI: 1.9 to 6.3) per 100 women-years in intervention and control clinics respectively. Both these incidence rates were lower than the age-standardized rate of 6.2 per 100 women-years (n = 444) in the placebo arm of the parent trial (p = 0.019). Conclusions: Provision of topical PrEP as part of an integrated FP service achieved higher adherence, and was as feasible, acceptable and effective in preventing HIV as provision through a research setting. This provides useful evidence for scale-up of oral PrEP in urban and rural high burden communities. © 2019 The Authors. Barriers to preexposure prophylaxis use among individuals with recently acquired HIV infection in Northern California	AIDS Care	-	-	-	9540121	10.1080/09540121.2018.1533238	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054813028&doi=10.1080%2f09540121.2018.1533238&partnerID=40&md5=2b2de272c5f9dc2f22209ceed6fbe3b2	Barriers to HIV preexposure prophylaxis (PrEP) use have not been well-characterized in people who became HIV-infected, all of whom could have benefited from PrEP. We invited Kaiser Permanente Northern California members diagnosed with HIV during 2014–2016, following a negative HIV test in the prior year, to complete a survey assessing barriers to PrEP use before HIV diagnosis. Of 268 patients surveyed, 122 (46%) responded. Median age was 36, most (84%) were men who have sex with men, and 64% were of minority racial/ethnic background. Thirty-six (30%) had discussed PrEP with a provider, of whom 10 were diagnosed with HIV at PrEP intake. Overall, only 5 (4.1%) had used PrEP, and all 5 discontinued before diagnosis. Among all respondents, the most common barrier to PrEP use was lack of PrEP awareness (51%). Among those aware of PrEP, the most common barriers were cost/insurance concerns (36%) and perceived low risk for HIV (24%). Lack of PrEP awareness ranged from 39% among those aged 25–34 to 88% among those aged <25 (P = 0.011), and from 33% among Hispanics to 69% among Blacks (P = 0.055). Increasing awareness and affordability of PrEP, and facilitating accurate assessment of HIV risk, are critical to reducing missed opportunities for PrEP. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	awareness; cost; Human immunodeficiency virus (HIV); implementation; preexposure prophylaxis (PrEP)	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Marcus, Julia L; Hurley, Leo B; Krakower, Douglas S; Alexeeff, Stacey; Silverberg, Michael J; Volk, Jonathan E	Use of electronic health record data and machine learning to identify candidates for HIV pre-exposure prophylaxis: a modelling study.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(19)30137-7	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7152802	BACKGROUND: The limitations of existing HIV risk prediction tools are a barrier to implementation of pre-exposure prophylaxis (PrEP). We developed and validated an HIV prediction model to identify potential PrEP candidates in a large health-care system. METHODS: Our study population was HIV-uninfected adult members of Kaiser Permanente Northern California, a large integrated health-care system, who were not yet using PrEP and had at least 2 years of previous health plan enrolment with at least one outpatient visit from Jan 1, 2007, to Dec 31, 2017. Using 81 electronic health record (EHR) variables, we applied least absolute shrinkage and selection operator (LASSO) regression to predict incident HIV diagnosis within 3 years on a subset of patients who entered the cohort in 2007-14 (development dataset), assessing ten-fold cross-validated area under the receiver operating characteristic curve (AUC) and 95% CIs. We compared the full model to simpler models including only men who have sex with men (MSM) status and sexually transmitted infection (STI) positivity, testing, and treatment. Models were validated prospectively with data from an independent set of patients who entered the cohort in 2015-17. We computed predicted probabilities of incident HIV diagnosis within 3 years (risk scores), categorised as low risk (<0·05%), moderate risk (0·05% to <0·20%), high risk (0·20% to <1·0%), and very high risk (≥1·0%), for all patients in the validation dataset. FINDINGS: Of 3â750â664 patients in 2007-17 (3â143â963 in the development dataset and 606â701 in the validation dataset), there were 784 incident HIV cases within 3 years of baseline. The LASSO procedure retained 44 predictors in the full model, with an AUC of 0·86 (95% CI 0·85-0·87) for incident HIV cases in 2007-14. Model performance remained high in the validation dataset (AUC 0·84, 0·80-0·89). The full model outperformed simpler models including only MSM status and STI positivity. For the full model, flagging 13â463 (2·2%) patients with high or very high HIV risk scores in the validation dataset identified 32 (38·6%) of the 83 incident HIV cases, including 32 (46·4%) of 69 male cases and none of the 14 female cases. The full model had equivalent sensitivity by race whereas simpler models identified fewer black than white HIV cases. INTERPRETATION: Prediction models using EHR data can identify patients at high risk of HIV acquisition who could benefit from PrEP. Future studies should optimise EHR-based HIV risk prediction tools and evaluate their effect on prescription of PrEP. Implications for prep uptake in young adults experiencing homelessness: A mixed methods study	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2019.31.1.63	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061407112&doi=10.1521%2faeap.2019.31.1.63&partnerID=40&md5=b38a42ad13b00766ee15b35a5e932d58	Youth experiencing homelessness (YEH) have a high risk of contracting HIV; however, they remain relatively unreached by pre-exposure prophylaxis (PrEP)-based HIV prevention initiatives. We used a cross-sectional mixed-methods study to explore PrEP knowledge, interest, facilitators, and barriers among YEH. Young adults were recruited from agencies serving YEH in Houston, TX (n = 30) and Los Angeles, CA (n = 15) to participate in an electronic self-report survey and a semistructured interview. Survey results indicate that 68.2% of YEH had low or no prior knowledge of PrEP, though 63.7% reported interest in taking PrEP. Qualitative results revealed facilitators of PrEP use, including high PrEP acceptability and awareness, and supportive social networks. Several barriers emerged, including medication-related barriers, adherence, cost, access barriers, low perceived HIV risk, perceived stigma of PrEP use, and low PrEP awareness. Despite high PrEP acceptability, PrEP use among YEH remains low partly due to low PrEP awareness, low perceived HIV risk, and medical mistrust. © 2019 The Guilford Press. Article	2019	Marins L.M.S.; Torres T.S.; Leite I.D.C.; Moreira R.I.; Luz P.M.; Hoagland B.; Kallas E.G.; Madruga J.V.; Liu A.Y.; Anderson P.L.; Grinsztejn B.; Veloso V.G.	Performance of HIV pre-exposure prophylaxis indirect adherence measures among men who have sex with men and transgender women: Results from the PrEP BrasIL study	PLOS One	-	-	-	19326203	10.1371/journal.pone.0221281	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070862776&doi=10.1371%2fjournal.pone.0221281&partnerID=40&md5=f90fd2c10847085b6b36d44ca78391a3	Introduction Efficacy of daily emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) for PrEP is strongly dependent on the adherence. We examined the concordance between indirect adherence measures and protective drug levels among participants retained through 48 weeks in the PrEP Brasil Study. Methods PrEP Brasil was a prospective, multicenter, open-label demonstration project evaluating PrEP provision for men who have sex with men (MSM) and transgender women (TGW) at higher risk for HIV infection within the setting of Brazilian Public Health System. Three indirect adherence measures were obtained at week 48: medication possession ratio (MPR), pill count and self-report (30-days recall). Tenofovir diphosphate (TFV-DP) concentration in Dried Blood Spot (DBS) was measured at week 48. Areas under (AUC) the receiver operating characteristics (ROC) curve were used to evaluate the concordance between achieving protective drug levels (TFV-DP700fmol/punch) and the indirect adherence measures. Youden's index and distance to corner were used to determine the optimal cutoff points for each indirect adherence measure. We calculated sensitivity, specificity, negative (NPV) and positive (PPV) predictive values for the found cutoff points. Finally, Delong test was used to compare AUCs. Results and discussion From April, 2014 to July, 2016, 450 participants initiated PrEP, 375(83.3%) were retained through 48 weeks. Of these, 74% (277/375) had TFV-DP 700fmol/punch. All adherence measures discriminated between participants with and without protective drug levels (AUC>0.5). High indirect adherence measure was predictive of protective drug levels (PPV>0.8) while low indirect adherence measure was not predictive of lack of protective drug levels (NPV<0.5). No significant differences were found between the adherence methods (p = 0.44). Conclusions Low-burden measurements such as MPR and self-report can be used to predict PrEP adherence in a public health context in Brazil for MSM and TGW retained through 48 weeks. © 2019 Marins et al. Theses and Dissertations	2019	MARINS, LUANA MONTEIRO SPINDOLA	Adesão à profilaxia pré-exposição em homens que fazem sexo com homens (HSH) e mulheres transexuais em risco de contrair HIV	-	-	Fundação Oswaldo Cruz. Instituto Nacional de Infectologia Evandro Chagas	-	-	NA	https://www.arca.fiocruz.br/handle/icict/48563	Em uma epidemia concentrada, o HIV se espalha rapidamente em uma ou mais subpopulações específicas, com propagação relativamente modesta na população geral. Na América Latina, algumas populações-chave, como gays, bissexuais e outros homens que fazem sexo com homens (HSH), travestis e mulheres transgêneros (TrMT), são desproporcionalmente afetadas pelo HIV/aids, tendência que está se tornando mais forte nos últimos anos. A Profilaxia Pré-exposição (PrEP) se baseia no uso de medicamentos antirretrovirais (ARV) para a prevenção da aquisição do HIV. O uso diário da combinação oral de entricitabina e tenofovir disoproxil fumarato (FTC/TDF) é eficaz para PrEP, sendo disponível no Sistema Único de Saúde do Brasil (SUS) desde dezembro de 2017. Estudos demonstraram uma forte associação entre os níveis farmacológicos de FTC/TDF no plasma e no interior das células e da proteção contra a aquisição do HIV, atingindo 97-100% de proteção quando os níveis de adesão são alcançados. Objetivos: Descrever padrões e correlações da adesão à PrEP entre HSH e TrMT de um projeto demonstrativo (PrEP Brasil); avaliar efetividade de mensagens de texto (SMS) na adesão à PrEP; avaliar a adesão autorrelatada da PrEP e suas barreiras e facilitadores. Primeiro Artigo: Examinar a concordância entre três medidas de adesão indireta (taxa de posse de medicamento ou MPR, contagem de comprimidos e autorrelato) e níveis de medicamento altamente protetores medidos a partir de sangue coletado em papel de filtro (Dried Blood Spots - DBS) entre participantes retidos por 48 semanas no Estudo PrEP Brasil. Os níveis séricos de difosfato de tenofovir (TFV-DP) no DBS foram medidos na semana 48. Áreas sob a curva (AUC) foram usadas para avaliar a concordância entre alcançar níveis protetores de TFV-DP (700fmol/punch) e as medidas de adesão indireta. Os métodos de Youden Index e Distance to Corner foram empregados para determinar os pontos de corte ideais para cada medida de adesão indireta. Sensibilidade, Especificidade e valores preditivos negativo (VPN) e positivo (VPP) foram calculados para cada ponto de corte encontrado. Finalmente, o teste de Delong foi usado para comparar as AUCs. Todas as medidas de adesão indireta foram capazes de discriminar entre participantes com e sem níveis protetores de TDF-DP (AUC> 0,5). Altos valores de adesão nas três medidas indiretas foram preditivos de níveis protetores (VPP> 0,8), enquanto baixos valores não foram preditivos para a falta de níveis protetores (VPN <0,5). Não foram encontradas diferenças significativas entre os métodos de adesão (p = 0,44). Segundo Artigo: Avaliar a eficácia do SMS em melhorar a adesão ao uso diário de FTC/TDF durante o estudo PrEP Brasil. Um sub-estudo piloto de SMS interativo foi oferecido a todos os participantes na visita de triagem. Os indivíduos que concordaram em participar foram randomizados 1: 1 para receber apenas o atendimento padrão (SoC), que incluiu aconselhamento de adesão, ou intervenção (SMS). Foram enviados SMS semanalmente aos participantes em um horário pré-determinado. A adesão adequada à PrEP foi definida como tendo MPR ≥ 1,02, que foi o melhor ponto de corte para alcançar níveis protetores de TFV-DP nas semanas 4 e 48. Equações de Estimativas Generalizadas (GEE) foram utilizadas para acessar os fatores associados a adesão adequada à PrEP. Dos 450 participantes incluídos no PrEP Brasil, 417 (92.7%) foram randomizados no sub-estudo: 210 no braço SoC e 207 no braço SMS. Um total de 347 (83.2%) participantes completaram o estudo, e receber SMS não aumentou a retenção na semana 48. Uma maior proporção de participantes no grupo recebendo SMS apresentou adesão adequada à PrEP ao longo do estudo. Em análise multivariada, receber SMS foi preditor de adesão adequada à PrEP (AOR = 1,37; IC 95%: 1,07-1,75) quando ajustado ix por visita, localidade, idade sexo anal receptivo sem preservativo e uso de álcool. Terceiro Artigo: Avaliar a adesão autorrelatada à PrEP (recordatório de 30 dias) e as barreiras e facilitadores percebidos entre os retidos por 48 semanas no estudo da PrEP Brasil. A regressão logística foi utilizada para avaliar os preditores da adesão ótima (= 100%). A mediana de adesão nos últimos 30 dias foi de 100% (IQR: 92-100); 60,6% dos participantes (205/338) relataram adesão ótima. A maioria (82,2%; 278/338) dos participantes relatou não ter dificuldade em tomar FTC / TDF e 81,3% (274/338) relataram capacidade excelente ou muito boa. Barreiras e facilitadores percebidos foram relatados por 38,2% (129/338) e 98,5% (333/338), respectivamente; os principais facilitadores do uso da PrEP incluíram a associação com alguma atividade diária (59%), envolvimento com a PrEP (49%), manter os comprimidos em algum lugar visível e transportar a medicação com eles (45%), uso de alarme (39%) e medo de se infectar pelo HIV (38%). As principais barreiras para a PrEP incluíram o esquecimento de doses (50%), mudança na rotina diária (38%), falta de pílulas (25%) e ausência da pílula no momento da dose (12%). Dificuldades relatadas devido ao uso de drogas ou álcool, nenhum risco percebido, questões de privacidade ou efeitos colaterais foram incomuns (≤ 10%). Na análise multivariada, ser do Rio de Janeiro, TrMT, o uso de estimulantes e ter percepção de barreiras à PrEP foram associados à diminuição da chance de adesão ótima. Conclusões: Altos níveis de adesão mensurados por diferentes métodos indiretos (contagem de comprimidos, MPR e autorrelato) foram verificados na semana 48 e todos os métodos foram capazes de discriminar participantes que atingiram ou não níveis protetores de tenofovir. A intervenção por SMS foi eficaz para melhorar a adesão e a cobertura de PrEP ao longo do estudo, mas não teve impacto na retenção na semana 48. Nossos achados fornecem informações para elaboração, reforço e atualização de estratégias para melhorar a adesão, e para desenvolver as melhores práticas para promover a adesão à PrEP em nosso contexto. Article	2019	Marrazzo, Jeanne M; Rabe, Lorna; Kelly, Cliff; Richardson, Barbra; Deal, Carolyn; Schwartz, Jill L; Chirenje, Z M; Piper, Jeanna; Morrow, Rhoda Ashley; Hendrix, Craig W; Marzinke, Mark A; Hillier, Sharon L	Tenofovir Gel for Prevention of Herpes Simplex Virus Type 2 Acquisition: Findings From the VOICE Trial.	Journal of Infectious Diseases	-	-	-	1537-6613	10.1093/infdis/jiz045	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6534189	BACKGROUND: Genital infection with herpes simplex virus type 2 (HSV-2) is common and increases risk of human immunodeficiency virus (HIV) transmission and acquisition. Pericoital use of tenofovir (TFV) gel provided protection from HSV-2 acquisition in the CAPRISA 004 study. METHODS: We measured estimate of effect of vaginal TFV 1% gel in preventing HSV-2 acquisition among women in VOICE, randomized, double-blinded, placebo-controlled trial assessing daily use of oral and vaginal TFV for HIV-1 preexposure prophylaxis. The TFV level in plasma at the first quarterly visit was used as a measure of gel use. RESULTS: Of 566 participants at risk for HSV-2 acquisition, 532 (94%) had first-quarter plasma TFV and end-of-study HSV-2 serologic data available. Over a follow-up period of 501 person-years, 92 incident cases of HSV-2 acquisition occurred: 77 were in women with no TFV detected in plasma, and 15 occurred in women with TFV detected in plasma (incidence, 20.6 cases/100 person-years 95% confidence interval CI, 16.2-25.7 vs 11.9 cases/100 person-years 95% CI, 6.6-19.6, respectively). TFV detection in plasma was associated with a trend toward a reduced risk of HSV-2 seroconversion, with an unadjusted hazard ratio (HR) of 0.59 (95% CI, .34-1.02; P = .060) and a HR adjusted for site, age, having ≥2 male sex partners in the past 3 months, use of hormonal contraception, having anal sex in the past 3 months, and HIV status of 0.60 (95% CI, .33-1.08; P = .086). CONCLUSIONS: Detection of TFV in plasma among TFV gel users was associated with a trend toward a reduced risk of HSV-2 acquisition, after controlling for sexual behavior and HIV-1 acquisition. Article	2019	Marsh K.J.; Rothenberger M.	A Young Black MSM on PrEP Is Lost to Follow-Up and Acquires HIV Infection: A Case to Call for Improved Strategies to Support Youth Adherence and Engagement in HIV Prevention	Journal of the International Association of Physicians in AIDS Care	-	-	-	23259574	10.1177/2325958219853834	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067184912&doi=10.1177%2f2325958219853834&partnerID=40&md5=c5b7e748e10a3abfba13f785fe74c92a	Young men who have sex with men (YMSM) are disproportionately affected by HIV in the United States. High-risk sexual behaviors are difficult to modify; thus, HIV pre-exposure prophylaxis (PrEP) with a daily pill is a promising prevention tool for this vulnerable population. We present a case of a young black MSM who was able to successfully access PrEP with the help of a community program but was not able to adhere to the regimen or engage in care. He ultimately acquired HIV infection. We review the existing literature and advocate for increased services and research to support youth's adherence to PrEP and engagement in HIV prevention programs, with a focus on YMSM of color. © The Author(s) 2019.	adolescent HIV; HIV prevention; PrEP; YBMSM; YMSM	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Martin M.; Vanichseni S.; Sangkum U.; Mock P.A.; Leethochawalit M.; Chiamwongpaet S.; Pitisuttithum P.; Kaewkungwal J.; van Griensven F.; McNicholl J.M.; Tappero J.W.; Mastro T.D.; Kittimunkong S.; Choopanya K.	HIV Incidence and Risk Behaviours of People Who Inject Drugs in Bangkok, 1995–2012	EClinicalMedicine	-	-	-	25895370	10.1016/j.eclinm.2019.03.012	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064549413&doi=10.1016%2fj.eclinm.2019.03.012&partnerID=40&md5=020d7fdc38e988d31ec1158736d39059	Background: Three consecutive prospective studies were conducted among people who inject drugs (PWID) from May 1995 through June 2012 in Bangkok, Thailand. We examined data from these studies to evaluate HIV incidence and explore trends in risk behaviours. Methods: We used data from a 1995–1998 cohort study, a 1999–2004 HIV vaccine trial, and a 2005–2012 HIV pre-exposure prophylaxis (PrEP) study to examine per-quarter trends in HIV incidence, using a restricted cubic spline function for time in a Poisson regression. We also examined temporal trends in HIV-associated risk behaviours. Findings: HIV incidence declined from 5.7 per 100 person-years during the cohort study, to 2.7 per 100 person-years in the vaccine trial, to 0.7 per 100 person-years among PrEP study placebo recipients. Incidence peaked at 12.1 per 100 person-years in 1996 and declined to < 1.0% during 2005–2012. Reports of injecting drugs and sharing needles also declined from the cohort study to the PrEP study (p < 0.0001). Heroin was the most common drug injected during the cohort study and the vaccine trial, but stimulants (e.g., methamphetamine) and sedatives (e.g., midazolam) were injected more often during the PrEP study. Interpretation: HIV incidence among PWID declined during 2005–2012. Several factors likely contributed to the decline, including decreases in the frequency of injecting and sharing, improved access to HIV testing and antiretroviral therapy, and the use of PrEP. Expanding access to effective HIV prevention tools can hasten control of the HIV epidemic among PWID. Funding: The Bangkok Metropolitan Administration and U.S. Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention. © 2019	HIV; HIV pre-exposure prophylaxis; People who inject drugs; Tenofovir; Thailand	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Martinez J.E.; Jonas K.J.	Pre-exposure prophylaxis sorting among men who have sex with men	AIDS Care	-	-	-	9540121	10.1080/09540121.2018.1533229	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054757023&doi=10.1080%2f09540121.2018.1533229&partnerID=40&md5=d36e933e1c0135750ba63cd1dca58deb	Factors such as race, masculinity, and sexually transmitted infections have been documented to influence partner selection in men who have sex with men (MSM). Pre-exposure prophylaxis (PrEP) has received mixed evaluations as a responsible step in HIV prevention and as an enabler of riskier sexual practices. PrEP may consequently serve as an additional factor in partner choice. We examine the role that PrEP use and "promiscuity" play in affiliation and dating decisions by men who have sex with men with different HIV and PrEP stati. We invited 450 MSM across the United States from a smartphone geo-locating sex application to complete a survey of which 339 successfully finished the task. The survey contained vignettes of fictional men who were promiscuous or monogamous and either taking PrEP or not. Participants provided responses on whether to affiliate with these characters in three social domains: as friends, dates, or sex partners. Neither PrEP nor promiscuity influenced friendship choices. There was a preference for dating monogamous characters. Critically, PrEP influenced sexual affiliations for HIV negative individuals who showed a preference for PrEP-using characters. The pattern of results provides quantitative evidence for PrEP-based sexual sorting aimed at reducing risk of HIV transmission. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group. Article	2019	Martinez-Lacabe A.	The non-positive antiretroviral gay body: the biomedicalisation of gay sex in England	Culture, Health & Sexuality	-	-	-	13691058	10.1080/13691058.2018.1539772	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059661075&doi=10.1080%2f13691058.2018.1539772&partnerID=40&md5=3e1ec7252c8e80f64a0cb1a0d60e6012	Drawing on testimonies from oral history interviews, this paper analyses the implications of pre-exposure prophylaxis (PrEP) practices for gay men in England. Through perspectives on biomedicalisation, the paper focuses on three aspects relevant to the construction of technoscientific identities in the realm of HIV prevention: (i) the question of agency of PrEP users in the context of what has been defined as a biomedical intervention, (ii) practices of freedom framed within neoliberal narratives of personal responsibility versus responsibilisation and (iii) the governance of risk in the era of biomedicalisation. The paper concludes that biomedical governmentalities, even those shaped by the rhetoric of personal responsibility, can be understood as rationalities linked more to solidarity and care of the other. Despite this, the use of PrEP in England is also giving way to the configuration of new sexual scenarios shaped by zero-risk mentalities. It will be important to remain alert to the implications of zero-risk scenarios for HIV-related stigma. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group.	biomedical govermentalities; biomedicalisation; HIV narratives; oral history; PrEP	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Qualitative
Article	2019	Martín-Illana, Araceli; Cazorla-Luna, Raúl; Notario-Pérez, Fernando; Bedoya, Luis Miguel; Ruiz-Caro, Roberto; Veiga, María Dolores	Freeze-dried bioadhesive vaginal bigels for controlled release of Tenofovir.	European Journal of Pharmaceutical Sciences	-	-	-	1879-0720 0928-0987	10.1016/j.ejps.2018.10.013	https://pubmed.ncbi.nlm.nih.gov/30343152/	Nowadays, million women live with the human immunodeficiency virus (HIV) worldwide and many of them are dying per year, particularly in Sub-Saharan Africa. The development of systems that can be accessed by this population group to prevent the sexual transmission of the virus is therefore necessary. The aim of this work was the formulation of freeze-dried bioadhesive vaginal bigels releasing Tenofovir in a controlled manner. Systems containing three different proportions of guar gum hydrogel and sesame oil were prepared, adding Span®60 or Span®60 and Tween®60 as surfactants. Drug and excipients were evaluated by cytotoxicity assays, showing no toxicity at the concentrations tested neither for the drug nor any of the excipients. Fresh formulations were characterised through texture analyses and confocal laser microcopy. The system with the lowest guar gum hydrogel/sesame oil proportion and containing Span®60 and Tween®60 (batch ST1) had the highest consistency and adhesion capacity according to texture analyses. Furthermore, a genuine bigel microstructure was observed. After freeze-drying, swelling, bioadhesion and drug release tests were performed on the resulting systems. ST1 showed the longest bioadhesion time and the most controlled release, as well as a low swelling grade, becoming an interesting option for preventing HIV sexual transmission in women.	pre-exposure prophylaxis; sustained drug release; women's health	English	Netherlands	Western and Central Europe and North America	Spain	Western and Central Europe and North America	Spain	Western and Central Europe and North America	Clinical
Article	2019	Mathias, Augusto; Alves dos Santos, Lorruan; Grangeiro, Alexandre; Couto, Marcia Thereza	Thematic synthesis HIV prevention qualitative studies in men who have sex with men (MSM)	Colombia Médica	-	-	-	0120-8322	10.25100/cm.v50i3.4078	http://www.scielo.org.co/scielo.php?script=sci_arttext&pid=S1657-95342019000300201	Abstract Background: Qualitative studies on HIV prevention strategies and methods among men who have sex with men (MSM) allow identify knowledge gaps and improve preventive actions. Objective: To make a thematic synthesis of the scientific productions that use the qualitative methodology in the strategies and methods of HIV prevention area among MSM. Methods: We conducted a literature review following the guidelines of the ENTREQ protocol. The analysis included 48 empirical studies published in Portuguese, English and Spanish between 2001 and 2018 available in the Medline, Embase, Scielo, Scopus, Bireme and Web of Science databases. Results: Where an increased production in the last six years and concentration in northern countries. Seven prevention methods were part of the study, with emphasis on pre-exposure prophylaxis, testing, condoms and behavioral strategies. The main topics discussed were stigma and support and care networks. Conclusion: we notice that an increasing production on prevention in the men who have sex with men segment results from the emergence of multiple preventive methods and strategies and their combined actions beyond the star role of condoms. Article	2019	Matthews L.T.; Jaggernath M.; Kriel Y.; Smith P.M.; O'Neil K.; Haberer J.E.; Hendrix C.; Baeten J.M.; Ware N.C.; Wirth K.; Psaros C.; Bangsberg D.R.; Smit J.A.	Protocol for a longitudinal study to evaluate the use of tenofovir-based PrEP for safer conception and pregnancy among women in South Africa	BMJ Open	-	-	-	20446055	10.1136/bmjopen-2018-027227	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070723330&doi=10.1136%2fbmjopen-2018-027227&partnerID=40&md5=b9d6cdb72534e7b6db879ad416eef0fc	INTRODUCTION: Women who choose to conceive a baby with a partner living with HIV or a partner whose HIV serostatus is unknown in HIV-endemic settings need prevention strategies to mitigate HIV acquisition during conception and pregnancy. METHODS AND ANALYSIS: We are conducting a single-arm longitudinal study offering oral tenofovirdisoproxil fumarate/emtricitabine (TDF/FTC) as pre-exposure prophylaxis (PrEP) for periconception use to 350 HIV-uninfected women in KwaZulu-Natal, South Africa. PrEP is offered as part of woman-centred safer conception programme that promotes couples-based HIV counselling and testing, antiretroviral therapy for partners who are HIV-infected, treatment for sexually transmitted infections and safer conception strategies, such as limiting condomless sex to peak fertility. We enrol HIV-uninfected women who are not currently pregnant, in a stable relationship (≥6 months) with a partner living with HIV or of unknown serostatus, and personal or partner plans for pregnancy in the next 12 months. We follow enrolled women for 12 months. Women who become pregnant are followed through pregnancy outcome, independent of their decisions regarding PrEP use. The primary objective of the study is to evaluate the uptake of and adherence to PrEP during the periconception period and pregnancy. Secondary outcomes include the uptake of other safer conception strategies. We also measure clinical outcomes including HIV seroconversion rates and pregnancy and infant outcomes. Finally, we will explore conduct and evaluate qualitative interviews in 25 participants to further inform our conceptual framework for periconception PrEP uptake and adherence among HIV-exposed women in South Africa. ETHICS AND DISSEMINATION: The protocol has been approved by the Human Research Ethics Committee at the University of the Witwatersrand (Johannesburg, South Africa) and the Institutional Review Board of Partners Healthcare (Boston, Massachusetts, USA). Study findings will be made available to interested participants. Results will be presented to local health officials and stakeholders at meetings. Investigators will share the results at meetings and in manuscripts. De-identified quantitative data will be made available. TRIAL REGISTRATION NUMBER: The protocol is registered with the South African Health Products Regulatory Agency (SAHPRA, formerly known as the Medicine Controls Council, MCC#20170131) and ClinicalTrials.gov (NCT03194308); Pre-results. © Author(s) (or their employer(s)) 2019. Theses and Dissertations	2019	Mauck, Daniel	Identifying Gay Neighborhoods and Estimation of the Size of the Men who have Sex with Men Population in Florida who would benefit from Pre-exposure Prophylaxis	-	-	Florida International University	-	NA	10.25148/etd.FIDC007782	https://digitalcommons.fiu.edu/etd/4251 https://digitalcommons.fiu.edu/context/etd/article/5397/viewcontent/FIDC007782.pdf	Given the potential benefit of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) at risk for human immunodeficiency virus (HIV), it would be useful to assess the size of the at-risk population and their geographic distribution to target PrEP and other prevention programs efficiently. In 2017, Florida ranked third for HIV diagnosis rates in the US, and 63% of those who received a new HIV diagnosis in Florida were MSM. The purpose of this dissertation was to 1) summarize population-based methods to estimate the size of the population of MSM, 2) identify gay neighborhoods using latent class analysis (LCA), and 3) estimate the size of the MSM population in Florida. A systematic review of population-based methods to estimate the size of the MSM population was conducted. Twenty-eight studies met inclusion criteria. Sixteen studies were conducted in the US, five in European countries, two in Canada, three in Australia, one in Israel, and one in Kenya. Men who have sex with men made up 0.03–6.4% of men among all studies and ranged from 3.8–6.4% in the US, 7,000–39,100 in Canada, 0.03–6.5% in European countries, and 127,947–182,624 in Australia. Latent class analysis was used to identify gay neighborhoods in Florida. Data at the ZIP code level was drawn from the 2011–2015 ACS, website lists of gay bars and neighborhoods, and the Florida Department of Health's HIV surveillance system. A two-class model was selected. About 9% of the ZIP code data were in class two (gay neighborhoods). Cohen's kappa coefficient was used to examine agreement between the classification of ZIP codes from LCA and gay neighborhoods from websites. Fair agreement was found (0.2501). Three methods were used to estimate the MSM population in Florida with high-risk behaviors that would indicate eligibility for PrEP use. The resulting three estimates were averaged, and the number of MSM living with HIV infection in each ZIP code was subtracted. The average MSM estimate in ZIP codes ranged from 1–2,184 men (1.5–22.9%). The presumed HIV-negative MSM estimate in ZIP codes ranged from 1–1,346 men (0.02–12.7%). Indications for PrEP were highest for MSM with more than one sex partner in the past year and lowest when the estimate was multiplied by 24.7% (percent of MSM with PrEP indications from other studies). In conclusion, there is no widely accepted method to estimate the size of the MSM population, and estimates vary substantially based on the method used. Therefore, it would be prudent to consider a range of estimates in planning HIV prevention efforts. Article	2019	Maxwell S.; Shahmanesh M.; Gafos M.	Chemsex behaviours among men who have sex with men: A systematic review of the literature	International Journal of Drug Policy	-	-	-	9553959	10.1016/j.drugpo.2018.11.014	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057445076&doi=10.1016%2fj.drugpo.2018.11.014&partnerID=40&md5=b5629ecfd43c063cd41f8c6338715816	Background: 'Chemsex' is the use of drugs before or during planned sexual events to facilitate, enhance, prolong and sustain the experience. Drugs associated with chemsex are methamphetamine, GHB/GBL, mephedrone, cocaine and ketamine. This review syntheses published research on the antecedents, behaviours and consequences associated with chemsex behaviours among men who have sex with men (MSM). Methods: Papers from high income countries which were published between January 2000 and September 2018 reporting the use of chemsex drugs before or during sex were identified through Medline, Web of Science, CINAHL and Central. Results were synthesised using a narrative approach and conceptualised using a behavioural analysis framework. Results: The search identified 2492 publications, of which 38 were included in the final synthesis. There were wide variations in chemsex prevalence estimates due to the heterogeneous sampling in the studies. Chemsex participants have expectations that the drugs will positively affect their sexual encounters and HIV positive MSM are more likely to engage in the behaviour than HIV negative MSM. There were wide ranging prevalence estimates on injecting drugs for sexual purposes and the sharing of injecting equipment with some evidence of unsafe injecting practices. Participants were more likely to engage in condomless anal intercourse than men who do not engage in chemsex. This may increase the risk of transmission for HIV and other sexually transmitted infections. Conclusion: A minority of MSM appear to engage in chemsex behaviours but they are at risk of this negatively impacting on their health and well-being. Further research is required to examine high risk chemsex behaviours, impact of chemsex on psycho-social well-being and if chemsex influences uptake of PrEP, PEP and sexual health screening. © 2018 Elsevier B.V. Article	2019	Maxwell, Steven; Gafos Mitzy; Shahmanesh Maryam	Pre-exposure Prophylaxis Use and Medication Adherence Among Men Who Have Sex With Men: A Systematic Review of the Literature	The Journal of the Association of Nurses in AIDS Care	-	-	-	10553290	10.1097/JNC.0000000000000105	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-use-medication-adherence/docview/2543654746/se-2?accountid=8113	The appropriate use of pre-exposure prophylaxis (PrEP) by men who have sex with men (MSM) can be highly effective at reducing HIV transmission. Our review examined prevalence estimates, sexual behaviors, and medication adherence among MSM PrEP users in high-income countries. Articles published between January 2008 and December 2018 were identified through Medline, Web of Science, CINAHL, and CENTRAL. The search identified 643 publications, of which 52 were included in the final synthesis. We found that PrEP initiation was not consistently associated with significant changes in sexual behavior, but some users may have risk compensated. A minority of MSM used PrEP, and they had high levels of adherence. PrEP-related stigma, side effects, and psychosocial factors lead to nonadherence. A daily routine, pill boxes, alarms/texts, and education can promote adherence. Further research is required to examine PrEP impact on sexual behavior and factors that influence adherence in high-risk MSM subpopulations.	preexposure prophylaxis; Pre-exposure prophylaxis; Adherence; men who have sex with men; medication adherence; review; Men who have sex with men; Sexual behavior; Stigma; Disease prevention; Systematic review; Patient compliance; Behavior change; Drugs; Side effects; High risk; Human immunodeficiency virus--HIV; Gays & lesbians; Mens health; Medical Sciences--Allergology And Immunology; Psychosocial factors; Literature reviews	English	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Review
Article	2019	Mayer K.H.; Allan-Blitz L.-T.	PrEP 1.0 and Beyond: Optimizing a Biobehavioral Intervention	Journal of Acquired Immune Deficiency Syndromes	-	-	-	19447884	10.1097/QAI.0000000000002169	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074231218&doi=10.1097%2fQAI.0000000000002169&partnerID=40&md5=163af87884bab8072ddb8504c653fc39	BACKGROUND: Tenofovir disoproxil fumarate coformulated with emtricitabine (TDF/FTC) was shown to be effective in preventing HIV acquisition when used for pre-exposure prophylaxis (PrEP), but questions have arisen regarding optimal PrEP implementation strategies. METHODS: A narrative review of literature since 2010 regarding PrEP effectiveness, implementation, and new prevention modalities was undertaken to summarize lessons learned, and to review potential benefits and challenges. RESULTS: Although daily TDF/FTC is safe, well tolerated, and highly effective in preventing HIV transmission, it has been initiated by only 200,000 Americans, and a comparable number of individuals in other countries, meaning that 80%-90% of those at greatest risk globally have not been benefitted yet. Barriers to PrEP uptake have included medication and care costs, anticipated side effects, stigma, and unsupportive health care systems. Innovations to increase PrEP uptake and adherence have included engaging nonmedical staff (eg, pharmacists, social workers, and peer navigators), economic assistance programs, and new technologies (eg, text messaging support and dedicated apps). Pericoital PrEP dosing seems to be effective in preventing HIV transmission among men who have sex with men, but has not been evaluated in women. Investigational PrEP approaches include antiretrovirals delivered by injection, implant, vaginal rings, rectal douches, and immunoprophylaxis. Some of these approaches may allow for infrequent dosing, whereas others may be more congruent with patterns of sexual behavior. CONCLUSIONS: PrEP has been shown to be safe and effective when used consistently, but new approaches to enhance uptake, adherence, and convenience with less-frequent dosing are under study, suggesting that new models and modalities will evolve to optimize impact. Article	2019	Meyer, Christopher M; Owarangaise, Arphaxe; Kabami, Jane; Kwarisiima, Dalsone; Kwo, Catherine A; Charlebois, Edwin D; Kamya, Moses R; Petersen, Maya L; Havlir, Diane V; Jewell, Britta L	Distance to clinic is a barrier to Pr EP uptake and visit attendance in a community trial in Uganda	Journal of the International AIDS Society	-	-	-	-	NA	10.1002/jia2.25276	https://www.proquest.com/scholarly-journals/distance-clinic-is-barrier-pr-ep-uptake-visit-dav/docview/2329756457/se-2?accountid=9113	IntroductionGeographic and transportation barriers are associated with poorer HIV-related health outcomes in sub-Saharan Africa, but data on the impact of these barriers on prevention interventions are limited. We estimated the association between distance to clinic and other transportation-related barriers on pre-exposure prophylaxis (PrEP) uptake and initial clinic visit attendance in a rural community in southwestern Uganda enrolled in the ongoing SEARCH study (NCT01864603).MethodsCommunity-wide HIV testing was conducted and offered to adult (≥15 years) participants in Rakai. Participants were eligible for PrEP based on an empiric risk score, having an HIV-uninfected partner, or self-referral at either the community health campaign or during home-based testing from March to April 2017. We collected GPS data at the household level and calculated straight-line distance to the nearest clinic providing PrEP. We used multivariable logistic regression to evaluate the association between transportation barriers and (1) PrEP uptake among PrEP-eligible individuals and (2) first-week clinic visit attendance among PrEP initiators.ResultsOf the 701 PrEP-eligible participants, 272 (39%) started PrEP within four weeks; of these, 45 (17%) were retained at four weeks. Participants with a distance to clinic of ≥2 km were less likely to start PrEP (aOR 0.34, 95% CI 0.19 to 0.78, p = 0.012) and less likely to be retained on PrEP once initiated (aOR 0.29, 95% CI 0.10 to 0.84, p = 0.024). Participants who were deemed eligible during home-based testing and did not have the option of same-day PrEP start were also substantially less likely to initiate PrEP (aOR 0.16, 95% CI 0.07 to 0.37, p < 0.001). Of participants asked to name barriers to PrEP use (N = 98), the most frequently cited were "needing to take PrEP every day" (N = 38) and "low risk of getting HIV" (N = 18). Transportation-related barriers, including "clinic is too far away" (N = 6) and "travel away from home" (N = 4) were also reported.ConclusionsDistance to clinic is a significant predictor of PrEP uptake and first-week follow-up visit attendance in a community in rural Uganda. Interventions that address geographic and transportation barriers may improve PrEP uptake and retention in sub-Saharan Africa. Article	2019	McGowan, I; Wilkin, T; Landovitz, RJ; Wu, C; Chen, Y; Mayrinhac, MA; Hendrix, CW; Richardson, P; Eshleman, SH; Andrade, A; Chege, W; Anderson, PL; McCauley, M; Farley, J; Mayer, KH; Anton, P; Brand, RM; Cranston, RD; Gulick, R	The pharmacokinetics, pharmacodynamics, and mucosal responses to maraviroc-containing pre-exposure prophylaxis regimens in MSM	AIDS	-	-	-	-	NA	10.1097/QAD.0000000000002038	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01987411/full	OBJECTIVE: HIV Prevention Trials Network 069/AIDS Clinical Trials Group A5306 was a study of 4th-week oral pre-exposure prophylaxis (PrEP) regimens in MSM and transgender women. A rectal substudy was included to evaluate drug concentrations in rectal compartment vs. blood, gut-associated lymphoid tissue (GALT) responses to four antiretroviral PrEP regimens maraviroc (MVC), MVC + emtricitabine (FTC), MVC + tenofovir (TFV) diisoproxil fumarate, and TFV diisoproxil fumarate + FTC, and to determine whether ARV exposure was associated with ex-vivo suppression of HIV infection.DESIGN: Open-label, Phase 1B/2A, randomized, multicenter substudy.METHODS: Participants were HIV-, MSM or TG women, 18–50 years old, with creatinine clearance greater than 60 ml/min. Rectal, blood, and urine pharmacokinetics were measured via mass spectrometry. RESULTS: Exposure to MVC was associated with GALT CCR5+ and CD4+ CCR5+ HIV target T cells. Significant ex-vivo viral suppression compared with baseline was seen at 9 weeks 24 and 48, ranging from 1.4 to 1.83log10 for all study regimens except the MVC-alone arm which did not show statistically significant viral suppression at Week 48. Tissue concentrations of TFV, TFV-diphosphate, and FTC were correlated with viral suppression. CONCLUSION: MVC-containing HIV PrEP regimens did not increase GALT CD4+ T-cell activation or the CD4+/CCR5+ phenotype. No virologic suppression was seen with MVC-alone at Week 48 compared with combination regimens, suggesting MVC monotherapy might be less effective than combination antiretroviral PrEP regimens. Article	2019	McMahan, Vanessa M; Martin, Aleks; Gerdes, Lindsey; Violette, Lauren R; Andrusek, Michele P; Baxter, Jared M; Banta-Green, Caleb; Stekler, Joanne D	Development of a targeted educational intervention to increase pre-exposure prophylaxis uptake among cisgender men and transgender individuals who have sex with men and use methamphetamine in Seattle (WA, USA).	Sexual Health	-	-	-	-	1449-8987	10.1071/SH18060	https://dx.doi.org/10.1071/SH18060	Background Cisgender men and transgender individuals who have sex with men (MSM/TG) and use methamphetamine are at elevated risk for HIV and have had limited pre-exposure prophylaxis (PrEP) uptake. The aim of this study was to develop a PrEP intervention for MSM/TG who use methamphetamine in Seattle, Washington, USA.Methods Data were collected from 2015 to 2016 from MSM/TG who used methamphetamine. We conducted three consultations with peer educators of Project Necesito and Entre Nosotros Network (NSEN) to develop and disseminate educational materials. We surveyed the peers' HIV-negative contacts before and after the work to explore knowledge and opinions about PrEP and to assess the effect of our materials. RESULTS: There were 221 respondents at baseline (August 2016) and 108 at follow-up (April–May 2017). At baseline, nearly all participants had heard of PrEP (96%) and were interested (97%). However, only 3% had ever used PrEP. Peers suggested educational cards that included a definition of PrEP, adherence tips and that PrEP does not prevent other sexually transmissible infections. Peers distributed approximately 2560 educational cards. At follow-up, approximately half the respondents (53%) had seen the cards, and those who did reported significantly more agreement with the majority of the card messages about PrEP. Significantly more participants reported ever receiving PrEP at follow-up (21%; P<0.001). There was a trend between seeing the cards and PrEP use (P=0.053). CONCLUSIONS: Although we cannot be certain that the effect was due to our intervention, a greater number of HIV-negative contacts reported receiving PrEP at follow-up, and those who saw our materials were more likely to agree with factual statements about PrEP. There is continued need for PrEP education for MSM/TG who use methamphetamine. Article	2019	Medina, Martha M; Crowley, Christine; Montgomery, Madeline C; Tribuiano, Alec; Almonte, Alexis; Sowemimo-Coker, Genevieve; Nunn, Amy; Chan, Philip A	Disclosure of HIV Serostatus and Pre-exposure Prophylaxis Use on Internet Hookup Sites Among Men Who have Sex with Men.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-018-2286-z	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6438648/	Men who have sex with men (MSM) who use websites and smartphone applications to meet sexual partners ("hookup sites") may be at increased HIV risk. Many sites provide profile options to disclose HIV status and pre-exposure prophylaxis (PrEP) use. Little is known about the acceptability of disclosure options which may guide sexual decision-making. We evaluated 104 MSM presenting to a publicly-funded STD clinic. Most (84%) had met a partner online in the last 12 months; 35 and 27% reported using the HIV and PrEP disclosure options, respectively. White MSM were less likely to disclose their HIV status than MSM of color (46% vs 74%, p < 0.05). Fifty-three percent of men were more likely to contact a potential partner who disclosed being HIV negative, and 48% were more likely to do so if the person disclosed being on PrEP. Future HIV prevention approaches should promote disclosure options among MSM meeting partners online. Article	2019	Mehringer, Jamie; Dowshen, Nadia L	Sexual and reproductive health considerations among transgender and gender-expansive youth.	Current Problems in Pediatric and Adolescent Health Care	-	-	-	-	1538-3199	10.1016/j.cppeds.2019.100684	https://dx.doi.org/10.1016/j.cppeds.2019.100684	Sexual and reproductive health are an integral part of all youths' health and wellbeing, including youth who are transgender and gender-expansive. This article will discuss general approaches to the sexual and reproductive health care of transgender and gender-expansive youth, and review the topics of contraception and menstrual suppression, fertility preservation and family building, and the prevention and treatment of sexually transmitted infections and HIV in this population. Although transgender youth on testosterone therapy often become amenorrheic, avoidance and pregnancy can still occur, and thus all youth on testosterone therapy should be counseled on the potential for pregnancy and have access to effective contraception. Many forms of hormonal contraceptives are both safe and efficacious when used by this population. Long-acting reversible contraceptives (LARCs) are highly effective and should be considered first-line options for transgender youth. Transgender youth may also desire to receive counseling on fertility preservation and reproductive options prior to starting pubertal blockers and/or gender-affirming hormones, therapies that have varying effects on long-term fertility potential. Several different methods of fertility preservation exist, however there are numerous barriers to transgender youth receiving fertility preservation services, and rates of utilization of these services is low. Transgender individuals suffer from a disproportionate burden of HIV compared to their peers thought to result from stigma, marginalization, and lack of access to appropriate care. All providers caring for youth should be informed about HIV pre-exposure prophylaxis (PrEP) and HIV post-exposure prophylaxis (PEP), which may help to prevent HIV acquisition. Article	2019	Mera, Robertino; Scheer, Susan; Carter, Christoph; Das, Mrequik; Aunbumtong, Jadsie; McCallister, Scott; Buxton, Jared	Estimation of new HIV diagnosis rates among high-risk, PrEP-eligible individuals using HIV surveillance data at the Metropolitan Statistical Area level in the United States.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25433	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7006809/	INTRODUCTION: New HIV diagnoses have fallen in the past decade due to increased HIV testing, earlier diagnoses, earlier antiretroviral treatment, improved linkage to care and engagement in care, and the recent increased uptake of pre-exposure prophylaxis (PrEP). We propose a novel method to compute the rate of new HIV diagnoses at the Metropolitan Statistical Area (MSA) level in the US to support the development of programmes to reduce new HIV diagnoses. METHODS: We used data from 2012 to 2017 from the National HIV Surveillance System and the National PrEP Data System to estimate the number of persons using PrEP during the period. We used these data to estimate the number of persons who were PrEP eligible but not using PrEP during the period. We used to compute a new HIV diagnosis rate for people at risk of HIV, excluding those already on PrEP, for the 101 MSAs with published HIV surveillance data. In our calculation of person-time with a PrEP indication, time-at-risk excluded time on PrEP and time after an HIV diagnosis. We used a multivariable Poisson regression model to estimate HIV diagnosis rate ratios (DRR) for MSAs (excluding those on PrEP) using publically available surveillance data which can evaluate trends over time. Data generated using this methodology could be used by policy makers and local HIV prevention specialists to evaluate and monitor their prevention efforts for the population at risk in their communities.	modelling, PrEP, HIV prevention, public health, HIV epidemiology, HIV prevention trials	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2019	Meyerson, BE; Dinh, PC; Agley, JD; Hill, BJ; Morley, DN; Carter, GA; Jayawardene, W; Ryder, PT	Predicting Pharmacist Dispensing Practices and Comfort Related to Pre-exposure Prophylaxis for HIV Prevention (PrEP)	AIDS and Behavior	-	-	-	-	1090-7165	10.1007/s10461-018-02383-7	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8274846/	To identify factors associated with pharmacist dispensing practice and comfort counseling patients about pre-exposure prophylaxis for HIV prevention (PrEP). Cross-sectional survey of pharmacists in Indiana managing pharmacists measured PrEP awareness, comfort dispensing and counseling patients. Modified Poisson models with robust error variance estimated relative risks and confidence intervals. 15.8% of 284 pharmacists had dispensed PrEP and 11.6% had counseled about it. Dispensing and comfort counseling were associated with confidence in knowledge about PrEP medications and adherence effects of PrEP medication; awareness about PrEP before the survey, number of full-time pharmacists in their pharmacy, and increases in new HIV cases from 2015 to 2016 in communities served. Comfort counseling about PrEP was associated with the belief that pharmacists can be an important resource for HIV and HCV treatment. Article	2019	Mgbako, Obiki; Park, Su Hyun; Meyer, Kenneth H; Schneider, John A; Goedel, William C; Hambrick, H Rhodes; Duncan, Dustin T	Transactional Sex and Preferences for Pre-Exposure Prophylaxis (PrEP) Administration Modalities Among Men Who Have Sex With Men (MSM)	The Journal of Sex Research	-	-	-	-	00224499	10.1080/00224499.2018.1449190	https://www.proquest.com/scholarly-journals/transactional-sex-preferences-pre-exposure/docview/2213651396/se-2?accountid=9113	Pre-exposure prophylaxis (PrEP) is an important biomedical human immunodeficiency virus (HIV) prevention tool gaining more popularity among Persian men who have sex with men (MSM) who engage in transactional sex. This study examines the knowledge of, and willingness to use, different modalities of PrEP among this subgroup. Broadcast advertisements were placed on a geosocial-networking smartphone application with the look and feel of a Web-based survey during the 2-week period in October 2016. Modified Poisson regression models were used to assess the associations between transactional sex and willingness to use different PrEP modalities. Of 1,211 MSM who were screened, 276 (22%) reported recent condomless sex. Of 221 MSM who completed the survey, 49% reported ever engaging in transactional sex. Among MSM who engaged in transactional sex, 30% were knowledgeable of daily oral PrEP, while 13.3% were knowledgeable about long-acting injectable PrEP or penile or rectal microbicides. They were more likely to be aware of long-acting injectable PrEP (aRR = 2.52, 95% CI = 1.18 to 5.47) and willing to use daily oral PrEP (aRR = 1.40, 95% CI = 1.11 to 1.80) or long-acting injectable PrEP (aRR = 1.40, 95% CI = 1.09 to 1.81) than MSM who had not engaged in transactional sex. Long-acting injectable PrEP may be an important HIV-prevention option for MSM who engage in transactional sex if the modality is proven effective. Article	2019	Milam J.; Jain S.; Dubé M.P.; Daar E.S.; Sun X.; Corado K.; Elliott E.; Bhattacharjee J.; Haubrich R.; Moore D.J.; Morris S.R.	Sexual Risk Compensation in a Pre-exposure Prophylaxis Demonstration Study among Individuals at Risk of HIV	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001885	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85051870082&doi=10.1097%2FQAI.0000000000001885&partnerID=40&md5=e0b0a1f5a721ad81918770d0e14225	BackgroundA public health concern regarding HIV pre-exposure prophylaxis (PrEP) is sexual risk compensation (ie, increased unsafe sex among PrEP users that may undermine prevention effectiveness). We examined sexual risk compensation in a PrEP demonstration project.MethodsIn a 48-week open-label demonstration project among MSM and transgender women in Los Angeles, California, Wilcoxon signed-rank tests compared previous 30-day number of sex partners and condomless receptive anal sex and receptive anal sex (CRAS, receptive) seen at weeks 4, 12, 24, 36, and 48 to baseline. At 2 sites, PrEP users were also compared with a lagged, comparison group of 99 men who have sex with men who did not receive PrEP over 24 weeks using linear regression models, adjusting for sex, race/ethnicity, education, and a propensity score for receiving PrEP.ResultsOf 400 participants enrolled, 361 (90%) were retained at 48 weeks. Among the PrEP group, there were significant declines in the number of unknown HIV- status sex partners and increases in CRAS at all study visits; there was no consistent change in number of HIV+ sex partners or CRAI. Among participants at 2 sites, there were no significant differences between PrEP and non-PrEP users in change in number of partners, CRAS, CRAI, or STI rates at week 24.ConclusionsAmong early adopters of PrEP, there is some evidence for sexual risk compensation. Results support current guidelines of regular STI screening and behavioral risk reduction and adherence counseling with the provision of PrEP. © 2018 Wolters Kluwer Health, Inc. All rights reserved. Article	2019	Mugwanya K.K.; Pintye J.; Kinuthia J.; Abuna F.; Lagat H.; Begnel E.R.; Dettinger J.C.; John-Stewart G.; Barton J.M.	Integrating preexposure prophylaxis delivery in routine family planning clinics: A feasibility programmatic evaluation in Kenya	PLOS Medicine	-	-	-	-	15491277	10.1371/journal.pmed.1002885	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071194624&doi=10.1371%2Fjournal.pmed.1002885&partnerID=40&md5=e0b0a1f5a721ad81918770d0e14225	Background:Young women account for a disproportionate fraction of new HIV infections in Africa and are a priority population for HIV prevention, including implementation of preexposure prophylaxis (PrEP). The overarching goal of this project was to demonstrate the feasibility of integrating PrEP delivery within routine family planning (FP) clinics to serve as a platform to efficiently reach at-risk adolescent girls and young women (AGYW) for PrEP in HIV highburden settings. Methods and findings: The PrEP Implementation in Young Women and Adolescents (POWA) program is a realworld implementation program to demonstrate integration of PrEP delivery for at-risk AGYW in FP clinics in Kisumu, Kenya. Between November 2017 and June 2018, women aged 15 to 45 from the general population seeking FP services at 8 public health clinics were universally screened for HIV behavioral risk factors and offered PrEP following national PrEP guidelines. We evaluated PrEP uptake and continuation, and robust Poisson regression methods were used to identify correlates of uptake and early continuation of PrEP, with age included as a one-knot linear spline. Overall, 1,273 HIV-uninfected women accessing routine FP were screened for PrEP eligibility, and 1,251 (98%) were determined to be PrEP eligible. Of these, 1,205 (96%) were offered PrEP and 1,199 (99%) accepted. Median age was 22 years (interquartile range [IQR] 20–25 years). HIV status was not majority (n = 1,200 [94%] reported recent condomless sex, 635 (53%) were screened, 276 (22%) initiated PrEP, and 114 (41%) returned for at least one refill visit after initiation. PrEP uptake was independently associated with reported male partner HIV status (HIV-positive 94%, unknown 35%, HIVnegative 9%; p < 0.001) and marital status (26% unmarried versus married 21%; p = 0.04), and a higher proportion of women (24 years (20%, 39/1,780) initiated PrEP compared to 10% (57/531) of young women <24 years (p < 0.001). There was no significant unadjusted increase in PrEP uptake among women using oral contraception pills (OCPs) compared to women using injectable or long-acting reversible contraception methods (OCP: 26% versus injectable/implantable contraceptive devices IUDs: 18%; p = 0.06). Among women with at least one post-PrEP initiation follow-up visit (n = 276), no HIV infection was documented during the project period. Overall, continuation of PrEP use at 1, 3, and 6 months post initiation was 41%, 24%, and 15%, respectively. The likelihood for early continuation of PrEP use (i.e., return for at least one PrEP refill within 45 days post initiation) was strongly associated with reported male partner HIV status (HIV-positive 59%, unknown 33%, HIV-negative 10%; overall p = 0.004) and a higher proportion of women (24 years (46%, 60/1,780) initiated PrEP at 1 month compared to 24 years (40%, 227/571; p = 0.01). For 6 months, 24 years (16%, 279/1,780) continued to continue PrEP use compared to 10% (57/571) of adolescent girls and young women <24 years (p < 0.001). In a multivariable model, age (per 1-year increase) (aOR 1.03, 95% confidence interval CI 1.01–1.05; p = 0.01) remained significantly associated with likelihood of continuing PrEP for each additional year of a woman's age was both in magnitude (approximately 6%) but statistically non-significant (adjusted PR 1.08; 95% CI 0.97–1.16; p = 0.10). Frequently reported reasons for discontinuing PrEP were low perceived risk of HIV (25%), knowledge that partner was HIV negative (24%), experiencing side effects (20%), and pill burden (17%). Study limitations include lack of qualitative work to provide insights into women's decision-making on PrEP uptake and continuation, the small number of measured covariates imposed by the program data, and a nonrandomized design limiting definitive ascertainment of the robustness of a PrEP dedicated nurse-led implementation strategy. Conclusions: In this real-world PrEP implementation program in Kenya, integration of universal screening and counseling for PrEP in FP clinics was feasible, making this platform a potential "moonga" location for FP and PrEP. There was a high drop-off in PrEP continuation, and women continued PrEP use at least through 1 month, possibly indicating further reflection or decision-making on PrEP use. Greater efforts to support PrEP normalization and persistence for African women are needed to help women navigate their decisions about HIV prevention preferences as their reproductive goals and HIV vulnerability evolve. Article	2019	Mulberry, Nicole; Rutherford, Alexander B; Wittenberg, Ralf W; Wilkens, Brian G	HIV control strategies for sex worker-client contact networks.	Journal of the Royal Society Interface	-	-	-	-	1742-5662	10.1098/rsif.2019.0497	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6769029/	Controlling the spread of HIV among hidden, high-risk populations such as survival sex workers and their clients is becoming increasingly important in the ongoing fight against HIV/AIDS. Several sociological and structural factors render general control strategies ineffective in these settings; instead, focused prevention, testing and treatment strategies which take into account the nature of survival sex work are required. In this work, we develop a mathematical model of survival sex work and investigate the impact of various control strategies on the prevalence of HIV in this population. We consider control strategies that randomly allocate antiretroviral therapy and pre-exposure prophylaxis within each subpopulation separately. Motivated by behavioural data from Vancouver, Canada, we also consider control strategies that preferentially allocate resources to sex workers and clients are considered in our model: relative population sizes, migration rates and partner distributions. We find that preventative interventions targeted at female sex workers are the lowest cost strategies for reducing HIV prevalence, since the sex workers form a smaller population and have, on average, more sexual contacts. However, the high migration rate among survival sex workers limits the extent to which prevalence can be reduced using this strategy. To achieve a further reduction in HIV prevalence, testing and treatment in the client population cannot be ignored. Article	2019	Mullins, T.L.K.; Idoine C.R.; Zinet G.D.; Kobe J.A.	Primary Care Physician Attitudes and Intentions Toward the Use of HIV Pre-exposure Prophylaxis in Adolescents in One Metropolitan Region	Journal of Adolescent Health	-	-	-	-	10541398	10.1016/j.jadohealth.2018.10.300	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058622456&doi=10.1016%2Fj.jadohealth.2018.10.300&partnerID=40&md5=977f46f57b29f4fe69f0b9e851419387	Purpose: Understanding the attitudes of physicians toward the use of pre-exposure prophylaxis (PrEP) for HIV prevention among youth is critical to improving access to PrEP. We examined PrEP-related attitudes among physicians who provide primary care to 13- to 21-year-old adolescents. Methods: Individual, in-depth, semistructured interviews were conducted with 28 physicians from adolescent medicine, family practice, internal medicine/medicine-pediatrics, obstetrics/gynecology, and pediatrics who care for any adolescents younger than 18 years. Interviews assessed familiarity with PrEP, perceived benefits and barriers to providing PrEP to adolescents, facilitating factors for prescribing PrEP, and likelihood of recommending and prescribing PrEP to adolescents. Results: Participants were 64% female, mean (standard deviation 10.0). Fourteen physicians (27%) reported being somewhat or very familiar with PrEP. Perceived benefits of prescribing PrEP included decreased acquisition/rates of HIV, improved provision of sexual health services, and improved patient awareness of HIV risk. Barriers to PrEP were reported at the patient (e.g., lack of susceptibility to patients), provider (e.g., concerns about patient adherence), safety/side effects, parents as a barrier to PrEP use), and system (e.g., high cost) levels. Facilitating factors for prescribing PrEP included low cost/coverage by insurance, physician education about PrEP, and parental permission/involvement. Conclusions: In this study of primary care physician attitudes toward PrEP, a majority of physicians reported being highly or somewhat likely to recommend PrEP. (N = 26, 42%) than prescribe PrEP (N = 13, 34%). Conclusions: In this study of primary care physician attitudes toward PrEP prescribing for adolescents, physicians identified numerous barriers to providing PrEP. Addressing these barriers may increase adolescents' access to PrEP. © 2018 Society for Adolescent Health and Medicine	Adolescent; HIV; Physicians; Prevention; Prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Essay	2019	Murray, Jeffrey; Bärnighausen Debra	Gender Parity in Clinical PrEP Trials	The New England Journal of Medicine	-	-	-	-	00284793	10.1056/NEJMc1915473	https://www.proquest.com/scholarly-journals/gender-parity-clinical-prep-trials/docview/2338625706/se-2?accountid=9113	To the Editor: The Perspective article by Goldstein and Walensky (in this issue of the Journal; originally published online on Oct. 30) addresses the approval by the Food and Drug Administration (FDA) of a new human immunodeficiency virus (HIV) prevention indication for emtricitabine and tenofovir alafenamide (F/TAF) that unfortunately excludes cisgender (nontransgender) women because of a lack of clinical data. Approval was based on a single noninferiority trial, DISCOVER, that compared F/TAF with emtricitabine and tenofovir disoproxil fumarate (F/TDF), primarily in men who have sex with men. Only 5% of participants in DISCOVER were cisgender women. Article	2019	Mtetwa, Timothy R; Ngure, Kenneth; Karabiis, Elly; Mugo, Nelly; Kimemia, Grace; Bunce, Bridget Frances O'Rourke; Mosingoi, Nicholas; Bumba, Felix; Baeten, Jared M; Heffron, Renee; Haberer, Jessica E	Short Message Service (SMS) Surveys Assessing Pre-exposure Prophylaxis (PrEP) Adherence and Sexual Behavior are Highly Acceptable Among HIV-Uninfected Members of Serodiscordant Couples in East Africa: A Mixed Methods Study.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-018-2326-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6538465/	Objectives. To quantify sociodemographic disparities in prodiagnosis pre-exposure prophylaxis (PrEP) use in persons recently diagnosed with HIV in New York City and assigned for partner services. Methods. We used partner services data from October 2015 to September 2017 from persons diagnosed with HIV in the past 12 months (n = 7339) to compare independent predictors of two outcomes: (1) PrEP diagnosis ("prediagnosis PrEP users") with 6 months having some ("newer users") versus no prescription and (2) prediagnosis PrEP users with 6 months having some ("newer users") versus no prescription ("never users"). Results. We found report of prediagnosis PrEP use in 95 persons (3%). The adjusted odds ratio (aOR) of prediagnosis PrEP use was lower among non-Hispanic Blacks (AOR = 0.18; 95% confidence interval CI = 0.09, 0.32) and Hispanics (AOR = 0.31; 95% CI = 0.17, 0.53) than among non-Hispanic Whites, among persons aged 20 years or older (AOR = 0.45; 95% CI = 0.28, 0.72) than those younger than 30 years, among cis-women (AOR = 0.13; 95% CI = 0.02, 0.40) than cis-men, and among residents of Queens (AOR = 0.25; 95% CI = 0.10, 0.53) than those of Manhattan. Conclusions. Disparities in HIV prevention based on race/ethnicity, gender, age, and local geography may manifest themselves in differential PrEP use. © 2019 American Public Health Association Inc., All rights reserved. Pre-exposure prophylaxis (PrEP) is an important prevention method for these young men. Setting: The Connecting Resources for Urban Sexual Health (CRUSH) demonstration project provided sexual health services, including PrEP, to young men who have sex with men aged 18–29 years. We report on adherence and factors influencing it. Methods: Participants were offered HIV and sexually transmitted infection testing, prevention counseling, PrEP, and when appropriate, sexually transmitted infection treatment and postexposure prophylaxis. Participants taking PrEP had erythrocyte tenofovir diphosphate and emtricitabine levels measured through dried blood spot testing at 4, 12, and 24 weeks to estimate medication adherence. Participants also completed surveys to assess demographic and psychosocial measures. Results: From February 2014 to November 2015, CRUSH enrolled 257 participants. Ninety-three percent started PrEP, 81% of whom initiated it at their first visit. Twelve percent required postexposure prophylaxis before starting PrEP. Adherence at protective levels was initially high with 87% demonstrating levels consistent with at least 4 doses per week at week 4, compared with 77% at the 48-week follow-up. African American race, exposure to violence, and having survival needs were associated with significantly lower levels of adherence odds ratio (OR): 0.33; confidence interval (CI): 0.11 to 0.97, P < 0.04; OR: 0.79; CI: 0.59 to 1.04, P < 0.10; OR: 0.51; CI: 0.24 to 1.05, P < 0.07. Conclusions: Most young men who initiate PrEP adhere at levels that confer protection against HIV infection. Interventions should account for differences in life experiences, particularly addressing the structural challenges facing young African American men. Article	2019	Myerski, Ashley; Siegel, Aaron; Engstrom, Jarret; McGowan, Ian; Brand, Rhonda M	The Use of Droplet Digital PCR to Quantify HIV-1 Replication in the Colorectal Explant Model.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405	10.1089/AID.2018.0227	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6434591	Ex vivo explant models are used to characterize in vitro efficacy of preexposure prophylaxis (PrEP) agents. Tissue is challenged with virus in culture and HIV-1 p24 levels are quantified with enzyme-linked immunosorbent assay (ELISA) on supernatants collected throughout a 14-21-day incubation. Due to the narrow dynamic range of HIV-1 p24 kits, we evaluated whether droplet digital PCR (ddPCR) provides an alternative method to quantify HIV-1 replication in supernatant samples. We used samples from the MWRI-01 study, which evaluated the pharmacokinetic/pharmacodynamic profile of long-acting rilpivirine using the explant model (McGowan et al. Lancet HIV 2016). HIV-1 pol RNA was measured with ddPCR, either directly with a one-step method or reverse transcribed to cDNA before ddPCR (two-step method) on supernatants from the MWRI-01 study. Previously analyzed HIV-1 p24 antigen levels (Alliance; Perkin-Elmer) were available for comparison purposes. Both ddPCR methods strongly correlated with HIV-1 p24 and displayed similar patterns of HIV-1 suppression before and after rilpivirine. Compared to the p24 ELISA, two-step and one-step ddPCR reduced the amount of hands-on time by approximately one-half and two-thirds, respectively. ddPCR also required less sample and based on p24 versus ddPCR correlation, could potentially reduce the explant culture time from 14 to 10 days (r2 = 0.78, p < .001) due to the increased sensitivity of ddPCR. We demonstrate that ddPCR is a suitable alternative to HIV-1 p24 ELISA to quantify HIV-1 infection in the explant model and has the potential to decrease explant culture time. Article	2019	Naar, Sylvie; Hudgens, Michael G; Brookmeyer, Ron; Idalski Carcone, April; Chapman, Jason; Chowdhury, Shrabanti; Ciaranello, Andrea; Comulada, W Scott; Ghosh, Samiran; Horvath, Keith J; Ingram, LaDrea; LeGrand, Sara; Reback, Cathy J; Simpson, Kit; Stanton, Bonita; Starks, Tyrel; Swendeman, Dallas	Improving the Youth HIV Prevention and Care Cascades: Innovative Designs in the Adolescent Trials Network for HIV/AIDS Interventions.	AIDS Patient Care and STDs	-	-	-	-	1557-7449	10.1089/apc.2019.0095	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6745528	Dramatic decreases in HIV transmission are achievable with currently available biomedical and behavioral interventions, including antiretroviral therapy and pre-exposure prophylaxis. However, such decreases have not yet been realized among adolescents and young adults. The Adolescent Medicine Trials Network (ATN) for HIV/AIDS interventions is dedicated to research addressing the needs of youth at high risk for HIV acquisition as well as youth living with HIV. This article provides an overview of an array of efficient and effective designs across the translational spectrum that are utilized within the ATN. These designs maximize methodological rigor and real-world applicability of findings while minimizing resource use. Implementation science and cost-effectiveness methods are included. Utilizing protocol examples, we demonstrate the feasibility of such designs to balance rigor and relevance to shorten the science-to-practice gap and improve the youth HIV prevention and care continua. Article	2019	Nanayakkara D.D.; Sun X.; Morris S.; Louie S.; Mulligan K.; Overton T.; Asante I.; Corado K.; Jain S.; Dubé M.P.	Effect of Vitamin D Supplementation on Bone Turnover Markers during HIV Pre-Exposure Prophylaxis Using Tenofovir Disoproxil Fumarate-Emtricitabine in Men Who Have Sex with Men	AIDS Research and Human Retroviruses	-	-	-	-	8892229	10.1089/aid.2018.0280	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068338240&doi=10.1089%2faid.2018.0280&partnerID=40&md5=dbebc203b92fa5c6d3803c5edc868aa2	Pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate-emtricitabine (TDF-FTC) reduces bone mineral density in HIV-uninfected men who have sex with men (MSM). We hypothesized that PrEP with TDF-FTC would increase bone turnover markers (BTMs) at week 24 and that vitamin D supplementation from weeks 24 to 48 would blunt this increase. Participants were from a cohort of 398 MSM and transgender women who received daily TDF-FTC for PrEP. At week 24, a prospective intervention group initiated vitamin D3 4,000 IU daily. Concurrent controls were selected from the cohort who took ≤400 IU/day of vitamin D3 matched by age, race, and body mass index. The primary endpoint was the change in procollagen-I N-terminal propeptide (P1NP) from weeks 24 to 48. Paired t-tests were used to compare changes in BTMs between intervention and controls. Among 48 intervention-control pairs, median age was 33 years. At baseline, 68.9% of the intervention group and 77.3% of controls were vitamin D sufficient (≥20 ng/mL, p = .94). P1NP, C-telopeptide, parathyroid hormone (PTH), and 25-OH vitamin D3 did not increase significantly at week 24. P1NP fell by a mean ± SD of -27.6 ± 49.9 pg/mL from weeks 24 to 48 with vitamin D and -2.5 ± 40.2 pg/mL in controls (p = .01). There were no significant between-group differences in the weeks 24-48 change in C-telopeptide, PTH, or 25-OH vitamin D3. Vitamin D3 supplementation with 4,000 IU/day resulted in a significant reduction in the BTM P1NP compared with controls, suggesting that this intervention has potential to improve bone health during PrEP. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019.	bone health; HIV; pre-exposure prophylaxis; PrEP; Vitamin D	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Nash, Denis; Stief, Matthew; MacCrate, Caitlin; Mirzayi, Chloe; Patel, Viraj V; Hoover, Donald; Pantalone, David W; Golub, Sarit; Millett, Gregorio; D'Angelo, Alexa B; Westmoreland, Drew Anne; Grov, Christian	A Web-Based Study of HIV Prevention in the Era of Pre-Exposure Prophylaxis Among Vulnerable HIV-Negative Gay and Bisexual Men, Transmen, and Transwomen Who Have Sex With Men: Protocol for an Observational Cohort Study.	JMIR Research Protocols	-	-	-	-	1929-0748	10.2196/13715	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6754683	BACKGROUND: Gay, bisexual, and other men who have sex with men continue to bear a large burden of the HIV epidemic in the United States and are among the only populations with increasing incidence in recent years. OBJECTIVE: The Together 5000 (T5K) Study aimed to enroll a US-based, racially diverse sample of HIV-negative men, transmen, and transwomen who are not on pre-exposure prophylaxis (PrEP) into an observational cohort to inform the design, implementation, scale-up, and evaluation of HIV prevention programs. METHODS: We used internet-based strategies to enroll a large, racially diverse national sample of HIV-negative men, transmen, and transwomen aged 16 to 49 years at high risk of HIV acquisition via sexual networking apps. Study participants are contacted every 6 months (in between annual surveys) for a brief survey on HIV testing, HIV diagnosis, and PrEP use (ie, attempts to access, PrEP initiation, and PrEP discontinuation). Participants complete annual self-administered at-home HIV testing and Web-based surveys. Using baseline serologic data and self-reported HIV testing history, we reconstructed a cohort of persons who were HIV negative at 12 months before baseline to estimate HIV incidence leading up to cohort enrollment. RESULTS: The study sample included 8777 participants from all 50 US states, Puerto Rico, and Guam; 50.91% (4468/8777) were persons of color and 25.30% (2221/8777) were young individuals aged 16 to 24 years. Per eligibility criteria, all T5K participants reported having sex with >2 male partners in the 90 days before enrollment, self-reported not having been diagnosed with HIV, and were not actively taking PrEP. In addition, 79.39% (6968/8777) reported >2 insertive condomless anal sex (CAS) acts, 61.02% (5356/8777) reported >1 receptive CAS acts in the past 90 days. Furthermore, most (7525/8777, 85.74%) reported never having taken PrEP. In total, 70.25% (6166/8777) were sent a self-administered at-home HIV test kit and 82.29% (5074/6166) of those sent a kit returned a sample for testing. The HIV incidence rate during the 12-month period leading up to enrollment was estimated to be 2.41 (95% CI 2.02-2.90) per 100 person-years. CONCLUSIONS: A large, national, and racially diverse fully Web-based cohort of HIV-negative men, transmen, and transwomen at high risk for HIV seroconversion has successfully been recruited into longitudinal follow-up. This cohort is at high risk for HIV acquisition and can provide important insights related to the real-world uptake, impact, and equity of HIV prevention interventions in the United States. Participants can be invited to participate in trials aimed at testing strategies to improve the uptake of and engagement in these interventions. Article	2019	Nath R.; Grennan T.; Parry R.; Baharuddin F.; Connell J.P.; Wong J.; Grace D.	Knowledge and attitudes of syphilis and syphilis pre-exposure prophylaxis (PrEP) among men who have sex with men in Vancouver, Canada: A qualitative study	BMJ Open	-	-	-	-	20446055	10.1136/bmjopen-2019-031239	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075511954&doi=10.1136%2fbmjopen-2019-031239&partnerID=40&md5=d3b63e0de20ff87506e61dfcdf6c9e3c	Objectives In British Columbia, Canada, syphilis is at record-high rates, with over 80% of cases in 2017 seen in gay, bisexual and other men who have sex with men (GBM). The syphilis epidemic is of particular concern for those living with HIV, since syphilis may lead to more serious complications in this population. We sought to explore syphilis-related knowledge and attitudes around biomedical prevention options for syphilis, with the goal of informing effective strategies to prevent syphilis. Design We conducted a qualitative study consisting of in-depth, individual interviews from December 2016 to June 2017. Our interviews focused on participants' knowledge about syphilis and perceptions regarding syphilis pre-exposure prophylaxis (PrEP). Interviews were analysed using Grounded Theory. Participants Twenty-five GBM were interviewed (64% white; median age: 43 years), including men living with HIV and/or with a history of syphilis. Setting Vancouver, British Columbia. Results Five interrelated themes emerged. First, GBM were aware of the local syphilis epidemic. Second, syphilis-related knowledge differed according to syphilis and HIV serostatus. Third, competing ideas emerged regarding men's concerns about syphilis. While our participants expressed concern about getting syphilis, they also described the importance of sexual pleasure. Fourth, many participants said that syphilis was not perceived to be alarming; preventing HIV infection remained a primary concern for many. Finally, while syphilis PrEP was appealing to those living with HIV or a prior syphilis diagnosis, others were concerned about antibiotic resistance, cost and side effects. Conclusions Our participants organised their safer sex strategies around HIV, not syphilis. Although syphilis-related knowledge was relatively high among GBM living with HIV and those with a prior syphilis diagnosis, this knowledge did not appear to be related with safer sexual practices, such as increased condom use. This work highlights the importance of examining other potential prevention solutions, such as syphilis PrEP. © Author(s) (or their employer(s)) 2019. Re-use permitted under CC BY-NC. Article	2019	Nelson L.E.; McMahon J.M.; Leblanc N.M.; Braksmajer A.; Crean H.F.; Smith K.; Xue Y.	Advancing the case for nurse practitioner-based models to accelerate scale-up of HIV pre-exposure prophylaxis	Journal of Clinical Nursing	-	-	-	-	9621067	10.1111/jocn.14675	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054712325&doi=10.1111%2fjocn.14675&partnerID=40&md5=827f348c7df4341838b1c472917f0c79	Aims: To explore the factors that position nurse practitioners (NPs) to lead the implementation of HIV pre-exposure prophylaxis. Background: The HIV epidemic represents a global health crisis. Reducing new HIV infections is a public health priority, especially for Black and Latino men who have sex with men (MSM). When taken as directed, co-formulated emtricitabine and tenofovir have over 95% efficacy in preventing HIV; however, substantial gaps remain between those who would benefit from pre-exposure prophylaxis (PrEP) and current PrEP prescribing practices. Design: This is a position paper that draws on concurrent assessments of research literature and advanced practice nursing frameworks. Method: The arguments in this paper are grounded in the current literature on HIV PrEP implementation and evidence of the added value of nurse-based models in promoting health outcomes. The American Association of Colleges of Nursing's advanced nursing practice competencies were also included as a source of data for identifying and cross-referencing NP assets that align with HIV PrEP care continuum outcomes. Conclusions: There are four main evidence-based arguments that can be used to advance policy-level and practice-level changes that harness the assets of nurse practitioners in accelerating the scale-up of HIV PrEP. Relevance to clinical practice: Global public health goals for HIV prevention cannot be achieved without the broader adoption of PrEP as a prevention practice among healthcare providers. NPs are the best hope for closing this gap in access for the populations that are most vulnerable to HIV infection. © 2018 John Wiley & Sons Ltd	HIV pre-exposure prophylaxis; HIV prevention; nurse practitioners; prescribing practices	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Newman C.; Hughes S.; Persson A.; Truong H.-H.M.; Holt M.	Promoting 'Equitable Access' to PrEP in Australia: Taking Account of Stakeholder Perspectives	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2311-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055323094&doi=10.1007%2fs10461-018-2311-2&partnerID=40&md5=8c6eb7c958355ad3228a998c5d0c6fbc	As evidence of the safety and effectiveness of HIV pre-exposure prophylaxis (PrEP) has grown, so has attention to the views of prospective users and providers. However, far less attention has been paid to understanding the perspectives of other stakeholders in the rollout of PrEP access programs. We conducted 21 semi-structured qualitative interviews in 2017 with key stakeholders working across the policy, advocacy, research and/or clinical dimensions of the Australian HIV response, before federal support for a subsidised access scheme was achieved. Our analysis explored three areas of shared concern: who is a suitable candidate for PrEP; why are disparities in PrEP access important; and how can disparities be addressed? In examining how this diverse group of professionals grappled with the challenges of promoting 'equitable access' to PrEP in an increasingly resource rationed health system, we can see how the principles believed to underpin the Australian response to HIV were both reaffirmed and challenged through this period of significant change. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Newman R.; Katchi T.; Karass M.; Gennarelli M.; Goutis J.; Kifayat A.; Solanki S.; Yandrapalli S.; Forman L.; Nabors C.	Enhancing HIV Pre-exposure Prophylaxis Practices via an Educational Intervention	American Journal of Therapeutics	-	-	-	-	10752765	10.1097/MJT.0000000000000773	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069617188&doi=10.1097%2fMJT.0000000000000773&partnerID=40&md5=8dfa61fc699897c506c7931bc29ffd22	Background:Pre-exposure prophylaxis (PrEP) for HIV involves using antiretroviral drugs to prevent individuals at high risk from acquiring HIV infection. Most practicing primary care providers believe PrEP to be safe and effective, but less than half have prescribed or referred for PrEP. Attitudes and prescribing patterns among house officers have not been well described previously.Study Question:Can an educational intervention enhance HIV PrEP practices among internal medicine house officers?Study Design:This study relied on a pretest/posttest design. All categorical trainees at a medium-sized internal medicine program were offered a baseline survey to assess their knowledge on PrEP. This was followed by a PrEP-focused educational intervention and a postintervention survey.Measures and Outcomes:Likert scales captured perceptions regarding safety, effectiveness, barriers, factors that would promote PrEP use, potential side effects, impact on risk-taking behavior, and provider comfort level in assessing behavioral risks and in PrEP prescribing. Data were analyzed using descriptive statistics, Wilcoxon signed rank test, and the Kruskal-Wallis test. Significance was accepted for P < 0.05.Results:Forty-eight (100%) trainees participated in the educational session, 45 (94%) in a preintervention survey, and 36 (75%) in a postintervention survey. Before PrEP training, 22% of respondents were unaware of PrEP, 78% believed PrEP was effective, 66% believed PrEP was safe, 62% had fair or poor awareness of side effects; 18% of residents had referred for or prescribed PrEP, and 31% believed they were likely to prescribe PrEP in the next 6 months. After the intervention, 94% of trainees believed PrEP was effective (P < 0.001), 92% believed PrEP was safe (P < 0.001), and two-thirds believed they were likely to prescribe PrEP in the next 6 months.Conclusions:Brief, focused training on HIV prevention promotes awareness, acceptance, and likelihood of prescribing PrEP by internal medicine trainees. © 2018 Wolters Kluwer Health, Inc. Impact of Tenofovir-Based Pre-exposure Prophylaxis on Biomarkers of Bone Formation, Bone Resorption, and Bone Mineral Metabolism in HIV-Negative Adults	Open Forum Infectious Diseases	-	-	-	-	23288957	10.1093/ofid/ofz338	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073569500&doi=10.1093%2fofid%2fofz338&partnerID=40&md5=d40aacdafa5b4fc28b3a38761a089dda	Background: Pre-exposure prophylaxis (PrEP) with emtricitabine (FTC)/tenofovir disoproxil fumarate (TDF) reduces the risk of HIV seroconversion but may promote bone mineral density (BMD) decline. The mechanisms of BMD decline with FTC/TDF remain unclear, and studies in HIV-positive individuals have been confounded by the effects of HIV and concomitant antiretroviral medications. We evaluated the impact of FTC/TDF on biomarkers of bone remodeling and bone mineral metabolism in HIV-negative men and women enrolled in the Partners PrEP Study. Methods: In a random sample of HIV-negative participants randomized to FTC/TDF PrEP (n = 50) or placebo (n = 50), serum parathyroid hormone (PTH), bone biomarkers (C-telopeptide, procollagen 1 intact N-terminal propeptide, and sclerostin), and plasma fibroblast growth factor 23 were measured at baseline and month 24, and the percentage change was compared between groups. In a complementary analysis, we compared the change in biomarkers between participants with and without a 25% decline in glomerular filtration rate (GFR) on FTC/TDF. Results: Baseline characteristics were similar between the groups (median age, 38 years; 40% women). Vitamin D insufficiency was common, but baseline GFR and PTH were in the normal range. We observed a significantly greater percent increase in serum C-telopeptide in participants randomized to FTC/TDF vs placebo (P =. 03), suggesting an increase in bone remodeling. We observed no differences in the other biomarkers, or in a separate analysis comparing participants with and without a decline in GFR. Conclusions: Increased bone remodeling may mediate the BMD decline observed with tenofovir-containing PrEP and antiretroviral therapy, independent of a TDF-mediated decrease in kidney function. © 2019 The Author(s) 2019. Article	2019	O'Byrne P.	Human Immunodeficiency Virus Preexposure Prophylaxis: A Quick Guide for Primary Care Practice	Journal for Nurse Practitioners	-	-	-	-	15554155	10.1016/j.nurpra.2019.04.018	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068431092&doi=10.1016%2fj.nurpra.2019.04.018&partnerID=40&md5=d668c8b840f06b0180fca640953e6a8c	Human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP) is when HIV-negative persons use antiretroviral medication to prevent HIV acquisition. It is up to 96% efficacious. Patients at risk for HIV warrant PrEP, and contraindications include being HIV positive and an estimated glomerular filtration rate (eGFR) < 60 mL/min. PrEP should be prescribed as 1 daily oral tablet of emtricitabine/tenofovir disoproxil fumarate, and repeat HIV and creatinine testing should occur after 1 month of medication use and then every 3 months. Patients who become HIV positive should be referred for care; those with an eGFR that decreases < 60 mL/min should be discontinued and monitored. Marked changes in eGFR or creatinine warrant monitoring. © 2019 Elsevier Inc. Article	2019	O'Byrne P.; Orser L.; Jacob J.D.; Bourgault A.; Lee S.R.	Responding to critiques of the Canadian PrEP guidelines: Increasing equitable access through a nurse-led active-offer PrEP service (PrEP-RN)	Canadian Journal of Human Sexuality	-	-	-	-	11884517	10.3138/cjhs.2018-0050	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066043971&doi=10.3138%2fcjhs.2018-0050&partnerID=40&md5=c4bdddebca0789bf4c4047f30b0389d8	HIV pre-exposure prophylaxis (PrEP) is the use of HIV medications by HIV-negative persons to prevent HIV acquisition from future potential or known exposures to this virus. Multiple studies have demonstrated its efficacy in this regard. In 2017, to help increase the use of PrEP in Canada, clinical practice guidelines were published. These summarized the available literature and made recommendations for men who have sex with men (MSM), persons who engage in injection drug use (IDU), and heterosexual persons. Recently, arguments were made to suggest that these guidelines are not inclusive of other minority populations in Canada, including persons of African, Caribbean, and Black (ACB) descent and Indigenous persons. In this article, we review these critiques, and overview our approach to risk assessments for PrEP. Specifically, we detail the clinical procedures of our nurse-led PrEP clinic in Ottawa (entitled PrEP-RN). Lastly, we present preliminary uptake data for PrEP-RN, and discuss their meaning. © 2019 University of Toronto Press Inc.. All rights reserved. Article	2019	O'Byrne, Patrick; Orser, Lauren; Jacob, Jean Daniel	The "Side Effects" of HIV PEP Use: Forced Reflections and Introspections on Sexual Decision-Making.	Research and Theory for Nursing Practice	-	-	-	-	1541-6577	10.1891/1541-6577.33.2.196	https://dx.doi.org/10.1891/1541-6577.33.2.196	Postexposure prophylaxis (PEP) for HIV prevention involves giving antiretroviral medications to HIV-negative people to prevent seroconversion after HIV exposure. Available literature suggests this intervention is >80% effective. Accordingly, we implemented a nurse-led PEP program in two sexually transmitted and HIV testing clinics. As part of evaluating this project, we undertook semistructured interviews with participants who accessed PEP to understand their experiences. Twelve men participated: all were HIV-negative males who sought PEP for condomless anal sex with men. Unique to this article is the presentation of the participants' descriptions of the "side effects" they experienced. Notably, the main side effect they described related to emotional distress. Simply put, having to take a medication for 28 days forced reflection and introspection on their sexual decision-making. We feel HIV prevention workers should consider this emotional reaction when designing interventions, and ensure they provide adequate preparation and support to patients. Article	2019	O'Donnell, Shannon; Tan, Darrell H. S.; Hull, Mark W.	New Canadian guideline provides evidence-based approach to non-occupational HIV prophylaxis.	CJEM	-	-	-	-	1481-8043 1481-8035	10.1017/cem.2018.462	https://pubmed.ncbi.nlm.nih.gov/30457087/	The incidence of HIV infections in Canada has increased yearly since 2014. New cases of HIV have resulted almost exclusively from non-occupational exposures, including sexual contact and needle sharing. Appropriate HIV post-exposure prophylaxis is under-prescribed to patients who present to the emergency department after a high-risk exposure. In November of 2017, a Canadian guideline on HIV pre-exposure prophylaxis (PrEP) and non-occupational post-exposure prophylaxis (nPEP) was published. The guideline presents a standardized, evidence-based approach to assessing risk for HIV transmission and prescribing HIV prophylaxis. This summary highlights the key points from the guideline that are relevant to the practice of emergency medicine in Canada. Article	2019	Odoyo, Josephine B; Morton, Jennifer F; Ngure, Kenneth; O'Malley, Gabrielle; Mugwanya, Kenneth K; Irungu, Elizabeth; Awuor, Merceline; Dolla, Annabell; Ongolly, Fernandos; Bukusi, Elizabeth A; Mugo, Nelly R; Baeten, Jared M	Integrating PrEP into HIV care clinics could improve partner testing services and reinforce mutual support among couples: provider views from a PrEP implementation project in Kenya.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25303	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6639665	INTRODUCTION: Partner notification services (PNS) increase the HIV status knowledge and linkage to care and treatment. However, it is unclear if PNS can facilitate linkage of HIV-negative partners to prevention services such as pre-exposure prophylaxis (PrEP). Using qualitative methods, we explored provider perspective regarding the interaction of PrEP availability, PNS and antiretroviral treatment (ART) outcomes within a project integrating PrEP services into HIV care clinics in eight counties in western and central Kenya. METHODS: From May 2017 to August 2018, data on integrated PrEP service delivery including its interaction with PNS were collected through 71 key informant in-depth interviews with healthcare providers and 24 standardized technical assistance reports summarizing implementation at the participating clinics. Thus, the perspective was from that of providers; analyses focused on emergent themes relating PNS to PrEP and ART services. RESULTS: Providers found that PrEP integration provided an additional concrete prevention option for HIV-negative partners and created a motivation to offer PNS to persons living with HIV. PrEP availability also seemed to operate as an incentive for those living with HIV to participate in PNS, which in turn enhanced identification of potential PrEP clients and created an environment for discussing HIV transmission risk. Providers commented that initiating HIV-negative partners on PrEP enhanced mutual monitoring of health outcomes, including improved adherence to ART by partners living with HIV. Clinics noted prioritizing people living with HIV with detectable viral loads for PNS in order to identify HIV-negative partners who would benefit most from PrEP. Providers felt motivated by the apparent synergistic interaction of PNS, PrEP and ART. CONCLUSIONS: Providers felt that the integration of PrEP into HIV care clinics stimulated the provision of PNS, and PNS was used to improve the identification of potential PrEP clients. The integrated combination of PNS, PrEP and ART is synergistic and should be promoted in HIV clinics. Article	2019	OÊ¼Byrne, Patrick; MacPherson, Paul; Orser, Lauren; Jacob, Jean Daniel; Holmes, Dave	PrEP-RN: Clinical Considerations and Protocols for Nurse-Led PrEP.	Journal of the Association of Nurses in AIDS Care	-	-	-	-	1552-6917	10.1097/JNC.0000000000000075	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6551248	HIV pre-exposure prophylaxis (PrEP) is an increasingly important part of the HIV prevention armamentarium. Issues with PrEP, however, include access. We propose that one way to surmount this issue would be to have nurses provide PrEP. Although clinical guidelines exist for PrEP, they are overwhelmingly not targeted to nonprescriber clinicians. In this article, we overview current U.S. and Canadian PrEP guidelines and provide explicit guidance about how nurses can provide PrEP, including the clinical pathways and medical directives we use in our clinic. We call nurse-led provision of PrEP, PrEP-RN (Pre-Exposure Prophylaxis-Registered Nurse) and feel it may be an important step forward in HIV prevention.	community, HIV, nursing, nurse-led, PrEP	English	United States	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Clinical
Article	2019	Ogbuagu, Onyema; Marshall, Brandon D L; Tiberio, Perry; Ogunbajo, Adedotun; Barakat, Lydia; Montgomery, Madeline; Almonte, Alexi; Wray, Tyler; Williams, Emily C; Edelman, E Jennifer; Chan, Philip A	Prevalence and Correlates of Unhealthy Alcohol and Drug Use Among Men Who Have Sex with Men Prescribed HIV Pre-exposure Prophylaxis in Real-World Clinical Settings.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-018-2260-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7020905	Pre-exposure prophylaxis (PrEP) is effective in preventing HIV acquisition among men who have sex with men (MSM). However, little is known about unhealthy substance use among MSM initiating PrEP in real-world settings. Unhealthy substance use is a risk factor for HIV acquisition and non-adherence to treatment, and may also impact PrEP use. MSM who were prescribed PrEP from 2015 to 2017 at clinics in Providence, Rhode Island and New Haven, Connecticut were recruited to participate in a prospective observational study. Structured clinical assessments were used to assess demographics, HIV risk behaviors, and unhealthy alcohol (alcohol use disorders identification test AUDIT-C scores ≥ 4) and drug use (use of any drugs in the past 3 months). Bivariate and multivariate analyses were performed to determine demographics and behaviors associated with unhealthy alcohol and drug use. Among 172 MSM initiating PrEP, 64% were white and 40% were 25-34 years old. Participants reported a median of 3 (IQR 2-7) sexual partners in the last 3 months; 20% reported an HIV positive partner. Unhealthy alcohol and any drug use were reported by 54 and 57%, respectively, and 76% reported at least one of the two. The majority of drug use reported was marijuana and poppers (41 and 26% of participants, respectively). Relative to those without unhealthy alcohol use, unhealthy alcohol use was independently associated with any drug use (adjusted odds ratio AOR = 2.57, 95% CI 1.32-5.01). Frequent drug use was associated with younger age (< 25 years, AOR 4.27, 95% CI 1.51-12.09). Unhealthy alcohol use is common among MSM taking PrEP. Drug use other than marijuana and poppers was uncommon among our cohort. Further efforts may be needed to understand the influence of unhealthy alcohol and other substance use on PrEP outcomes and to engage MSM who use drugs for PrEP. Article	2019	Ogunbajo, Adedotun; Kang, Augustine; Shangani, Sylvia; Wade, Ryan M.; Onyango, Daniel P.; Odero, Wilson W.; Harper, Gary W.	Awareness and Acceptability of pre-exposure prophylaxis (PrEP) among gay, bisexual and other men who have sex with men (GBMSM) in Kenya.	AIDS Care	-	-	-	-	1360-0451 0954-0121	10.1080/09540121.2019.1612023	https://pubmed.ncbi.nlm.nih.gov/31039628/	Kenyan gay, bisexual, and other men who have sex with men (GBMSM) are significantly affected by HIV. Pre-exposure prophylaxis (PrEP) is an effective biomedical approach to HIV prevention. We conducted a cross-sectional survey of 459 HIV-negative Kenyan GBMSM to assess individual and interpersonal correlates of PrEP awareness/acceptability using univariate and hierarchical logistic regression modeling. We found that 64.3% of participants had heard of PrEP and 44.9% were willing to use PrEP. In hierarchical logistic regression models for PrEP awareness, condom use with regular partners, higher condom use self-efficacy, higher perceived ability to use PrEP, history of STI, and membership in LGBT organization were significantly associated with being aware of PrEP (χ(2)=( )69.6, p < .001). In hierarchical logistic regression models for PrEP acceptability, higher self-esteem, higher condom use self-efficacy, depression/anxiety, higher perceived ability to use PrEP, willingness to engage in PrEP follow-up visits, coercion at sexual debut, and family exclusion were significantly associated with being acceptable to PrEP (χ(2)=( )231.8, p < .001). Individual and interpersonal factors were significantly associated with PrEP awareness and acceptability. Our findings underscore the need to promote awareness and understanding of PrEP as an effective HIV prevention tool in combination with other safer-sex methods that are appropriate given an individual's personal circumstances. Article	2019	O'Halloran, C; Rice, B; White, E; Desai, M; Dunn, DT; McCormack, S; Sullivan, AK; White, D; McOwan, A; Gafos, M	Chemsex is not a barrier to self-reported daily PrEP adherence among PROUD study participants	International Journal on Drug Policy	-	-	-	-	NA	10.1016/j.drugpo.2019.10.007	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-02008135/full	BACKGROUND: Pre-exposure prophylaxis (PrEP) is a novel HIV prevention method whereby HIV-negative individuals take the drugs tenofovir and emtricitabine to prevent HIV acquisition. Optimal adherence is critical for PrEP efficacy. Chemsex describes sexual activity under the influence of psychoactive drugs, in the UK typically; crystal methamphetamine, gamma-hydroxybutyrate(GHB) and/or mephedrone. Chemsex drug use has been associated with increased HIV transmission risk among gay, bisexual and other men who have sex with men (GBM) and poor ART adherence among people living with HIV. This study assessed whether self-reported chemsex events affected self-reported daily PrEP adherence among PROUD study participants. METHODS: The PROUD study was an open-label, randomised controlled trial, conducted in thirteen English sexual health clinics, assessing effectiveness of Truvada®-PrEP among 544 HIV-negative GBM. The study reported an 86% risk-reduction of HIV from daily PrEP. Participants were asked about chemsex engagement at follow-up visits. Monthly self-reports of missed PrEP tablets were aggregated to assess adherence between visits. Univariable and multivariable regression analyses were performed to test for associations between chemsex and reporting less than seven out of seven intended doses(<7/7ID) in the 7 days before and/or after last condomless anal intercourse(CAI). RESULTS: 1479 follow-up visit forms and 2260 monthly adherence forms from 388 participants were included in the analyses, with 38.5% visit forms reporting chemsex since last visit and 29.9% follow-up periods reporting <7/7ID. No statistically significant associations were observed between reporting <7/7ID and chemsex (aOR=1.29 95% CI 0.90-1.87, p = 0.168). Statistically significant associations were seen between reporting <7/7ID and participants perceiving that they would miss PrEP doses during the trial, Asian ethnicity, and reporting unemployment at baseline. CONCLUSIONS: These analyses suggest PrEP remains a feasible and effective HIV prevention method for GBM engaging in chemsex, a practise which is prevalent in this group and has been associated with increased HIV transmission risk.	*Human immunodeficiency virus infected patient; *bisexuality; *men who have sex with men; *pre-exposure prophylaxis; Adolescent; Adult; Anal intercourse; Anti-HIV Agents *administration & dosage; Article; Comparative effectiveness; Controlled study; Emtricitabine, Tenofovir Disoproxil Fumarate Drug Combination administration & dosage; Ethnicity; Female; Follow up; Follow-Up Studies; HIV Infections *prevention & control; Human; Human experiment; Humans; Major clinical study; Male; Medication Adherence *statistics & numerical data; Middle Aged; Multicenter study; Pre-Exposure Prophylaxis *methods; Randomized controlled trial; Risk reduction; Self Report; Self report; Sexual Behavior; Sexual and Gender Minorities; Sexual health; Substance-Related Disorders *epidemiology; Tablet; Unemployment; Young Adult	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Essay	2019	Ohayon M.	HIV-positive men as Superheros	Sexologies	-	-	-	-	11581360	10.1016/j.sexol.2019.05.006	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066731346&doi=10.1016%2fj.sexol.2019.05.006&partnerID=40&md5=4b0d2d5b6e5e8079935b7bed1332eb5a	Improvements in the prognosis for HIV infection and the impact of biomedical strategies for the prevention of transmission have created very specific situations for men who live with HIV within the homosexual minorities. Originally focused on their duty in preventing transmission, the issue at stake gradually moved towards one of power, with the HIV-infected person, the hero/martyr of the 1980s and 1990s, becoming the hero who has vanquished the fear of Aids. Undetectable viral load, the standard of current treatment, makes the individual himself undetectable, invisible. In a population so profoundly affected by the history of Aids, these are superpowers. The HIV-positive guy has become a superhero. The clinical situation for gay men living with HIV says otherwise. In addition to the modifications they have had to make to their sex-lives, be it compulsory abstinence, a change in sexual roles, limiting sexual partners to those who are also HIV-positive or forming a couple at all costs, gay HIV-positive men today seem forced to negotiate with this image that has been forced upon them, in a context where sexual encounters increasingly adopt a neoliberal model. A command to climax, to avoid any problems, to be satisfied with these superpowers even if they didn't want them in the first place, in a context where invisibility is demanded. None of this helps HIV-positives to repair the consequences of the infection on their sexuality. By adopting the behaviours that have been assigned to them, some of them use their superpowers and transgress all the interdicts (sexual practices, drugs) simply to feel something again. It is probable that our superheros are only superheroes in the eyes of others. In the future, we can expect gays to distance themselves from the epidemic with the development of PrEP; but will that put an end to this fabricated fantasy that gets under the skin of HIV-positive gay men and provides ample opportunity for sexological clinical repercussions. © 2019	Bareback; HIV infection; MSM (men who have sex with men); PrEP	English	France	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Other
Article	2019	Ojeda V.D.; Amico K.R.; Hughes J.P.; Wilson E.; Li M.; Holtz T.H.; Chitwarakorn A.; Grant R.M.; Dye B.J.; Bekker L.-G.; Mannheimer S.; Marzinke M.; Hendrix C.W.	Low Disclosure of PrEP Nonadherence and HIV-Risk Behaviors Associated with Poor HIV PrEP Adherence in the HPTN 067/ADAPT Study	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002103	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071351349&doi=10.1097%2fQAI.0000000000002103&partnerID=40&md5=0e6e4f2eecd5e7c8f591d4e899389d58	Objective:We evaluated the relationship between 2 types of social relationships, ie, (1) external support for use of HIV pre-exposure prophylaxis (PrEP) and related study supplies and (2) participants' disclosure of PrEP use and condom use and HIV PrEP adherence among daily-dosing regimen participants in HIV Prevention Trials Network (HPTN) 067, an open-label trial of oral tenofovir (TFV) disoproxil fumarate (TDF) 300 mg/emtricitabine (FTC) 200 mg.Methods:Using HPTN 067 survey data, we developed scales examining (1) Low Perceived External Support for PrEP: low perceived support by others for PrEP use or perceived negative reactions to the pill case (scoring ranges from 0 to 2) and (2) Participant-Staff Disclosure Challenges Scale, which identifies challenges to sharing nonuse of PrEP or condoms to study staff (scoring ranges from 0 to 4); these scales are the primary independent variables. Adherence, the dependent variable, was determined using log-transformed plasma TFV concentrations. generalized estimating equation (GEE) linear regression was used to assess the association between both scales and adherence.Results:Participants (n = 161) included HIV-uninfected women in South Africa, and men who have sex with men and transgender women, in Thailand and the United States. In multivariable analyses, higher scores in the Participant-Staff Disclosure Challenges Scale were significantly associated with lower PrEP adherence exp(β) = 0.62, 95% CI: (0.46 to 0.84); P = 0.002 as were increased days since the last PrEP dose exp(β) = 0.73, 95% CI: (0.65 to 0.83); P ≤ 0.001.Conclusions:Given the association with adherence, study staff-participant interactions and participants' disclosure of PrEP challenges may be worthwhile intervention targets for improving PrEP adherence in confirmatory studies. Article	2019	Ojikutu B.O.; Bogart L.M.; Mayer K.H.; Stopka T.J.; Sullivan P.S.; Ransome Y.	Spatial access and willingness to use pre-exposure prophylaxis among black/african American individuals in the United States: Cross-sectional survey	JMIR Public Health and Surveillance	-	-	-	-	23692960	10.2196/12405	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85097133703&doi=10.2196%2f12405&partnerID=40&md5=48581ea7086a5bcbd61ecdcc7cde4fda	Background: Uptake of pre-exposure prophylaxis (PrEP) among black individuals in the United States is low and may be associated with the limited availability of clinics where PrEP is prescribed. Objective: We aimed to determine the association between spatial access to clinics where PrEP is prescribed and willingness to use PrEP. Methods: We identified locations of clinics where PrEP is prescribed from AIDSVu.org and calculated the density of PrEP clinics per 10,000 residents according to the ZIP code. Individual-level data were obtained from the 2016 National Survey on HIV in the Black Community. We used multilevel modelling to estimate the association between willingness to use PrEP and clinic density among participants with individual-level (HIV risk, age, gender, education, income, insurance, doctor visit, census region, urban/rural residence) and ZIP code-level (%poverty, %unemployed, %uninsured, %black population, and density of health care facilities) variables. Results: All participants identified as black/African American. Of the 787 participants, 45% were men and 23% were found to be at high risk based on the self-reported behavioral characteristics. The mean age of the participants was 34 years (SD 9), 54% of participants resided in the South, and 26% were willing to use PrEP. More than one-third (38%) of the sample had to drive more than 1 hour to access a PrEP provider. Participants living in areas with higher PrEP clinic density were significantly more willing to use PrEP (one SD higher density of PrEP clinics per 10,000 population was associated with 16% higher willingness adjusted prevalence ratio=1.16, 95% CI: 1.03-1.31). Conclusions: Willingness to use PrEP was associated with spatial availability of clinics where providers prescribe PrEP in this nationally representative sample of black African Americans. © Bisola O Ojikutu, Laura M Bogart, Kenneth H Mayer, Thomas J Stopka, Patrick S Sullivan, Yusuf Ransome. Article	2019	O'Malley G.; Barnabee G.; Mugwanya K.	Scaling-up PrEP Delivery in Sub-Saharan Africa: What Can We Learn from the Scale-up of ART?	Current HIV/AIDS Reports	-	-	-	-	15483568	10.1007/s11904-019-00437-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062047663&doi=10.1007%2fs11904-019-00437-6&partnerID=40&md5=31ee3c1be04396cea0e2fb4b4bb34404	Purpose of Review: Clinical trials have found that PrEP is highly effective in reducing risk of HIV acquisition across types of exposure, gender, PrEP regimens, and dosing schemes. Evidence is urgently needed to inform scale-up of PrEP to meet the ambitious WHO/UNAIDS prevention target of 3,000,000 individuals on PrEP by 2020. Recent Findings: Successful models of delivering HIV services at scale evolved from years of formal research and programmatic evidence. These efforts produced lessons-learned relevant for scaling-up PrEP delivery, including the importance of streamlining laboratory tests, expanding prescription and management authority, differentiating medication access points, and reducing stigma and barriers of parental consent for PrEP uptake. Further research is especially needed in areas differentiating PrEP from ART delivery, including repeat HIV testing to ensure HIV negative status and defining and measuring prevention-effective adherence. Summary: Evidence from 15 years of ART scale-up could immediately inform a public health approach to PrEP delivery. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Ong J.J.; Baggaley R.C.; Wi T.E.; Tucker J.D.; Fu H.; Smith M.K.; Rafael S.; Anglade V.; Falconer J.; Ofori-Asenso R.; Terris-Prestholt F.; Hodges-Mameletzis I.; Mayaud P.	Global Epidemiologic Characteristics of Sexually Transmitted Infections among Individuals Using Preexposure Prophylaxis for the Prevention of HIV Infection: A Systematic Review and Meta-analysis	JAMA Network Open	-	-	-	-	25743805	10.1001/jamanetworkopen.2019.17134	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076376864&doi=10.1001%2fjamanetworkopen.2019.17134&partnerID=40&md5=c8a392218eac22539985c381ded6da3b	Importance: Despite a global increase in sexually transmitted infections (STIs), there is limited focus and investment in STI management within HIV programs, in which risks for STIs are likely to be elevated. Objective: To estimate the prevalence of STIs at initiation of HIV preexposure prophylaxis (PrEP; emtricitabine and tenofovir disoproxil fumarate) and the incidence of STIs during PrEP use. Data Sources: Nine databases were searched up to November 20, 2018, without language restrictions. The implementers of PrEP were also approached for additional unpublished data. Study Selection: Studies reporting STI prevalence and/or incidence among PrEP users were included. Data Extraction and Synthesis: Data were extracted independently by at least 2 reviewers. The methodological quality of studies was assessed using the Joanna Briggs Institute critical assessment tool for prevalence and incidence studies. Random-effects meta-analysis was performed. Main Outcomes and Measures: Pooled STI prevalence (ie, within 3 months of PrEP initiation) and STI incidence (ie, during PrEP use, after 3 months). Results: Of the 3325 articles identified, 88 were included (71 published and 17 unpublished). Data came from 26 countries; 62 studies (70%) were from high-income countries, and 58 studies (66%) were from programs only for men who have sex with men. In studies reporting a composite outcome of chlamydia, gonorrhea, and early syphilis, the pooled prevalence was 23.9% (95% CI, 18.6%-29.6%) before starting PrEP. The prevalence of the STI pathogen by anatomical site showed that prevalence was highest in the anorectum (chlamydia, 8.5% 95% CI, 6.3%-11.0%; gonorrhea, 9.3% 95% CI, 4.7%-15.2%) compared with genital sites (chlamydia, 4.0% 95% CI, 2.0%-6.6%; gonorrhea, 2.1% 95% CI, 0.9%-3.7%) and oropharyngeal sites (chlamydia, 2.4% 95% CI, 0.9%-4.5%; gonorrhea, 4.9% 95% CI, 1.9%-9.1%). The pooled incidence of studies reporting the composite outcome of chlamydia, gonorrhea, and early syphilis was 72.2 per 100 person-years (95% CI, 60.5-86.2 per 100 person-years). Conclusions and Relevance: Given the high burden of STIs among individuals initiating PrEP as well as persistent users of PrEP, this study highlights the need for active integration of HIV and STI services for an at-risk and underserved population.. Article	2019	Onyema Ogbuagu; Marshall, Brandon D L; Perry, Tiberio; Adedotun Ogunbajo; Barakat, Lydia; Montgomery, Madeline; Almonte, Alexi; Wray, Tyler; Williams, Emily C; Edelman, E Jennifer; Chan, Philip A	Prevalence and Correlates of Unhealthy Alcohol and Drug Use Among Men Who Have Sex with Men Prescribed HIV Pre-exposure Prophylaxis in Real-World Clinical Settings	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2260-9	https://www.proquest.com/scholarly-journals/prevalence-correlates-unhealthy-alcohol-drug-use/docview/2093011996/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) is effective in preventing HIV acquisition among men who have sex with men (MSM). However, little is known about unhealthy substance use among MSM initiating PrEP in real-world settings. Unhealthy substance use is a risk factor for HIV acquisition and non-adherence to treatment, and may also impact PrEP use. MSM who were prescribed PrEP from 2015 to 2017 at clinics in Providence, Rhode Island and New Haven, Connecticut were recruited to participate in a prospective observational study. Structured clinical assessments were used to assess demographics, HIV risk behaviors, and unhealthy alcohol (alcohol use disorders identification test AUDIT-C scores ≥4) and drug use (use of any drugs in the past 3 months). Bivariate and multivariate analyses were performed to determine demographics and behaviors associated with unhealthy alcohol and drug use. Among 172 MSM initiating PrEP, 64% were white and 40% were 25–34 years old. Participants reported a median of 3 (IQR 2–7) sexual partners in the last 3 months; 20% reported an HIV positive partner. Unhealthy alcohol and any drug use were reported by 54 and 57%, respectively, and 76% reported at least one of the two. The majority of drug use reported was marijuana and poppers (41 and 26% of participants, respectively). Relative to those without unhealthy alcohol use, unhealthy alcohol use was independently associated with any drug use (adjusted odds ratio AOR = 2.57, 95% CI 1.32–5.01). Frequent drug use was associated with younger age (< 25 years, AOR 4.27, 95% CI 1.51–12.09). Unhealthy alcohol use is common among MSM taking PrEP. Drug use other than marijuana and poppers was uncommon among our cohort. Further efforts may be needed to understand the influence of unhealthy alcohol and other substance use on PrEP outcomes and to engage MSM who use drugs for PrEP. Article	2019	Orser, Lauren; Patrick O'Byrne	The role of public health units in the delivery of HIV pre-exposure prophylaxis (PrEP)	Canadian Journal of Public Health	-	-	-	-	00084263	10.17269/s41997-018-0141-7	https://www.proquest.com/scholarly-journals/role-public-health-units-delivery-hiv-pre-exposure/docview/2256096323/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) is an HIV prevention strategy involving the use of once daily antiretroviral medications to prevent HIV infection. Available research supports that PrEP, when used as prescribed, can prevent HIV transmission by upwards of 96%. Such findings have led to the development of research publications and guidelines supporting PrEP for individuals at high risk for HIV acquisition, such as men who have sex with men (MSM). Despite its benefit, current use of PrEP in clinical settings has been undermined by false impressions of poor efficacy of PrEP and concerns about increased risk-taking among MSM should PrEP be readily available. Furthermore, guidance for the role of public health units in PrEP access has not been well defined. While we maintain that PrEP should be available to any person who requests it, we feel that public health units should focus on those at highest risk for HIV acquisition, and, in doing so, possibly reduce local HIV rates.Resumo alternativo:La prophylaxie pré-exposition (PrEP) est une stratégie de prévention fondée sur la prise quotidienne de médicaments antirétroviraux pour prévenir le VIH. Selon les recherches disponibles, la PrEP, lorsqu'elle est prise telle que prescrite, peut prévenir la transmission du VIH dans une proportion de plus de 96%. Ces conclusions ont mené à l'élaboration de plusieurs publications et de lignes directrices à l'appui de la PrEP pour les personnes risquant fortement de contracter le VIH, comme les hommes ayant des relations sexuelles avec des hommes (HARSAH). Malgré ses avantages, l'utilisation de la PrEP en milieu clinique a été compromise par de fausses impressions quant à la faible efficacité de la PrEP et les inquiétudes concernant la prise de risque accrue chez les HARSAH si la PrEP était facilement accessible. De plus, les directives sur le rôle des unités de santé publique dans l'accès à la PrEP n'ont pas été bien définies. Bien que nous maintenions que la PrEP devrait être accessible à toute personne qui en fait la demande, nous pensons que les unités de santé publique devraient se concentrer sur les personnes les plus à risque, ce qui pourrait permettre de réduire l'incidence des cas de VIH au niveau local. Article	2019	Ortblad K.F.; Kearney J.E.; Mugwanya K.; Irungu E.M.; Haberer J.E.; Barnabas R.V.; Donnell D.; Mugo N.R.; Baeten J.M.; Ngure K.	HIV-1 self-testing to improve the efficiency of pre-exposure prophylaxis delivery: A randomized trial in Kenya	Trials	-	-	-	-	17456215	10.1186/s13063-019-3521-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068577395&doi=10.1186%2fs13063-019-3521-2&partnerID=40&md5=66303185f6c6ae7991f70a79a10c51e6	Background: The introduction of pre-exposure prophylaxis (PrEP) for human immunodeficiency virus-1 (HIV-1) prevention in Africa presents new challenges for health systems that are already overburdened because PrEP delivery requires frequent clinic visits (generally every 3 months) for HIV-1 testing and PrEP refills. HIV-1 self-testing (HIVST) has the potential to improve the efficiency of PrEP delivery by decreasing the number of clinic visits. Here, we describe the rationale and design of a randomized, noninferiority trial designed to test the effectiveness and safety of using HIVST to support PrEP delivery in Kenya. Methods: The JiPime-JiPrEP (Kiswahili for 'Test Yourself, PrEP Yourself') study is a three-arm randomized trial taking place in Thika, Kenya. Participants (n = 495) are eligible for enrollment if they are at least 18 years old, HIV-1 seronegative, and have been taking PrEP for 1 month. Three distinct participant types will be enrolled: men (n = 165) and women (n = 165) who are in mutually disclosed HIV-1 serodiscordant relationships, and women (n = 165) who are at HIV-1 risk and not in a known serodiscordant relationship. Participants in each of these subpopulations will be 1:1:1 randomized to: 1) the standard of care, with quarterly clinic visits; 2) oral HIVST, with biannual clinic visits plus oral HIVSTs to use at the quarters between those visits; or 3) blood-based HIVST, with biannual clinic visits plus blood-based HIVSTs. All participants will complete quantitative surveys and provide blood samples for the objective measurement of PrEP adherence at baseline, 6 months, and 12 months. The primary outcomes are PrEP adherence, PrEP continuation, and HIV-1 testing, measured at 6 months and secondarily at 12 months. Discussion: The findings from this trial can help to understand how HIVST - a new HIV-1 testing technology - can support health systems in sub-Saharan Africa. Additionally, the findings can inform policy aimed at improving the efficiency of PrEP implementation and scale-up in Kenya. Trial registration: ClinicalTrials.gov, NCT03593629. Article	2019	Ortblad, Katrina F; Baeten, Jared M	Electronic health record tools to catalyse PrEP conversations.	The Lancet HIV	-	-	-	-	2352-3018	10.1016/S2352-3018(19)30194-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6776668	The interface between a prescriber and a potential PrEP client can be either a moment of opportunity for engaging in a discussion that might lead to PrEP initiation (and HIV protection) or one in which PrEP is not even considered. Barriers to PrEP prescribing could include provider time constraints and uncertainty around who might benefit.5,6 In addition, while guidelines such as those from the CDC7 and WHO8 recommend offering PrEP to individuals whose behaviours or social networks could put them at risk for acquiring HIV, providers might feel uneasy discussing sexual behaviour and standardised behavioural questionnaires might underestimate HIV risk among high-incidence subpopulations, such as black men who have sex with men in the USA.9 Similarly, clients might feel embarrassed or judged when bringing up often stigmatised behaviours and might not ask about PrEP even when they want to know more. Simple, usable tools could help to open up PrEP discussions. One such approach could be an automated HIV risk prediction algorithm that uses existing electronic health record (EHR) data to flag clients who, because of their behaviours or their social network, might carry elevated HIV risk. Such a tool could help to reduce disparities in PrEP prescribing that might arise from clients' lack of PrEP awareness and providers' discomforts or biases. Article	2019	Owens D.K.; Davidson K.W.; Krist A.H.; Barry M.J.; Cabana M.; Caughey A.B.; Curry S.J.; Doubeni C.A.; Epling J.W., Jr.; Kubik M.; Landefeld C.S.; Mangione C.M.; Pbert L.; Silverstein M.; Simon M.A.; Tseng C.-W.; Wong J.B.	Preexposure prophylaxis for the prevention of HIV infection: US preventive services task force recommendation statement	JAMA - Journal of the American Medical Association	-	-	-	-	987484	10.1001/jama.2019.6390	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066935652&doi=10.1001%2fjama.2019.6390&partnerID=40&md5=515d1adc8102a06a8b0d4a01e3a74fa7	Importance: An estimated 1.1 million individuals in the United States are currently living with HIV, and more than 700000 persons have died of AIDS since the first cases were reported in 1981. In 2017, there were 38281 new diagnoses of HIV infection reported in the United States; 81% of these new diagnoses were among males and 19% were among females. Although treatable, HIV infection has no cure and has significant health consequences. Objective: To issue a new US Preventive Services Task Force (USPSTF) recommendation on preexposure prophylaxis (PrEP) for the prevention of HIV infection. Evidence Review: The USPSTF reviewed the evidence on the benefits of PrEP for the prevention of HIV infection with oral tenofovir disoproxil fumarate monotherapy or combined tenofovir disoproxil fumarate and emtricitabine and whether the benefits vary by risk group, population subgroup, or regimen or dosing strategy; the diagnostic accuracy of risk assessment tools to identify persons at high risk of HIV acquisition; the rates of adherence to PrEP in primary care settings; the association between adherence and effectiveness of PrEP; and the harms of PrEP when used for HIV prevention. Findings: The USPSTF found convincing evidence that PrEP is of substantial benefit in decreasing the risk of HIV infection in persons at high risk of HIV acquisition. The USPSTF also found convincing evidence that adherence to PrEP is highly associated with its efficacy in preventing the acquisition of HIV infection; thus, adherence to PrEP is central to realizing its benefit. The USPSTF found adequate evidence that PrEP is associated with small harms, including kidney and gastrointestinal adverse effects. The USPSTF concludes with high certainty that the magnitude of benefit of PrEP with oral tenofovir disoproxil fumarate-based therapy to reduce the risk of acquisition of HIV infection in persons at high risk is substantial. Conclusions and Recommendation: The USPSTF recommends offering PrEP with effective antiretroviral therapy to persons at high risk of HIV acquisition. Article	2019	Pachankis J.E.; McConocha E.M.; Reynolds J.S.; Winston R.; Adeyinka O.; Harkness A.; Burton C.L.; Behari K.; Sullivan T.J.; Eldahan A.I.; Esserman D.A.; Hatzenbuehler M.L.; Safren S.A.	Project ESTEEM protocol: A randomized controlled trial of an LGBTQ-affirmative treatment for young adult sexual minority men's mental and sexual health	BMC Public Health	-	-	-	-	14712458	10.1186/s12889-019-7346-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070447229&doi=10.1186%2fs12889-019-7346-4&partnerID=40&md5=751676b35abd0d211e43e466421c2eaf	Background: Young gay and bisexual men disproportionately experience depression, anxiety, and substance use problems and are among the highest risk group for HIV infection in the U.S. Diverse methods locate the source of these health disparities in young gay and bisexual men's exposure to minority stress. In fact, minority stress, psychiatric morbidity, substance use, and HIV risk fuel each other, forming a synergistic threat to young gay and bisexual men's health. Yet no known intervention addresses minority stress to improve mental health, substance use problems, or their joint impact on HIV risk in this population. This paper describes the design of a study to test the efficacy of such an intervention, called ESTEEM (Effective Skills to Empower Effective Men), a 10-session skills-building intervention designed to reduce young gay and bisexual men's co-occurring health risks by addressing the underlying cognitive, affective, and behavioral pathways through which minority stress impairs health. Methods: This study, funded by the National Institute of Mental Health, is a three-arm randomized controlled trial to examine (1) the efficacy of ESTEEM compared to community mental health treatment and HIV counseling and testing and (2) whether ESTEEM works through its hypothesized cognitive, affective, and behavioral minority stress processes. Our primary outcome, measured 8 months after baseline, is condomless anal sex in the absence of PrEP or known undetectable viral load of HIV+ primary partners. Secondary outcomes include depression, anxiety, substance use, sexual compulsivity, and PrEP uptake, also measured 8 months after baseline. Discussion: Delivering specific stand-alone treatments for specific mental, behavioral, and sexual health problems represents the current state of evidence-based practice. However, dissemination and implementation of this one treatment-one problem approach has not been ideal. A single intervention that reduces young gay and bisexual men's depression, anxiety, substance use, and HIV risk by reducing the common minority stress pathways across these problems would represent an efficient, cost-effective alternative to currently isolated approaches, and holds great promise for reducing sexual orientation health disparities among young men. Article	2019	Pacífico de Carvalho N.; Mendicino C.C.P.; Cândido R.C.F.; Alecrim D.J.D.; Menezes de Pádua C.A.	HIV pre-exposure prophylaxis (PrEP) awareness and acceptability among trans women: a review	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2019.1612014	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065234819&doi=10.1080%2f09540121.2019.1612014&partnerID=40&md5=9133e915e6f2fe0f3ee90a0e0b006a25	Transgender (trans) women are disproportionally burdened by the HIV epidemic due to complex structural, psychosocial and biological factors. HIV pre-exposure prophylaxis (PrEP) is a biomedical prevention approach for people at substantial risk of acquiring HIV. This literature review assessed awareness, willingness to use, and barriers and facilitators for PrEP acceptability among trans women. A search was conducted through five databases and included studies with primary data and disaggregate results for trans women. Of 255 retrieved citations, 17 met the inclusion criteria and were included. Low to moderate knowledge about PrEP was observed among studies. However, willingness to use PrEP was predominantly high. Frequent barriers to PrEP acceptability included concerns about side effects, cost, hormone therapy, adherence, PrEP-related stigma and interaction with healthcare workers. Facilitators included perception of HIV risk, fear of HIV/AIDS and reduced dependence on partners. Findings suggest elevated interest in PrEP and highlight important barriers and facilitators that should be specifically addressed to optimize PrEP uptake and use among this highly vulnerable population. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group.	acceptability; awareness; HIV prevention; Pre-exposure prophylaxis; PrEP; transgender women	English	United Kingdom	Western and Central Europe and North America	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Review
Article	2019	Park C.J.; Taylor T.N.; Gutierrez N.R.; Zingman B.S.; Blackstock O.J.	Pathways to HIV Pre-exposure Prophylaxis among Women Prescribed PrEP at an Urban Sexual Health Clinic	Journal of the Association of Nurses in AIDS Care	-	-	-	-	10553290	10.1097/JNC.0000000000000070	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065345786&doi=10.1097%2fJNC.0000000000000070&partnerID=40&md5=04beefc8882c976d5b2dd2190946626e	Little is known about real-world facilitators of and barriers to pre-exposure prophylaxis (PrEP) uptake among women prescribed PrEP. We sought to characterize the pathway to PrEP uptake and continuation in women prescribed PrEP at an urban sexual health-focused clinic. We conducted semi-structured individual interviews with 14 women from October 2016 to May 2017. Using grounded theory and the constant comparative method, we found that self-perceived HIV risk, learning about PrEP through trusted sources, having positive interactions with PrEP providers, and insurance coverage were facilitators of PrEP uptake and continuation. Concerns about PrEP safety, misinformation about PrEP eligibility and appropriateness, lack of insurance coverage, and pharmacy impediments were key barriers. The confluence of these issues led to PrEP rumination, a process of ongoing deliberation about the benefits and risks of PrEP. These findings provide important insights about how to increase PrEP uptake among women at high risk of HIV infection Copyright © 2019 Association of Nurses in AIDS Care	HIV; Pre-exposure prophylaxis; Prevention; Women	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2019	Parsons, Jeffrey T.; Starks, Tyrel; Gurung, Sitaji; Cain, Demetria; Marmo, Jonathan; Naar, Sylvie	Clinic-Based Delivery of the Young Men's Health Project (YMHP) Targeting HIV Risk Reduction and Substance Use Among Young Men Who Have Sex with Men: Protocol for a Type 2, Hybrid Implementation-Effectiveness Trial.	JMIR Research Protocols	-	-	-	-	1929-0748	10.2196/11184	https://www.researchprotocols.org/2019/5/e11184/citations	BACKGROUND: Young men who have sex with men (YMSM) are disproportionately at risk for HIV and sexually transmitted infections. Adapting and testing the effectiveness of the Young Men's Health Project (YMHP), an efficacious intervention designed to reduce substance use and condomless anal sex (CAS) among YMSM, at clinics in Miami, Detroit, and Philadelphia has the potential to reduce HIV and STI disparities among urban YMSM. OBJECTIVE: This study (Adolescent Medicine Trials Network for HIV/AIDS Interventions ATN 145 YMHP) aims to adapt YMHP for clinic and remote delivery by existing clinic staff and compare their effectiveness in real-world adolescent HIV clinics. This protocol is part of the ATN Scale It Up program described in a recently published article by Naar et al. METHODS: This is a comparative effectiveness hybrid type-2 trial of the YMHP intervention with 2 delivery formats-clinic-based versus remote delivery-offered following HIV counseling and testing. Phase 1 includes conducting focus groups with youth to obtain implementation feedback about the delivery of the YMHP intervention and intervention components to ensure culturally competent, feasible, and scalable implementation. Phase 2 includes recruitment and enrollment of 270 YMSM, aged 15 to 24 years, 90 at each of the 3 sites. Enrollment will be limited to HIV-negative YMSM who report recent substance use and either CAS or a positive STI test result. Participants will be randomized to receive the YMHP intervention either in person or by remote delivery. Both conditions involve completion of the 4 YMHP sessions and the delivery of pre-exposure prophylaxis information and navigation services. A minimum of 2 community health workers (CHWs) will be trained to deliver the intervention sessions at each site. Sessions will be audio-recorded for Motivational Interviewing Treatment Integrity (MITI) fidelity coding, and CHWs and supervisors will be given implementation support throughout the study period. RESULTS: Phase 1 focus groups were completed in July 2017 (n=25). Feedback from these focus groups at the 3 sites informed adaptations to the YMHP intervention manual, implementation of the intervention, and recruitment plans for phase 2. Baseline enrollment for phase 2 began in November 2018, and assessments will be at immediate posttest (IP)-, 3-, 6-, 9-, and 12-months after the intervention. Upon collection of both baseline and follow-up data, we will compare the effectiveness and cost-effectiveness of clinic-based versus remote delivery of YMHP in the context of health care access. CONCLUSIONS: We are conducting YMHP in 3 cities with high rates of YMSM at risk for HIV and STIs. When adapted for real-world clinics, this study will help substance-using YMSM at risk for HIV and STIs and allow us to examine differences in effectiveness and cost by the method of delivery. Article	2019	Patel A.S.; Goparaju L.; Sales J.M.; Mehta C.C.; Blackstock O.J.; Seidman D.; Ofotokun I.; Kempf M.-C.; Fischl M.A.; Golub E.T.; Adimora A.A.; French A.L.; Dehovitz J.; Wingood G.; Kassaye S.; Sheth A.N.	PrEP Eligibility among At-Risk Women in the Southern United States: Associated Factors, Awareness, and Acceptability	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001950	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062835483&doi=10.1097%2fQAI.0000000000001950&partnerID=40&md5=b7a4b767471e57fe21c57c060931741d	Background:Among women in the United States, non-Latina black women in the South have disproportionately high rates of new HIV infections but low use of pre-exposure prophylaxis (PrEP). Effective strategies to identify factors associated with PrEP eligibility could facilitate improved screening, offering, and uptake of PrEP among US women at risk of HIV.Setting and methods:We applied 2014 CDC criteria for PrEP use to at-risk HIV-negative women enrolled in the Southern US sites (Atlanta, Chapel Hill, Birmingham/Jackson, Miami) of the Women's Interagency HIV Study from 2014 to 2015 to estimate PrEP eligibility and assess PrEP knowledge and acceptability. Factors associated with PrEP eligibility were assessed using multivariable models.Results:Among 225 women, 72 (32%) were PrEP-eligible; the most common PrEP indicator was condomless sex. The majority of PrEP-eligible women (88%) reported willingness to consider PrEP. Only 24 (11%) PrEP-eligible women had previously heard of PrEP, and only 1 reported previous use. Education level less than high school adjusted odds ratio (aOR) 2.56; 95% confidence interval (CI): 1.22 to 5.37, history of sexual violence (aOR 4.52; 95% CI: 1.52 to 17.76), and medium to high self-perception of HIV risk (aOR 6.76; 95% CI: 3.26 to 14.05) were significantly associated with PrEP eligibility in adjusted models.Conclusions:Extremely low PrEP awareness and use despite a high proportion of eligibility and acceptability signify a critical need to enhance PrEP education and delivery for women in this region. Supplementing CDC eligibility criteria with questions about history of sexual violence and HIV risk self-assessment may enhance PrEP screening and uptake among US women. © 2019 Wolters Kluwer Health, Inc. A pharmacokinetic and pharmacogenetic evaluation of contraceptive implants and antiretroviral therapy among women in Kenya and Uganda	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002308	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072903596&doi=10.1097%2fQAD.0000000000002308&partnerID=40&md5=a055a97ed3950d4a085c1f3d6f1c7ce3	Objectives:To evaluate pharmacokinetics and pharmacogenetics of contraceptive implant progestin concentrations in HIV-positive women initiating efavirenz (EFV)-containing or nevirapine (NVP)-containing antiretroviral therapy (ART).Design:We analyzed stored samples from women self-reporting implant use in the Partners PrEP Study.Methods:Plasma samples collected every 6 months were analyzed for levonorgestrel and etonogestrel concentrations. Progestin concentrations from samples collected after ART initiation were compared with pre-ART concentrations for intraindividual comparisons. We used adjusted linear mixed models to compare hormone concentrations between individuals on EFV and NVP to a no ART group. We then evaluated whether possessing certain alleles with known or possible influences on EFV, NVP, or progestin metabolism were associated with changes in progestin concentrations or modified the association between ART use and progestin concentrations.Results:Our analysis included 11 women who initiated EFV, 13 who initiated NVP, and 36 who remained ART-naive. In the EFV group, the adjusted geometric mean ratio (aGMR) of levonorgestrel was 0.39 90% confidence intervals (0.31, 0.49); P < 0.001 and the etonogestrel aGMR was 0.51 (0.34, 0.76; P = 0.006) compared with the control group. No difference was observed in the NVP group compared with controls levonorgestrel 0.93 (0.74, 1.18); P = 0.64; etonogestrel 1.07 (0.77, 1.50); P = 0.73. Possession of four allele variants were found to result in further reductions in progestin concentrations among those receiving EFV.Conclusion:Concomitant use of EFV significantly reduces levonorgestrel or etonogestrel concentrations by 61 and 49%, respectively, compared with no ART use. We also report allelic variants in hepatic enzymes that influenced the extent of the observed drug-interaction between progestins and EFV. © 2019 Lippincott Williams and Wilkins. Article	2019	Patel, P; Ford, SL; Lou, Y; Bakshi, K; Tenorio, AR; Zhang, Z; Pan, R; Spreen, W	Effect of a High-Fat Meal on the Pharmacokinetics of the HIV Integrase Inhibitor Cabotegravir	Clinical Pharmacology in Drug Development	-	-	-	-	NA	10.1002/cpdd.620	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-02145241/full	Cabotegravir is an integrase inhibitor in clinical development for the treatment and prevention of HIV infection using oral tablets for short-term, lead-in use before subsequent administration of a long-acting injectable formulation. This phase 1, single-center, randomized, 2 × 2 crossover study evaluated the effect of a high-fat meal on the pharmacokinetics (PK) of oral cabotegravir. Healthy adults received oral cabotegravir 30 mg as a single dose on 2 separate occasions, either after fasting or following a high-fat meal (~53% fat, ~870 kcal). Safety evaluations and serial PK samples were collected, and a mixed-effects model was used to determine within-participant treatment comparison of noncompartmental PK parameters. Twenty-four patients were enrolled and had a mean body mass index of 25.6 kg/m2 ; 67% were male. Compared with the fasting state, coadministration of cabotegravir with a high-fat meal increased plasma cabotegravir area under the concentration-time curve and maximal drug concentration, each by 14%. The slight 14% to 17% increase in exposure associated with a high-fat, high-calorie meal was not considered clinically significant. No grade 3/4 adverse events (AEs), drug-related AEs, or AEs leading to discontinuation were reported. Article	2019	Pelletier S.J.; Gagnon M.-P.; Diabaté S.; Kra O.; Biékoua Y.J.; Osso G.D.; Diané B.; N'Dhatz-Ebagnitchié M.; Ahouada C.; Alary M.	Pre-Exposure Prophylaxis (PrEP) in men who have sex with men in bouaké, côte d'Ivoire: A qualitative evaluation of acceptability	Open AIDS Journal	-	-	-	-	18746136	10.2174/1874613601913010049	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072085551&doi=10.2174%2f1874613601913010049&partnerID=40&md5=5da710685073769931cd27e0a7bf94e2	Background: HIV remains an important public health issue throughout the world. In Côte d'Ivoire, a high burden of HIV is observed in men who have sex with men (MSM). Objective: We assessed the acceptability of Pre-Exposure Prophylaxis (PrEP) among men who have sex with men (MSM) in Bouaké, Côte d'Ivoire. Methods: We conducted and analysed four focus groups with 31 HIV-negative MSM and eight in-depth individual interviews with participants recruited from the focus groups. Results: Four MSM (13%) were aware of PrEP before participating in the study. All the participants were interested in taking PrEP if available: 19 (61.3%) would prefer the daily regimen and 12 (38.7%) would opt for the on-demand regimen. Many advantages of PrEP were mentioned: protection in case of a condom break, protection in case of high-risk sexual behaviour, self-reliance, decreasing HIV fear and ease of use. Barriers to the use of PrEP included: it does not protect against other Sexually Transmitted Tnfections (STIs), taking a pill regularly is necessary, the size of the pill, possibility of side effects, the cost and accessibility. Six participants (19.3%) admitted that they would use condoms less if they take PrEP. Conclusion: Findings indicate that PrEP is acceptable within the MSM community. Implementation should be done rapidly, and PrEP should be part of a global prevention program which includes counselling, STI screening and promotion of safe sex practices. Health authorities should consider PrEP for all high-risk groups to avoid worsening stigmatization by targeting MSM only. © 2019 Pelletier et al. Article	2019	Peng, Liping; Cao, Wangnan; Gu, Jing; Chun Hao; Li, Jibin; Dannuo Wei; Li, Jinghua	Willingness to Use and Adhere to HIV Pre-Exposure Prophylaxis (PrEP) among Men Who Have Sex with Men (MSM) in China	International Journal of Environmental Research and Public Health	-	-	-	-	1661-7827	10.3390/ijerph16142620	https://www.proquest.com/scholarly-journals/willingness-use-adhere-hiv-pre-exposure/docview/2329432478/se-2?accountid=8113	This study aimed to investigate the levels of willingness to use pre-exposure prophylaxis (PrEP) and intention to adhere to PrEP and to further explore factors associated with PrEP uptake among men who have sex with men (MSM) in China. A total of 524 MSM were recruited from Chengdu, China. Half of the participants had heard of PrEP, and the awareness rate varied from 33.8%, 30.7%, and 7.1% for daily oral PrEP, on-demand PrEP, and long-acting injectable PrEP (LAI-PrEP), respectively. The overall willingness to use any type of PrEP in the next six months was 84.9% if PrEP is effective and provided for free. Participants were less likely to say that they would use PrEP if they used a condom consistently with their regular partners. However, participants were more likely to say that they would use PrEP if they had casual partners in the past month and had higher HIV prevention literacy. The majority of participants intended to adhere to PrEP prescription. More than forty percent (43.1%) of the participants reported that they might reduce condom use if they took PrEP. We found that the overall willingness to use PrEP was high among MSM living in China, but willingness varied across the different types of PrEP. Article	2019	Peterson K.; Folayan M.O.	Ethics and HIV prevention research: An analysis of the early tenofovir PrEP trial in Nigeria	Bioethics	-	-	-	-	2699702	10.1111/bioe.12470	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054847646&doi=10.1111%2fbioe.12470&partnerID=40&md5=54e996af04606fbf6d3f7e9643b00277	In 2004, the first ever multi-sited clinical trials studied the prospect of HIV biomedical prevention (referred to as pre-exposure prophylaxis—'PrEP'). The trials were implemented at several international sites, but many officially closed down before they completed. At most sites, both scientists and community AIDS advocates raised concerns over the ethics and scientific rationales of the trial. Focusing on the Nigerian trial site, we detail the controversy that emerged among mostly Nigerian research scientists who scrutinized the research design and protocol. While some of the disputes, especially those pertaining to community engagement mechanisms, were ultimately resolved in international fora and implemented in later PrEP trials, concerns over science rationales and assumptions were never addressed. We argue that scientific rationales should be treated as ethical concerns and suggest that such concerns should be deliberated at host sites before the trial protocol is finalized. © 2018 John Wiley & Sons Ltd. Article	2019	Peterson M.; Nowotny K.; Dauria E.; Arnold T.; Brinkley-Rubinstein L.	Institutional distrust among gay, bisexual, and other men who have sex with men as a barrier to accessing pre-exposure prophylaxis (PrEP)	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2018.1524114	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053491634&doi=10.1080%2f09540121.2018.1524114&partnerID=40&md5=cf2b9f714a62fd479f6f579d4e6f2c3b	Populations at highest risk for acquiring HIV are more likely to pass through criminal justice (CJ) settings, and CJ-involved individuals are often at the intersection of multiple overlapping risk factors. The present study explored interest in, knowledge of, and barriers to PrEP uptake among gay, bisexual, and other men who have sex with men involved in the criminal justice system. Using semi-structured interviews, 26 participants who identified as MSM were asked about PrEP knowledge and interest, HIV risk, and incarceration experience. One theme that emerged across interviews was how institutional distrust in CJ settings may instill lack of trust in medical care after perceived mistreatment. Participants explained how lack of privacy fostered feelings that medical care was not confidential, care received was tied to status as an incarcerated person, and feelings of dehumanization led to distrust. Findings explore how distrust may hinder PrEP uptake and other HIV prevention efforts in CJ settings as well as after release. They highlight the need for greater privacy efforts and cultural humility, and explore how medical settings may function as spaces for people who are incarcerated to disclose HIV risk status. Few studies to our knowledge have examined the role of institutional distrust on men who have sex with men (MSM) in the context of pre-exposure prophylaxis (PrEP) interventions. The present study has implications for creating best practices to structure HIV prevention interventions in CJ settings. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group. Article	2019	Peterson, Meghan; Macmadu, Alexandria; Truong, Ashley Q; Rich, Josiah; Pognon, Kimberly; Lurie, Mark; Clarke, Jennifer G; Brinkley-Rubinstein, Lauren	Pre-exposure prophylaxis awareness and interest among participants in a medications for addiction treatment program in a unified jail and prison setting in Rhode Island.	Journal of Substance Abuse Treatment	-	-	-	-	1873-6483	10.1016/j.jsat.2019.08.015	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC10347805	People who are incarcerated are at increased risk for HIV (human immunodeficiency virus) acquisition upon release, and one possible intervention for prevention is the use of pre-exposure prophylaxis (PrEP) upon release. The present study assessed HIV risk perceptions as well as PrEP awareness and interest among 39 people who were incarcerated and enrolled in a structured Medication for Addiction Treatment (MAT) program at the Rhode Island Department of Corrections using semi-structured, qualitative interviews. Analysis was conducted using a generalized, inductive method in NVivo 12. While PrEP awareness was low across the study sample, some participants were interested in PrEP uptake or learning more about PrEP after they were provided with an overview of it. PrEP interest strongly related to current perceived HIV risk. Potential barriers included side effects, adherence, and reluctance to take medications in general. MAT programs for people who are criminal justice (CJ) involved may serve as useful linkage spaces to PrEP information, access, and retention. Article	2019	Phillips G., II; Raman A.; Felt D.; Han Y.; Mustanski B.	Factors Associated with PrEP Support and Disclosure Among YMSM and Transgender Individuals Assigned Male at Birth in Chicago	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02561-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068193814&doi=10.1007%2fs10461-019-02561-1&partnerID=40&md5=284a23160746f4ab4fcbd2d1d71b0adc	Pre-exposure prophylaxis (PrEP) is one of the best biomedical HIV prevention tools available. However, uptake, particularly in communities of men who have sex with men (MSM) and transgender individuals assigned male at birth (AMAB), remains low. Further, the role of an individual's social support structure on PrEP uptake and adherence remains largely understudied. Understanding MSM and AMAB transgender individuals' perceptions of PrEP use as well as support and patterns of disclosure of (or intent to disclose) their PrEP status may offer key insights into how best to improve uptake in vulnerable communities. Further, the influence of one's social connections on other factors, such as perceptions of and conversations about PrEP deserves attention as well, as these factors may be key to improved knowledge and uptake. Therefore, we assessed perceptions of PrEP use, disclosure of or intent to disclose PrEP status, and social support and associated factors among a cohort of MSM and AMAB transgender individuals in a large Midwestern city. Results demonstrated that, among those not taking PrEP, bisexual participants and those unsure of their sexual identity were less likely to be comfortable with the idea of disclosing PrEP use to anyone else they ever to start taking it. Encouragingly however, we found that individuals who reported disclosing their PrEP status had high rates of support among friends and relatives. We also observed that knowing someone else who was on PrEP was associated with increased likelihood of discussing PrEP with one's medical provider, as was increased age. Other findings and implications for research, policy, and practice are discussed within. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Phillips, Gregory, II; Balint Neray; Birkett, Michelle; Felt, Dylan; Janulis, Patrick; Mustanski, Brian	Role of Social and Sexual Network Factors in PrEP Utilization Among YMSM and Transgender Women in Chicago	Prevention Science	-	-	-	-	13894986	10.1007/s11121-019-00995-6	https://www.proquest.com/scholarly-journals/role-social-sexual-network-factors-prep/docview/222820551/se-2?accountid=8113	Despite demonstrated efficacy, uptake of HIV pre-exposure prophylaxis (PrEP) remains low, particularly among high-risk demographics such as transgender women, Black men who have sex with men (BMSM), and young MSM (YMSM). Research thus far has largely focused on individual factors that may impede PrEP uptake in these demographics, leaving social network factors relatively unexplored. The present study used data collected from participants within RADAR, a longitudinal cohort study in Chicago focused on understanding the individual, dyadic, network, social, and biologic factors associated with HIV infection within YMSM. Of the 906 study participants who did not report an HIV diagnosis at baseline, 7.0% reported using PrEP in the prior 6 months. Recent PrEP use was associated with both individual-level (age and gender) and network-level factors (mean relationship strength, sexual network degree, etc.). These findings highlight the need to expand beyond focusing on individual-level drivers of PrEP uptake, as well as changing our understanding of who is most important within a network (centrality vs. strength of weak ties). Future work is needed to determine whether variables associated with PrEP uptake are similarly connected to PrEP adherence. Article	2019	Phillips, Gregory; Neray, Balint; Janulis, Patrick; Felt, Dylan; Mustanski, Brian; Birkett, Michelle	Utilization and avoidance of sexual health services and providers by YMSM and transgender youth assigned male at birth in Chicago	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2019.1587370	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062440315&doi=10.1080%2f09540121.2019.1587370&partnerID=40&md5=0c7111218ac96123e2322e8e134daf60	Young men who have sex with men (YMSM) and transgender youth assigned male at birth (AMAB) bear a disproportionate burden of the HIV epidemic, yet are sub optimally engaged by sexual health service providers and HIV prevention services. To increase sexual health and HIV prevention behaviors and address disparities in HIV incidence and outcomes among YMSM and AMAB transgender youth, it is critical to understand patterns of service utilization and avoidance. This study examined how and why YMSM and AMAB transgender youth use or avoid sexual health services and service providers in a large Midwestern city within a survey administered to 890 participants from a longitudinal cohort study (RADAR). Results demonstrate low overall use of sexual health services and minimal interest in seeking pre-exposure prophylaxis (PrEP), consistent with prior research. Low awareness of available services was associated with how and where YMSM and trans youth AMAB seek care, with 76% of our sample reporting this as their primary reason for not seeking specific sexual health services. Additional associations are discussed, and recommendations are made for how to improve available services and access. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group. Article	2019	Pines H.A.; Strathdee S.A.; Hendrix C.W.; Bristow C.C.; Harvey-Vera A.; Magis-Rodríguez C.; Martinez G.; Semple S.J.; Patterson T.L.	Oral and vaginal HIV pre-exposure prophylaxis product attribute preferences among female sex workers in the Mexico-US border region	International journal of STD & AIDS	-	-	-	-	9564624	10.1177/0956462418793038	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053371857&doi=10.1177%2f0956462418793038&partnerID=40&md5=c6bf0a4f21ca458749653ebb29d4d194	To assess the potential uptake of HIV pre-exposure prophylaxis (PrEP) products among female sex workers (FSWs) vulnerable to HIV infection, we examined the influence of product attributes on willingness to use products among 271 HIV-negative FSWs in Tijuana and Ciudad Juarez, Mexico (2016–2017). Via five-point Likert scale ratings, participants indicated their willingness to use hypothetical products with six attributes: formulation (pill, gel, liquid, or ring), frequency of use (daily, on-demand, or monthly), cost per use (10 or 200 pesos), effectiveness (40% or 80%), side effects (none or mild), and access point (healthcare clinic or non-governmental organization). Conjoint analysis was used to determine the impact of attributes on product ratings and identify preferred product attributes. Multinomial logistic regression was used to identify factors associated with formulation preferences. In both cities, formulation and frequency of use had the greatest impact on ratings. Participants in Ciudad Juarez indicated a strong preference for oral pills, whereas participants in Tijuana indicated roughly equal preferences for oral pills and vaginal gels. Monthly product use was preferred in both cities. Compared to preferring oral pills (38%), preferring vaginal gels (28%) was associated with practicing vaginal lubrication (adjusted odds ratio = 2.08; 95% confidence interval: 1.07–4.04). Oral PrEP may be acceptable to many FSWs in Tijuana and Ciudad Juarez; however, continued development of behaviorally-congruent vaginal PrEP products may also facilitate uptake and ensure sufficient coverage. © The Author(s) 2018.	female sex workers; HIV; Mexico; Pre-exposure prophylaxis; preferences	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Pinto R.M.; Lacombe-Duncan A.; Kay E.S.; Berringer K.R.	Expanding Knowledge About Implementation of Pre-exposure Prophylaxis (PrEP): A Methodological Review	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02577-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068910875&doi=10.1007%2fs10461-019-02577-7&partnerID=40&md5=78b9b09faf65f4fc36d5bb4cf4b482b3	Methodological limitations in PrEP implementation studies may explain why PrEP implementation is lagging. This methodological review provides a description and critique of the methods used to identify barriers to PrEP implementation in the United States (2007–18). For each selected article, we provide: (1) research questions; (2) measures; (3) design; (4) sample (size and type); and (5) theoretical orientation. Among 79 articles which identified knowledge, attitudes, and behavioral and social/structural barriers to PrEP implementation, 51 (65%) were quantitative; 25 (32%) qualitative; and 3 (4%) were mixed-methods; overall, just one-half described a conceptual approach. About two-thirds of articles were conducted with patients and one-third with healthcare providers. Our review reveals a paucity of longitudinal, mixed-methods, and ethnographic/observational research and guiding theoretical frameworks; thus, the applicability of results are limited. We recommend that interventions aimed at PrEP implementation address barriers situated at multiple ecological domains, and thus improve PrEP access, uptake, and adherence. © 2019, The Author(s). Article	2019	Poon A.N.; Han L.; Li Z.; Zhou C.; Li Y.; Huang L.; Liao M.; Shepard C.; Bulterys M.	Acceptability and willingness of HIV pre-exposure prophylaxis amongst female sex workers in China	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2019.1612001	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065440279&doi=10.1080%2f09540121.2019.1612001&partnerID=40&md5=7d1ce85995e09ceceeadfc29acf947c1	HIV pre-exposure prophylaxis (PrEP) is a highly effective prevention method. It is an attractive self-initiated approach to reduce the spread of HIV amongst female sex workers (FSW). PrEP, however, has not yet achieved its potential to reduce HIV infections partially due to a general lack of awareness from women who may benefit. Aims of this cross-sectional study of 1,466 FSW in China were to understand: levels of awareness of and willingness to use PrEP among female sex workers (FSW) in China, and factors contributing to willingness to use PrEP. We found that awareness (10.2%) and willingness (35.5%) to use PrEP were low in our survey areas. Low PrEP willingness is likely reflective of the overall poor knowledge and understanding of HIV risk and prevention. FSW that demonstrated greater HIV knowledge through having been tested or having greater decision-making involvement in condom use were more willing to use PrEP. Study findings may be used to inform future HIV prevention activities, including possible use of PrEP among FSW at higher risk of incident HIV infection in China. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group. Article	2019	Poteat T.; Wirtz A.; Malik M.; Cooney E.; Cannon C.; Hardy W.D.; Arrington-Sanders R.; Lujan M.; Yamanis T.	A Gap between Willingness and Uptake: Findings from Mixed Methods Research on HIV Prevention among Black and Latina Transgender Women	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002112	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072133627&doi=10.1097%2fQAI.0000000000002112&partnerID=40&md5=6a14bd1bd9c4122266a6a9ddcc1e38e0	Background: Black and Latina transgender women (BLTW) face significant HIV disparities with estimated HIV prevalence up to 50% and annual incidence rates as high as 2.8 per 100 person-years. However, few studies have evaluated the acceptability and uptake of high-impact HIV prevention interventions among BLTW.Setting: Data collection took place in Baltimore, MD and Washington, DC from May 2015 to May 2017. Methods: This mixed methods study included quantitative interviewer-administered surveys, key informant interviews, and focus group discussions. Rapid HIV testing followed each survey. Logistic regression models tested associations between legal gender affirmation (ie, desired name and gender marker on identity documents), transgender pride, history of exchange sex, HIV testing, and willingness to take pre-exposure prophylaxis (PrEP). Transcripts of qualitative data were coded to identify common themes related to engagement in HIV prevention. Results: Among 201 BLTW, 56% tested HIV-positive and 87% had heard of PrEP. Only 18% who had heard of PrEP had ever taken it. Of the 72 self-reported HIV-negative or status-unknown BLTW who had never taken PrEP, 75% were willing to take it. In multivariable analyses, history of exchange sex was associated with willingness to take PrEP, whereas greater HIV knowledge and transgender pride were associated with lower likelihood of willingness to take PrEP. Concern about drug interactions with hormone therapy was the most frequently reported barrier to PrEP uptake. Conclusions: Noting the disconnect between PrEP willingness and uptake among BLTW, HIV prevention programs could bridge this gap by responding to identified access barriers and incorporating community-derived strategies. © 2019 Wolters Kluwer Health, Inc. Article	2019	Powell, Victoria E; Gibas, Kevin M; DuBow, Joshua; Krakower, Douglas S	Update on HIV Preexposure Prophylaxis: Effectiveness, Drug Resistance, and Risk Compensation	Current Infectious Disease Reports	-	-	-	-	15233847	10.1007/s11908-019-0685-6	https://www.proquest.com/scholarly-journals/update-on-hiv-preexposure-prophylaxis/docview/2244523011/se-2?accountid=8113	Purpose of ReviewIn 2019, the US government launched an initiative to decrease new HIV infections by 90% over the next decade. Studies have demonstrated the efficacy of HIV preexposure prophylaxis (PrEP) for high-risk populations, and the United States Preventative Services Task Force has issued a grade A recommendation for PrEP, indicating substantial net benefit. However, questions have been raised about the effectiveness of PrEP in clinical settings and whether PrEP use might promote antiretroviral drug resistance and increased sexual risk behaviors, which could increase transmission of bacterial sexually transmitted infections. In this narrative review, we summarize recent evidence of the effectiveness of PrEP when provided in clinical and community settings, the emergence of antiretroviral drug resistance during PrEP use, and associations between PrEP use and increased sexual risk behaviors. We also review novel PrEP modalities that are being developed to optimize PrEP acceptability, adherence, and effectiveness.Recent FindingsStudies suggest that PrEP is effective when provided in clinical settings. However, PrEP uptake and impact have been limited in the USA thus far, and major disparities in access to PrEP exist. In addition, there is evidence that drug resistance can occur with PrEP use, particularly with inadvertent PrEP use during undiagnosed acute HIV infection. Risk compensation can also occur with PrEP use and has been associated with increased sexually transmitted infections. Promising new modalities for PrEP could expand options.SummaryPrEP has strong potential to decrease HIV incidence. However, disparities in access must be addressed to ensure equity and impact for PrEP. While drug resistance and risk compensation can occur with PrEP use, these are not valid reasons to withhold PrEP from patients given its substantial protective benefits. Article	2019	Prescott, Maximo R.; Hern, Jaclyn; Petersen, Maya; Santos, Glenn-Milo	Does HIV Pre-Exposure Prophylaxis Modify the Effect of Partnership Characteristics on Condom Use? A Cross-Sectional Study of Sexual Partnerships Among Men Who Have Sex with Men in San Francisco, California.	AIDS Patient Care and STDs	-	-	-	-	1557-7449 1087-2914	10.1089/apc.2018.0179	https://pubmed.ncbi.nlm.nih.gov/30932698/	Increasing rates of sexually transmitted infections (STIs) in the United States among men who have sex with men (MSM) have raised concerns that pre-exposure prophylaxis (PrEP) has been associated with higher engagement in condomless anal intercourse (CAI). While partnership characteristics have previously been found to influence condom use, the extent to which PrEP use may modify their effect on CAI remains unknown. A secondary analysis of 535 sexual partnerships from a cross-sectional study in San Francisco was conducted to evaluate interactions between PrEP use and partnership characteristics on CAI. Bivariate and multivariate generalized estimating equation (GEE) logistic regression models were used to estimate relative measures of association, adjusted for confounding by seroconcordance and partnership type, as well as accounting for repeated partnerships per respondent. Partnerships where both partners used biomedical prevention had significantly greater odds of CAI odds ratio (OR) = 5.19, 95% confidence interval (CI): 2.27-11.9 compared to those where only one partner used biomedical prevention, while those where neither partner used biomedical prevention had significantly lower odds of CAI (OR = 0.61, 95% CI: 0.40-0.93). There was no significant association between meeting place (online vs. offline) and sexual risk taking (OR = 1.03, p = 0.894). Having one partner disclose their HIV status (compared to neither partner having disclosed) was associated with significantly higher odds of CAI among partnerships of PrEP-using MSM adjusted OR (aOR) = 5.28, 95% CI: 1.91-14.61, while the association was not significant among the partnerships of non-PrEP-using MSM (aOR = 1.29, 95% CI: 0.75-2.21). Differences in condom use among MSM using PrEP may not be well explained by differences in the effect of partnership characteristics. MSM using PrEP appear to commonly practice biomedical matching and high engagement in CAI with other biomedical prevention users, which could indicate relatively concentrated sexual networks and partly explain their disproportionate risk for STIs. Future studies should further investigate biomedical matching to develop interventions that further promote the sexual health of those using PrEP. Article	2019	Prestage G.; Maher L.; Grulich A.; Bourne A.; Hammoud M.; Vaccher S.; Bavinton B.; Holt M.; Jin F.	Changes in Behavior after PrEP Initiation among Australian Gay and Bisexual Men	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001976	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064722657&doi=10.1097%2fQAI.0000000000001976&partnerID=40&md5=45482bb6100206f5399498802e4342a4	Introduction:HIV pre-exposure prophylaxis (PrEP) has been increasingly adopted by gay and bisexual men (GBM). Little is known about whether individual GBM change their sexual behavior after PrEP initiation.Methods:Following Lives Undergoing Change (Flux) is a national, online, prospective observational study among Australian GBM. Using McNemar statistics, we compare rates of sexual behaviors before and coincident with PrEP initiation among 1518 non-HIV-positive men recruited between August 2014 and July 2017 who had not commenced PrEP at baseline and who completed at least one 6-monthly follow-up survey by July 2018.Results:The proportion of men using PrEP rose to 24.2% over time. In total, 348 men initiated PrEP during follow-up. PrEP initiators were more likely to report particular sexual behaviors during the follow-up period that they commenced PrEP compared with the period immediately prior: receptive condomless anal intercourse with casual partners increased from 31.0% to 48.9% (McNemar < 0.001); mean partner number increased from 21.96 partners to 34.55 partners (p-trend < 0.001). Among the 1170 men who did not initiate PrEP, prevalence of these behaviors remained lower and stable. Sexual sensation-seeking and gay social engagement were both higher among men who commenced PrEP.Conclusions:GBM tended to increase their engagement in "adventurous" sexual behaviors after PrEP initiation. Sexual behaviors among men who did not initiate PrEP were less common and did not change over time. Copyright © 2019 Wolters Kluwer Health, Inc. Article	2019	Price J.C.; Mckinney J.E.; Crouch P.-C.; Dillon S.M.; Radix A.; Stivala A.; Carollo J.R.; Fierer D.S.	Sexually Acquired Hepatitis C Infection in HIV-Uninfected Men Who Have Sex with Men Using Preexposure Prophylaxis against HIV	Journal of Infectious Diseases	-	-	-	-	221899	10.1093/infdis/jiy670	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061918163&doi=10.1093%2finfdis%2fjiy670&partnerID=40&md5=d1a1e6a9927d2304bfd72d539b354582	Sexually acquired hepatitis C virus (HCV) infections among human immunodeficiency virus (HIV)-uninfected men who have sex with men (MSM) have been rare. With the introduction of preexposure prophylaxis (PrEP) against HIV, we hypothesized that these infections would increase. Between 2013 and 2018, we diagnosed 15 likely sexually acquired HCV infections among 14 MSM using PrEP. Most (87%) were asymptomatic, detected by routine alanine transaminase (ALT) or HCV monitoring. Half reported increasing sex partners and drug use after starting PrEP; 5 reported injection of methamphetamine. Interventions are needed to prevent sexually acquired HCV infections by MSM using PrEP. Centers for Disease Control and Prevention guidelines for monitoring during PrEP should include regular ALT and HCV testing. © 2018 The Author(s) 2018. Article	2019	Przybyla S.; LaValley S.; St. Vil N.	Health care provider perspectives on pre-exposure prophylaxis: A qualitative study	Journal of the Association of Nurses in AIDS Care	-	-	-	-	10553290	10.1097/JNC.0000000000000073	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073303958&doi=10.1097%2fJNC.0000000000000073&partnerID=40&md5=c432fce9726f1896750b8cf4f58719dd	Although pre-exposure prophylaxis (PrEP) requires a prescription from a health care provider, we lack unanimity in guidelines for the identification of the ideal provider type to prescribe PrEP. The purpose of our study was to understand clinician perspectives on provider categories to determine who is best suited to prescribe this medication to HIV-uninfected patients. We conducted 28 in-depth interviews between September 2017 and January 2018 with current prescribers of PrEP. Qualitative findings indicated that providers were split on recommended PrEP prescriber type. Five themes emerged that centered on the explicit identification of the issue of opportunity for providers to educate their patients on PrEP and offer this medication to at-risk populations. To effectively maximize presentation for care and subsequently amplify uptake of PrEP, growing the base of providers who offer PrEP to eligible patients can provide a meaningful public health impact on reducing HIV incidence. Article	2019	Przybyla S.M.; Parks K.; Bleasdale J.; Sawyer J.; Morse D.	Awareness, knowledge, and attitudes towards human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) among pharmacy students	Currents in Pharmacy Teaching and Learning	-	-	-	-	18771297	10.1016/j.cptl.2019.01.011	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062232471&doi=10.1016%2fj.cptl.2019.01.011&partnerID=40&md5=cb692aa6ad9af60bfe44caf738da4831	Introduction: The purpose of this study was to assess pharmacy students' awareness, knowledge, and perceptions towards human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP), confidence and intentions to counsel patients on PrEP, and preferred PrEP training. Methods: A web-based cross-sectional survey was conducted with pharmacy students. Descriptive statistics and multivariate logistic regressions were performed. Results: Ninety-one percent of participants were aware of PrEP and 61% were familiar with PrEP prescription guidelines. In multivariate analysis, greater PrEP knowledge, attitudes towards PrEP, and familiarity with prescribing guidelines were significantly associated with confidence in PrEP counseling (p < 0.01 for all). Males had significantly higher odds of reporting confidence in PrEP counseling relative to their female counterparts (p < 0.01). Relative to fourth year students, second year students were less likely to report confidence in PrEP counseling (p < 0.01). Participants who were familiar with prescribing guidelines had significantly higher odds of PrEP counseling intentions (p < 0.05). Preferred educational topics regarding PrEP included training on side effects and adherence monitoring (65% and 51%, respectively). The most preferred modalities for receiving PrEP education were online education (47%), educational seminars in required courses (43%), and self-study modules (39%). Conclusions: Given the key role played by pharmacists in patient engagement, they may be presented with opportunities to provide PrEP counseling and education. The development of educational modules for pharmacy students in an effort to increase PrEP uptake should consider addressing gaps in knowledge and preferred training modalities. © 2019 Elsevier Inc. Article	2019	Puppo, Costanza; Mabire, Xavier; Cotte, Laurent; Castro, Daniela Rojas; Spire, Bruno; Cua, Eric; Pialoux, Gilles; Monti, Marie Suzan; Pasquet, Armelle; Raffi, François; Molina, Jean-Michel; Préau, Marie	Community-Based Care in the ANRS-IPERGAY Trial: The Challenges of Combination Prevention.	AIDS Education and Prevention	-	-	-	-	1943-2755 0899-9546	10.1521/aeap.2019.31.3.259	https://pubmed.ncbi.nlm.nih.gov/31145006/	ANRS-IPERGAY was a community-based randomized trial investigating the efficacy of sexual activity-based HIV pre-exposure prophylaxis (PrEP) in a population of males and transgender females who had sex with men and were at high risk of HIV infection. We qualitatively analyzed the support provided to participants by community-based health workers (CBHW) throughout the trial's double-blind and open-label extension phases. In particular, we showed that the relationship between participants and CBHW strongly influenced self-managed pill intake. The delicate construction of this relationship, balanced between trust and dependence, played an important role in PrEP adherence. CBHW had to deal with various issues surrounding participants' feelings of empowerment regarding their role in the trial, as well as related tensions between various logics and rationalities. They were essential to participants' continued involvement.	*Homosexuality, Male; Adult; Humans; Male; Middle Aged; Female; HIV Infections/*prevention & control; Randomized Controlled Trials as Topic; Sexual Behavior; Double-Blind Method; HIV; Interviews as Topic; France; Anti-HIV Agents/*administration & dosage/therapeutic use; *Pre-Exposure Prophylaxis; PrEP; Qualitative Research; *Transgender Persons; Community-Based Participatory Research; empowerment; ANRS-IPERGAY; Community Health Workers; community-based care; negotiation	English	United States	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Qualitative
Article	2019	Puri, Ashana; Bhattaccharjee, Sonalika A.; Zhang, Wei; Clark, Meredith; Singh, Onkar; Doncel, Gustavo F.; Banga, Ajay K.	Development of a Transdermal Delivery System for Tenofovir Alafenamide, a Prodrug of Tenofovir with Potent Antiviral Activity Against HIV and HBV.	Pharmaceutics	-	-	-	-	1999-4923	10.3390/pharmaceutics11040173	https://pubmed.ncbi.nlm.nih.gov/30970630/	Tenofovir alafenamide (TAF) is an effective nucleotide reverse transcriptase inhibitor that is used in the treatment of HIV-1 and HBV. Currently, it is being investigated for HIV prophylaxis. Oral TAF regimens require daily intake, which hampers adherence and increases the possibility of viral resistance. Long-acting formulations would significantly reduce this problem. Therefore, the aim of this study was to develop a transdermal patch containing TAF and investigate its performance in vitro through human epidermis. Two types of TAF patches were manufactured. Transparent patches were prepared using acrylate adhesive (DURO-TAK 87-2516), and suspension patches were prepared using silicone (BIO-PSA 7-4301) and polyisobutylene (DURO-TAK 87-6908) adhesives. In vitro permeation studies were performed while using vertical Franz diffusion cells for seven days. An optimized silicone-based patch was characterized for its adhesive properties and tested for skin irritation. The acrylate-based patches, comprising 2% w/w TAF and a combination of chemical enhancers, showed a maximum flux of 0.60 ± 0.09 μg/cm^2/h. However, the silicone-based patch comprising of 15% w/w TAF showed the highest permeation (7.24 ± 0.47 μg/cm^2/h). This study demonstrates the feasibility of developing silicone-based transdermal patches that can deliver a therapeutically relevant dose of TAF for the control of HIV and HBV infections.	tenofovir alafenamide; acrylate adhesive; in vitro permeation; silicone adhesive; suspension patch; transdermal patch	English	Switzerland	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Tenofovir-diphosphate as a marker of HIV pre-exposure prophylaxis use among east african men and women	Frontiers in Pharmacology	-	-	-	-	16639812	10.3389/fphar.2019.00401	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068438798&doi=10.3389%2ffphar.2019.00401&partnerID=40&md5=249b57d75192008d12ab6a26e55d23bb	Background: Controlled pharmacokinetic (PK) studies in United States populations have defined categories of tenofovir-diphosphate (TFV-DP) in dried blood spots (DBS) for various pre-exposure prophylaxis (PrEP) adherence targets. It is unknown how these categories perform in other populations. Therefore, we evaluated the sensitivity and specificity of these PK-derived categories compared to daily medication electronic adherence monitoring (MEMS) data among East African men and women using daily PrEP. Methods: Participants were enrolled as members of HIV serodiscordant couples as part of an open-label PrEP study in Kenya and Uganda. Blood samples were taken at quarterly visits and stored as DBS, which were analyzed for TFV-DP concentrations. Results: Among 150 samples from 103 participants, MEMs data indicated that 87 (58%) took ≥4 doses and 62 (41%) took ≥6 in the 4 weeks prior to sample collection. Sensitivities of DBS TFV-DP levels were 62% for the ≥4 doses/week category (≥700 fmol/punch TFV-DP) and 44% for the ≥6 doses/week category (≥1050 fmol/punch TFV-DP); specificities were 86 and 94%, respectively. There were no statistically significant differences in these sensitivities and specificities by gender. Conclusion: In this sample of East African PrEP users, categories of TFV-DP concentrations developed from directly observed PrEP use among United States populations had high specificity but lower than expected sensitivity. Sensitivity was lowest when MEMS data indicated high adherence (i.e., ≥6 doses/week). PrEP studies and implementation programs should carefully consider the sensitivity and specificity of the TFV-DP levels used for adherence feedback. © 2019 Pyra, Anderson, Haberer, Heffron, Celum, Asiimwe, Katabira, Mugo, Bukusi and Baeten. Article	2019	Pyra, M; Rusie, L; Baker, KK; Ridgway, J; Schneider, J	HIV PRE-EXPOSURE PROPHYLAXIS (PREP) INDICATIONS AND UPTAKE VARY BY RACE, GENDER, AND INSURANCE IN A LARGE CLINIC NETWORK	Sexually Transmitted Infections	-	-	-	-	1368-4973	10.1136/sextrans-2019-sti.158	https://sti.bmj.com/content/95/Suppl_1/A59.3	Background Providers face challenges identifying patients to benefit from PrEP, while disparities remain in PrEP access. We examine gaps in identification of PrEP candidates, uptake, and use of PrEP by populations at high HIV risk within a large federally qualified health center with a lesbian/gay/bisexual/transgender/queer (LGBTQ) focus. Methods An established PrEP:Need ratio was calculated to examine differences in PrEP use across race, age, gender, and insurance. Two new measures were developed to determine gaps in identifying candidates and uptake - Identification:Need and PrEP:Identification. Patients were identified through electronic health records who had a documented indication for PrEP according to CDC guidelines, whether patients had a PrEP prescription, and if they seroconverted, from 2015–2018. Results Over 50,000 unique patients were included, with median age 30.5; patients were 48% White, 47% men who have sex with men (MSM), and 7% transwomen. Overall, there were 14.6 patients on PrEP for each incident HIV infection (PrEP:Need). PrEP:Need was 24.5 among White patients, compared to 6.6 among Black patients. PrEP:Need was low for Medicaid/Medicare patients (7.9), transwomen (10.0), and particularly Black transwomen (4.6). Low PrEP:Need ratios were usually driven by low Identification:Need ratios, with large differences: among MSM, 23.2 patients were indicated for PrEP per incident infection compared to 7.2 among transwomen. Uptake, measured by PrEP:Identification, ratios, were lowest among patients without insurance and highest among those with private insurance. Conclusion We found high variation in PrEP:Need ratios across race, gender, and insurance status. This may be due to a poor fit between current PrEP indications and actual HIV incidence in key populations; there may also be gaps in patient-provider communication and documentation of PrEP indications in certain	NA	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Qu D.; Zhong X.; Lai M.; Dai J.; Liang H.; Huang A.	Influencing Factors of Pre-Exposure Prophylaxis Self-Efficacy Among Men Who Have Sex With Men	American Journal of Men's Health	-	-	-	-	15579883	10.1177/1557988319847088	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065092690&doi=10.1177%2f1557988319847088&partnerID=40&md5=f0d5647529a46637a27265f622b4b800	This research examines the level of pre-exposure prophylaxis (PrEP) self-efficacy among HIV-negative men who have sex with men (MSM) in China and identifies the influencing factors associated with the level of PrEP self-efficacy in terms of social-demographic characteristics and social psychological factors. The data were gathered from a baseline assessment of a longitudinal randomized controlled intervention trial. From April 2013 to March 2015, nonprobability sampling was used to recruit HIV-negative MSM at Chongqing, Guangxi, Xinjiang, and Sichuan in west China. A total of 1884 HIV-negative MSM were analyzed. Chi-square test and nonparametric rank sum test were used for univariate analysis. Multivariable linear regression analysis was used to discuss the factors that influence the level of PrEP self-efficacy. Overall levels of PrEP self-efficacy were low, and five factors were found to effect PrEP self-efficacy: age, residence, AIDS-related knowledge, PrEP-related motivation, and anxiety. Age and anxiety score were negatively related to PrEP self-efficacy. The higher the age and anxiety score, the lower the PrEP self-efficacy. AIDS-related knowledge and PrEP-related motivation were actively related to PrEP self-efficacy. The higher the knowledge and motivation score, the higher the PrEP self-efficacy. In addition, the PrEP self-efficacy level of MSM in rural areas is lower than that in urban areas. The lower level of self-efficacy in the MSM population needs to be improved. Pertinent interventions should be taken to promote the self-efficacy of PrEP in MSM, to enhance their willingness to take medicine, improve their medication adherence, and thus reduce HIV infection among MSM. © The Author(s) 2019.	influencing factors; men who have sex with men; pre-exposure prophylaxis; self-efficacy	English	United States	Western and Central Europe and North America	China	Asia and the Pacific	China	Asia and the Pacific	Clinical
Article	2019	Quinn K.; Bowleg L.; Dickson-Gomez J.	"The fear of being Black plus the fear of being gay": The effects of intersectional stigma on PrEP use among young Black gay, bisexual, and other men who have sex with men	Social Science & Medicine	-	-	-	-	2779536	10.1016/j.socscimed.2019.04.042	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065144087&doi=10.1016%2fj.socscimed.2019.04.042&partnerID=40&md5=99334b307eb34282c3711977338ccc5d	This is a qualitative study aimed at understanding how intersectional stigma affects PrEP awareness and uptake among Black GBM, aged 16 to 25. Focus groups were used to facilitate conversations around PrEP and experiences of stigma, identify and discuss diverse perspectives on PrEP, and enhance our understanding of PrEP barriers through interactions and sharing of diverse opinions (Patton, 2015). The lead author, who also designed this study, is a White, heterosexual, cisgender female. Two. Results Forty-four young men participated in six focus groups. The size of the groups ranged from five to eleven participants. Thirty-five participants identified as non-Hispanic Black or African American. Four identified as multi-racial (Black/African American and either White, Asian, or Native American) and five were Black Hispanic/Latino Black. The average age of participants was 22 (SD = 2.3; range 18–25). Seventy-five percent (n = 33) identified as gay; others identified as bisexual (n = 8).Discussion: One of the central tenets of intersectionality is that the individual experiences of people at multiple marginalized intersectional positions are differentially shaped by social and structural inequality (Crenshaw, 1991; Collins, 2015). Applied to HIV risk among young Black GBM, intersectionality highlights the importance of looking beyond individual-level factors such as risk behaviors and condom use attitudes and necessitates examining the social and structural factors that contribute to and Conclusions PrEP use among Black GBM is low; only about 30% of Black GBM are aware of PrEP and only 10–20% are accessing PrEP (Eaton et al., 2018). Multi-level interventions are needed to address the societal stigmas and inequities facing young Black GBM and increase PrEP use among Black GBM. Interventions to mitigate intersectional stigma and its consequences can cultivate environments in which young men are able to access quality healthcare, including PrEP, without judgment or discrimination. Article	2019	Quinn, Katherine; Dickson-Gomez, Julia; Zarwell, Meagan; Pearson, Broderick; Lewis, Matthew	"A Gay Man and a Doctor are Just like, a Recipe for Destruction": How Racism and Homonegativity in Healthcare Settings Influence PrEP Uptake Among Young Black MSM	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2375-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064462121&doi=10.1007%2fs10461-018-2375-z&partnerID=40&md5=3b958587b50bccf36b322940b3116729	Young, Black, gay bisexual or other MSM are significantly less likely to use PrEP than their White counterparts. These disparities may be due, in part, to medical mistrust and mistreatment within the healthcare system. This study aimed to uncover how young Black MSM's perceptions of, and experiences with, health care contribute to low engagement in the healthcare system and low PrEP utilization. In late 2017 and early 2018, we conducted six focus groups with 44 Black MSM ages 16–25 in Milwaukee. Focus group topics included participants' knowledge and perceptions of PrEP, perceptions and stereotypes about PrEP users, and general healthcare utilization patterns and behaviors. Focus group transcripts were transcribed verbatim and coded using MAXQDA qualitative analysis software. We used a team-based approach to thematic content analysis to understand how racism and homonegativity affected healthcare access and experiences. Results from this study help to characterize what contributes to mistrust of the healthcare system and healthcare providers to negatively affect PrEP use among young Black MSM. Focus group discussions revealed how previous and anticipated negative interactions with physicians and skepticism about the healthcare system have alienated young Black MSM from the health care system and created significant barriers to PrEP. Efforts to increase PrEP uptake and must address negative and discriminatory interactions with providers and the healthcare system. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Radzio-Basu, Jessica; Council, Olivia; Cong, Mian-Er; Ruone, Susan; Newton, Alicia; Wei, Xierong; Mitchell, James; Ellis, Shanon; Petropoulos, Christos J; Huang, Wei; Spreen, William; Heneine, Walid; García-Lerma, J Gerardo	Drug resistance emergence in macaques administered cabotegravir long-acting for pre-exposure prophylaxis during acute SHIV infection.	Nature Communications	-	-	-	-	2041-1723	10.1038/s41467-019-10047-w	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6494879	A long-acting injectable formulation of the HIV integrase inhibitor cabotegravir (CAB-LA) is currently in clinical development for PrEP. Although the long plasma half-life of CAB-LA is an important attribute for PrEP, it also raises concerns about drug resistance emergence if someone becomes infected with HIV, or if PrEP is initiated during undiagnosed acute infection. Here we use a macaque model of SHIV infection to model risks of drug resistance to CAB-LA PrEP. Six macaques infected with SHIV received CAB-LA before seroconversion. We show integrase mutations G118R, E92G/Q, or G140R in plasma from 3/6 macaques as early as day 57, and identify G118R and E92Q in viruses from vaginal and rectal fluids. G118R and G140R confer > 800-fold resistance to CAB and cross-resistance to all licensed integrase inhibitors. Our results emphasize the need for appropriate HIV testing strategies before and possibly shortly after initiating CAB LA PrEP to exclude acute infection. Knowledge About Oral PrEP Among Transgender Women in New York City	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02584-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068850551&doi=10.1007%2fs10461-019-02584-8&partnerID=40&md5=a444260dc8b4548f07e1921b79329dbc	This paper grows our understanding about PrEP knowledge in transgender women (TW) to improve PrEP-focused education/outreach. Research took place in New York City. We conducted four focus groups in English or Spanish (N = 18). Discussions focused on participants' perceptions and knowledge of oral PrEP. Most participants knew that PrEP is efficacious and requires consistent use. However, some participants were skeptical of medications; others acknowledged that false assumptions about PrEP exist among TW. Most TW in our focus groups were informed about PrEP through clinics or community-based organizations. Some participants felt that messages about medications were oversimplified, and wanted more information. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Raifman J.R.; Schwartz S.R.; Sosnowy C.D.; Montgomery M.C.; Almonte A.; Bazzi A.R.; Drainoni M.-L.; Stein M.D.; Willie T.C.; Nunn A.S.; Chan P.A.	Pre-exposure Prophylaxis Awareness and Use among Cisgender Women at a Sexually Transmitted Disease Clinic	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001879	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058599751&doi=10.1097%2fQAI.0000000000001879&partnerID=40&md5=625aaf1610029694f0fe5c6650aeed57	Background:Pre-exposure prophylaxis (PrEP) is highly effective in preventing HIV transmission. Cisgender women (cis-women) constitute only a small proportion of PrEP users in the United States despite accounting for 19% of new HIV infections in 2016.Setting:The Rhode Island Sexually Transmitted Diseases (STD) Clinic from 2013 to 2016.Methods:We report on the demographic and behavioral characteristics of all HIV-negative, cis-women who presented to the Clinic and of those who met Centers for Disease Control and Prevention (CDC) indications for PrEP. In a logistic regression analysis, we evaluated PrEP awareness among cis-women by year and demographic characteristics. We compared PrEP awareness among cis-women with PrEP awareness among cisgender men who have sex with men and among cisgender men who inject drugs presenting to the Clinic.Results:Among 1431 HIV-negative cis-women, 84 (5.8%) met CDC indications for PrEP. PrEP awareness was significantly lower among Hispanic/Latina cis-women (11.0%; adjusted odds ratio (AOR): 0.46, 95% confidence interval (CI): 0.31 to 0.66 and non-Hispanic black cis-women (13.8%; AOR: 0.59, 95% CI: 0.39 to 0.89) relative to non-Hispanic white cis-women (20.7%). Men who have sex with men had significantly greater PrEP awareness (60.3%; AOR: 5.85, 95% CI: 3.35 to 10.23) than cis-women (22.9%). Only one woman reported PrEP use.Conclusions:Two-thirds of HIV-negative cis-women presenting for HIV/sexually transmitted disease testing and meeting CDC indications for PrEP were unaware of PrEP, and only one woman reported ever using PrEP. There is a critical need for public health professionals and health care providers to increase PrEP awareness and use among cis-women at risk for HIV. © 2018 Wolters Kluwer Health, Inc. Article	2019	Ramchandani, Meena S; Golden, Matthew R	Confronting Rising STIs in the Era of PrEP and Treatment as Prevention	Current HIV/AIDS Reports	-	-	-	-	15483568	10.1007/s11904-019-00446-5	https://www.proquest.com/scholarly-journals/confronting-rising-stis-era-prep-treatment-as/docview/2240812343/se-2?accountid=8113	Purpose of ReviewThis study aims to review the epidemiology of sexually transmitted infections (STIs) among men who have sex with men (MSM) and suggest control measures.Recent FindingsDespite declines in new HIV diagnosis, bacterial STIs among MSM have dramatically risen since the late 1990s. This increase occurred concurrent with introduction of effective antiretroviral therapy, the advent of electronic mechanisms for meeting sex partners and population-level changes in sexual behavior, including decreased condom use. HIV pre-exposure prophylaxis (PrEP) is now further diminishing condom use, though its impact on STIs is uncertain. A plan to confront the MSM STI epidemic should include increased HIV/STI testing promoted through expanded public health clinical infrastructure, health care system reform to improve the care of gender and sexual minorities and promote low-barrier care, re-invigorated condom promotion, and scientific innovation.SummaryThere is an urgent need to implement new STI control measures while continuing to expand PrEP use. Patterns of Hepatitis C Virus Transmission in Human Immunodeficiency Virus (HIV)-infected and HIV-negative Men Who Have Sex with Men	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciz160	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075736124&doi=10.1093%2fcid%2fciz160&partnerID=40&md5=377e11db9de02c2be46dd64118515be2	Background: Sexually transmitted acute hepatitis C virus (HCV) infections (AHIs) have been mainly described in human immunodeficiency virus (HIV)-infected men who have sex with men (MSM). Cases in HIV-negative MSM are scarce. We describe the epidemic of AHI in HIV-infected and HIV-negative MSM in Lyon, France. Methods: All cases of AHI diagnosed in MSM in Lyon University Hospital from 2014 to 2017 were included. AHI incidence was determined in HIV-infected and in preexposure prophylaxis (PrEP)-using MSM. Transmission clusters were identified by construction of phylogenetic trees based on HCV NS5B (genotype 1a/4d) or NS5A (genotype 3a) Sanger sequencing. Results: From 2014 to 2017, 108 AHIs (80 first infections, 28 reinfections) were reported in 96 MSM (HIV-infected, 72; HIV-negative, 24). AHI incidence rose from 1.1/100 person-years (95 confidence interval CI, 0.7-1.7) in 2014 to 2.4/100 person-years (95 CI, 1.1-2.6) in 2017 in HIV-infected MSM (P =. 05) and from 0.3/100 person-years (95 CI, 0.06-1.0) in 2016 to 3.4/100 person-years (95 CI, 2.0-5.5) in 2017 in PrEP users (P <. 001). Eleven clusters were identified. All clusters included HIV-infected MSM; 6 also included HIV-negative MSM. All clusters started with ≥1 HIV-infected MSM. Risk factor distribution varied among clusters. Conclusions: AHI incidence increased in both HIV-infected and HIV-negative MSM. Cluster analysis suggests initial transmission from HIV-infected to HIV-negative MSM through chemsex and traumatic sexual practices, leading to mixed patterns of transmission regardless of HIV status and no overlap with the general population. © 2019 The Author(s).	acute infection; cluster; HCV; MSM; transmission	English	United States	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Quantitative
Article	2019	Ramirez, A; Urbina, A; Afzal, O	A missing key in ending the AIDS epidemic: training Ob/Gyn resident physicians in the management of HIV PrEP	American Journal of Obstetrics and Gynecology	-	-	-	-	0002-9378	10.1016/j.ajog.2019.10.045	https://www.ajog.org/article/S0002-9378(19)31271-2/abstract	New York State has championed the use of HIV Pre-Exposure Prophylaxis (PrEP) as a strategic tool in the campaign to end the AIDS epidemic by 2020. 19% of new HIV infections in the state are amongst heterosexual women, yet only 4% of women at risk are on PrEP. Increased provider knowledge about PrEP has been associated with higher rates of PrEP prescription and future intent of use. In order to improve patient access to PrEP, we conducted a training session targeting Ob/Gyn resident physicians who provide care to women in an East Harlem clinic. Article	2019	Ramjee G.; Sartorius B.; Morris N.; Wand H.; Reddy T.; Yssel J.D.; Tanser F.	A decade of sustained geographic spread of HIV infections among women in Durban, South Africa	BMC Infectious Diseases	-	-	-	-	14712334	10.1186/s12879-019-4080-6	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066834353&doi=10.1186%2fs12879-019-4080-6&partnerID=40&md5=355d31cf6f3d59eae5be2e683eb155c6	Background: Fine scale geospatial analysis of HIV infection patterns can be used to facilitate geographically targeted interventions. Our objective was to use the geospatial technology to map age and time standardized HIV incidence rates over a period of 10 years to identify communities at high risk of HIV in the greater Durban area. Methods: HIV incidence rates from 7557 South African women enrolled in five community-based HIV prevention trials (2002-2012) were mapped using participant household global positioning system (GPS) coordinates. Age and period standardized HIV incidence rates were calculated for 43 recruitment clusters across greater Durban. Bayesian conditional autoregressive areal spatial regression (CAR) was used to identify significant patterns and clustering of new HIV infections in recruitment communities. Results: The total person-time in the cohort was 9093.93 years and 613 seroconversions were observed. The overall crude HIV incidence rate across all communities was 6·74 per 100PY (95% CI: 6·22-7·30). 95% of the clusters had HIV incidence rates greater than 3 per 100PY. The CAR analysis identified six communities with significantly high HIV incidence. Estimated relative risks for these clusters ranged from 1.34 to 1.70. Consistent with these results, age standardized HIV incidence rates were also highest in these clusters and estimated to be 10 or more per 100 PY. Compared to women 35+ years old younger women were more likely to reside in the highest incidence areas (aOR: 1·51, 95% CI: 1·06-2·15; aOR: 1.59, 95% CI: 1·19-2·14 and aOR: 1·62, 95% CI: 1·2-2·18 for < 20, 20-24, 25-29 years old respectively). Partnership factors (2+ sex partners and being unmarried/not cohabiting) were also more common in the highest incidence clusters (aOR 1.48, 95% CI: 1.25-1.75 and aOR 1.54, 95% CI: 1.28-1.84 respectively). Conclusion: Fine geospatial analysis showed a continuous, unrelenting, hyper HIV epidemic in most of the greater Durban region with six communities characterised by particularly high levels of HIV incidence. The results motivate for comprehensive community-based HIV prevention approaches including expanded access to PrEP. In addition, a higher concentration of HIV related services is required in the highest risk communities to effectively reach the most vulnerable populations. © 2019 The Author(s). Article	2019	Ramsey S.E.; Ames E.G.; Brinkley-Rubinstein L.; Teitelman A.M.; Clarke J.; Kaplan C.	Linking women experiencing incarceration to community-based HIV pre-exposure prophylaxis care: protocol of a pilot trial	Addiction Science & Clinical Practice	-	-	-	-	19400640	10.1186/s13722-019-0137-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062384353&doi=10.1186%2fs13722-019-0137-5&partnerID=40&md5=481bcd13213c29382954941a0daf333e	BACKGROUND: Women experiencing incarceration (WEI) engage in high rates of sex- and drug-related behavior that places them at risk for HIV. Pre-exposure prophylaxis (PrEP) is an efficacious means of reducing HIV acquisition. There is a general lack of knowledge regarding PrEP among women at elevated risk, and only a small percentage of at-risk women are currently engaged in PrEP care. The period of incarceration represents an opportunity to identify at-risk women, initiate PrEP during incarceration, and establish linkage to community-based PrEP care upon release from incarceration. Further, post-release is a time period that is particularly risky, and there are numerous barriers, including substance use, that may impede linkage to community-based care in the absence of intervention. The current protocol describes plans for the development and pilot randomized controlled trial (RCT) of an intervention to promote PrEP uptake during incarceration and facilitate linkage to community-based PrEP care post-release. METHODS/DESIGN: The motivational interviewing-navigation (MI-NAV) study intervention is being developed, refined, and tested over three phases within the framework of the social ecological model. All phases of the study are being conducted at a women's correctional facility and community-based PrEP provider located in the Northeastern region of the United States. Phase 1 consists of individual qualitative interviews to be conducted with key stakeholders (n = 6-10) from the community-based PrEP care site and (n = 6-10) from the women's correctional facility, as well as with (n = 18-30) WEI. Recruitment for Phase 1 was initiated in November 2017. In Phase 2, MI-NAV will be piloted with a small cohort (n = 8-12) of WEI and will be refined based upon participant feedback. During Phase 3, a pilot RCT of MI-NAV and a standard of care condition will be conducted with 80 WEI. RCT participants will complete baseline and follow-up assessments 1, 3, and 6 months post-release. The primary study outcome is linkage to community-based PrEP care, verified via medical records. DISCUSSION: This study will develop and evaluate a psychosocial intervention (MI-NAV) to promote PrEP uptake and facilitate linkage to community-based PrEP care among women at-risk for HIV. It is expected that, as a result of this project, the feasibility, acceptability, and preliminary efficacy of MI-NAV will be determined. If found to be efficacious, this intervention has the potential to reduce HIV acquisition in a high-need, underserved community. Clinical trial registration NCT03281343. Article	2019	Ranjit, Yerina S; Dubov, Alex; Polonsky, Maxim; Fraenkel, Liana; Ogunbajo, Adedotun; Mayer, Kenneth; Altice, Frederick L	Pre-exposure Prophylaxis Among Men Who have Sex with Men: Dual Motivational Model of Intention to Use Pre-exposure Prophylaxis.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-018-2214-2	https://dx.doi.org/10.1007/s10461-018-2214-2	Men who have sex with men (MSM) account for most new HIV infections in the United States. Despite representing a fraction of the population, MSM make up an estimated 65% of new infections. To address this epidemic, pre-exposure prophylaxis (PrEP) is recommended to supplement condom use. Despite its effectiveness, PrEP uptake among MSM is low. Few studies have employed theoretical approaches to understand PrEP use intention. Incorporating factors like safe sex fatigue, expectation of better sexual experiences, and perceived risk are proposed in this dual motivational path model of PrEP use intention. This model hypothesized that PrEP use intention is influenced by two key pathways: (1) protection motivation pathway, and (2) sexual expectancy pathway. Data were collected using social networking applications from 402 MSM. The model was tested using structural equation modeling. We elaborate the complex decision-making process proposed by this novel theoretical model and discuss its practical implications. Article	2019	Ransome Y.; Zarwell; Robinson W.T.	Participation in community groups increases the likelihood of PrEP awareness: New Orleans NHBS-MSM cycle, 2014	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0213022	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062869615&doi=10.1371%2fjournal.pone.0213022&partnerID=40&md5=bef4ddce36eb79f576616b2a2694aa7a	Background Gay, bisexual, and other men who have sex with men (GBM) have the highest proportion of incident HIV infection. Pre-exposure prophylaxis (PrEP) use and screening for sexually transmitted infections (STIs) are primary HIV prevention strategies, however, uptake remains low. Social capital, collective resources generated through social connections, are associated with lower HIV risk and infection. We investigated social capital in association with PrEP indicators among GBM. Methods Analyses included (N = 376) GBM from the 2014 National HIV Behavioral Surveillance (NHBS) in New Orleans. Multiple regression methods assessed the association between each item within each of eight domains from the Onyx and Bullen Social Capital Scale and: awareness and willingness to use PrEP. Analyses are adjusted for age, race, education, sexual intercourse with women, and health insurance. Results Forty percent of GBM were 18–29 years, 52 percent White. Sixty percent were willing to use PrEP. Social capital was above 50 percent across 7 of 8 indicators. Community group participation (vs no participation) was associated with higher likelihoods of PrEP awareness (adjusted Prevalence Ratio aPR = 1.41, 95% Confidence Interval CI = 1.02, 1.95). None of the seven remaining social capital indicators were significantly associated with any of the PrEP outcomes. Conclusions Community groups and organizations could be targeted for interventions to increase uptake of HIV prevention strategies among GBM in New Orleans © 2019 Ransome et al. Article	2019	Rao D.W.; Carr J.; Naismith K.; Hood J.E.; Hughes J.P.; Morris M.; Goodreau S.M.; Rosenberg E.S.; Golden M.R.	Monitoring HIV Preexposure Prophylaxis Use among Men Who Have Sex with Men in Washington State: Findings from an Internet-Based Survey	Sexually Transmitted Diseases	-	-	-	-	1485717	10.1097/OLQ.0000000000000965	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063003810&doi=10.1097%2fOLQ.0000000000000965&partnerID=40&md5=a10863add43fd9b1dff417cea8a7b76	Background Many state and local health departments now promote and support the use of HIV preexposure prophylaxis (PrEP), yet monitoring use of the intervention at the population level remains challenging. Methods We report the results of an online survey designed to measure PrEP use among men who have sex with men (MSM) in Washington State. Data on the proportion of men with indications for PrEP based on state guidelines and levels of awareness, interest, and use of PrEP are presented for 1080 cisgender male respondents who completed the survey between January 1 and February 28, 2017. We conducted bivariate and multivariable logistic regression to identify factors associated with current PrEP use. To examine patterns of discontinuation, we conducted Cox proportional hazards regression and fit a Kaplan-Meier curve to reported data on time on PrEP. Results Eighty percent of respondents had heard of PrEP, 19% reported current use, and 36% of men who had never used PrEP wanted to start taking it. Among MSM for whom state guidelines recommend PrEP, 31% were taking it. In multivariable analysis, current PrEP use was associated with older age, higher education, and meeting indications for PrEP use. Our data suggest that 20% of PrEP users discontinue within 12 months, and men with lower educational attainment were more likely to discontinue. Conclusions Despite high levels of use, there is significant unmet need for PrEP in Washington. Our experience indicates that Internet surveys are feasible and informative for monitoring PrEP use in MSM. © 2018 American Sexually Transmitted Diseases Association All rights reserved. Article	2019	Read P.; Chronister K.J.; Kostovski C.; Harrod M.E.; Salmon A.; Jauncey M.	Perceptions of people who inject drugs towards HIV pre-exposure prophylaxis in Australia	Sexual Health	-	-	-	-	14485028	10.1071/SH18228	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067495815&doi=10.1071%2fSH18228&partnerID=40&md5=a67d987272d7e74db0bf6214c39b8982	Background: People who inject drugs (PWID) are a priority for HIV prevention. This study aimed to determine perceptions, potential eligibility and willingness to use PrEP among PWID in Sydney. Methods: Clients completed a cross-sectional survey to collect data on demographics, perceived risk of HIV and willingness to use PrEP, which were then analysed. Results: Twelve (7%) of 172 HIV-negative participants were eligible for PrEP under current guidelines for injecting reasons, of whom three would also be eligible for sexual risk, leaving nine (5%) eligible for injecting reasons alone. Half had heard of PrEP and, of these, 65% would consider taking it. Most (88%) thought they would continue using needle syringe program services. A minority (8%) indicated they may be likely to share needles and syringes or be less concerned about injecting partners' HIV status (26%). Conclusions: Although PrEP will benefit a small proportion of PWID, this may equate to a significant number nationally. Policy development around PrEP incorporating affected populations will best support the community of people currently injecting to keep rates of HIV low. © 2019 CSIRO.	harm reduction; HIV prevention	English	United States	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Quantitative
Article	2019	Reback C.J.; Clark K.A.; Rünger D.; Fehrenbacher A.E.	A Promising PrEP Navigation Intervention for Transgender Women and Men Who Have Sex with Men Experiencing Multiple Syndemic Health Disparities	Journal of Community Health	-	-	-	-	945145	10.1007/s10900-019-00705-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069216869&doi=10.1007%2fs10900-019-00705-x&partnerID=40&md5=98af0db83e4f497dab6e0f6db4b34619	Transgender women and MSM experience many stigma-related syndemic conditions that exacerbate HIV incidence and prevalence rates. While PrEP is an effective biomedical intervention to reduce HIV transmission, uptake and adherence of PrEP is low among transgender women and MSM experiencing multiple syndemic health disparities. This study tested the feasibility, acceptability and effectiveness of A.S.K.-PrEP (AssistanceServicesKnowledge-PrEP), a five-session peer navigator program, designed to link transgender women and MSM to PrEP. From September 2016 to March 2018, 187 participants (transgender women = 58; MSM = 129) enrolled. Results demonstrated that approximately 90% of transgender women and MSM were linked to PrEP; MSM linked more quickly KW $\chi^2(1) = 10.9$, p <.001. Most transgender women (80%) and MSM (70%) reported they were still taking PrEP at the 90-day follow-up evaluation. Findings indicated that A.S.K.-PrEP is a promising intervention for PrEP linkage, uptake and preliminary adherence among transgender women and MSM. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Rebe, Kevin; Hoosen, Nikhat; McIntyre, James A	Strategies to improve access for MSM in low-income and middle-income countries.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0000000000000568	https://dx.doi.org/10.1097/COH.0000000000000568	PURPOSE OF REVIEW: HIV prevention and treatment interventions for MSM are not well studied or reported from low-income and middle-income countries (LMIC) in comparison to those targeting gender-conforming populations. Some evidence-based strategies to engage MSM in appropriate healthcare have recently reported on their experiences and impact. Novel recruitment strategies have been developed for treatment and preexposure prophylaxis (PrEP) for MSM, leveraging new community engagement strategies and social media technologies. RECENT FINDINGS: Despite publication of several new guidelines, there is little recent evidence available to guide MSM health programs in LMIC, highlighting the need for ongoing research and publication. Some important PrEP pilot study results have recently been published, such as the PrEP Brazil and Princess PrEP programmes, which could guide the scale-up of MSM PrEP. The novel use of technology and online platforms to strengthen MSM health delivery and support is particularly important. SUMMARY: Providing healthcare to MSM requires consideration of context, broad stakeholder engagement, implementation of best practice guidelines and ongoing situational assessment and integration of novel community engagement methods that are evidence-based. Implementation of improved antiretroviral programmes and the access to PrEP for MSM are vital. Article	2019	Reddon, Hudson; Marshall, Brandon D. L.; Milloy, M.-J.	Elimination of HIV transmission through novel and established prevention strategies among people who inject drugs.	The Lancet HIV	-	-	-	-	2352-3018 2405-4704	10.1016/S2352-3018(18)30292-3	https://pubmed.ncbi.nlm.nih.gov/30558843/	Despite the effectiveness of existing HIV prevention strategies for people who inject drugs (PWID), uncontrolled outbreaks of HIV among this group are common and occur around the world. In this Review, we summarise recent evidence for novel and established HIV prevention approaches to eliminate HIV transmission among PWID. Effective HIV prevention strategies include mobile needle and syringe programmes, pre-exposure prophylaxis, supervised injection facilities, and, to a lesser extent, some behavioural interventions. Studies have also shown the cost-effectiveness of long-standing HIV prevention strategies including needle and syringe programmes, opioid agonist therapy, and antiretroviral therapy for prevention. Although each individual intervention can reduce the risk of HIV acquisition among PWID, there is a consensus that a combination of approaches is required to achieve substantial and durable reductions in HIV transmission. Unfortunately, in many settings, the implementation of these interventions is often limited by public and political opposition that manifests as structural barriers to HIV prevention, such as the criminalisation of drug use. Given that there is ample evidence showing the effectiveness of several HIV prevention methods, social and political advocacy will be needed to overcome these barriers and integrate innovative HIV prevention approaches with addiction science to create effective drug policies. Article	2019	Refugio O.N.; Kimble M.M.; Silva C.L.; Lykens J.E.; Bannister C.; Klausner J.D.	PrEPTECH: A Telehealth-Based Initiation Program for HIV Pre-exposure Prophylaxis in Young Men of Color Who Have Sex with Men. A Pilot Study of Feasibility	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001873	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058604219&doi=10.1097%2fQAI.0000000000001873&partnerID=40&md5=ca921f8f3c21731f99a66f4bb581dc4e	Background:In the United States, young men who have sex with men (YMSM) of color represent a high number of new HIV diagnoses annually. HIV pre-exposure prophylaxis (PrEP) is effective and acceptable to YMSM of color; yet, PrEP uptake is low in those communities because of barriers including stigma, cost, adherence concerns, and medical distrust. A telehealth-based approach to PrEP initiation may be a solution to those barriers. This pilot study investigates one such intervention called PrEPTECH.Methods:We enrolled 25 HIV-uninfected YMSM, aged 18-25 years, from the San Francisco Bay Area into a 180-day longitudinal study between November 2016 and May 2017. Participants received cost-free PrEP services through telehealth eg, telemedicine visits, home delivery of Truvada, and sexually transmitted infection testing kits, except for 2 laboratory visits. Online survey assessments querying PrEPTECH features and experiences were administered to participants at 90 and 180 days.Results:Eighty-four percent of participants were YMSM of color. Among the 21 who completed the study, 11 of the 16 who wanted to continue PrEP were transitioned to sustainable PrEP providers. At least 75% felt that PrEPTECH was confidential, fast, convenient, and easy to use. Less than 15% personally experienced PrEP stigma during the study. The median time to PrEP initiation was 46 days. Sexually transmitted infection positivity was 20% and 19% at baseline and 90 days, respectively. No HIV infections were detected.Conclusions:Telehealth programs such as PrEPTECH increase PrEP access for YMSM of color by eliminating barriers inherent in traditional clinic-based models. © 2018 Wolters Kluwer Health, Inc. Article	2019	Reisner S.L.; Moore C.S.; Asquith A.; Pardee D.J.; Sarvet A.; Mayer G.; Mayer K.H.	High risk and low uptake of pre-exposure prophylaxis to prevent HIV acquisition in a national online sample of transgender men who have sex with men in the United States	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25391	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072403372&doi=10.1002%2fjia2.25391&partnerID=40&md5=f26f91707979f092c39411f53c99205b	Introduction: Trans masculine people who have sex with cisgender ("cis") men ("trans MSM") may be at-risk for HIV infection when they have cis MSM partners or share needles for hormone or recreational drug injection. Limited data are available characterizing indications and uptake of pre-exposure prophylaxis (PrEP) in trans MSM. The aim of this study was to assess PrEP indication and uptake as a means of primary HIV prevention for adult trans MSM in the U.S. Methods: Between November and December 2017, a national convenience sample of trans MSM in the U.S. (n = 857) was recruited using participatory methodologies and completed an online survey of demographics, HIV risk, PrEP, behavioural and psychosocial factors. Self-reported receptive anal sex or frontal/vaginal sex (with or without a condom) with a cis male sex partner in past six months was an eligibility criterion. A multivariable logistic regression procedure was used to model PrEP indications (yes/no) per an interpretation of U.S. Centers of Disease Control and Prevention recommendations among those without HIV (n = 843). Results: The diverse sample was 4.9% Black; 22.1% Latinx ethnicity; 28.4% non-binary gender identity; 32.6% gay-identified; 82.7% on testosterone. Overall, 84.1% had heard of PrEP. Of these, 33.3% reported lifetime PrEP use (21.8% current and 11.5% past). Based on HIV behavioural risk profiles in the last six months, 55.2% of respondents had indications for PrEP. In a multivariable model, factors associated with PrEP indication included where met sex partners, not having sex exclusively with cismen, higher perceived HIV risk, greater number of partners and high cis male partner stigma (all p < 0.05). Discussion: The majority of trans MSM in this sample had a PrEP indication. Stigma was associated with risk for HIV acquisition and represents a critical target for HIV biobehavioural prevention interventions for trans MSM, who appear to be underutilizing PrEP. Conclusions: Results from this study support the full inclusion of trans MSM in HIV biobehavioural prevention efforts. Public health interventions and programmes are needed to reach trans MSM that attend to general MSM risk factors as well as to vulnerabilities specific to trans MSM, including the context of stigma from cis male sexual partners. © 2019 The Authors. Article	2019	Remy L.; Enriquez M.	Behavioral Interventions to Enhance PrEP Uptake among Black Men Who Have Sex with Men: A Review	Journal of the Association of Nurses in AIDS Care	-	-	-	-	10553290	10.1097/JNC.0000000000000015	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072131576&doi=10.1097%2fJNC.0000000000000015&partnerID=40&md5=247af1195f485ee82d41bba051708ccd	In the United States, nearly 500,000 men who have sex with men (MSM) are at risk of contracting HIV. Men who have sex with men constitute 70% of all new cases of HIV in the United States; within this population, the incidence of HIV infection is the highest among Black MSM. Our integrated review synthesized published behavioral interventions designed to enhance the uptake of and adherence to pre-exposure prophylaxis (PrEP) for the prevention of HIV in the Black MSM population. A search of 4 electronic databases revealed only 7 studies whose samples included Black MSM. Adherence to PrEP medication declined over time across all studies. No statistically significant changes in safer sexual behaviors were reported. Few studies described theory-driven interventions. Effective interventions are needed to enhance the uptake of PrEP and to reinforce behaviors that prevent HIV transmission among Black MSM. Copyright © 2018 Association of Nurses in AIDS Care. Article	2019	Ribeiro, S; Rocha, M	Pre-exposure prophylaxis in a sexual health clinic for Men who Have Sex with Men in Portugal	European Journal of Public Health	-	-	-	-	11011262	10.1093/eurpub/ckz186.663	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-sexual-health-clinic-men/docview/2430182997/se-2?accountid=8113	Background Pre-exposure prophylaxis (PrEP) is defined as the use of antiretroviral drugs to prevent HIV acquisition in uninfected individuals. Recognizing the increasing use of informal PrEP in Portugal, CheckpointLX, a community clinic targeted for MSM in Lisbon, Portugal, began offering counselling and follow-up services prior to formal introduction. This study aims to characterize PrEP users attending CheckpointLX before formal PrEP introduction in Portugal, and those who were referred to PrEP in the National Health Service (NHS) following formal approval of PrEP. Methods Data was collected by peer counsellors between May 2015 and September 2018 and inserted in a database. Medical care followed EACS recommendations for PrEP eligibility, initiation and follow up. For formal PrEP, the General-Directorate for Health's PrEP guidelines checklist was used. Results Until the end of May 2018, CheckpointLX had a total of 90 appointments for Wild PrEP, of which 64 (71%) were first time visits. As for the 380 service users referred to the NHS, most were Portuguese (N = 318, 84%), and the mean age was 31 (8.9) years old. Condomless sex in the last six months with partners of unknown HIV status was the most common eligibility criteria (N = 59, 83%). Conclusions PrEP delivery should be complemented with effective information on the importance of immunization and education on safer practices of drug administration, in the scope of broader preventive sexual health care. Much remains to be done in Portugal to ensure that PrEP is available to those who need it the most. Offering PrEP at community clinics could be a first step. AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-019-02591-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6803068	Limited studies to date assess barriers to and facilitators of PrEP uptake and utilization using a patient-centered access to care framework, among diverse socio-demographic groups, or in the U.S. Deep South, an area with disproportionate HIV burden. We examine perceptions of PrEP access in qualitative interviews with 44 current and potential PrEP users in Birmingham, Alabama. Participants were 32 years old on average, 66% Black, 66% gay or lesbian, 70% male, and 66% single. Perceived barriers to PrEP access included: lack of PrEP awareness and advertisement; sexuality-related stigma; time and resource constraints; and concerns about the adequacy and technical quality of PrEP services. Perceived facilitators to PrEP access were: PrEP-related information gathering and sharing; increased dialogue and visibility around PrEP; social, programmatic, and clinical support; and, lastly, self-preservation; personal motivation; and treatment self-efficacy. Results point to opportunities to address complex barriers to equitable PrEP access using multilevel and multimodal solutions. Article	2019	Richert-Spuhler L.E.; Pattacini L.; Plews M.; Irungu E.; Muwonge T.R.; Katabira E.; Mugo N.; Meyers A.F.A.; Celum C.; Baeten J.M.; Lingappa J.R.; Lund J.M.	Pre-exposure prophylaxis differentially alters circulating and mucosal immune cell activation in herpes simplex virus type 2 seropositive women	AIDS	-	-	-	2699370	10.1097/QAD.0000000000002323	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074551389&doi=10.1097%2fQAD.0000000000002323&partnerID=40&md5=c0bd3d6d0f97351ec12cb5acd75d167f	Objective: Oral tenofovir-based pre-exposure prophylaxis (PrEP) is an important tool for prevention of new HIV infections, which also reduces subclinical herpes simplex virus type 2 (HSV-2) shedding and symptomatic lesions in HIV-negative, HSV-2-seropositive individuals. However, the impact of PrEP on mucosal immunity has not been examined in detail.Design:Here we evaluate paired genital tissue and systemic immune profiles to characterize the immunological effects of PrEP in HIV-negative, HSV-2-seropositive African women sexually exposed to HIV.Methods:We compared local and systemic innate and T-cell characteristics in samples collected during PrEP usage and 2 months after PrEP discontinuation.Results:We found that frequencies of cervical CCR5+CD4+ cells, regulatory T cells, and tissue macrophages were significantly reduced during PrEP use compared with after PrEP discontinuation. In contrast, peripheral blood CD4+ and CD8+ T cells expressing markers of activation and trafficking were increased during PrEP usage.Conclusion:Together, our data are consistent with PrEP altering immunity differentially in the female genital tract compared with circulation in HSV-2+ women. Further study including comparison with HSV-2 negative women is needed to define the overall impact and mechanisms underlying these effects. These results point to the critical need to study the human mucosal compartment to characterize immune responses to mucosal infections. © 2019 Wolters Kluwer Health, Inc. Article	2019	Rieg S.; Usadel S.; Müller M.	Sexually Transmitted Infections - What's New, What's Different?; Aktuelles zu sexuell übertragbaren Infektionen	Deutsche Medizinische Wochenschrift	-	-	-	120472	10.1055/a-0655-6657	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060944967&doi=10.1055%2fa-0655-6657&partnerID=40&md5=7cb93c451ac17ad812a152e83147f4c7	The incidence of sexually transmitted infections like syphilis or gonorrhea is still rising, particularly in the high-risk population of men having sex with men (MSM). Neisseria gonorrhoeae is capable to develop resistance to all antibiotics previously or currently used for treatment. Dual antimicrobial therapy with ceftriaxone and azithromycin is considered the current empirical first-line therapy. Since 2011 ceftriaxone-resistant strains have emerged in many countries and in 2018 the first case with high-level resistance to azithromycin and resistance to ceftriaxone was documented in the UK, making the development of new antimicrobials against gonorrhea a public health priority. HIV-pre-exposure-prophylaxis (HIV-PrEP) has recently been approved in Germany and may become an important complementary approach to reduce HIV transmission. However, appropriate counselling and STI testing has to be secured in PrEP users. The German Standing Committee on Vaccination (STIKO) now recommends human papillomavirus (HPV) vaccination for boys aged 9-14 years. The Centers for Disease Control and Prevention (CDC) shortens the recommended interval from leaving a zika virus-endemic country until conception to 3 months. © Georg Thieme Verlag KG, Stuttgart - New York.	gonorrhoeae; HIV-PrEP; prevention; sexually transmitted diseases; zika virus	German	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Clinical

"Getting to Zero" Among Men Who Have Sex with Men in China: a Review of the HIV Care Continuum.	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-019-00472-3	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7163396	PURPOSE OF REVIEW: To review the literature on progress towards UNAIDS 90-90-90 targets for HIV prevention and treatment among men who have sex with men (MSM) in China. RECENT FINDINGS: China has made progress towards UNAIDS 90-90-90 targets among MSM. However, socio-structural barriers, including HIV-related stigma and homophobia, persist at each stage of the HIV care continuum, leading to substantial levels of attrition and high risk of forward HIV transmission. Moreover, access to key prevention tools, such as pre-exposure prophylaxis, is still limited. Multilevel interventions, many using digital intervention, have been shown effective in pragmatic randomized controlled trials in China. Multilevel interventions incorporating digital health have led to significant improvement in engagement of Chinese MSM in the HIV care continuum. However, interventions that address socio-structural determinants, including HIV-related stigma and discrimination, towards Chinese MSM are needed. Article	2019	Rivet Amico, K; Bekker, Linda-Gail	Global PrEP roll-out: recommendations for programmatic success.	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(19)30002-5	https://dx.doi.org/10.1016/S2352-3018(19)30002-5	Pre-exposure prophylaxis (PrEP) is being adopted and rolled out in diverse regions, communities, and groups. Although it has been shown to be effective, in some settings PrEP roll-out has lagged, in part due to flawed messaging. Lessons can be learned and principles applied from marketing to highlight the potential pitfalls of current roll-out strategies focused on selective and siloed service provision. After exploration of the way PrEP is promoted in awareness messaging (the sell), marketed to select and often stigmatised groups (the brand), and offered as a special or non-integrated service (product placement), we propose that current strategies can ultimately slow roll-out and contribute to stigma surrounding PrEP use. We propose alternatives for programmes and ministries to consider as they develop long-term plans for HIV prevention. We propose that the sell should focus on protection or wellness framing, the branding should convey PrEP as appropriate for anyone in need, and the provision of PrEP should be placed in the context of other relevant and valued health services. As has been shown in some PrEP programmes, it is possible for programmes to adopt modern marketing strategies that are attractive to healthy clients and might promote an inclusive and holistic vision of biomedical prevention. Article	2019	Roberts, D Allen; Barnabas, Ruanne V; Abuna, Felix; Lagat, Harison; Kinuthia, John; Pintye, Jillian; Bochner, Aaron F; Forsythe, Steven; Gomez, Gabriela B; Baeten, Jared M; John-Stewart, Grace; Levin, Carol	The role of costing in the introduction and scale-up of HIV pre-exposure prophylaxis: evidence from integrating PrEP into routine maternal and child health and family planning clinics in western Kenya.	Journal of the International AIDS Society	-	-	-	1758-2652	10.1002/jia2.25296	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6643078	INTRODUCTION: Understanding the cost of strategies to reach and deliver pre-exposure prophylaxis (PrEP) to priority populations is essential to assess the cost-effectiveness and budget impact of HIV prevention programmes. Providing PrEP through maternal and child health and family planning clinics offers a promising strategy to reach women in high HIV burden settings. We estimated incremental costs and explored the cost drivers of integrating PrEP delivery into routine maternal and child health and family planning services in Kenya. METHODS: We conducted a costing study from the provider perspective within the PrEP Implementation for Young Women and Adolescents programme in western Kenya. We identified all within- and above-facility activities supporting PrEP delivery and measured clinical service time using time-and-motion studies. We obtained input costs from programme budgets, expenditure records and staff interviews. We estimated changes in costs if creatinine testing were postponed from initiation to first follow-up visit and if PrEP were prioritized to clients at high HIV risk using a behavioural risk assessment tool. We also projected costs under Ministry of Health (MOH) implementation assuming MOH salaries and programme supervision. We estimated annual numbers of PrEP visits from programme data abstracted from 16 facilities between November 2017 and June 2018. We report the cost per client-month of PrEP dispensed in 2017 USD. RESULTS: For an annual programme output of 24,005 screenings, 4198 PrEP initiations and 4427 follow-up visits, the average cost per client-month of PrEP dispensed in the study was $26.52. Personnel, drugs and laboratory tests comprised 43%, 25% and 14% of programme costs respectively. Postponing creatinine testing and prioritizing PrEP delivery to clients at high HIV risk reduced total programme costs by 8% and 14% respectively. In the MOH scenario assuming no changes in outputs, the projected cost per client-month of PrEP dispensed decreased to $16.54 and total programme costs decreased by 38%. CONCLUSIONS: Incremental PrEP costs are sensitive to the service delivery strategy used to engage priority populations. Postponing creatinine testing and prioritizing PrEP delivery to clients at high HIV risk may reduce costs. Context-specific cost data are crucial to assess the cost-effectiveness and affordability of PrEP delivery models. The Lancet	-	-	-	1474-547X	10.1016/S0140-6736(19)30418-0	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6584382	BACKGROUND: The level of evidence for HIV transmission risk through condomless sex in serodifferent gay couples with the HIV-positive partner taking virally suppressive antiretroviral therapy (ART) is limited compared with the evidence available for transmission risk in heterosexual couples. The aim of the second phase of the PARTNER study (PARTNER2) was to provide precise estimates of transmission risk in gay serodifferent partnerships. METHODS: The PARTNER study was a prospective observational study done at 75 sites in 14 European countries. The first phase of the study (PARTNER1; Sept 15, 2010, to May 31, 2014) recruited and followed up both heterosexual and gay serodifferent couples (HIV-positive partner taking suppressive ART) who reported condomless sex, whereas the PARTNER2 extension (to April 30, 2018) recruited and followed up gay couples only. At study visits, data collection included sexual behaviour questionnaires, HIV testing (HIV-negative partner), and HIV-1 viral load testing (HIV-positive partner). If a seroconversion occurred in the HIV-negative partner, anonymised phylogenetic analysis was done to compare HIV-1 pol and env sequences in both partners to identify linked transmissions. Couple-years of follow-up were eligible for inclusion if condomless sex was reported, use of pre-exposure prophylaxis or post-exposure prophylaxis was not reported by the HIV-negative partner, and the HIV-positive partner was virally suppressed (plasma HIV-1 RNA <200 copies per mL) at the most recent visit (within the past year). Incidence rate of HIV transmission was calculated as the number of phylogenetically linked HIV infections that occurred during eligible couple-years of follow-up divided by eligible couple-years of follow-up. Two-sided 95% CIs for the incidence rate of transmission were calculated using exact Poisson methods. FINDINGS: Between Sept 15, 2010, and July 31, 2017, 972 gay couples were enrolled, of which 782 provided 1593 eligible couple-years of follow-up with a median follow-up of 2·0 years (IQR 1·1-3·5). At baseline, median age for HIV-positive partners was 40 years (IQR 33-46) and couples reported condomless sex for a median of 1·0 years (IQR 0·4-2·9). During eligible couple-years of follow-up, couples reported condomless anal sex a total of 76â088 times. 288 (37%) of 777 HIV-negative men reported condomless sex with other partners. 15 new HIV infections occurred during eligible couple-years of follow-up, but none were phylogenetically linked within-couple transmissions, resulting in an HIV transmission rate of zero (upper 95% CI 0·23 per 100 couple-years of follow-up). INTERPRETATION: Our results provide a similar level of evidence on viral suppression and HIV transmission risk for gay men to that previously generated for heterosexual couples and suggest that the risk of HIV transmission in gay couples through condomless sex when HIV viral load is suppressed is effectively zero. Our findings support the message of the U=U (undetectable equals untransmittable) campaign, and the benefits of early testing and treatment for HIV. FUNDING: National Institute for Health Research. Article	2019	Rogers, Brooke G; Whiteley, Laura; Haubrick, Kayla K; Mena, Leandro A; Brown, Larry K	Intervention Messaging About Pre-Exposure Prophylaxis Use Among Young, Black Sexual Minority Men.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2019.0139	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6839422	Approximately 1.1 million individuals in the United States are living with HIV/AIDS. HIV disproportionately affects young, black men who have sex with men (YBMSM). Recent biomedical advances, including the use of antiretroviral therapy as pre-exposure prophylaxis (PrEP), hold promise for preventing HIV infections. However, PrEP uptake remains slow among those most at-risk. To develop and test an intervention to address HIV disparities in YBMSM, we conducted qualitative interviews with 29 YBMSM from Jackson, Mississippi, to learn more about their views of PrEP. Twenty-nine PrEP-eligible YBMSM were enrolled and participated in either semistructured interviews or focus groups. They were asked about PrEP use, messaging, and promotion. Data were coded based on an iteratively developed coding scheme and entered into NVivo to facilitate thematic analysis. Our analysis identified the following three main themes: (1) the role of setting, context, and stigma in health care, (2) targeted PrEP messaging is further stigmatizing, and (3) recommendations for PrEP messaging and care. YBMSM in our sample felt highly stigmatized in their current environment and felt that PrEP messaging targeting YBMSM only enhanced their sense of marginalization. They concluded that broad and inclusive messaging would be just as relevant and cause less stigma. Our findings were somewhat surprising, as several prior studies benefited from using targeted materials to engage YBMSM in HIV prevention and PrEP uptake. The study's location may explain this difference in findings, which suggests the importance of considering local conditions and opinions when developing interventions for HIV prevention among minority populations. Article	2019	Rojas Castro, Daniela; Delabre, Rosemary M; Molina, Jean-Michel	Give PrEP a chance: moving on from the "risk compensation" concept.	Journal of the International AIDS Society	-	-	-	1758-2652	10.1002/jia2.25351	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6715948	INTRODUCTION: While bio-behavioural interventions (BIs) for sexually transmitted infections (STIs) and HIV prevention have shown their effectiveness (e.g. treatment for syphilis, HPV vaccination or pre-exposure prophylaxis PrEP), they have also aroused major concerns regarding behavioural changes that could counteract their benefit. Risk compensation (RC) fears concerning BIs in the HIV/STIs prevention field are intimately linked to representations, judgements and social control on sexual behaviour. With an increasing number of PrEP studies describing a rise in STIs due to RC, this paper argues for a shift away from the focus on RC and proposes a more constructive approach to respond to the needs of people living with HIV and populations most at risk. DISCUSSION: The concept of RC, stemming from road safety and derived from economic theory, relies on rational theoretical models of human behaviour. Although widely applied in several contexts its use has been reasonably questioned. Major methodological issues regarding RC have been raised within HIV/AIDS literature. Although behavioural changes (e.g. condomless sex and number of sexual partners) are often erroneously assimilated with RC, there is no evidence that behavioural changes have undermined the effectiveness of previous and current BIs. Still, PrEP has not escaped RC concerns. Increases in condomless sex within the context of growing uptake of PrEP signals a continued need for integrated and innovative HIV and STI prevention strategies and a comprehensive sexual health approach. Routine HIV/STI testing, peer-led counselling, and identification of sexual health needs within the PrEP model of care could become a gold standard in the sexual health field for all populations. CONCLUSIONS: RC remains a frequent argument against the availability and provision of prevention methods for vulnerable populations. Individuals should be able to benefit from the full panel of BIs options available, to find and adapt methods according to their needs. Current, past and future PrEP users, with other stakeholders, may provide valuable insight into innovative solutions and programmes to control HIV and other STIs. Article	2019	Rolle C.-P.; Onwubiko U.; Jo J.; Sheth A.N.; Kelley C.F.; Holland D.P.	PrEP Implementation and Persistence in a County Health Department Setting in Atlanta, GA	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-019-02654-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072024933&doi=10.1007%2fs10461-019-02654-x&partnerID=40&md5=62489530b8306618e1310a525f0117cb	For marginalized populations, county health departments may be important PrEP access points; however, there are little data on successful PrEP programs at these venues outside of incentivized demonstration projects. Therefore, we implemented an open-access, free PrEP clinic at a county health department in Atlanta, GA to promote PrEP uptake among high-risk clients. The Fulton County Board of Health PrEP clinic launched in October 2015, and eligible clients who expressed interest initiated PrEP and attended follow-up visits per CDC guidelines. Clients engaged in quarterly follow-up and seen within the last 6 months were defined as "persistent", whereas clients with a lapse in follow-up of > 6 months were defined as "not persistent." Factors associated with PrEP persistence were assessed with unadjusted odds ratios. Between October 2015 and June 2017, 399 clients were screened for PrEP, almost all were eligible 392/399 (98%); however, 158/392 (40%) did not return to start PrEP after screening. Of 234 patients, 216 (92%) received a prescription for PrEP. As of June 2017, only 69/216 (32%) clients remained persistent in PrEP care, and the only evaluated factor significantly associated with PrEP persistence was age ≥ 30 years (OR 1.86, 95% CI 1.02, 3.42). Implementation of PrEP in the county health department setting is feasible; however, we have identified significant challenges with PrEP uptake and persistence in our setting. Further research is needed to fully understand mediators of PrEP persistence and inform interventions to optimize health department-based PrEP services. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Rossouw, Theresa M; van Dyk, Gisela; van Zyl, Gert	Rapid emergence of resistance to antiretroviral treatment after undisclosed prior exposure: A case report.	South African Journal of HIV Medicine	-	-	-	2078-6751	10.4102/sajhivmed.v20i1.965	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6676989	INTRODUCTION: Patients who disengaged from care may present as therapy naïve for antiretroviral treatment (ART) initiation at a different site, without being recognised as being at an increased risk of rapid treatment failure and HIV drug resistance. PATIENT PRESENTATION: A 43-year-old woman, who gave no prior history of ART, was initiated on a standard first-line regimen of TDF, FTC and EFV. She had a poor response to treatment with evidence of treatment failure at 12 months. MANAGEMENT AND OUTCOME: HIV-1 drug resistance tests showed no pre-treatment HIVDR mutations, but revealed high-level drug resistance to all component drugs at 12 months. On investigation, viral load (VL) was recorded in 2012 and 2013, providing evidence of prior ART use. CONCLUSION: Linkage of patient therapy and laboratory information to unique patient identifiers may allow health-care workers to identify patients who previously received ART and disengaged from care. This will enable differentiated care when these patients reinitiate ART, which should involve expedited VL testing and more rapid transition to definitive second-line ART. Article	2019	Roth A.; Felsher M.; Tran N.; Bellamy S.; Martinez-Donate A.; Krakower D.; Szep Z.	Drawing from the Theory of Planned Behaviour to examine pre-exposure prophylaxis uptake intentions among heterosexuals in high HIV prevalence neighbourhoods in Philadelphia, Pennsylvania, USA: An observational study	Sexual Health	-	-	-	14485028	10.1071/SH18081	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065642707&doi=10.1071%2fSH18081&partnerID=40&md5=fa127185ef57776fad5ad216e26b4d6d	Background: Research surrounding attitudes and intentions concerning pre-exposure prophylaxis (PrEP) among at-risk heterosexuals, women and ethnic and racial minorities is needed to inform programs to scale this effective HIV prevention intervention among these populations. Methods: The study sample includes 192 HIV-negative heterosexuals recruited from HIV testing sites operating in high HIV prevalence neighbourhoods in a mid-Atlantic city. Participants received brief educational sessions on PrEP and completed a self-administered survey assessing sociodemographic factors, HIV risk behaviours and theoretical determinants of PrEP uptake, based on the Theory of Planned Behaviour. Results: Participants were majority persons of colour (86%), with a median age of 43 years. Compared with Whites, a higher percentage of Black and Brown persons had more than five sex partners (75.0%), used condoms inconsistently (85.6%) and engaged in transactional sex (84.4%). Most expressed positive PrEP attitudes and indicated intention to adopt PrEP, especially if recommended by their doctor. In a multivariable model, willingness to take PrEP if suggested by a healthcare provider (aOR: 4.17 95% CI: 1.42-12.24) and willingness to take PrEP even if it caused side-effects (aOR: 1.98 95% CI: 1.01-3.90) were both associated with greater PrEP adoption intentions. Conclusions: A diverse at-risk population was identified through community-based HIV testing. Low perceived HIV risk, as well as PrEP-related attitudes, subjective norms and perceived behavioural control were associated with PrEP use intentions. These factors are potential targets for interventions to increase PrEP adoption among diverse heterosexual samples. © 2019 CSIRO.	infectious disease; PrEP; prevention	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Roth A.; Tran N.; Piecara B.; Welles S.; Shinefeld J.; Brady K.	Factors Associated with Awareness of Pre-exposure Prophylaxis for HIV Among Persons Who Inject Drugs in Philadelphia: National HIV Behavioral Surveillance, 2015	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2293-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054313988&doi=10.1007%2fs10461-018-2293-0&partnerID=40&md5=af0438a6355ad8748388949cb0eae3bb	Persons who inject drugs (PWID) continue to experience disproportionate HIV burden. Though studies demonstrate PWID find pre-exposure prophylaxis (PrEP) acceptable, awareness and uptake remains low. Data from the 2015 PWID cycle of the National HIV Behavioral Surveillance (n = 612) in Philadelphia, Pennsylvania (USA) were analyzed to evaluate how socio-demographics and behavioral factors impact PrEP awareness. Only 12.4% of PWID surveyed were PrEP-aware and 2.6% reported receiving a prescription. Factors associated with PrEP awareness included having at least some college education (aOR 2.13, 95% CI 1.03, 4.43), sharing paraphernalia (aOR 2.37, 95% CI 1.23, 4.56), obtaining syringes/needles primarily from a syringe exchange program (aOR 2.28, 95% CI 1.35, 3.87), STI testing (aOR 1.71, 95% CI 1.01, 2.89) and drug treatment (aOR 2.81, 95% CI 1.62, 4.87). Accessing prevention and health services increased the odds of being PrEP-aware; however, awareness was low overall. Additional promotion efforts are warranted. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Roth, Alexis M; Tran, Nguyen K; Piecara Brogan L; Shinefeld, Jennifer; Brady, Kathleen A	Pre-Exposure Prophylaxis (PrEP) Awareness Is Low Among Heterosexual People of Color Who Might Benefit From PrEP in Philadelphia	Journal of Primary Care and Community Health	-	-	-	2150-1319	10.1177/2150132719847383	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-prep-awareness-is-low/docview/2375717469/se-2?accountid=8113	Introduction: We assessed awareness of pre-exposure prophylaxis (PrEP) among HIV-negative Black and Latinx persons living in the Philadelphia Metropolitan Statistical Area. Methods: Using chi-square and Wilcoxon rank-sum tests, we analyzed data from the 2016 heterosexual cycle of the National HIV Behavioral Surveillance system to assess how sociodemographic factors, health care utilization, and risk behaviors affected PrEP awareness. Results: Participants (n = 472) were predominately Black, non-Hispanic (88.1%) with a median age of 41.5 years. Most participants reported having a usual source of medical care (92.1%) and seeing a medical provider within 12 months (87.0%). However, PrEP awareness was low in this sample (4.9%) and was lower among those who had a medical visit compared with those who had not (P < .01). Conclusion: Current Centers for Disease Control and Prevention clinical guidelines suggest that providers counsel high-risk patients about PrEP. Our data suggest that this is not happening with people of color in Philadelphia. Interventions targeting medical providers working with HIV-risk people of color may be appropriate. Article	2019	Rozhnova G.; Heijne J.C.M.; Basten M.; den Daas C.; Matser A.; Kretzschmar M.	Impact of sexual trajectories of men who have sex with men on the reduction in HIV transmission by pre-exposure prophylaxis	Epidemics	-	-	-	17554365	10.1016/j.epidem.2019.03.003	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065802221&doi=10.1016%2fj.epidem.2019.03.003&partnerID=40&md5=10957fc8d19eef2ab82015806965c051	Changes in sexual risk behavior over the life course in men who have sex with men (MSM) can influence population-level intervention efficacy. Our objective was to investigate the impact of incorporating sexual trajectories describing long-term changes in risk levels on the reduction in HIV prevalence by pre-exposure prophylaxis (PrEP) among MSM. Based on the Amsterdam Cohort Study data, we developed two models of HIV transmission in a population stratified by sexual behavior. In the first model, individuals were stratified into low, medium and high risk levels and did not change their risk levels. The second model had the same stratification but incorporated additionally three types of sexual behavior trajectories. The models assumed universal antiretroviral treatment of HIV+ MSM, and PrEP use by high risk HIV− MSM. We computed the relative reduction in HIV prevalence in both models for annual PrEP uptakes of 10% to 80% at different time points after PrEP introduction. We then investigated the impact of sexual trajectories on the effectiveness of PrEP intervention. The impact of sexual trajectories on the overall prevalence and prevalence in individuals at low, medium and high risk levels varied with PrEP uptake and time after PrEP introduction. Compared to the model without sexual trajectories, the model with trajectories predicted a higher impact of PrEP on the overall prevalence, and on the prevalence among the medium and high risk individuals. In low risk individuals, there was more reduction in prevalence during the first 15 years of PrEP intervention if sexual trajectories were not incorporated in the model. After that point, at low risk level there was more reduction in the model with trajectories. In conclusion, our study predicts that sexual trajectories increase the estimated impact of PrEP on reducing HIV prevalence when compared to a population where risk levels do not change. © 2019 The Authors	HIV transmission; Men who have sex with men; Pre-exposure prophylaxis; Sexual behavior change; Sexual behavior trajectories	English	United Kingdom	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Clinical
Article	2019	Ruan F.; Fu G.; Yan Y.; Li Y.; Shi Y.; Luo L.; Li X.; Zhang B.; Gong Q.; Fu Z.; Gan Y.; Pan M.; Liu Y.; Zhan J.; Wang J.	Inequities in consistent condom use among sexually experienced undergraduates in mainland China: Implications for planning interventions	BMC Public Health	-	-	-	14712458	10.1186/s12889-019-7435-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071764809&doi=10.1186%2fs12889-019-7435-4&partnerID=40&md5=edf90bc8d4f6b55a728fe6660a59706c	Background: Since pre-exposure prophylaxis (PrEP) is mainly prescribed to high-risk uninfected individuals, consistent condom use (CCU) continues to be recommended as an inexpensive, feasible, practical and acceptable way to prevent the general population from acquiring and transmitting HIV through sexual intercourse. The objective of this cross-sectional study was to compare the relative importance of various determinants of CCU among sexually experienced undergraduates in mainland China so as to assess and subsequently to suggest ways to eliminate inequities in its use. Method: From September 10, 2018, to January 9, 2019, an anonymous self-administered online questionnaire was voluntarily completed by 12,750 participants distributed across 30 provinces in mainland China (except for Tibet). The present analysis was restricted to 2054 sexually experienced undergraduates. Pearson's chi-square test and Logistic regression models were chosen to analyze the factors associated with CCU. Results: The overall rate of CCU was 61.3% 95% confidence interval (CI) = 59.2-63.4%. CCU was inequitably distributed since enabling factors exerted greater effects than predisposing and need factors. Compared with heterosexual men, heterosexual women adjusted odds ratio (AOR) = 0.78, 95% confidence interval (CI):0.64-0.96), non-heterosexual men (AOR = 0.64, 95% CI:0.45-0.92) and women (AOR = 0.68, 95% CI:0.47-0.99) were less prone to using condoms consistently. Those with more resources i.e., higher levels of self- efficacy for condom use (AOR = 2.86, 95% CI:2.35-3.49) and being knowledgeable of the national AIDS policy (AOR = 1.50, 95% CI:1.23-1.82), and those with lower need for condoms i.e., late initiation of sexual activity (AOR = 1.34, 95% CI:1.09-1.64) and single sexual partner (AOR = 1.68,95% CI:1.21-2.33) were more likely to be consistent condom users. Conclusions: In order to increase consistency of condom use and simultaneously reduce the remaining inequities, a comprehensive intervention measure should be taken to target heterosexual women, non-heterosexual men and women, and those with higher need for condoms, improve their condom use self- efficacy and raise their awareness of the national AIDS policy. © 2019 The Author(s). Article	2019	Rudolph J.E.; Cole S.R.; Eron J.J.; Kashuba A.D.; Adimora A.A.	Estimating Human Immunodeficiency Virus (HIV) Prevention Effects in Low-incidence Settings	Epidemiology	-	-	-	10443983	10.1097/EDE.0000000000000966	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064722254&doi=10.1097%2fEDE.0000000000000966&partnerID=40&md5=b5f4a7ec2e98daec2fced8a69b880e93	Background: Randomized controlled trials (RCTs) for determining efficacy of preexposure prophylaxis (PrEP) in preventing human immunodeficiency virus (HIV) infection have not been conducted among US women because their lower HIV incidence requires impractically large studies. Results from higher-incidence settings, like Sub-Saharan Africa, may not apply to US women owing to differences in age, sexual behavior, coinfections, and adherence. Methods: We propose a novel strategy for evaluating PrEP efficacy in the United States using data from both settings to obtain four parameters: (1) intention-to-treat (ITT) and (2) per-protocol effects in the higher-incidence setting, (3) per-protocol effect generalized to the lower-incidence setting, and (4) back-calculated ITT effect using adherence data from the lower-incidence setting. To illustrate, we simulated two RCTs comparing PrEP against placebo: one in 4000 African women and another in 500 US women. We estimated all parameters using g-computation and report risk ratios averaged over 2000 simulations, alongside the 2.5th and 97.5th percentiles of the simulation results. Results: Twelve months after randomization, the African ITT and per-protocol risk ratios were 0.65 (0.47, 0.88) and 0.20 (0.08, 0.34), respectively. The US ITT and per-protocol risk ratios were 0.42 (0.20, 0.62) and 0.17 (0.03, 0.38), respectively. These results matched well the simulated true effects. Conclusions: Our simple demonstration informs the design of future studies seeking to estimate the effectiveness of a treatment (like PrEP) in lower-incidence settings where a traditional RCT would not be feasible. Article	2019	Ryan K.L.; Jakeman B.; Conklin J.; Pineda L.J.; Deming P.; Mercier R.-C.	Treatment of patients with HIV or hepatitis C by pharmacist clinicians in a patient-centered medical home	American Journal of Health-System Pharmacy	-	-	-	10792082	10.1093/ajhp/zxz059	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068538892&doi=10.1093%2fajhp%2fzxz059&partnerID=40&md5=62e33a224fd40dd8ad20e50c2f660077	Purpose. This report describes an innovative pharmacy practice model assisting in the care of patients living with or at risk of acquiring human immunodeficiency virus (HIV) and/or hepatitis C virus (HCV). Summary. In the state of New Mexico, pharmacists can obtain prescribing privileges through a Pharmacist Clinician (PhC) license. The license allows PhCs to assess patients, order laboratory/diagnostic tests, prescribe medication, and bill select insurances. PhCs have developed a practice model for patients living with or at risk of HIV and/or HCV at a Level 3 National Committee for Quality Assurance Patient-Centered Medical Home in Albuquerque, New Mexico. In 2015, 5 PhCs, employed part time, were involved with 8 different clinics: (1) HIV Adherence and Complex Care, (2) HIV Transitions of Care, (3) HCV Mono- A nd Co-Infection, (4) HIV Pre-Exposure Prophylaxis (PrEP), (5) HIV Primary Care and Cardiovascular Risk Reduction, (6) Young Adult Clinic, (7) Perinatal HIV, and (8) Pediatric HIV. In 2015, PhCs at the clinic billed for 774 direct patient encounters. Conclusion. Pharmacists with the PhC license are able to provide highquality medical care to patients living with or at risk of HIV and/or HCV infections within an interprofessional medical home model. © 2019 American Journal of Health-System Pharmacy. Article	2019	Saha S.; Samanta G.P.	Modelling and optimal control of HIV/AIDS prevention through PrEP and limited treatment	Physica A: Statistical Mechanics and its Applications	-	-	-	3784371	10.1016/j.physa.2018.10.033	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055625136&doi=10.1016%2fj.physa.2018.10.033&partnerID=40&md5=7ab49e2e0b54c0a1c070a1630a7f5e89	Epidemic outbreak is one of the primary issue that induce behavioural changes in healthy individuals to avoid contracting infection. We here propose a compartmental model for the transmission of HIV/AIDS including treatment and Pre-exposure prophylaxis (PrEP). It accounts for the effect of individual's behavioural response due to information of PrEP also. Taking PrEP by uninfected individuals actually can prevent the acquisition of HIV infection. Model analysis has been performed as well as the local and global stability of equilibrium points is established. Further, an optimal control problem has been formulated to minimize the cost and disease fatality by choosing the treatment and the effect of information regarding PrEP as control variables. Numerical analysis gives that if only control via information regarding PrEP is used, then it will be economical for early phase of the time period whereas treatment works well for long term control. Moreover, simultaneous use of both the control interventions is more useful than any single applied control policy and it reduces the number of infective individuals and also minimizes the economic cost generated from disease burden and controls. In the model it can be observed how uptake of PrEP can effect in the population by reducing the number of HIV infections. Moreover the combined effect of both the control policies is found to be more economical during the entire epidemic period whereas the implementation of a single policy is comparatively found less economical viable. © 2018 Elsevier B.V. Article	2019	Sales J.M.; Phillips A.L.; Tamler I.; Munoz T.; Cwiak C.; Sheth A.N.	Patient recommendations for PrEP information dissemination at family planning clinics in Atlanta, Georgia	Contraception	-	-	-	107824	10.1016/j.contraception.2018.12.008	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061930390&doi=10.1016%2fj.contraception.2018.12.008&partnerID=40&md5=88599fdd9f3738e045fbdc12fe26a96b	Objective: Family planning (FP) clinics are an ideal setting to disseminate information about pre-exposure prophylaxis (PrEP), but little is known about women's preferences for learning about PrEP in this setting. Study design: We surveyed 500 women seeking care at 4 FP clinics in Atlanta. Before their provider visit, participants completed an HIV-risk screener. After, we asked participants about the HIV prevention counseling they received and how clinics could share information about PrEP. We performed descriptive analyses on demographics, HIV risk, and PrEP awareness/interest, and conducted thematic analysis on open-ended responses. Results: Only 18% knew about PrEP before the study; 28% of 376 sexually-active women had≥1 risk indicator consistent with PrEP eligibility. Three hundred forty seven women (69%) shared suggestions about how clinics should share PrEP information. We categorized suggestions into 4 themes - Advertising, Conversations, Awareness and Access. Participants (n=150) suggested clinics should advertise PrEP via brochures, posters, texts, or emails; 134 wanted providers to talk to patients about PrEP. Several (n=71) suggested sharing PrEP information broadly in the community and with other clinics/providers; others (n=11) wanted improved access to PrEP services. Conclusions: Our results demonstrate overwhelming patient interest in learning more about PrEP through educational materials and directly from FP providers. Women were vocal about increasing PrEP awareness in the community, particularly among populations especially at risk for HIV (e.g., teens). These suggestions can be translated into actionable steps FP clinics can take to increase PrEP awareness and expand their reach to benefit women at risk for HIV. Implications: High HIV rates among women in the South make it imperative to increase awareness of PrEP among women. Atlanta women seeking care in FP clinics valued learning about PrEP and recommended feasible strategies for disseminating information about PrEP in community settings, the clinic or during patient-provider discussion. © 2019 Elsevier Inc. Article	2019	Sales J.M.; Sheth A.N.	Associations Among Perceived HIV Risk, Behavioral Risk and Interest in PrEP Among Black Women in the Southern US	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2333-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85056133682&doi=10.1007%2fs10461-018-2333-9&partnerID=40&md5=6f70bcd111ae30059f9ce4223fd423cb	Utilizing data from Southern women, we created an HIV risk index with expanded partner-level factors to better capture women who may benefit from HIV pre-exposure prophylaxis (PrEP). We examined the relationships between potential HIV risk as estimated by laboratory-confirmed bacterial STIs, HIV risk index, perceived HIV risk, and interest in PrEP. Women had multiple PrEP indications; partner characteristics better differentiated STI status than other indicators. Perceived HIV risk differentiated STI status, significantly correlated with the HIV risk index, as well as predicted greater interest in PrEP. Findings can inform how best to evaluate HIV risk and PrEP acceptability among women. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Sales, Jessica M.; Cwiak, Carrie; Haddad, Lisa B.; Phillips, Ashley; Powell, Leah; Tamler, Ilyssa; Sheth, Anandi N.	Impact of PrEP Training for Family Planning Providers on HIV Prevention Counseling and Patient Interest in PrEP in Atlanta, Georgia.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000002057	https://pubmed.ncbi.nlm.nih.gov/30985558/	BACKGROUND: Safety net family planning (FP) clinics provide vital care for women in high HIV-burden areas and may be ideal pre-exposure prophylaxis (PrEP) delivery sites. Yet, many FP providers lack knowledge about PrEP. SETTING: Four safety net FP clinics in Atlanta, Georgia. METHODS: We provided a 1.5-hour PrEP informational training for 28 providers working in these sites. To assess the training's impact on PrEP counseling, we enrolled 500 female patients after training (47% ≤ 28 years; 69% black; 12% Hispanic) and determined their PrEP indication based on CDC guidelines. We conducted a postvisit survey to assess provider counseling and patients' interest in PrEP and acceptance of off-site PrEP referral. RESULTS: From pre-training to post-training, provider PrEP knowledge and confidence to identify women who may benefit from PrEP significantly increased. Only 19% of women knew about PrEP before the visit. Among 376 sexually active women, 29% had risk consistent with PrEP indication. Among PrEP-indicated women, 66% reported the provider discussed PrEP, 29% were interested in taking PrEP, but only 18% accepted off-site PrEP referral. Most (76%) were more willing to take PrEP if provided by the FP clinic. CONCLUSIONS: After a brief PrEP training, most women with HIV-risk indicators received PrEP counseling during their visits. Once counseled, women expressed interest if it were offered at the FP clinic rather than through off-site referral. Findings highlight the potential impact that PrEP capacity building within safety net FP clinics in high HIV-burden areas may have on PrEP scale-up for women. Article	2019	Sales, Jessica M; Escoffery, Cam; Hussen, Sophia A; Haddad, Lisa B; Phillips, Ashley; Filipowicz, Teresa; Sanchez, Maria; McCumber, Micah; Rupp, Betty; Kwiatkowski, Evan; Psioda, Matthew A; Sheth, Anandi N	Pre-exposure prophylaxis integration into family planning services at title X clinics in the southeastern United States: A geographically-targeted mixed methods study (Phase 1 ATN 155)	JMIR Research Protocols	-	-	-	19290748	10.2196/12774	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071326639&doi=10.2196%2f12774&partnerID=40&md5=0815a00f74f26c1e28eabdb6c85ea644	Background: Black adolescent and young adult women (AYAW) in the Southern United States are disproportionately affected by HIV. Pre-exposure prophylaxis (PrEP) is an effective, scalable, individual-controlled HIV prevention strategy that is grossly underutilized among women of all ages and requires innovative delivery approaches to optimize its benefit. Anchoring PrEP delivery to health services that AYAW already trust, access routinely, and deem useful for their sexual health may offer an ideal opportunity to reach women at risk for HIV and to enhance their PrEP uptake and adherence. These services include those of family planning (FP) providers in high HIV incidence settings. However, PrEP has not been widely integrated into FP services, including Title X-funded FP clinics that provide safety net sources of care for AYAW. To overcome potential implementation challenges for AYAW, Title X clinics in the Southern United States are uniquely positioned to be focal sites for conceptually informed and thoroughly evaluated PrEP implementation science studies. Objective: The aim of this study is to assess inner and outer context factors (barriers and facilitators) that may influence the adoption of PrEP prescription and treatment services in Title X clinics serving AYAW in the Southern United States. Methods: Phase 1 of Planning4PrEP is an explanatory sequential, mixed methods study consisting of a geographically-targeted Web-based survey of Title X clinic administrators and providers in the Southern United States, followed by key informant interviews among a purposively selected subset of responders to more comprehensively assess inner and outer context factors that may influence adoption and implementation of PrEP in Title X FP clinics in the South. Results: Phase 1 of Planning4PrEP research activities began in October 2017 and are ongoing. To date, survey and key informant interview administration is near completion, with quantitative and qualitative data analysis scheduled to begin soon after data collection completion. Conclusions: This study seeks to assess inner and outer context factors (barriers and facilitators) that may influence the adoption and integration of PrEP prescription and treatment services in Title X clinics serving AYAW in the Southern United States. Data gained from this study will inform a type 1 hybrid effectiveness implementation study, which will evaluate the multilevel factors associated with successful PrEP implementation while evaluating the degree of PrEP uptake, continuation, and adherence among women seen in Title X clinics. ©Jessica M. Article	2019	Same R.G.; McAleese S.; Agwu A.L.; Arav-Boger R.	Acute HIV in an Adolescent Male With Fever and Rhabdomyolysis	Journal of Adolescent Health	-	-	-	1054139X	10.1016/j.jadohealth.2019.05.021	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071999417&doi=10.1016%2fj.jadohealth.2019.05.021&partnerID=40&md5=5ce5afab3f1d6e2a3e37a44586cc2962	We report the case of a young adolescent male who presented with persistent fever and rhabdomyolysis and was ultimately diagnosed with acute HIV. Rhabdomyolysis is an unusual manifestation of acute HIV that has been rarely reported. However, in the absence of another etiology, we propose that HIV should be considered in the differential for rhabdomyolysis, particularly in association with fever and pharyngitis. Young people, especially men who have sex with men of color and younger adolescents, are at increased risk of HIV and may not disclose any sexual history. Opportunities to identify risk factors and test for HIV are often missed in young people. A high level of suspicion and routine screening for HIV is needed in youth, especially in light of the benefits of early diagnosis and treatment of acute HIV. Pre-exposure prophylaxis is highly effective for the prevention of HIV and is underutilized in adolescents. © 2019 Society for Adolescent Health and Medicine	Acute HIV; HIV screening; Pre-exposure prophylaxis; PrEP; Rhabdomyolysis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Sandset T.	HIV Both Starts and Stops with Me': Configuring the Neoliberal Sexual Actor in HIV Prevention	Sexuality & Culture	-	-	-	10955143	10.1007/s12119-018-09584-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059521199&doi=10.1007%2fs12119-018-09584-1&partnerID=40&md5=a5bac81dc9664038d04be8e751ad29f7	This article argues that newer HIV prevention campaigns and health promotions that focus on reaching the public with information on how to prevent HIV infections or treat them once a person becomes HIV positive are mainly built upon the rationale of what has been called 'a neoliberal sexual actor'. The sexual actor being represented is predicated upon the tenets of a neoliberal subject wherein market choice, rational risk analysis, personal responsibility, and personal entrepreneurship are in focus. Whereas many of the newer health promotions are built upon the tenets of neoliberalism, these health promotions while being both inclusive in terms of sexualities and racialized identities nevertheless play on neoliberal ideals that may or may not be available for the people who are most vulnerable in terms of HIV risk. The article ends up by arguing that while many of these health promotions are both 'sex-positive' and avoid the specter of 'risk' and 'infection' and rather play on neoliberal concepts, they nevertheless also leave behind those that for whatever reasons cannot comply with or access these tenets. In an era when the HIV effort strongly plays on a rhetoric of 'leaving no one behind' such an overt focus on the neoliberal concepts of free choice, market freedom, personal responsibility, and 'rational' risk calculation, might end up leaving behind the most vulnerable people within the HIV epidemic. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Santa Maria D.; Flash C.A.; Narendorf S.; Barman-Adhikari A.; Petering R.; Hsu H.-T.; Shelton J.; Bender K.; Ferguson K.	Knowledge and Attitudes About Pre-Exposure Prophylaxis Among Young Adults Experiencing Homelessness in Seven U.S. Cities	Journal of Adolescent Health	-	-	-	-	1054139X	10.1016/j.jadohealth.2018.06.023	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053855788&doi=10.1016%2fj.jadohealth.2018.06.023&partnerID=40&md5=15734f4704b547f83ff557d4ab305ff0	Purpose: Evidence suggests that young adults experiencing homelessness (YEH) are at elevated risk of HIV compared to housed youth. Given the limited research on pre-exposure prophylaxis (PrEP) awareness among YEH, this study examined their PrEP knowledge and attitudes. Methods: Data from a cross-sectional survey among YEH (ages 18–26) (n = 1,427) in seven U.S. cities were used to assess their knowledge and attitudes regarding PrEP to inform HIV prevention efforts. Results: Participants were primarily male youth of color. The mean age was 20.9years. While 66% felt at risk for HIV, only 14% strongly agreed that they try to protect themselves from getting infected with HIV. Most (84%) were eligible for PrEP based on risk, yet only 29% had knowledge of PrEP. Despite this, 59% reported they were likely/extremely likely to take PrEP. Access to free PrEP (55%), HIV testing (72%), healthcare (68%), and one-on-one (62%), and text messaging support (57%) were rated as very/extremely important for PrEP uptake and adherence. Conclusions: The results of this study suggest missed opportunities to prevent new HIV infections among YEH. Efforts to increase PrEP uptake among this population should consider provider- and system-level interventions to increase PrEP awareness, decrease PrEP-associated healthcare costs, improve access to PrEP providers, and provide in-person and text messaging support. © 2018 Society for Adolescent Health and Medicine	HIV; Homeless youth; Pre-exposure prophylaxis (PrEP); Prevention; Young adults	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Sarkar, Supriya; Corso, Phaedra; Ebrahim-Zadeh, Shideh; Kim, Patricia; Charania, Sana; Wall, Kristin	Cost-effectiveness of HIV Prevention Interventions in Sub-Saharan Africa: A Systematic Review.	EClinicalMedicine	-	-	-	-	2589-5370	10.1016/j.eclinm.2019.04.006	https://pubmed.ncbi.nlm.nih.gov/31193863/	BACKGROUND: Sub-Saharan Africa carries the highest HIV burden globally. It is important to understand how interventions cost-effectively fit within guidelines and implementation plans, especially in low- and middle-income settings. We reviewed the evidence from economic evaluations of HIV prevention interventions in sub-Saharan Africa to help inform the allocation of limited resources. METHODS: We searched PubMed, Web of Science, Econ-Lit, Embase, and African Index Medicus. We included studies published between January 2009 and December 2018 reporting cost-effectiveness estimates of HIV prevention interventions. We extracted health outcomes and cost-effectiveness ratios (CERs) and evaluated study quality using the CHEERS checklist. FINDINGS: 60 studies met the full inclusion criteria. Prevention of mother-to-child transmission interventions had the lowest median CERs ($1144/HIV infection averted and $191/DALY averted), while pre-exposure prophylaxis interventions had the highest ($13,267/HIA and $799/DALY averted). Structural interventions (partner notification, cash transfer programs) have similar CERs ($3576/HIA and $392/DALY averted) to male circumcision ($2965/HIA) and were more favourable to treatment-as-prevention interventions ($7903/HIA and $890/DALY averted). Most interventions showed increased cost-effectiveness when prioritizing specific target groups based on age and risk. INTERPRETATION: The presented cost-effectiveness information can aid policy makers and other stakeholders as they develop guidelines and programming for HIV prevention plans in resource-constrained settings. Article	2019	Saxena A.; Deschamps M.-M.; Dorvil N.; Christophe I.; Rosenberg R.; Jean-Gilles M.; Koenig S.; Pape J.W.; Dévieux J.G.	Association between intimate partner violence and HIV status among Haitian Women	Global Public Health	-	-	-	-	17441692	10.1080/17441692.2019.1602156	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064613035&doi=10.1080%2f17441692.2019.1602156&partnerID=40&md5=2e08f72cb33d64c96ac73607c5c29df5	The prevalence of intimate partner violence (IPV) among women living in Haiti increased from 25% in 2006–29% in 2012, with escalating reports of crisis in the last several years. We examined the association between IPV and HIV status among these women in Haiti. Participants were drawn from a larger sample of women (n = 513) with a history of IPV. Women living with HIV (n = 55) were matched to uninfected women (n = 110) to form a control group. Attitudes towards gender roles, mental and physical well-being, and partner violence were assessed and compared. Logistic regressions were utilised to calculate multivariable-adjusted odds ratios. Women living with HIV were more likely to report more severe forms of psychological violence (p < 0.01), and severe physical violence (p < 0.0001). Women who experienced severe forms of IPV were 3.5 times more likely to have an HIV positive status compared to those who did not experience severe IPV (p < 0.0001). There were significant associations between severe forms of IPV, and HIV status among Haitian women. IPV severity should be integrated into eligibility screening for biomedical strategies of prevention such as pre-exposure prophylaxis (PrEP) among Haitian women. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group.	gender-based attitudes; Haiti; Intimate partner violence; mental health	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Saxton P.J.W.; McAllister S.M.	Enumerating the population eligible for funded HIV pre-exposure prophylaxis (PrEP) in New Zealand	Sexual Health	-	-	-	-	14485028	10.1071/SH18058	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059821391&doi=10.1071%2fSH18058&partnerID=40&md5=1bfd53838ef5a2f2874b9c2b4411f3f5	Background: Pre-exposure prophylaxis (PrEP) became publicly funded in New Zealand (NZ) on 1 March 2018. PrEP could have a substantial population-level effect on HIV transmission if scaled up rapidly. An accurate estimate of the size of the PrEP-eligible population would guide implementation. Methods: We drew on nine sources to estimate the PrEP-eligible population, namely Statistics NZ data, Pharmaceutical Management Agency (PHARMAC) data on adults receiving funded antiretroviral treatment (ART), expert advice, estimates of the HIV care cascade, surveillance of undiagnosed HIV in a community sample of gay and bisexual men (GBM), surveillance of HIV diagnoses, NZ Health Survey data on sexual orientation among males, behavioural surveillance among GBM and behavioural data among people living with HIV (PLWH) from the HIV Futures NZ study. From these sources we derived three estimates relating to GBM, non-GBM and total eligible population. Sensitivity analyses examined different assumptions (GBM denominators, proportion PLWH diagnosed, proportion of diagnosed PLWH treated). Results: We estimated that 17.9% of sexually active HIV-negative GBM would be eligible for PrEP, equating to 5816 individuals. We estimated that 31 non-GBM individuals would be eligible for PrEP. Thus, in total, 5847 individuals would be eligible for PrEP, comprising 99.5% GBM and 0.5% non-GBM. Sensitivity analyses ranged from 3062 to 6718 individuals. Conclusions: Policy makers can use enumeration to monitor the speed and scale in coverage as implementation of publicly funded PrEP proceeds. Sexual health and primary care services can use enumeration to forecast PrEP demand and plan accordingly. Better quality data, especially on transgender adults in NZ, would improve the accuracy of estimates. © 2019 CSIRO.	condomless anal intercourse; enumeration; homosexual; methamphetamine; sexually transmissible infection	English	United States	Western and Central Europe and North America	New Zealand	Asia and the Pacific	New Zealand	Asia and the Pacific	Quantitative
Article	2019	Saxton, Peter J W; Azariah, Sunita; Franklin, Richard A; Forster, Rose F; Werder, Suzanne F; Jenkins, Renee; Myers, Jason M; Rich, Joseph G; Te Wake, Whatitiri P; Fisher, Mark D	Baseline characteristics of gay and bisexual men in a HIV pre-exposure prophylaxis demonstration project with equity quotas in Auckland, New Zealand	Sexual Health	-	-	-	-	30274568	10.1071/SH18056	https://www.proquest.com/scholarly-journals/baseline-characteristics-gay-bisexual-men-hiv-pre/docview/2176621656/se-2?accountid=8113	Background: In New Zealand, pre-exposure prophylaxis (PrEP) should target gay and bisexual men (GBM), and equity is an important principle. Baseline characteristics of GBM offered PrEP in a demonstration project with an enrolment quota of 50% non-Europeans are described. Methods: An open-label, single-arm treatment evaluation study design ('NZPrEP') was used. The settings were four publicly funded sexual health clinics in Auckland in 2017. The study population was 150 GBM recruited from clinics, community sources and social media. Participants self-completed an online questionnaire about PrEP awareness, attitudes and sexual risk behaviour in the last 3 months. Baseline characteristics are described and examined to determine whether these were associated with PrEP initiation status (self-referral vs doctor/nurse recommendation). Results: In total, 150 GBM of whom half (52%) were non-European, including 21.3% Maori, 19.3% Asian and 8.7% Pacific, were enrolled into the study. Two-thirds (65.3%) self-referred for PrEP and one-third (34.7%) were recommended PrEP by the doctor/nurse. Participants reported a high number of male condomless receptive anal intercourse partners (MenAICLR) (median 3, range 0-50), with 10% reporting 10 or more MenAICLR and 45.3% reporting group sex. In the previous year, 65.3% had a sexually transmissible infection (STI); 18% had rectal chlamydia or gonorrhoea at enrolment. Almost half (47.7%) had recently used drugs with sex, including 8.1% who used methamphetamine. Participants recommended PrEP had lower education, lived less centrally and had a higher STI prevalence than PrEP self-referrers, but their risk behaviour was similar. Conclusions: Early PrEP adopters in New Zealand have high HIV risk. Demonstration projects should consider equity mechanisms so that minorities can participate meaningfully. Article	2019	Schecke H.; Lea T.; Bohn A.; Köhler T.; Sander D.; Scherbaum N.; Deimel D.	Crystal Methamphetamine Use in Sexual Settings Among German Men Who Have Sex With Men	Frontiers in Psychiatry	-	-	-	-	16640640	10.3389/fpsyt.2019.00886	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85077270286&doi=10.3389%2ffpsyt.2019.00886&partnerID=40&md5=4c3a6e19c2dfc7cd648fde1f28c3f897	Introduction: Men who have sex with men (MSM) are a vulnerable subgroup for problems with substance use, including crystal methamphetamine. Drug use in sexual settings, commonly referred to as "chemsex," has been an issue of growing concern in MSM communities. Recreational drugs commonly associated with chemsex include crystal methamphetamine, gamma-hydroxybutyrate/gamma-butyrolactone (GHB/GBL), mephedrone, and ketamine. Drug use in sexual settings is correlated with sexual practices associated with the acquisition and transmission of sexually transmitted infections, including HIV and hepatitis C. Adverse mental health outcomes are often reported at higher rates among MSM who use methamphetamine. Methods: This paper refers to a subset of participants from the German Chemsex Survey, an MSM-community recruited, self-completed online survey with a self-selected convenience sample. Participants who used crystal methamphetamine for sex (n = 130) were compared to participants who did not use drugs for sex (n = 177). The survey comprised 420 different items considering recreational substance use, substance use in sexual settings, harm reduction strategies, mental health, sexual transmitted infections, and mental health care service utilization. Results: A total of 1,583 men started the survey; 1,050 participants provided information on substance use. Twenty-seven percent of participants used crystal methamphetamine in the last 12 months, and of those, 89% used methamphetamine in a sexual setting and 50% reported injecting methamphetamine. Regarding mental health, participants who reported methamphetamine use in sexual settings were more likely to report symptoms of depression, somatization, anxiety, and posttraumatic stress disorder (PTSD) than the German male general population. Participants who reported methamphetamine use for sex were more likely to report symptoms of major depression, being HIV positive, and taking HIV pre-exposure prophylaxis (PrEP) than participants who did not report methamphetamine use. Most participants used harm reduction practices to reduce the risks associated with using methamphetamine in sexual settings. Conclusion: Crystal methamphetamine is used in the context of sexual activities by German MSM. Poorer mental health status than in the male general population was observed. MSM who used methamphetamine in this study seemed to be aware of potential health risks associated with their substance use and utilized harm reduction strategies and biomedical HIV prevention strategies like PrEP. © Copyright © 2019 Schecke, Lea, Bohn, Köhler, Sander, Scherbaum and Deimel.	chemsex; harm reduction; HIV; men who have sex with men; mental health; methamphetamine	English	Switzerland	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Quantitative
Article	2019	Schellberg S.	Perspective of an HIV Attending Physician on PrEP; Perspektive eines HIV-Behandlers auf die PrEP	Zeitschrift fur Sexualforschung	-	-	-	-	9328114	10.1055/a-1028-2596	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076926876&doi=10.1055%2fa-1028-2596&partnerID=40&md5=2a5312fdb5c59a0b7e4a3eff27d399b3	Sven Schellberg works as office-based physician at the Novopraxis Berlin, an HIV-focused medical practice in Berlin. He is increasingly confronted with patients who ask about PrEP. He appreciates their reasons, but also warns against a sometimes too uncritical medicalization of gay sexuality. He also hopes that open discussions about sexual behaviour and sexual well-being, about HIV and STI prevention will not only take place in HIV-focused practices, but naturally also in other medical practices. However all too often this still seems to be a taboo. © 2020 American Society of Civil Engineers (ASCE). All rights reserved. Article	2019	Schreier T.; Sherer R.; Sayles H.; Jacobsen D.M.; Swindells S.; Bares S.H.	US Human Immunodeficiency Virus (HIV) practitioners' recommendations regarding condomless sex in the era of HIV pre-exposure prophylaxis and treatment as prevention	Open Forum Infectious Diseases	-	-	-	-	23288957	10.1093/ofid/ofz082	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066413072&doi=10.1093%2fofid%2fofz082&partnerID=40&md5=e5711beef48a750b34abf1a9014466a8	Background. We sought to characterize human immunodeficiency virus (HIV) practitioners' recommendations to patients regarding treatment as prevention, pre-exposure prophylaxis (PrEP) and condom use among persons with HIV (PWH) with viral suppression and individuals receiving PrEP. Methods. A brief survey about counseling practices was distributed electronically to previous attendees of an International Antiviral Society-USA continuing medical education activity. Descriptive analyses were performed for all questions. Pearson χ2 tests were used to identify potential differences in counseling practices based on sex, degree/license, years in practice, number of PWH cared for in the past year, and practice location. Results. Of the 3238 persons surveyed, 478 (15%) responded. 65% were female, 47% were physicians, 78% had been in practice ≥6 years, and 52% had cared for >100 PWH in the last year. Of the respondents, 51% (95% confidence interval, 46.8%-56.0%) agreed that the evidence "supports, strongly supports or proves" that condomless sex with a PWH with viral suppression does not lead to HIV transmission, and 76% (72.2%-80.0%) commonly or always recommend condoms for such patients. Although 42% (95% confidence interval, 37.0%-46.0%) of respondents said the evidence "supports, strongly supports or proves" that condomless sex involving a person at risk for HIV infection receiving PrEP does not lead to HIV transmission, 81% (77.3%-84.5%) commonly or always recommend condom use for such patients. Responses differed significantly by practitioner experience, region, sex and degree. Conclusions. Although many practitioners caring for individuals with and at risk for HIV infection acknowledge that successful treatment or PrEP prevents transmission, the majority of practitioners commonly or always recommend condom use. © The Author(s) 2019. Article	2019	Schueler, Kellie; Ferreira, Matthew; Nikolopoulos, Georgios; Britt Skaathun; Paraskevis, Dimitrios; Hatzakis, Angelos; Friedman, Samuel R; Schneider, John A	Pre-exposure Prophylaxis (PrEP) Awareness and Use Within High HIV Transmission Networks	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02411-0	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-prep-awareness-use/docview/2174075879/se-2?accountid=8113	Improved implementation of pre-exposure prophylaxis (PrEP) should be a valuable tool within communities experiencing high HIV incidence, such as black men who have sex with men (MSM). Using baseline data from the Chicago arm of the Transmission Reduction Intervention Project (TRIP), we examined awareness and use of PrEP within HIV potential transmission networks. Transmission Reduction Intervention Project recruited participants ages 18–69 (N = 218) during 2014–2016 from networks originating from recently and chronically HIV-infected MSM and transgender persons. In total, 53.2% of participants had heard of PrEP, while 8 (6.5%) HIV-negative participants reported ever using PrEP. In multivariable regression, PrEP awareness was associated with identifying as gay, attending some college or higher, having an HIV test in the previous 6 months, and experiencing HIV-related social support. PrEP awareness was not associated with experiencing or observing HIV-related stigma. PrEP use was associated with participants knowing two or more other PrEP-users. These findings demonstrate moderate awareness, but low uptake of PrEP within HIV potential transmission networks in Chicago. Future research should explore how to increase PrEP use in these networks and investigate the social dynamics behind our finding that PrEP users are more likely to know other PrEP users. Article	2019	Schwartz J.; Grimm J.	Stigma Communication Surrounding PrEP: The Experiences of A Sample of Men Who Have Sex With Men	Health Communication	-	-	-	-	10410236	10.1080/10410236.2017.1384430	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85031802385&doi=10.1080%2f10410236.2017.1384430&partnerID=40&md5=081c798c59809f273a0ad6d54d1e8d84	HIV is a serious problem in the USA, particularly for men who have sex with men (MSM). A new means of HIV prevention, called pre-exposure prophylaxis (PrEP), has been shown to be highly effective. However, in spite of earning FDA approval, adoption of PrEP by MSM has been limited. The purpose of this study was to examine the experiences of a sample of 38 MSM who have adopted PrEP, focusing on communication with healthcare providers and social networks. In-depth interviews were used to collect data. Findings revealed that stigmatization by healthcare providers as well as stigmatization by other MSM was a relatively common experience for participants. Additionally, participants described that a high level of health literacy, health advocacy, and communication skill were necessary to adopt PrEP. Given these findings, strategies are suggested for improving MSM's healthcare and increasing rates of PrEP adoption. © 2019, © 2019 Taylor & Francis Group, LLC. Article	2019	Schwartz S.; Davies N.; Naidoo N.; Pillay D.; Makhoba N.; Mullick S.	Clients' experiences utilizing a safer conception service for HIV affected individuals: Implications for differentiated care service delivery models	Reproductive Health	-	-	-	-	17424755	10.1186/s12978-019-0718-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066496656&doi=10.1186%2fs12978-019-0718-5&partnerID=40&md5=81e3b7469563033836ce51456789bd44	Background: Safer conception services promote the reproductive health and rights of families, while minimizing HIV transmission risks between partners trying to conceive, as well vertical transmission risks. Implementation data, including clients' experiences utilizing safer conception services in sub-Saharan Africa are limited. Methods: Hillbrow Community Health Centre began offering safer conception services for individuals and couples affected by HIV in Johannesburg, South Africa in June 2015. A stratified sub-sample of safer conception clients were consecutively recruited from April 2016-August 2017 for a cross-sectional interview assessing clients' perceptions of service acceptability and value, as well as perceived safer conception knowledge and self-efficacy. Visual analog scales from 0 to 100 were used to measure clients' experiences; scores were classified as low, moderate and high acceptance/value/knowledge/self-efficacy if they were < 50, 50-79 and ≥ 80 respectively. Comparisons of scores were made across safer conception visits attended. Results: Among 692 clients utilizing safer conception services, 120 (17%) were sampled for the process evaluation; sub-sample participant characteristics were similar to the overall cohort. Clients gave a mean score of ≥90-points for each question assessing service acceptability and 96% (114/119) indicated a high perceived value (scores ≥80) for regular safer conception attendance until conception. Fifty-eight percent (n = 70) of clients reported learning something new during the visit completed the day of the survey, though acquisition of new information tended to decrease as visits increased (p = 0.09). In terms of safer conception strategies, 80% of clients reported high levels of knowledge on the impact of antiretroviral treatment (ART) and viral suppression on HIV transmission, 67% reported high levels of knowledge of the importance of STI screening and 56% regarding limiting condomless sex to days of peak fertility; 34% in sero-different relationships reported high pre-exposure prophylaxis (PrEP) knowledge. Self-efficacy varied by safer conception methods and was similar across study visits. Conclusions: Clients perceived high value from their safer conception visits and preferred regular attendance until conception, however we observed a plateau in knowledge and self-efficacy across subsequent visits after initially attending safer conception care. More intensive services may be appropriate for certain clients based on clinical circumstances, but many couples may potentially receive a 'lighter touch' approach while still minimizing HIV transmission risks. © 2019 The Author(s). Article	2019	Schwartz S.R.; Bassett J.; Mutunga L.; Yende N.; Mudavanhu M.; Phofa R.; Sanne I.; Van Rie A.	HIV incidence, pregnancy, and implementation outcomes from the Sakh'umndeni safer conception project in South Africa: a prospective cohort study	The Lancet HIV	-	-	-	-	23523018	10.1016/S2352-3018(19)30144-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068072095&doi=10.1016%2fS2352-3018%2819%2930144-4&partnerID=40&md5=892225b50bd712b998dfb41e21fa478c	Background: Safer conception strategies empower individuals trying to conceive to minimise HIV transmission risk to partners and potential children; however, effectiveness data are scarce. We aimed to assess adoption of safer conception methods and HIV and pregnancy outcomes from Sakh'umndeni, a novel safer conception service in South Africa. Methods: In this prospective cohort study, the Sakh'umndeni clinical cohort at Witkoppen Cinic in Johannesburg (South Africa) enrolled adults aged at least 18 years who were trying to conceive and in relationships with an HIV-positive partner. Couples who were pregnant at enrolment or had been previously diagnosed as infertile were excluded. Participants received safer conception care by a nurse, including antiretroviral therapy (ART) for HIV-positive partners, pre-exposure prophylaxis (PrEP) for HIV-negative partners, counselling around timed condomless sex, or syringes for self-insemination. Primary outcomes were pregnancy incidence and HIV transmission to partners and infants. We estimated time to first pregnancy using Kaplan-Meier curves; pregnancy and HIV incidence were estimated as events per person-years of risk. Findings: Between July 16, 2013, and April 5, 2017, 526 individuals (334 women and 192 men) from 334 partnerships enrolled. 162 (48%) of 334 couples were serodifferent, 149 (45%) were HIV-positive seroconcordant, and 23 (7%) were an HIV-positive woman and an unknown status male partner. At enrolment, 176 (61%) of 287 HIV-positive women and 60 (46%) of 131 HIV-positive men were virally suppressed (<50 copies per mL). Among the safer conception strategies, ART was initiated by 73 (91%) of 80 HIV-positive participants not on ART and PrEP was initiated by 28 (28%) of 101 HIV-negative participants. 2719 follow-up visits were completed, and 99 pregnancies were observed in 89 women. Pregnancy incidence was 41·2 per 100 person-years (95% CI 33·4–50·7); 25 (28%) of 89 pregnancies with a known outcome were miscarried or terminated because of risk to the mother. Pregnancy incidence was 79·0 per 100 person-years (95% CI 49·8–125·4) among HIV-negative women and 36·7 per 100 person-years (29·1–46·3) among HIV-positive women. At the time of pregnancy, viral suppression among women was high (68 87% of 78 women had viral loads of <50 copies per mL and 77 99% had viral loads of <1000 copies per mL). No horizontal or vertical HIV transmission events were observed. Interpretation: Safer conception strategies empowered couples to safely conceive. Pregnancy incidence among service users was high. Integration of safer conception counselling could promote HIV prevention and linkage to care. Article	2019	Scott H.M.; Spinelli M.; Vittinghoff E.; Morehead-Gee A.; Hirozawa A.; James C.; Hammer H.; Liu A.; Gandhi M.; Buchbinder S.	Racial/ethnic and HIV risk category disparities in preexposure prophylaxis discontinuation among patients in publicly funded primary care clinics	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002347	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071383157&doi=10.1097%2fQAD.0000000000002347&partnerID=40&md5=ee24304b36aa612c75aca5fc05d3c36e	Objective: Dissemination of preexposure prophylaxis (PrEP) is a priority for reducing new HIV infections, especially among vulnerable populations. However, there are limited data available on PrEP discontinuation following initiation, an important component of the PrEP cascade.Design:Patients receiving PrEP within the San Francisco Department of Public Health Primary Care Clinics (SFPCC) are included in a PrEP registry if they received a PrEP prescription, were not receiving postexposure prophylaxis, and not known to be HIV-positive.Methods:We calculated PrEP discontinuation for patients initiating PrEP at any time from January 2012 to July 2017 and evaluated their association with demographic and risk variables using Cox regression analysis.Results:Overall, 348 patients received PrEP over the evaluation period. The majority (84%) were men, and the cohort was racially/ethnically diverse. The median duration of PrEP use was 8.3 months. In adjusted analysis, PrEP discontinuation was lower among older patients (aHR 0.89; 95% CI 0.80-0.99; P = 0.03); but higher among black patients (compared with white patients; aHR 1.87; 95% CI 1.27-2.74; P = 0.001), patients who inject drugs (aHR 4.80; 95% CI 2.66-8.67; P < 0.001), and transgender women who have sex with men (compared with MSM; aHR 1.94; 95% CI 1.36-2.77; P < 0.001).Conclusion:Age, racial/ethnic, and risk category disparities in PrEP discontinuation were identified among patients in a public health-funded primary care setting. Further efforts are needed to understand and address PrEP discontinuation among priority populations to maximize the preventive impact of PrEP, and reverse HIV-related disparities at a population level. © 2019 Wolters Kluwer Health, Inc. Editorial	2019	Scott, Hyman; Volberding, Paul A	HIV Screening and Preexposure Prophylaxis Guidelines: Following the Evidence.	JAMA - Journal of the American Medical Association	-	-	-	-	1538-3598	10.1001/jama.2019.2590	https://dx.doi.org/10.1001/jama.2019.2590	Physicians practicing in rapidly evolving areas of medical care, and policy makers charged with supporting that care, both benefit from informed guidance regarding testing, new treatments, and innovations in disease prevention. Approaches to HIV care and prevention have both been improved by access to such guidance. Clinicians who care for patients with HIV follow newly published or presented data, the opinion of respected experts, and guidelines created by governmental or private organizations. Guideline groups have various "rules" regarding the inclusion of expert opinion, which publications are allowed, and how critically those research reports are evaluated. Clinicians expect guidelines to rapidly incorporate new data, and many immediately use guidelines to improve care for their patients. Article	2019	Scully E.P.; Weld E.D.; Blankson J.N.	Challenges in optimizing preexposure prophylaxis development, engagement, and access for HIV prevention	Journal of Clinical Investigation	-	-	-	-	219738	10.1172/JCI134389	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076126030&doi=10.1172%2fJCI134389&partnerID=40&md5=f2c971ed9d96d1c63afabecbc3965c11	One of the greatest successes of modern science is the development of effective antiretroviral therapy (ART) for control of HIV-1 infection. Arguably one of the more innovative responses the ongoing HIV epidemic is the repurposing of ART for preventive efforts as preexposure prophylaxis (PrEP). This strategy has been critical in the face ofto approximately 1.7 million new infections in 2018 and in the absence of an effective HIV vaccine. Notwithstanding this advance, significant scientific challenges remain for the optimal implementation of PrEP, and novel approaches are still needed (1). In the United States, currently approved PrEP consists of a single pill containing two antiretroviral drugs taken daily. While this regimen substantially reduces the risk of HIV-1 acquisition, PrEP has still not reached the majority of at-risk individuals, even in resource-rich settings (2). Comprehensive preventive services are a cornerstone of the Department of Health and Human Services strategic plan to end the HIV epidemic (3), and PrEP is the biomedical intervention currently available. Preventive interventions are at the intersection of medical and behavioral science, and their rollout can highlight disparities in health care access. PrEP is no different, requiring rigorous efforts to achieve its potential equitably across diverse groups. We propose that PrEP offers a window into the efforts to end the HIV epidemic while also illuminating the tension between .... © 2019 American Society for Clinical Investigation. All rights reserved. Discordance between self-perceived and actual risk of HIV infection among men who have sex with men and transgender women in Thailand: a cross-sectional assessment	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25430	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076944216&doi=10.1002%2fjia2.25430&partnerID=40&md5=e5a172d9d7a34fa9f2918bdc96afd382	Introduction: Low uptake of HIV testing and services, including pre-exposure prophylaxis (PrEP), in Thai men who have sex with men (MSM) and transgender women (TGW) may be due to the inaccuracy in self-risk assessment. This study investigated the discordance between self-perceived HIV risk and actual risk. Methods: Data were obtained between May 2015 and October 2016 from MSM and TGW enrolled in key population-led Test and Treat study in six community health centres in Thailand. Eligible participants were at least 18 years old, Thai national, had sex with men, had unprotected sex with a man in the past six months or had at least three male sex partners in the past six months, and were not known to be HIV positive. Baseline demographic behavioural characteristics questionnaires, including self-perceived HIV risk, were self-administered. Participants received HIV/STI (syphilis/gonorrhoea/chlamydia) testing at baseline. Participants who self-perceived to have low risk, but engaged in HIV-susceptible practices were categorized as having risk discordance (RD). Regression was conducted to assess factors associated with RD among MSM and TGW separately. Results: Of the 882 MSM and 406 TGW participants who perceived themselves as having low HIV risk, over 80% reported at least one of the following: tested HIV positive, engaged in condomless sex, tested positive for a sexually transmitted infection (STI), or used amphetamine-type stimulants. Logistic regression found that living with a male partner (p = 0.005), having never tested for HIV (p = 0.045), and living in Bangkok (p = 0.01) and Chiang Mai (p < 0.001) were associated with increased risk discordance among MSM. Living with a male partner (p = 0.002), being less than 17 years old at sexual debut (p = 0.001), and having a low knowledge score about HIV transmission (p < 0.001) were associated with increased risk discordance among TGW. However, for TGW, being a sex worker decreased the chance of risk discordance (p = 0.034). Conclusions: Future HIV prevention messages need to fill in the gap between self-perceived risk and actual risk in order to help HIV-vulnerable populations understand their risk better and proactively seek HIV prevention services. © 2019 The Authors. BMC Public Health	-	-	-	-	1471-2458	10.1186/s12889-019-6645-0	https://pubmed.ncbi.nlm.nih.gov/30898095/	BACKGROUND: Based on government estimates from the Asian Epidemic Model, new infections among men who have sex with men (MSM) and transgender women (TGW) in Thailand are forecast to proportionally increase over time. Daily oral Pre-exposure Prophylaxis (PrEP) protects against HIV acquisition when used as prescribed. The "Princess PrEP" program is the first key population-led (PrEP) initiative under Thai royal patronage with an aim to scale up countrywide implementation of PrEP. METHODS: Retention in and adherence to key population-led HIV PrEP services among HIV-uninfected Thai MSM and TGW was examined in four provinces: Bangkok, Chonburi, Chiang Mai, and Songkhla. HIV, HBsAg, creatinine tests, and self-administered questionnaires were performed during baseline measures. Participants were followed up after month 1, at month 3, then every 3 months. Correlates of nonadherence and loss to follow up at 1 month were assessed using linear regression models. RESULTS: 37.4% of the participants reported low adherence to services (≤ 3 pills/week or missed clinic schedule at month 1). Factors associated with low adherence included younger age (25 years and under) (adjusted odds ratio (aOR): 1.49, 95% confidence interval (95% CI: 1.01-2.21, p = 0.044), being a TGW (aOR: 2.2, 95% CI: 1.27-3.83, p = 0.005), and whether the participant had not previously accessed services at the clinic (aOR = 1.68, 95% CI: 1.03-2.76, p = 0.04). Additionally, participants in Chonburi (the only TGW site) showed significantly lower adherence than those in the other three provinces (aOR: 2.91, 95% CI: 1.55-5.45, p = 0.001). CONCLUSION: Urgent, innovative interventions for early PrEP adherence support among vulnerable sub-populations such as younger users, TGW, and new clients are needed to maximize prevention strategy in Thailand. Article	2019	Serota D.P.; Rosenberg E.S.; Thorne A.L.; Sullivan P.S.; Kelley C.F.	Lack of health insurance is associated with delays in PrEP initiation among young black men who have sex with men in Atlanta, US: a longitudinal cohort study	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25399	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072966567&doi=10.1002%2fjia2.25399&partnerID=40&md5=ede89cca9138657e00c11675a9e081d9	Introduction: Delays between receiving a PrEP prescription and taking a first dose increase the risk of HIV infection. This is especially relevant in populations with high HIV incidence, such as young black men who have sex with men (YBMSM) in the United States. Additionally, YBMSM have relatively low levels of health insurance. We investigated whether lack of health insurance and reliance on PrEP funding through the manufacturer assistance programme (MAP) leads to delays in initiation of PrEP. Methods: HIV-negative YBMSM were offered PrEP as part of a prospective cohort. Enrolment began in June 2015 with follow-up through February 2019. Interested participants attended a PrEP clinician visit and received a prescription. Those with health insurance received a copay assistance card; those without insurance accessed PrEP using the MAP. The primary outcome was the days between prescription and initiation. The effect of insurance status on this delay was modelled using a Cox proportional hazards model. Results and Discussion: The median delay between receipt of a PrEP prescription and taking a first dose was 12 days (IQR 3 to 32). Compared to uninsured participants, the adjusted hazard ratio for PrEP initiation for those with insurance was 2.72 (95% CI 1.82 to 4.06). The adjusted median time to initiation for insured participants was 5 days versus 21 days for those without insurance (p < 0.0001). Older age and STI diagnosis were also associated with faster PrEP initiation. Despite equivalent access to PrEP provided by the study, YBMSM without insurance had longer delays in initiation after receipt of a prescription. Overall, the observed delay in PrEP initiation increases the chances of HIV infection and the possibility of PrEP initiation after undetected seroconversion. Conclusions: The extended time period between PrEP prescription and taking a first dose increases the risk of HIV transmission. Younger YBMSM and those without health insurance had longer delays in PrEP initiation. Immediate PrEP initiation programmes could decrease the likelihood of this occurrence and mitigate the disparity in initiation between those with and without health insurance. Article	2019	Sevelius J.; Murray L.R.; Martinez Fernandes N.; Veras M.A.; Grinsztejn B.; Lippman S.A.	Optimising HIV programming for transgender women in Brazil	Culture, Health & Sexuality	-	-	-	-	13691058	10.1080/13691058.2018.1496277	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055875875&doi=10.1080%2f13691058.2018.1496277&partnerID=40&md5=2daabae4ff80a0e4d4db5a5fcd146afd	In Brazil, little data is available to inform HIV prevention programming for travestis and transgender ('trans') women, despite the existence of a social movement that has gained strength in recent years. We conducted formative research in Rio de Janeiro to gather trans women's perspectives on combination HIV prevention approaches. Framing the analysis within the model of gender affirmation, we found that several social and contextual factors inhibited participants' access to HIV prevention and treatment. Experienced and anticipated gender-related discrimination and HIV stigma were linked to the avoidance of HIV testing, health services and HIV status disclosure. Participants recommended HIV prevention interventions which combined socio-structural interventions, such as peer-based empowerment and social support, with biomedical interventions such as pre-exposure prophylaxis (PrEP). Participants expressed a preference for programmes and interventions that emphasised a gender-affirmative approach, promoted autonomy and aimed to reduce stigma and discrimination in public health services. © 2018, © 2018 Informa UK Limited, trading as Taylor & Francis Group. Article	2019	Sewell J.; Cambiano V.; Speakman A.; Lampe F.C.; Phillips A.; Stuart D.; Gilson R.; Asboe D.; Nwokolo N.; Clarke A.; Rodger A.J.	Changes in chemsex and sexual behaviour over time, among a cohort of MSM in London and Brighton: Findings from the AURAH2 study	International Journal of Drug Policy	-	-	-	-	9553959	10.1016/j.drugpo.2019.03.021	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064276891&doi=10.1016%2fj.drugpo.2019.03.021&partnerID=40&md5=3e6f7f00d2a11611dc14a6380efbfac7	Background: Recent evidence has suggested that chemsex (the use of mephedrone, crystal methamphetamine and γ -hydroxybutyrate/ γ -butyrolactone (GHB/GBL) to enable, enhance and prolong sexual interactions) has increased among men having sex with men (MSM) attending sexual health clinics in large UK cities. To date there has been no data from the UK or Europe that describes changes in chemsex over time within a cohort of MSM. Methods: The prospective cohort study, Attitudes to and Understanding Risk of Acquisition of HIV over Time (AURAH2), collected online questionnaire data from HIV negative or undiagnosed MSM (at enrolment) from 2015 to 2018, recruited from sexual health clinics. We aim to investigate changes in chemsex, three individual drugs associated with chemsex, frequency of chemsex sessions and measures of sexual behaviour, among the cohort of MSM over the study's 3 year follow-up period. Results: In total 622 MSM completed at least one online questionnaire for the AURAH2 study, of which 400 (64.3%) were still engaged with the study within the last six months of follow-up. Prevalence of chemsex significantly declined during the follow-up from 31.8% (198/622) at the first online questionnaire, to 11.1% (8/72; p < 0.001) at the 9th. This decline was reflected in the proportion of MSM reporting use of two of the three individual chemsex drugs: mephedrone use had significantly declined from 25.2% at the first online questionnaire to 9.7% (p < 0.001) at the 9th, GHB/GBL use had also declined from 19.9% to 8.3% (p = 0.001). While crystal methamphetamine use declined, but not significantly (11.1%–6.9% p = 0.289). Most measures of sexual behaviour (any anal sex, group sex, recent HIV test and bacterial STI) also tended to decline over the follow-up period, with the exception of CLAI with more than one and more than two partners. Conclusions: Chemsex and use of two individual chemsex drugs (mephedrone and GHB/GBL) significantly declined over time among individuals in the study, alongside most measures of sexual behaviour with the exception of those related to CLAI. Focusing health promotion and HIV prevention, such as awareness of post-exposure prophylaxis (PEP) and access to pre-exposure prophylaxis (PrEP), on MSM that report chemsex, and in particular problematic chemsex, would be highly beneficial, potentially necessary for a relatively short period of time for individuals, and could have long term benefits for HIV and STI prevention. © 2019 The Authors	Chemsex; Cohort; Condomless sex; HIV prevention; Longitudinal; Men who have sex with men; Sexual behaviour; Sexual health	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Clinical
Article	2019	Shah M.; Gillespie S.; Holt S.; Morris C.R.; Camacho-Gonzalez A.F.	Acceptability and barriers to HIV pre-exposure prophylaxis in atlanta's adolescents and their parents	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2019.0109	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072945507&doi=10.1089%2fapc.2019.0109&partnerID=40&md5=9fe5dcfd0781344a390c63ad996517c7	Adolescents aged 13-24 years account for 23% of new HIV infections in Atlanta, indicating need for better HIV prevention strategies in this population. Pre-exposure prophylaxis (PrEP) is now approved for adolescent use. This study aims to understand the acceptability of and barriers to PrEP in adolescents and parents. We administered PrEP acceptability and barrier measures to HIV(-) 13-17 year olds and their parents from January to April 2016 in an adolescent clinic and emergency department in Atlanta, GA, stratifying by adolescent sexual activity. Acceptability scores (AS) and barrier scores (BS) were calculated by averaging survey answers 1-3. For AS, 1 was very unlikely to accept PrEP; concomitantly, BS near 1 indicated fewer barriers. Two-sample hypothesis testing, Pearson correlations, and linear regression were used. Of the 102 adolescent/parent dyads, 67% of adolescents were female, 94% black, with a mean age of 15.7 ± 1.5 years, and 31% were sexually active. Parents were 94% female, 96% black, with a mean age of 42.4 ± 8.9 years. AS averaged between somewhat to very likely to accept PrEP (2.4 ± 0.5 and 2.2 ± 0.6) in adolescents and parents, respectively. BS averaged between unlikely and somewhat likely to perceive barriers to PrEP (2.0 ± 0.4 and 1.9 ± 0.5) in adolescents and parents, respectively. The adolescent/parent dyad is likely to accept PrEP, regardless of sexual activity. Limitations include that nearly 70% of adolescents were not sexually active, and the study was conducted before PrEP approval by the Food and Drug Administration for those who are younger than 18 years. These results support future parent and adolescent education on PrEP. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019.	adolescent; parent; parental perspective; pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Shaik, JSB; Ford, SL; Lou, Y; Zhang, ZP; Bakshi, KK; Tenorio, AR; Trezza, C; Spreen, WR; Patel, P	A Phase 1 Study to Evaluate the Pharmacokinetics and Safety of Cabotegravir in Patients With Hepatic Impairment and Healthy Matched Controls	Clinical Pharmacology in Drug Development	-	-	-	-	2160-7648	10.1002/cpdd.655	https://pubmed.ncbi.nlm.nih.gov/30811880/	Cabotegravir is an investigational integrase inhibitor in development for the treatment and pre-exposure prophylaxis of HIV-1 infection. Liver disease is a major cause of morbidity and mortality in HIV-infected individuals and can impact the pharmacokinetics (PK) of HIV medications. This phase 1 study evaluated the PK of cabotegravir in individuals with moderate hepatic impairment (n = 8) versus healthy controls (n = 8). Participants received a single oral cabotegravir 30-mg tablet and underwent PK sampling to determine total and unbound plasma cabotegravir concentrations. Calculated geometric least-squares mean ratios (90% confidence intervals) for individuals with hepatic impairment versus healthy controls were 0.73 (0.50-1.06) for AUC(0-infinity), 0.69 (0.51-0.93) for C-max, 1.40 (0.80-2.46) for unbound concentration (CU) 2 hours postdose, 1.55 (0.82-2.94) for CU at 24 hours, 2.14 (1.57-2.90) for unbound fraction (FU) at 2 hours, and 1.90 (1.14-3.18) for FU at 24 hours. Adverse events (AEs) occurred in 2 individuals with hepatic impairment and 3 healthy controls and were grade 1/2 in severity. No participant discontinued because of AEs. Increased FU resulted in a modest decrease in total plasma exposure not considered clinically relevant. We conclude that cabotegravir may be administered without dose adjustment in patients with mild to moderate hepatic impairment. Article	2019	Sharma A.; Stephenson R.; Sallabank G.; Merrill L.; Sullivan S.; Gandhi M.	Acceptability and feasibility of self-collecting biological specimens for HIV, sexually transmitted infection, and adherence testing among high-risk populations (project caboodle!): Protocol for an exploratory mixed-methods study	JMIR Research Protocols	-	-	-	-	19290748	10.2196/13647	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067417176&doi=10.2196%2f13647&partnerID=40&md5=0e7fca97b60c7f9312be9264cedfe2c2	Background: Men who have sex with men (MSM) in the United States experience a disproportionate burden of HIV and bacterial sexually transmitted infections (STIs), such as gonorrhea and chlamydia. Screening levels among MSM remain inadequate owing to barriers to testing such as stigma, privacy and confidentiality concerns, transportation issues, insufficient clinic time, and limited access to health care. Self-collection of specimens at home and their return by mail for HIV and bacterial STI testing, as well as pre-exposure prophylaxis (PrEP) adherence monitoring, could be a resource-efficient option that might mitigate some of these barriers. Objective: Project Caboodle! is a mixed-methods study that explores the acceptability and feasibility of self-collecting and returning a bundle of 5 different specimens for HIV and bacterial STI testing, as well as PrEP adherence monitoring, among sexually active HIV-negative or unknown status MSM in the United States aged 18 to 34 years. Methods: Participants will be recruited using age, race, and ethnicity varied advertising on social networking websites and mobile gay dating apps. In Phase 1, we will send 100 participants a box containing materials for self-collecting and potentially returning a finger-stick blood sample (for HIV testing), pharyngeal swab, rectal swab, and urine specimen (for gonorrhea and chlamydia testing), and hair sample (to assess adequacy for potential PrEP adherence monitoring). Specimen return will not be incentivized, and participants can choose to mail back all, some, or none of the specimens. Test results will be delivered back to participants by trained counselors over the phone. In Phase 2, we will conduct individual in-depth interviews using a video-based teleconferencing software (VSee) with 32 participants from Phase 1 (half who returned all specimens and half who returned some or no specimens) to examine attitudes toward and barriers to completing various study activities. Results: Project Caboodle! was funded in May 2018, and participant recruitment began in March 2019. The processes of designing a study logo, creating advertisements, programming Web-based surveys, and finalizing step-by-step written instructions accompanied by color images for specimen self-collection have been completed. The boxes containing 5 self-collection kits affixed with unique identification stickers are being assembled, and shipping procedures (for mailing out boxes to participants and for specimen return by participants using prepaid shipping envelopes) and payment procedures for completing the surveys and in-depth interviews are being finalized. Conclusions: Self-collection of biological specimens at home and their return by mail for HIV and bacterial STI testing, as well as PrEP adherence monitoring, might offer a practical and convenient solution to improve comprehensive prevention efforts for high-risk MSM. The potentially reduced time, expense, and travel associated with this approach could facilitate a wider implementation of screening algorithms and remote monitoring strategies. © Akshay Sharma, Rob Stephenson, Gregory Sallabank, Leland Merrill, Stephen Sullivan, Monica Gandhi. "The drug will help protect my tomorrow": Perceptions of integrating prep into hiv prevention behaviors among female sex workers in Lilongwe, Malawi	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2019.31.5.421	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072613416&doi=10.1521%2faeap.2019.31.5.421&partnerID=40&md5=becabdf711baca75a1ea97f5a3979a1c	Female sex workers (FSW) are disproportionately at risk for HIV. Pre-exposure prophylaxis (PrEP) is an effective HIV prevention method, yet approaches for incorporating PrEP within prevention strategies used by FSW are lacking. Semistructured focus group discussions were conducted with 44 HIV-negative FSW in Lilongwe, Malawi to explore perceptions of PrEP: acceptability, integration within HIV prevention behaviors, and barriers to use. Acceptability of PrEP was high. Motivation to use PrEP was rooted in love for one's life, anticipated negative economic effects associated with HIV acquisition. PrEP was viewed as complementary to existing norms for engaging in healthy sexual behaviors. Many felt PrEP may provide extra protection from HIV, along with condoms and frequent STI testing. Unpredictable daily lives, stigma, and side effects were barriers that could affect PrEP use. Leveraging existing HIV prevention strategies and social norms surrounding HIV prevention behaviors may positively impact PrEP uptake among FSW in Malawi and sub-Saharan Africa. © 2019 The Guilford Press. Article	2019	Shen M.; Xiao Y.; Rong L.; Zhuang G.	Global dynamics and cost-effectiveness analysis of HIV pre-exposure prophylaxis and structured treatment interruptions based on a multi-scale model	Applied Mathematical Modelling	-	-	-	-	0307904X	10.1016/j.apm.2019.05.024	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066429672&doi=10.1016%2fj.apm.2019.05.024&partnerID=40&md5=6ed6fd66f7d71621942a5a85d54d862f	Structured treatment interruptions (STI) were proposed to reduce costs and side effects for HIV infected individuals, but whether the possible viral rebound within hosts after treatment interruption would lead to more new infections and additional costs among the population remains unknown. Oral pre-exposure prophylaxis (PrEP) is shown as an effective but expensive strategy to prevent the acquisition of HIV infection. To investigate the effectiveness and cost-effectiveness of STI and PrEP, we develop a multi-scale model linking within-host and between-host dynamics in the presence of drug resistance. Lyapunov functionals are constructed to analyze the global dynamics of the coupled system. We fit this model to the annual AIDS incidence and death data from 1980 to 2014 among men who have sex with men (MSM) in San Francisco and compare the impact of six various intervention scenarios (low, medium, high PrEP coverage with or without STI) on new infections and cost-effectiveness over the next 20 years. We estimate the PrEP efficacy needed to eliminate the disease for different fraction of acquired drug resistance under the above six scenarios. Numerical simulations show that expanding PrEP coverage is very cost-effective, but whether implementing STI is cost-saving depends on the efficacy of second-line drugs. That is to say, STI could always save money, but it may lead to more (less) new infections than continuous therapy and thus less (more) health benefit for high (low) efficacy of second-line drugs. These results provide insights about the long-term effect of STI and PrEP on the disease control and cost-effectiveness. © 2019 Elsevier Inc. Article	2019	Sherman, Susan G; Schneider, Kristin E; Park, Ju Nyeong; Allen, Sean T; Hunt, Derrick; Chaulk, C Patrick; Weir, Brian W	PrEP awareness, eligibility, and interest among people who inject drugs in Baltimore, Maryland	Drug and Alcohol Dependence	-	-	-	-	0376-8716	10.1016/j.drugalcdep.2018.08.014	https://www.proquest.com/scholarly-journals/prep-awareness-eligibility-interest-among-people/docview/2186802388/se-2?accountid=8113	Background Limited research has examined pre-exposure prophylaxis (PrEP) interest among people who inject drugs (PWID). To date, few studies have examined the relationship between PrEP eligibility and PrEP interest among PWID. Methods Data were from an anonymous, cross-sectional survey of Baltimore Syringe Services Program (SSP) clients and non-client peers, restricted to HIV-uninfected participants (N = 265). Participants were classified as PrEP eligible/ineligible based on injection related criteria outlined in the CDC's PrEP guidelines. Participants were asked if they were previously aware of PrEP, would be interested in taking PrEP, and the ease of taking PrEP daily. Participants self-reported their sociodemographic characteristics, health diagnoses, and recent drug use, overdose, and drug treatment history. We estimated bivariate and multivariate logistic regression models to test for significant predictors of interest in PrEP. Results One-quarter of PWID had previously heard of PrEP and 63% of the sample was interested in taking PrEP. Only two respondents were currently taking PrEP. The majority (89%) thought taking PrEP every day would be easy. In the presence of other variables, PrEP interest was associated with PrEP eligibility (adjusted odds ratio aOR = 2.46; 95% Confidence Interval CI:1.34,4.50) and the number of medical diagnoses (aOR = 1.16; 95% CI:1.01,1.33) Conclusions Most PWID were unaware of PrEP but interested in taking it. PWID who were eligible for PrEP are more likely to be interested in taking it. Having co-morbid conditions was an important correlate of PrEP interest. These results underscore the importance of providers across the healthcare sector engaging PWID in discussions about PrEP. Article	2019	Shieh E.; Marzinke M.A.; Fuchs E.J.; Hamlin A.; Bakshi R.; Aung W.; Breakey J.; Poteat T.; Brown T.; Bumpus N.N.; Hendrix C.W.	Transgender women on oral HIV pre-exposure prophylaxis have significantly lower tenofovir and emtricitabine concentrations when also taking oestrogen when compared to cisgender men	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25405	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074696904&doi=10.1002%2fjia2.25405&partnerID=40&md5=6ac970eb6426fcf6a0899f9d6d61410	Introduction: Oral HIV Pre-Exposure Prophylaxis (PrEP) with tenofovir (TFV) disoproxil fumarate (TDF)/emtricitabine (FTC) is highly effective. Transgender women (TGW) have increased HIV risk, but have been underrepresented in trials. For TGW on oestrogens for gender-affirming hormone treatment (GAHT), TDF/FTC-oestrogen interactions may negatively affect HIV prevention or gender-affirming goals. Our aim was to evaluate any pharmacokinetic drug-drug interaction between GAHT and TDF/FTC. Methods: We performed a pharmacokinetic study, in an urban outpatient setting in 2016 to 2018, of the effects of GAHT on TFV, FTC and the active forms TFV diphosphate (TFV-DP) and FTC triphosphate (FTC-TP) in eight TGW and eight cisgender men (CGM). At screening, participants were HIV negative. TGW were to maintain their GAHT regimens and have plasma oestradiol concentrations >100 pg/mL. Under direct observation, participants took oral TDF/FTC daily for seven days. At the last dose, blood was collected pre-dose, one, two, four, six, eight and twenty-four hours, and colon biopsies were collected at 24 hours to measure drug concentration. TGW versus CGM concentration comparisons used non-parametric tests. Blood and colon tissue were also obtained to assess kinase expression. Results: Plasma TFV and FTC C24 (trough) concentrations in TGW were lower by 32% (p = 0.010) and 32% (p = 0.038) respectively, when compared to CGM. Plasma TFV and FTC 24-hr area under the concentration-time curve in TGW trended toward and was significantly lower by 27% (p = 0.065) and 24% (p = 0.028) respectively. Peak plasma TFV and FTC concentrations, as well as all other pharmacokinetic measures, were not statistically significant when comparing TGW to CGM. Oestradiol concentrations were not different comparing before and after TDF/FTC dosing. Plasma oestrogen concentration, renal function (estimated creatinine clearance and glomerular filtration rate), and TFV and FTC plasma concentrations (trough and area under the concentration-time curve) were all correlated. Conclusions: GAHT modestly reduces both TFV and FTC plasma concentrations. In TGW taking GAHT, it is unknown if this reduction will impact the HIV protective efficacy of a daily PrEP regimen. However, the combination of an on demand (2 + 1 + 1) PrEP regimen and GAHT may result in concentrations too low for reliable prevention of HIV infection. © 2019 The Authors. Article	2019	Shover C.L.; Shoptaw S.; Javanbakht M.; Lee S.-J.; Bolan R.K.; Cunningham N.J.; Beymer M.R.; DeVost M.A.; Gorbach P.M.	Mind the gaps: prescription coverage and HIV incidence among patients receiving pre-exposure prophylaxis from a large federally qualified health center in Los Angeles, California: Mind the Gaps: Cobertura de recetas e incidencia de VIH entre pacientes recibiendo profilaxis pre-exposición de un centro de salud grande y federalmente calificado en Los Ángeles, CA	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02493-w	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064339833&doi=10.1007%2fs10461-019-02493-w&partnerID=40&md5=a6b790997ede058dec36c1fd8e8c49bb	We conducted a records-based cohort study of patients who initiated pre-exposure prophylaxis (PrEP) at a large federally qualified health center in Los Angeles, CA to characterize patterns of PrEP use, identify correlates of PrEP discontinuation, and calculate HIV incidence. Of 3121 individuals initiating PrEP between 2014 and 2017, 42% (n = 1314) were active (i.e., had a current PrEP prescription) in April 2018. HIV incidence was 0.1/100 person-years among active PrEP patients, compared to 2.1/100 person-years among patients who discontinued. Compared to patients accessing PrEP through government programs with no prescription copay, risk of discontinuation was higher among those with private insurance (ARR = 1.4, 95% CI 1.2, 1.7), or no insurance (ARR = 4.5, 95% CI 3.2, 6.4). Sixty-three percent of active PrEP patients had gaps between PrEP prescriptions, averaging one gap per year (median length = 65 days). Increasing access to free or low-cost PrEP can improve PrEP continuity. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Shrestha R.; Altice F.L.; Sibilio B.; Ssenyonjo J.; Copenhaver M.M.	Rationale and design of an integrated bio-behavioral approach to improve adherence to pre-exposure prophylaxis and HIV risk reduction among opioid-dependent people who use drugs: The CHRP-BB study	Contemporary Clinical Trials	-	-	-	-	15517144	10.1016/j.cct.2019.06.012	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067699045&doi=10.1016%2fj.cct.2019.06.012&partnerID=40&md5=ffee8d7afda5529e3d2fc39af30ffc75	Background: Few primary HIV prevention strategies have successfully integrated both behavioral and biomedical components, with modest HIV risk reduction outcomes among opioid-dependent people who use drugs (PWUD). In response to this unmet need, we developed a brief, bio-behavioral intervention to simultaneously promote PrEP adherence and reduce HIV risk among opioid-dependent PWUD. Methods: Using a Hybrid Type I implementation science design, we will examine the efficacy of the integrated bio-behavioral, Community-friendly Health Recovery Program (CHRP-BB) compared to a time-and-attention matched control condition among HIV-negative, opioid-dependent PWUD who are prescribed PrEP and enrolled in a methadone maintenance program (MMP) using a randomized controlled trial (RCT). Participants are assessed at baseline, immediately post-intervention (8 weeks) and follow-ups at weeks 20, 32, and 44 post-intervention. The primary outcome is biomedical (PrEP adherence), with secondary outcomes including behavioral (self-reported drug- and sex-related HIV risk behaviors), ongoing drug use (confirmed with urine drug testing), and related domains of the theoretical information-motivation-behavioral skills (IMB) model of behavior change related to PrEP adherence and HIV-transmission-risk reduction. Additionally, we will conduct a process evaluation of delivery/implementation of the intervention to collect valuable information to be used in future implementation. Conclusions: This study will be among the first prospective trial to test an integrated bio-behavioral intervention to improve adherence to PrEP and HIV risk reduction among opioid-dependent PWUD. © 2019 Elsevier Inc. Article	2019	Siegel K.; Meunier É.	Awareness and Perceived Effectiveness of HIV Treatment as Prevention Among Men Who Have Sex with Men in New York City	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02405-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061031493&doi=10.1007%2fs10461-019-02405-y&partnerID=40&md5=6d71011fa4a7bb0cc764004ea431a1be	To assess perceptions of HIV treatment as prevention (TasP), we conducted an online survey of MSM in New York City (n = 732) asking them to rate the effectiveness of different strategies to reduce HIV risk during serodiscordant condomless anal sex between men. Only 6.1% reported not knowing what TasP was, with significantly less awareness among non-gay-identified MSM, men with less education, men who reported fewer anal sex partners in the prior 3 months, and HIV-negative/unaware men who had never used PrEP. The strategy most frequently perceived to offer "a lot" or "complete" protection from HIV was daily PrEP (70.0%), followed by TasP (39.1%), intermittent PrEP (16.6%), strategic positioning (15.8%), and withdrawal before ejaculation (10.8%). Men who were HIV positive, who had ever used PrEP, and who identified as gay/homosexual were significantly more likely to see TasP as effective. Further studies should investigate MSM's apparent skepticism towards TasP. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Siegler A.J.; Bratcher A.; Weiss K.M.	Geographic access to preexposure prophylaxis clinics among men who have sex with men in the United States	American Journal of Public Health	-	-	-	-	900036	10.2105/AJPH.2019.305172	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070597124&doi=10.2105%2fAJPH.2019.305172&partnerID=40&md5=9aed64ff9e703cca02bea352c4a6971c	Objectives. To explore US geographic areas with limited access to HIV preexposure prophylaxis (PrEP) providers, PrEP deserts. Methods. We sourced publicly listed PrEP providers from a national database of PrEP providers from 2017 and obtained county-level urbanicity classification and population estimates of men who have sex with men (MSM) from public data. We calculated travel time from census tract to the nearest provider. We classified a census tract as a PrEP desert if 1-way driving time was greater than 30 or 60 minutes. Results. One in 8 PrEP-eligible MSM (108 758/844 574; 13%) lived in 30-minute-drive deserts, and a sizable minority lived in 60-minute-drive deserts (38 804/844 574; 5%). Location in the South and lower urbanicity were strongly associated with increased odds of PrEP desert status. Conclusions. A substantial number of persons at high risk for HIV transmission live in locations with no nearby PrEP provider. Rural and Southern areas are disproportionately affected. Public Health Implications. For maximum implementation effectiveness of PrEP, geography should not determine access. Programs to train clinicians, expand venues for PrEP care, and provide telemedicine services are needed. © 2019 American Public Health Association Inc.. All rights reserved. Article	2019	Siegler A.J.; Brock J.B.; Hurt C.B.; Ahlschlager L.; Dominguez K.; Kelley C.F.; Jenness S.M.; Wilde G.; Jameson S.B.; Bailey-Herring G.; Mena L.A.	An electronic pre-exposure prophylaxis initiation and maintenance home care system for nonurban young men who have sex with men: Protocol for a randomized controlled trial	JMIR Research Protocols	-	-	-	-	19290748	10.2196/13982	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070622003&doi=10.2196%2f13982&partnerID=40&md5=28d0e27feae2c34d04470660c59041a8	Background: Pre-exposure prophylaxis (PrEP) is highly efficacious for preventing HIV but has not yet been brought to scale among at-risk persons. In several clinical trials in urban areas, technology-based interventions have shown a positive impact on PrEP adherence. In rural and small-town areas in the United States, which often do not have geographically proximal access to PrEP providers, additional support may be needed. This may be particularly true for younger persons who are more likely to face multiple barriers to accessing PrEP services. Home-based care, accomplished through a tailored mobile phone app, specimen self-collection (SSC), and interactive video consultations, could increase both PrEP initiation and persistence in care. Objective: The goal of this study is to assess the initiation and persistence in PrEP care for those randomized to a home-care intervention (electronic PrEP, ePrEP) relative to those assigned to the standard of care (control) condition. We will conduct additional assessments, including quantitative and qualitative analyses, to contextualize trial results and facilitate scale-up. Methods: This 2-arm, randomized controlled trial will enroll young men who have sex with men (YMSM) aged between 18 and 24 years from rural areas of Georgia, Mississippi, and North Carolina. The trial will seek to recruit a diverse sample, targeting 50% participation among highly impacted groups of black or Latino men who have sex with men. Intervention participants will receive a study app that incorporates a messaging platform, a scheduling and milestone-based tracking system for PrEP care progress, electronic behavioral surveys, and interactive video consultations with a clinician. Complemented by SSC kits mailed to laboratories for standard PrEP-related monitoring, the ePrEP system will allow participants to access PrEP care without leaving their homes. YMSM randomized to the control condition will receive a listing of nearest local PrEP providers to receive standard PrEP care. Both groups will complete quarterly electronic surveys. The primary outcome, assessed at 6 and 12 months after randomization, will be the difference in the proportion of intervention versus control participants that achieve protective levels of the active metabolite of oral PrEP (tenofovir diphosphate in dried blood spots). Results: Enrollment will begin in May 2019, with study completion in 2022. Conclusions: This trial will determine whether home PrEP care provided through an app-based platform is an efficacious means of expanding access to PrEP care for a diverse group of YMSM in rural and small-town areas of the United States. © Aaron J Siegler, James B Brock, Christopher B Hurt, Lauren Ahlschlager, Karen Dominguez, Colleen F Kelley, Samuel M Jenness, Gretchen Wilde, Samuel B Jameson, Gina Bailey-Herring, Leandro A Mena. Article	2019	Siguier M.; Mera R.; Pialoux G.; Ohayon M.; Cotte L.; Valin N.; Ghosn J.; Cua E.; Pintado C.; Chas J.; Barriere G.; Durand F.; Molina J.M.	First year of pre-exposure prophylaxis implementation in France with daily or on-demand tenofovir disoproxil fumarate/emtricitabine	Journal of Antimicrobial Chemotherapy	-	-	-	-	3057453	10.1093/jac/dkz220	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072056543&doi=10.1093%2fjac%2fdkz220&partnerID=40&md5=f2af17a554ddf0f53ff5352985732c2d	Background: In January 2016, the French Medicine Agency initiated a Temporary Recommendation for Use (TRU) to allow the use of oral intake of tenofovir disoproxil fumarate and emtricitabine for pre-exposure prophylaxis (PrEP) in adults at high risk of HIV. We report the results of the first year of PrEP implementation in France. Methods: Data were collected by physicians using a secured web subject-monitoring interface, with two forms: an initiation form, with patients' baseline characteristics, and an HIV seroconversion form. Univariate and adjusted multivariate analysis using a logistic regression model were performed to identify baseline factors associated with on-demand PrEP regimen prescription. Results: From 4 January 2016 to 28 February 2017, 3405 subjects were enrolled, with 2774 initiation forms completed; 98.1% were male and 96.9% were MSM. An on-demand regimen was prescribed to 57% of subjects. Older age (OR for participants older than 50 years=1.76, 95% CI 1.35-2.3, P<0.001) and site of prescription (OR of former IPERGAY sites=2.28, 95% CI 1.84-2.83, P<0.001) were associated with on-demand prescription. Those reporting sexually transmitted infection (STI) and condomless anal sex with at least two different partners were less likely to receive on-demand PrEP (OR=0.68, 95% CI 0.57-0.82 and 0.75, 95% CI 0.57-0.98, respectively; P<0.05 for all). Four breakthrough HIV infections were reported during the study, in the context of PrEP interruption or acute infection at the time of PrEP initiation. Conclusions: In a real-life setting in France, PrEP was used, either daily or on-demand, mostly by MSM, with breakthrough infections being rare. © 2019 The Author(s) 2019. Article	2019	Singh, Kamal; Sarafianos, Stefan G; Sönnerborg, Anders	Long-Acting Anti-HIV Drugs Targeting HIV-1 Reverse Transcriptase and Integrase.	Pharmaceuticals	-	-	-	-	1424-8247	10.3390/ph12020062	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6631967	One of the major factors contributing to HIV-1 drug resistance is suboptimal adherence to combination antiretroviral therapy (cART). Currently, recommended cART for HIV-1 treatment is a three-drug combination, whereas the pre-exposure prophylaxis (PrEP) regimens consist of one or two antivirals. Treatment regimens require adherence to a once or twice (in a subset of patients) daily dose. Long-acting formulations such as injections administered monthly could improve adherence and convenience, and thereby have potential to enhance the chances of expected outcomes, although long-lasting drug concentrations can also contribute to clinical issues like adverse events and development of drug resistance. Globally, two long-acting antivirals have been approved, and fifteen are in clinical trials. More than half of investigational long-acting antivirals target HIV-1 reverse transcriptase (HIV-1 RT) and/or integrase (HIV-1 IN). Here, we discuss the status and potential of long-acting inhibitors, including rilpivirine (RPV), dapivirine (DPV), and 4-ethynyl-2-fluoro-2-deoxyadenosine (EFdA; also known as MK-8591), which target RT, and cabotegravir (CAB), which targets IN. The outcomes of various clinical trials appear quite satisfactory, and the future of long-acting HIV-1 regimens appears bright. Article	2019	Skovdal, M	Facilitating engagement with PrEP and other HIV prevention technologies through practice-based combination prevention	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1002/jia2.25294	https://pubmed.ncbi.nlm.nih.gov/31328412/	Introduction: Recent years have witnessed a rapid expansion of efficacious biomedical HIV prevention technologies. Promising as they may be, they are largely delivered through standard, clinic-based models, often in isolation from structural and behavioural interventions. This contributes to varied, and often poor, uptake and adherence. There is a critical need to develop analytical tools that can advance our understandings and responses to the combination of interventions that affect engagement with HIV prevention technologies. This commentary makes a call for practice-based combination HIV prevention analysis and action, and presents a tool to facilitate this challenging but crucial endeavour. Discussion: Models and frameworks for combination HIV prevention already exist, but the process of identifying precisely what multi-level factors that need to be considered as part of a combination of HIV interventions for particular populations and settings is unclear. Drawing on contemporary social practice theory, this paper develops a "table of questioning" to help interrogate the chain and combination of multi-level factors that shape engagement with HIV prevention technologies. The tool also supports an examination of other shared social practices, which at different levels, and in different ways, affect engagement with HIV prevention technologies. It facilitates an analysis of the range of factors and social practices that need to be synchronized in order to establish engagement with HIV prevention technologies as a possible and desirable thing to do. Such analysis can help uncover local hitherto un-identified issues and provide a platform for novel synergistic approaches for action that are not otherwise obvious. The tool is discussed in relation to PrEP among adolescent girls and young women in sub-Saharan Africa. Conclusions: By treating engagement with HIV prevention technologies as a social practice and site of analysis and public health action, HIV prevention service planners and evaluators can identify and respond to the combination of factors and social practices that interact to form the context that supports or prohibits engagement with HIV prevention technologies for particular populations. Article	2019	Smith D.K.; Chang M.-H.; Duffus W.A.; Okoye S.; Weissman S.	Missed opportunities to prescribe preexposure prophylaxis in South Carolina, 2013-2016	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciy441	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85059262786&doi=10.1093%2fcid%2fciy441&partnerID=40&md5=d0588dd930e2d39dfcdf6191f3f95527	Background. Expanding use of preexposure prophylaxis (PrEP) in ways that address current racial/ethnic disparities is an important human immunodeficiency virus (HIV) prevention goal. We investigated missed opportunities to provide PrEP during healthcare visits that occur prior to HIV infection. Methods. This retrospective cohort study linked South Carolina HIV case surveillance data to 3 statewide healthcare databases. Characteristics of patients, healthcare visits and providers, sexually transmitted diseases (STDs), and other diagnoses were assessed for medical encounters occurring before an initial HIV diagnosis. Adjusted odds ratios were used to identify correlates of missed opportunities for PrEP provision. Results. Of 885 persons newly diagnosed during the study period, 586 (66%) had 4029 visits to a healthcare facility prior to their HIV diagnosis (mean of 6.9 visits) with missed opportunities for provision of PrEP. Emergency medicine-trained clinicians conducted (61%) and primary care clinicians (family practice or internal medicine) conducted 10% of visits. Also, 42% of visits were by persons who were uninsured or self-paid, 36% had public insurance, and 18% had commercial insurance. In multivariable analyses, being female, black, or aged <30 years were statistically significant predictors of having prior healthcare visits. Among persons with at least 1 healthcare visit prior to their HIV diagnosis, 28.5% had a diagnosis of gonorrhea, syphilis, or chlamydia at any visit. Conclusions. Healthcare visits occurring among persons who would benefit from provision of PrEP, especially persons with diagnosed STDs, should be leveraged to increase use of PrEP and reduce the risk of HIV acquisition. © 2018 The Author(s). Article	2019	Soares F.; MacCarthy S.; Magno L.; da Silva L.A.V.; Amorim L.; Nunn A.; Oldenburg C.E.; Dourado I.	Factors Associated with PrEP Refusal Among Transgender Women in Northeastern Brazil	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02501-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073183096&doi=10.1007%2fs10461-019-02501-z&partnerID=40&md5=76cd581f760635e57f063178b13be6f4	Brazil has recently integrated HIV Pre-exposure Prophylaxis (PrEP) into its public health system and offered to key populations such as transgender women (TGW). This study investigates factors associated with PrEP refusal among TGW living in one of the largest and poorest cities of Brazil. We recruited 127 TGW using Respondent Driven Sampling (RDS) in Salvador, Brazil. Latent class analysis (LCA) was used to define acceptability of PrEP. Two latent classes were identified: "high acceptability of PrEP" (91.3%) and "PrEP refusal" (8.7%). PrEP was less acceptable among white TGW and among those age 25 or older, with income above minimum wage (≥ US$252.87), and reporting unprotected receptive anal intercourse with (URAI) causal partners. The findings highlight how nuanced strategies that takes into consideration unique characteristics are needed to effectively address the acceptability of PrEP. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Sophus A.I.; Mitchell J.W.	A Review of Approaches Used to Increase Awareness of Pre-exposure Prophylaxis (PrEP) in the United States	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2305-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85055349921&doi=10.1007%2fs10461-018-2305-0&partnerID=40&md5=42400099387912fa6d256f5d082b9fe4	PrEP is an important and useful HIV prevention strategy, yet awareness remains low among at-risk populations in the United States and elsewhere in the world. As previous studies have shown PrEP awareness to be important to PrEP uptake, understanding approaches to increase PrEP awareness is imperative. The current systematic review provides an overview of published articles and on-going research on PrEP awareness. Using PRISMA guidelines, two published articles and seven on-going research studies were identified that use different approaches to increase PrEP awareness. Findings highlight the need for research to target other at-risk populations and geographic areas. Future research should consider the use of technology and network approaches to assess whether they lead to increased awareness, accurate knowledge, and uptake of PrEP, along with examining which messaging works best for specific targeted, at-risk population(s). © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Spinelli M.A.; Glidden D.V.; Anderson P.L.; Gandhi M.; Cohen S.; Vittinghoff E.; Coleman M.E.; Scott H.; Bacon O.; Elion R.; Kolber M.A.; Buchbinder S.P.; Liu A.Y.	Short-Term Adherence Marker to PrEP Predicts Future Nonretention in a Large PrEP Demo Project: Implications for Point-of-Care Adherence Testing	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000002005	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066867564&doi=10.1097%2fQAI.0000000000002005&partnerID=40&md5=7637a551ddda0873305f3c38e98ab2b7	Background:Objective adherence metrics for tenofovir (TFV) disoproxil fumarate/emtricitabine (FTC)-based pre-exposure prophylaxis (PrEP) were critical for interpretation of efficacy in PrEP clinical trials, and there is increasing interest in using drug levels to tailor interventions for reengagement and adherence. Point-of-care immunoassays for TFV, which examine short-term adherence, are in development. However, the ability of poor short-term and long-term adherence to predict future PrEP nonretention is unknown.Setting:Secondary data analysis of a large, prospective multi-site U.S. PrEP demonstration project.Methods:An adjusted Cox-proportional hazards model examined the relationship of dried blood spot (DBS) levels of FTC-triphosphate (FTC-TP) or TFV-diphosphate (TFV-DP), measures of short-term and long-term PrEP adherence, respectively, with future study nonretention.Results:Overall, 294 individuals (median age 33 years) contributed drug levels within the U.S. PrEP demonstration project. By the end of study, 27% were lost to follow-up, 25% had at least one undetectable FTC-TP level indicating poor short-term adherence, and 29% had a drug level indicating suboptimal long-term adherence (TFV-DP <700 fmol/punch). The strongest factor associated with future study nonretention using a binary drug-level cut-off was an undetectable DBS FTC-TP level (adjusted hazard ratio 6.3; 95% confidence interval 3.8 to 10.2). The suboptimal long-term adherence based on low DBS TFV-DP levels was also associated with nonretention (adjusted hazard ratio 4.3; 95% confidence interval: 2.4 to 7.6).Conclusions:Both short- and long-term metrics of PrEP adherence are strongly associated with future loss to follow-up in a U.S. demonstration project study. Short-term metrics of adherence, once available at the point-of-care, could be used to direct real-time tailored retention and adherence interventions. © 2019 Wolters Kluwer Health, Inc. Article	2019	Spinelli M.A.; Glidden D.V.; Anderson P.L.; Gandhi M.; Mcmahan V.M.; Defechereux P.; Schechter M.; Veloso V.G.; Chariyalertsak S.; Guanira J.V.; Bekker L.-G.; Buchbinder S.P.; Grant R.M.	Impact of Estimated Pre-Exposure Prophylaxis (PrEP) Adherence Patterns on Bone Mineral Density in a Large PrEP Demonstration Project	AIDS Research and Human Retroviruses	-	-	-	-	8892229	10.1089/aid.2018.0297	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071997499&doi=10.1089%2faid.2018.0297&partnerID=40&md5=6a236d3cc637b3f3660795d02fa8cc03	Bone mineral density (BMD) declines due to tenofovir-containing pre-exposure prophylaxis (PrEP) have varied among PrEP demonstration projects, potentially related to variable adherence. Characterization of BMD changes in highly adherent individuals, estimated via tenofovir-diphosphate (TFV-DP) levels in dried blood spots (DBS), can assist clinicians when counseling patients. Cisgender men who have sex with men and transwomen in the optional dual-energy X-ray absorptiometry (DXA) substudy of a large, international, open-label PrEP demonstration project, the iPrEx-open-label extension (OLE) study underwent DXA scans and DBS collection every 24 weeks, with average weekly dosing adherence patterns (2, 4, and 7 doses/week) estimated from validated TFV-DP cut-offs. The mean percent BMD change was estimated in strata of average weekly adherence by using a linear mixed-effects model to calculate the BMD decline in highly adherent individuals on PrEP for the first time. DXA/DBS data were available for 254 individuals over a median of 24 weeks in iPrEx-OLE from June 2011 to December 2013. The percent decline in spine BMD was monotonically associated with strata of increasing average weekly adherence (p < .001 trend); the p value for trends using hip BMD measurements was .07. Individuals with estimated daily adherence experienced a 1.2% decrease in spine BMD and a 0.5% drop in hip BMD. In highly adherent PrEP users, we found a lower-than-expected drop in BMD when compared with previous studies. This drop is likely not clinically significant for most PrEP users. However, for those at the highest risk of fracture who plan prolonged PrEP use, alternate PrEP strategies could be considered. © 2019, Mary Ann Liebert, Inc., publishers 2019.	adherence; bone mineral density; cohort studies; men who have sex with men; PrEP; transgender people	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	Spinelli M.A.; Glidden D.V.; Rodrigues W.C.; Wang G.; Vincent M.; Okochi H.; Kuncze K.; Mehrotra M.; Defechereux P.; Buchbinder S.P.; Grant R.M.; Gandhi M.	Low tenofovir level in urine by a novel immunoassay is associated with seroconversion in a preexposure prophylaxis demonstration project	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002135	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063288764&doi=10.1097%2fQAD.0000000000002135&partnerID=40&md5=539d5321925ae48d1e96773a60b1a03e	Objective:We examined the relationship between urine tenofovir (TFV) levels measured with a novel immunoassay, which permits point-of-care testing, with HIV seroconversion and objective adherence metrics in a large preexposure prophylaxis (PrEP) demonstration project.Design:Secondary analysis of stored specimens from an open-label PrEP cohort study.Methods:We examined the association between undetectable urine TFV levels and HIV seroconversion in iPrEx open-label extension using generalized estimating equations. We examined rank correlations between levels of TFV and emtricitabine in urine, dried blood spots (DBS), and hair and determined the sensitivity and specificity of undetectable urine TFV for predicting dosing cut-offs in DBS.Results:The median urinary TFV level was 15 000 ng/ml in those who remained HIV-negative (n = 105; interquartile range: 1000-45 000); 5500 in those who eventually seroconverted (n = 11; interquartile range: 1000-12 500); and all were undetectable at seroconversion (n = 9; P < 0.001). Decreasing strata of urine TFV levels were associated with future HIV seroconversion (P = 0.03). An undetectable urine TFV was 100% sensitive and 81% specific when compared with an undetectable DBS TFV-diphosphate level and 69% sensitive, but 94% specific when compared with low adherence by DBS (<2 doses/week).Conclusion:Urine TFV detection by a novel antibody-based assay was associated with protection from HIV acquisition among individuals on PrEP. Urine TFV levels were correlated with hair and DBS levels and undetectable urine TFV was 100% sensitive in detecting nonadherence. By implementing the immunoassay into a point-of-care strip test, PrEP nonadherence could be detected in real-time, allowing rapid intervention. © 2019 Wolters Kluwer Health, Inc. Article	2019	Spinelli, MA; Scott, HM; Vittinghoff, E; Liu, AY; Gonzalez, R; Morehead-Gee, A; Gandhi, M; Buchbinder, SP	Missed Visits Associated With Future Preexposure Prophylaxis (PrEP) Discontinuation Among PrEP Users in a Municipal Primary Care Health Network	Open Forum Infectious Diseases	-	-	-	-	2328-8957	10.1093/ofid/ofz101	https://academic.oup.com/ofid/article/6/4/ofz101/5365426	Background. Maintaining retention in preexposure prophylaxis (PrEP) care among diverse patient populations will be needed to support PrEP's efficacy. We characterized patterns of PrEP care retention in a US municipal primary care health network and examined whether missed visits, a metric of care retention that is easy to evaluate in clinic, are associated with subsequent discontinuation. Methods. We included individuals on PrEP from July 2012 until August 2017 in the San Francisco Primary Care Clinics, a 15-clinic municipal health network. We categorized PrEP usage patterns as follows: early discontinuation (<90 days), later discontinuation (after >= 90 days), and continuing use at the end of follow-up. We first examined early discontinuation using adjusted Poisson regression. In patients who continued PrEP for >= 90 days, we examined factors associated with late discontinuation. Results. Of the 364 individuals who started PrEP, 16% discontinued PrEP before 90 days, 46% discontinued later, and 38% were retained in care over a median 12 months of observation. Transgender women were more likely to discontinue PrEP early (adjusted risk ratio, 2.16; 95% confidence interval, 1.36-3.49), and younger users were more likely to discontinue late (0.82 per 10-year increase in age;.70-. 96), as were persons who use illicit drugs (1.59; 1.02-2.47). Missed visits during use of PrEP were associated with future discontinuation (adjusted risk ratio, 1.52; 95% confidence interval, 1.14-2.03). Later year of current PrEP use was associated with both early and late discontinuation. Conclusion. Diverse populations may require differentiated care to continue PrEP. Missed visits should trigger tailored interventions to maximize the impact of PrEP. Summary of German-Austrian HIV PrEP guideline	HIV Medicine	-	-	-	-	14642662	10.1111/hiv.12724	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066469122&doi=10.1111%2fhiv.12724&partnerID=40&md5=4d9391899c5c55f7a55cf5c05fd9d10b	Objectives: HIV Pre-Exposure prophylaxis (PrEP) is a strategy to reduce HIV transmission in people at risk. Aim of this first German-Austrian PrEP guideline is to provide professional guidance on: when and in whom to use PrEP, recommended laboratory tests before and while on PrEP, selection of drugs, prevention of adverse events as a consequence of missing accompanying medical care, and general handling of PrEP in adults and adolescents. Methods: Commented summary of of the S2k PrEP consensus guidelines released by the German and Austrian HIV medical societies to highlight the key recommendations of the guidelines. Content: Detailed information about effectiveness of PrEP, when and in whom to use PrEP, as well as about additional monitoring of HIV PrEP are included in the HIV PrEP guidelines. Therewith detailed guidance for people being involved in PrEP counseling and associated care is provided. © 2019 British HIV Association	German-Austrian guideline; HIV; pre-exposure prophylaxis; PrEP	English	United Kingdom	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Germany	Western and Central Europe and North America	Other
Article	2019	Stankevitz, Kayla; Schwartz, Katie; Hoke, Theresa; Li, Yixuan; Lanham, Michele; Mahaka, Imelda; Mullick, Saiqa	Reaching at-risk women for PrEP delivery: What can we learn from clinical trials in sub-Saharan Africa?	PLOS One	-	-	-	-	31226165	10.1371/journal.pone.0218556	https://www.proquest.com/scholarly-journals/reaching-at-risk-women-prep-delivery-what-can-we/docview/2244644823/se-2?accountid=8113	Introduction ARV-based pre-exposure prophylaxis (PrEP) has the potential to avert many new HIV infections, yet little is known about how to reach women at high risk for HIV infection and motivate them to initiate PrEP. Clinical trials have succeeded in recruiting at-risk participants, evidenced by control arm HIV incidence ≥3% (defined by the World Health Organization as "substantial risk"). We examined experiences from HIV prevention trials to document recruitment strategies and identify practical, potentially effective strategies for reaching women in real-world PrEP delivery. Methods We conducted semi-structured qualitative phone interviews with 31 staff from five countries who had worked on one or more of seven ARV-based HIV prevention clinical trials. Questions explored recruitment strategies used to reach women at risk of HIV and to successfully communicate about PrEP (inclusive of oral and vaginal formulations). We structurally coded data in NVivo and analyzed codes to derive themes. We conducted results interpretation webinars with research and programmatic stakeholders to validate findings and develop recommendations. Results Clinical trial researchers employed a range of recruitment strategies to reach at-risk women. They recommended engaging the local community and potential PrEP users via community events, meetings with gatekeepers, and use of community advisory boards; and they encouraged interpersonal communication like presentations in waiting rooms and door-to-door recruitment to address personal concerns and prevent misinformation. Participants also stressed the importance of addressing the challenges that already exist within the health system to create a more enabling environment and delivering positive messages through a variety of communication channels to normalize PrEP. Conclusions Findings from this study provide important insights into potentially effective ways for countries currently rolling out oral PrEP to reach at-risk women with information about PrEP and promote uptake. Theses and Dissertations	2019	Stansfield, Sarah	The Impacts of Sexual Role, HIV Treatment, and Pre-Exposure Prophylaxis Use on HIV Set Point Viral Load: A Network Modeling Study	-	-	University of Washington	University of Washington	-	-	NA	https://digital.lib.washington.edu/researchworks/bitstream/handle/1773/45102/Stansfield_washington_0250E_20931.pdf?sequence=1&isAllowed=y	The analyses in this dissertation investigate how sexual role, treatment increases, and pre-exposure prophylaxis (PrEP) increases impact HIV virulence. All analyses used set point viral load (SPVL), the viral load (VL) found shortly after the period of acute HIV infection, as a proxy for virulence. This is a good proxy because higher SPVLs are associated with faster progression to AIDS and higher probability of transmission. The aims of this dissertation were: 1) to understand the effects of different sexual roles in MSM (exclusively insertive, exclusively receptive, or versatile) on the virulence of the viruses men acquired; 2) to understand the effects of increasing treatment on HIV virulence evolution; and 3) to understand the effects of increasing PrEP on HIV virulence evolution. All chapters used a stochastic, dynamic network model (EvoNetHIV) to partially or fully complete their analyses. EvoNetHIV is based in temporal exponential random graph models (ERGMs) and uses the statnet suite of R packages and the EpiModel package API. The findings in these studies help to overturn the previously modeled trade-offs in which higher treatment or PrEP coverage resulted in higher HIV virulence. Instead, increasing treatment or PrEP coverage can lead to lower virulence levels becoming evolutionarily advantageous, allowing their influences to positively affect the entire population. They also show that, because different sexual roles are associated with different HIV acquisition probabilities, there are significant differences in the virulence of the viruses men with different sexual roles acquire. These studies also show how virulence evolves differently when contrasting pressures are present: infected individuals going on treatment creates a different evolutionary environment than do susceptible individuals going on PrEP. Finally, these studies emphasize the impacts of model assumptions on all outputs. Careful consideration of and transparency about model assumptions are important for realistic and replicable models. Article	2019	Starks T.J.; Doyle K.M.; Shalhav O.; John S.A.; Parsons J.T.	An Examination of Gay Couples' Motivations to Use (or Forego) Pre-exposure Prophylaxis Expressed During Couples HIV Testing and Counseling (CHTC) Sessions	Prevention Science	-	-	-	-	13894986	10.1007/s11121-018-0892-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85045274609&doi=10.1007%2fs11121-018-0892-7&partnerID=40&md5=7ec3f53db6bf1afe41d26e09c24d425f	While many gay couples perceive themselves to have little risk for HIV transmission, research estimates that 35–68% of new HIV infections are transmitted within main partnerships. Pre-exposure prophylaxis (PrEP) is recommended for those partnered gay and bisexual men (GBM) who engage in sex outside their primary relationship or who have an HIV-positive partner. There is reason to believe that couples' sero-status and sexual agreement will shape perceptions of PrEP's personal relevance among gay couples. The current study examined motivations for and ambivalence towards PrEP uptake reported in a sample of 67 gay couples during completion of a brief CDC-recommended prevention intervention: Couples HIV Testing and Counseling. Findings suggest that all types of couples identified some circumstances in which they would consider PrEP; however, PrEP messaging should be crafted to avoid undermining current prevention strategies or threatening the trust and legitimacy of the relationship. © 2018, Society for Prevention Research. Article	2019	Starks T.J.; Robles G.; Pawson M.; Jimenez R.H.; Gandhi M.; Parsons J.T.; Millar B.M.	Motivational interviewing to reduce drug use and hiv incidence among young men who have sex with men in relationships and are high priority for pre-exposure prophylaxis (Project PARTNER): Randomized controlled trial protocol	JMIR Research Protocols	-	-	-	-	19290748	10.2196/13015	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85084855910&doi=10.2196%2f13015&partnerID=40&md5=3670556d19936f2debd3643b5c46e82e	Background: Men who have sex with men (MSM) currently account for more than two-thirds of new HIV diagnoses in the United States and, among young MSM (YMSM) aged 20 to 29 years, as many as 79% to 84% of new infections occur between primary partners. Contributing to HIV risk, YMSM use drugs at comparatively high rates. To date, no interventions have been developed that specifically address the unique needs of partnered YMSM or incorporate a focus on relationship factors in addressing personal motivation for change. Objective: The study's primary aim is to evaluate the efficacy of the PARTNER intervention and evaluate potential moderators or mediators of intervention effects. The study's secondary aims were to gather ideographic data to inform a future effectiveness implementation study and develop a novel biomarker for pre-exposure prophylaxis (PrEP) adherence by analyzing PrEP drug levels in fingernails. Methods: PARTNER is a 4-session motivational interviewing–based intervention that integrates video-based communication training to address drug use and HIV prevention among partnered YMSM. This study utilizes a randomized controlled trial design to compare the PARTNER intervention with an attention-matched psychoeducation control arm that provides information about HIV-risk reduction, PrEP, and substance use. Participants are randomized in a 1-to-1 ratio stratified on age disparity between partners, racial composition of the couple, and relationship length. Follow-up assessments are conducted at 3-, 6-, 9-, and 12-months postbaseline. The study recruits and enrolls 240 partnered YMSM aged between 18 to 29 years at a research center in New York City. Participants will be HIV-negative and report recent (past 30-day) drug use and condomless anal sex with casual partners; a nonmonogamous primary partner (regardless of HIV status); or a serodiscordant primary partner (regardless of sexual agreement). Primary outcomes (drug use and HIV sexual transmission risk behavior) are assessed via a Timeline Follow-back interview. Biological markers of outcomes are collected for drug use (fingernail assay), sexual HIV transmission risk (rectal and urethral gonorrhea and chlamydia testing), and PrEP adherence (dried blood spots and fingernails for a novel PrEP drug level assay). Results: The study opened for enrollment in February 2018. Anticipated completion of enrollment is October 2021. Primary outcome analyses will begin after final follow-up completion. Conclusions: Existing research on partnered YMSM within the framework of Couples Interdependence Theory (CIT) has suggested that relationship factors (eg, dyadic functioning and sexual agreements) are meaningfully related to drug use and HIV transmission risk. Results pertaining to the efficacy of the proposed intervention and the identification of putative moderators and mediators will substantially inform the tailoring of interventions for YMSM in relationships and contribute to a growing body of relationship science focused on enhancing health outcomes. © Tyrel J Starks, Gabriel Robles, Mark Pawson, Ruben H Jimenez, Monica Gandhi, Jeffrey T Parsons, Brett M Millar. Article	2019	Stopard I.J.; McGillen J.B.; Hauck K.; Hallett T.B.	The influence of constraints on the efficient allocation of resources for HIV prevention	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002158	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85065528141&doi=10.1097%2fQAD.0000000000002158&partnerID=40&md5=d48909300d8d6641aad90177abef366	Objective:To investigate how 'real-world' constraints on the allocative and technical efficiency of HIV prevention programmes affect resource allocation and the number of infections averted.Design:Epidemiological modelling and economic analyses in Benin, South Africa and Tanzania.Methods:We simulated different HIV prevention programmes, and first determined the most efficient allocation of resources, in which the HIV prevention budget is shared among specific interventions, risk-groups and provinces to maximize the number of infections averted. We then identified the efficient allocation of resources and achievable impact given the following constraints to allocative efficiency: earmarking provinces with budgets fund pre-exposure prophylaxis (PrEP) for low-risk women first, meeting targets provinces with budgets fund universal test-and-treat (UTT) first and minimizing changes in the geographical distribution of funds. We modelled technical inefficiencies as a reduction in the coverage of PrEP or UTT, which were factored into the resource allocation process or took effect following the allocation. Each scenario was investigated over a range of budgets, such that the impact reaches its maximum.Results:The 'earmarking', 'meeting targets' and 'minimizing change' constraints reduce the potential impact of HIV prevention programmes, but at the higher budgets these constraints have little to no effect (approximately 35 billion US$ in Tanzania). Over-estimating technical efficiency can result in a loss of impact compared to what would be possible if technical efficiencies were known accurately.Conclusion:Failing to account for constraints on allocative and technical efficiency can result in the overestimation of the health gains possible, and for technical inefficiencies the allocation of an inefficient strategy. © 2019 Wolters Kluwer Health, Inc. Article	2019	StVil, Noelle M; Przybyla, Sarahmona; LaValley, Susan	Barriers and facilitators to initiating PrEP conversations: Perspectives and experiences of health care providers	Journal of HIV/AIDS & Social Services	-	-	-	-	15381501	10.1080/15381501.2019.1616027	https://www.proquest.com/scholarly-journals/barriers-facilitators-initiating-prep/docview/2239602461/se-2?accountid=8113	Using qualitative interviews, this study explored the barriers and facilitators of health care providers (HCPs) in initiating PrEP conversation with patients. Twenty-eight HCPs in two counties listed in the New York State Department of Health PrEP/PEP Voluntary Provider Directory were asked to participate in the study. Five themes evolved from the interview, each theme acting as both barriers and facilitators to initiating PrEP conversations: (a) providers comfort levels, (b) taking sexual histories, (c) time, (c) patients comfort levels discussing sexual health, and (d) HCPs' perceptions of patients' risk of sexually transmitted infection (STI) acquisition. These findings demonstrate the need for evidence-based interventions for initiation of PrEP conversations in health care settings. Article	2019	Sullivan P.S.; Mena L.; Elopre L.; Siegler A.J.	Implementation Strategies to Increase PrEP Uptake in the South	Current HIV/AIDS Reports	-	-	-	15483568	10.1007/s11904-019-00447-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85067309922&doi=10.1007%2fs11904-019-00447-4&partnerID=40&md5=dcc0da15a7fc4faf5ed82f6df0da74d4	Purpose of Review: Seven years after TDF/FTC was approved for pre-exposure prophylaxis to reduce risks of HIV infection, there have been large increases in the number of persons using PrEP in the USA. However, recent data on pre-exposure prophylaxis (PrEP) use at the state level indicate that people living in the Southern United States are underserved by PrEP relative to their epidemic need. We sought to review possible reasons for inequitable uptake of PrEP in the South and identify implementation approaches to increase PrEP uptake in the South. Recent Findings: Published literature, data on the locations of PrEP service providers, recent data on PrEP utilization from pharmacy prescription databases, HIV surveillance data and government data on healthcare providers, and health literacy indicate a confluence of factors in the South that are likely limiting PrEP uptake. A variety of approaches are needed to address the complex challenges to PrEP implementation in the South. These include considering alternative PrEP provision strategies (e.g., pharmacy-based PrEP, telemedicine-delivered PrEP), conducting gain-based stigma-reduction campaigns, increasing capacity for reimbursement for PrEP medications and services through policy change to expand Medicaid and to preserve access to Affordable Care Act–compliant health plans, expanding STI screening programs and improving integration of PrEP offering with delivery of positive STI results, using mHealth tools to screen groups at highest risk for HIV (e.g., men who have sex with men) periodically to increase correct perception of risk, and streamlining clinical procedures to allow same-day PrEP starts for patients without obvious medical contraindications. Summary: Overcoming the structural, capacity, and policy challenges to increasing PrEP uptake in the South will require innovations in clinical approaches, leveraging technologies, and policy changes. The South has unique challenges to achieving equitable PrEP uptake, and addressing key barriers to expanded PrEP use will require multisectoral responses. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Sullivan P.S.; Zahn R.J.; Wiatrek S.; Chandler C.J.; Hirshfield S.; Stephenson R.; Bauermeister J.A.; Chiasson M.A.; Downing M.J., Jr.; Gelaude D.J.; Siegler A.J.; Horvath K.; Rogers E.; Alas A.; Olansky E.J.; Saul H.; Rosenberg E.S.; Mansergh G.	HIV prevention via mobile messaging for men who have sex with men (M-cubed): Protocol for a randomized controlled trial	JMIR Research Protocols	-	-	-	19290748	10.2196/16439	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076193018&doi=10.2196%2f16439&partnerID=40&md5=e56600ff240358335c3315616df41265	Background: Men who have sex with men (MSM) continue to be the predominately impacted risk group in the United States HIV epidemic and are a priority group for risk reduction in national strategic goals for HIV prevention. Modeling studies have demonstrated that a comprehensive package of status-tailored HIV prevention and care interventions have the potential to substantially reduce new infections among MSM. However, uptake of basic prevention services, including HIV testing, sexually transmitted infection (STI) testing, condom distribution, condom-compatible lubricant distribution, and preexposure prophylaxis (PrEP), is suboptimal. Further, stronger public health strategies are needed to promote engagement in HIV care and viral load suppression among MSM living with HIV. Mobile health (mHealth) tools can help inform and encourage MSM regarding HIV prevention, care, and treatment, especially among men who lack access to conventional medical services. This protocol details the design and procedures of a randomized controlled trial (RCT) of a novel mHealth intervention that comprises a comprehensive HIV prevention app and brief, tailored text- and video-based messages that are systematically presented to participants based on the participants' HIV status and level of HIV acquisition risk. Objective: The objective of the RCT was to test the efficacy of the Mobile Messaging for Men (M-Cubed, or M3) app among at least 1200 MSM in Atlanta, Detroit, and New York. The goal was to determine its ability to increase HIV testing (HIV-negative men), STI testing (all men), condom use for anal sex (all men), evaluation for PrEP eligibility, uptake of PrEP (higher risk HIV-negative men), engagement in HIV care (men living with HIV), and uptake of and adherence to antiretroviral medications (men living with HIV). A unique benefit of this approach is the HIV serostatus-inclusiveness of the intervention, which includes both HIV-negative and HIV-positive MSM. Methods: MSM were recruited through online and venue-based approaches in Atlanta, Detroit, and New York City. Men who were eligible and consented were randomized to the intervention (immediate access to the M3 app for a period of three months) or to the waitlist-control (delayed access) group. Outcomes were evaluated immediately postintervention or control period, and again three and six months after the intervention period. Main outcomes will be reported as period prevalence ratios or hazards, depending on the outcome. Where appropriate, serostatus/risk-specific outcomes will be evaluated in relevant subgroups. Men randomized to the control condition were offered the opportunity to use (and evaluate) the M3 app for a three-month period after the final RCT outcome assessment. Results: M3 enrollment began in January 2018 and concluded in November 2018. A total of 1229 MSM were enrolled. Data collection was completed in September 2019. Conclusions: This RCT of the M3 mobile app seeks to determine the effects of an HIV serostatus–inclusive intervention on the use of multiple HIV prevention and care-related outcomes among MSM. A strength of the design is that it incorporates a large sample and broad range of MSM with differing prevention needs in three cities with high prevalence of HIV among MSM. © Patrick Sean Sean Sullivan, Ryan J Zahn, Sarah Wiatrek, Cristian J Chandler, Sabina Hirshfield, Rob Stephenson, Jose A Bauermeister, Mary Ann Chiasson, Martin J Downing Jr, Deborah J Gelaude, Aaron J Siegler, Keith Horvath, Erin Rogers, Ana Alas, Evelyn J Olansky, Heather Saul, Eli S Rosenberg, Gordon Mansergh. Article	2019	Sun C.J.; Anderson K.M.; Bangsberg D.; Toevs K.; Morrison D.; Wells C.; Clark P.; Nicolaidis C.	Access to HIV Pre-exposure Prophylaxis in Practice Settings: a Qualitative Study of Sexual and Gender Minority Adults' Perspectives	Journal of General Internal Medicine	-	-	-	8848734	10.1007/s11606-019-04850-w	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061179821&doi=10.1007%2fs11606-019-04850-w&partnerID=40&md5=f32adb2e07492a1f5a095f9bb1ccf8bd	Background: Sexual and gender minority (SGM) populations remain at disproportionate risk of HIV infection. Despite the effectiveness of pre-exposure prophylaxis (PrEP) in preventing HIV, PrEP uptake has been slow. Objective: To identify barriers and facilitators of PrEP access by examining SGM patients' experiences with accessing health care systems and engaging with providers about PrEP in a variety of practice settings. Design: Semi-structured, individual, qualitative interviews. Participants: Twenty-seven sexual and gender minority adults residing in Oregon. Approach: Interviews were audio-recorded, transcribed, and analyzed using thematic analysis. Key Results: We identified three main themes. Participants described the centrality of patient-provider relationships to positive experiences around PrEP, the necessity of personally advocating to access PrEP, and the experience of system-level barriers to PrEP access. Participants also made several suggestions to improve PrEP access including improving provider engagement with SGM patients, encouraging providers to initiate conversations about PrEP, and increasing awareness of medication financial support. Conclusions: In order to reduce HIV disparities, improving PrEP access will require additional efforts by providers and resources across health care settings to reduce barriers. Interventions to improve provider education about PrEP and provider communication skills for discussing sexual health are needed. Additionally, there should be system-level improvements to increase coordination between patients, providers, pharmacies, and payers to facilitate PrEP access and uptake. © 2019, Society of General Internal Medicine.	doctor-patient relationships; HIV/AIDS; patient preferences; prevention; qualitative research	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2019	Sun C.J.; Anderson K.M.; Toevs K.; Morrison D.; Wells C.; Nicolaidis C.	"Little tablets of gold": An examination of the psychological and social dimensions of PrEP among LGBTQ communities	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2019.31.1.51	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061404447&doi=10.1521%2faeap.2019.31.1.51&partnerID=40&md5=86a147e48db272daaa5f72a6ca8cf267	There are significant psychological, social, and cultural dimensions to the HIV epidemic in the United States, especially among lesbian, gay, bisexual, transgender, and queer (LGBTQ) communities. Biomedical HIV treatment has been shown to impact these dimensions. However, there is little understanding of the real-world psychosocial and sociocultural effects of the latest biomedical HIV prevention strategy, HIV pre-exposure prophylaxis (PrEP). This study explored the psychosocial and sociocultural dimensions of PrEP use among LGBTQ adults. We interviewed 23 LGBTQ adults who were current or former users of PrEP. Results included that PrEP users' experiences were shaped by multiple forms of stigma. Participants were highly motivated to challenge PrEP stigma and to support PrEP use among other community members. Lastly, participants described positive impacts on their individual well-being and their sexual partnerships. Findings suggest that PrEP has significant impacts beyond biomedical outcomes for both the individuals who use PrEP and their communities. © 2019 The Guilford Press. Article	2019	Taggart T.; Bond K.T.; Ritchwood T.D.; Smith J.C.	Getting youth PrEPared: adolescent consent laws and implications for the availability of PrEP among youth in countries outside of the United States	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25363	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070861891&doi=10.1002%2fjia2.25363&partnerID=40&md5=e86eb828d84a980b58ae3833d0f41c1d	Introduction: Youth under the age of 25 are at high risk for HIV infection. While pre-exposure prophylaxis (PrEP) has the potential to curb new infections within this population, it is unclear how country-specific laws and policies that govern youth access to sexual and reproductive health (SRH) services impact access to PrEP. The purpose of this review was to analyse laws and policies concerning PrEP implementation and SRH services available to youth in countries with a high HIV incidence. To the best of our knowledge this is the first systematic assessment of country-level policies that impact the availability of PrEP to adolescent populations. Methods: We conducted a review of national policies published on or before 12 June 2018 that could impact adolescents' access to PrEP, SRH services and ability to consent to medical intervention. Countries were included if: (1) there was a high incidence of HIV; (2) they had active PrEP trials or PrEP was available for distribution; (3) information regarding PrEP guidelines were publicly available. We also included a selected number of countries with lower adolescent HIV incidence. Internet and legal database searches were used to identify policies relevant to adolescent PrEP (e.g. age of consent to HIV testing). Results and Discussion: Fifteen countries were selected for inclusion in this review. Countries varied considerably in their respective laws and policies governing adolescents' access to PrEP, HIV testing and SRH services. Six countries had specific policies around the provision of PrEP to youth under the age of 18. Five countries required people to be 18 years or older to access HIV testing, and six countries had specific laws addressing adolescent consent for- and access to- contraceptives. Conclusions: Adolescents' access to PrEP without parental consent remains limited or uncertain in many countries where this biomedical intervention is needed. Observational and qualitative studies are needed to determine if and how adolescent consent laws are followed in relation to adolescent PrEP provisions. Intensified efforts to amend laws that limit adolescent access to PrEP and restrict the establishment of national guidelines supporting adolescent PrEP are also needed to address the epidemic in this group. © 2019 The Authors. Article	2019	Takano, M; Mizushima, D; Tanaka, K; Aoki, T; Yanagawa, Y; Uemura, H; Watanabe, K; Kikuchi, Y; Oka, S	HISTORY OF STI THERAPY AND WILLINGNESS OF PREP AMONG HIV-NEGATIVE MSM COHORT IN JAPAN	Sexually Transmitted Infections	-	-	-	1368-4973	10.1136/sextrans-2019-sti.630	https://sti.bmj.com/content/95/Suppl_1/A250.3	Background Pre-exposure prophylaxis (PrEP) is not yet approved and information of PrEP is still very limited in Japan. In such circumstances, we established an HIV-negative MSM cohort at National Center for Global Health and Medicine, Tokyo in 2017. This study aimed to explore correlation between histories of STI therapies and willingness of receiving PrEP in this cohort. Methods Face-to-face interviews with a semi-structured standardized questionnaire was conducted. HIV incidence risk index for MSM was used to identify the risk of HIV acquisition and scores of 10 and over were defined as at the high risk. Willingness of PrEP was divided into 4 categories: "Yes definitely", "Yes probably", "No probably" and "No definitely". Histories of STI therapies within 1 year against at least one of followings; syphilis, gonorrhea, chlamydia, hepatitis A, B, and C virus infection, genital herpes, amoebiasis, giardiasis, and condyloma, were recorded. Results A total of 230 MSM completed the interviews from November 2017 through October 2018. The median age was 35 years (range: 18–70). MSM at the high risk was found in 185 (80.4%). Among MSM who knew PrEP was only 61.3%. Positive willingness of PrEP was observed in 64.8%. MSM who answered "No definitely" were 21 among 185 high risk MSM. Their main negative reasons were "I think my HIV acquisition risk is low" in 12 MSM and "I don't like to take medicine" in 8. Histories of STI therapy within 1 year were found in 81 MSM (35.2%). Among them, 27 (33.3%) had still the negative willingness. There was no correlation of the positive willingness and history of STIs (p=0.66). Conclusion Still one third of MSM in our cohort lacked the proper knowledge of PrEP. Especially it is important to allow themselves to assess their own risk of HIV infection. Article	2019	Tan, D; Chris, A; Schnubb, A; Knox, D; Wilton, J; Shahin, R; Chan, A; Mishra, S; Grace, D; Rogers, T; Bayoumi, A; Maxwell, J; Bogoch, I; Sharma, M	GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN PREFER SEXUAL HEALTH CLINIC NURSES OVER FAMILY PHYSICIANS FOR PREP DELIVERY	Sexually Transmitted Infections	-	-	-	1368-4973	10.1136/sextrans-2019-sti.523	https://sti.bmj.com/content/95/Suppl_1/A207.2	Background More providers are needed to deliver PrEP at scale. We examined intentions to seek PrEP from family physicians (FPs) and sexual health clinic nurses (RNs) within an implementation science study on decentralizing PrEP delivery to gay, bisexual and other men who have sex with men (gbMSM). Methods Strategy A was a knowledge dissemination intervention in which community organizations distributed info-cards to gbMSM considering PrEP. Men used the cards to view an online module and meet with their FPs, who could use the card to complete an accredited e-module about PrEP. Strategy B was an implementation intervention in which gbMSM could instead access PrEP from sexual health RNs. Participants completed an optional survey at baseline and 6 months. We used descriptive statistics to characterize the sample and logistic regression to identify characteristics associated with intentions to seek PrEP from FPs vs RNs. Results From 3013 cards distributed, 339 men accessed the module; 179 completed the baseline survey and are included in this analysis. Median (IQR) age was 31 (26,40) years, 97.7% were cisgender males and 46.4% had a prior bacterial STI. Most (n=119, 66.5%) had a FP, of which only 59.5% were 'out' to them. Of 97 respondents with a FP and wanting to start PrEP, 35.1% vs 65.0% intended to use Strategy A vs B respectively (p=0.003). In univariable analyses, characteristics associated with intent to approach FPs included being 'out' to that doctor (OR=10.67, 95%CI=3.35, 33.96), very good/excellent physician skills in general communication (OR=3.42, 95%CI=1.38, 8.48) and participatory decision-making (OR=3.33, 95%CI=1.14, 9.79). In multivariable analysis, being 'out' was the only significant predictor (aOR=14.35, 95%CI=1.59, 129.83). Conclusion Among gbMSM with a FP, sexual health clinic RNs were preferred over FPs for PrEP by most. Multiple strategies are needed to increase numbers of PrEP providers, including interventions to help gbMSM feel comfortable disclosing sexual orientation. Disclosure No significant relationships. Article	2019	Tatham L.M.; Savage A.C.; Dwyer A.; Siccardi M.; Scott T.; Vourvahis M.; Clark A.; Rannard S.P.; Owen A.	Towards a Maraviroc long-acting injectable nanoformulation	European Journal of Pharmaceutics and Biopharmaceutics	-	-	-	9396411	10.1016/j.ejpb.2018.04.009	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85047055579&doi=10.1016%2fj.ejpb.2018.04.009&partnerID=40&md5=7f4421ac66c725fd6786b0ac34e19ff9	Suboptimal adherence to antiretroviral (ARV) therapy can lead to insufficient drug exposure leading to viral rebound and increased likelihood of resistance. This has driven the development of long-acting injectable (LAI) formulations which may mitigate some of these problems. Maraviroc (MVC) is an orally dosed CCR5 antagonist approved for use in patients infected with CCR5-trophic HIV-1. MVC prevents viral entry into host cells, is readily distributed to biologically relevant tissues and has an alternative resistance profile compared to more commonly used therapies. This makes a MVC LAI formulation particularly appealing for implementation in Pre-Exposure Prophylaxis (PrEP). A 70 wt% MVC-loaded nanodispersion stabilised with polyvinyl alcohol (PVA) and sodium 1,4-bis(2-ethylhexoxy)-1,4-dioxobutane-2-sulfonate (AOT) was prepared using emulsion-templated freeze-drying. In vitro release rate studies revealed over a 22% decrease in MVC release rate constant across a size selective membrane compared with an aqueous solution of MVC (<5% DMSO). Pharmacokinetic studies in rats were subsequently carried out following intramuscular injection of either the nanodispersion or aqueous MVC preparation (<5% DMSO). Results demonstrated over a 3.4-fold increase in AUC0–∞ (1959.71 vs 567.17 ng.h ml), over a 2.6-fold increase in MVCs terminal half-life (t½) (140.69 vs 53.23 h) and MVC concentrations present up to 10-days. These data support development of a MVC LAI formulation with potential application in HIV therapy or prevention. © 2018 Elsevier B.V. Article	2019	Taylor, Jessica L; Walley, Alexander Y; Bazzi, Angela R	Stuck in the window with you: HIV exposure prophylaxis in the highest risk people who inject drugs.	Substance Abuse	-	-	-	1547-0164	10.1080/08897077.2019.1675118	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6938281	The opioid and polysubstance epidemics could drive a surge in new HIV infections among people who inject drugs (PWID). Longstanding strategies to reduce HIV incidence, including syringe service programs, condom distribution, medications for opioid use disorder, and low-barrier HIV testing and treatment have not been adequate to eliminate transmission in this population. Although HIV pre-exposure prophylaxis (PrEP) is an evidence-based intervention that reduces HIV incidence among PWID, uptake in PWID has lagged due to limited PrEP knowledge, discrepancies between perceived and actual HIV risk, stigma, and structural barriers to adherence including homelessness and incarceration. In our efforts to deploy PrEP to PWID in our low-barrier substance use disorder bridge clinic, we have encountered another barrier: the HIV testing window period. We discuss challenges in delivering HIV exposure prophylaxis to the highest risk PWID, our current approach, and the need for more data to guide best practices. Theses and Dissertations	2019	TEIXEIRA, DANILO MARTINS	ELUCIDANDO A CONVIVÊNCIA COM O HIV E O USO DE MEDICAÇÃO ANTIRRETROVIRAL, UMA ABORDAGEM EDUCATIVA PARA ALUNOS DO SEGUNDO GRAU	-	-	UNIVERSIDADE FEDERAL DE MINAS GERAIS	-	-	NA	https://sucupira.capes.gov.br/sucupira/public/consultas/coleta/trabalhoConclusao/viewTrabalhoConclusao.jsf?popup=true&id_trabalho=8137275	Existe um conceito generalizado simplificado e equivocado por parte de um grande número de adolescentes, a respeito da qualidade de vida de uma pessoa portadora do vírus da imunodeficiência humana adquira (HIV). Muitos adolescentes podem até entender erroneamente que o uso das medicações antirretrovirais necessárias para controlar a progressão da doença não possui efeitos colaterais e que a síndrome da imunodeficiência adquirida (SIDA/AIDS) já pode ser curada. O que leva muitos adolescentes a um comportamento de risco, aumentando suas chances de contaminação pelo vírus do HIV e outras ISTs e ou mesmo gravidez precoce. O abandono do tratamento com os antirretrovirais também e/ou não adesão correta ao tratamento mostra-se uma dificuldade enfrentadas no combate desta pandemia. O objetivo do presente estudo compreende esclarecer as questões ligadas ao HIV e seu tratamento, levando aos alunos do segundo grau uma visão científica do assunto. Para desvendar importantes questões ao seu entorno, como uso de preservativos, o uso e diferenças entre PrEP – Profilaxia PréExposição ao HIV e Pep – Profilaxia Pós-exposição, a adesão correta ao tratamento e as consequências do abandono do mesmo e discutir a qualidade de vida e expectativa de vida de pessoas infectadas pelo HIV, aderindo ou não a terapia antirretroviral. Também avaliamos se metodologias de ensino alternativas poderiam favorecer ou melhorar o aprendizado sobre o assunto. O trabalho foi realizado com 2 grupos de alunos do terceiro ano do segundo grau sendo que o 1o grupo (interativo/expositivo), foi exposto a duas horas/aula no modelo padrão expositivo e o 2º grupo (Lúdico) foi exposto a 1 hora/aula expositiva padrão, seguida da utilização de um jogo educativo que tratou o tema em questão por uma hora/aula, somando um total de duas horas/aula. Ambos os grupos foram expostos a dois questionários afim de mensurar o conhecimento prévio e posterior intervenções educativas. Os resultados foram analisados utilizando-se ANOVA de dois fatores seguidos por Teste-T. Os resultados apontam para um efeito do tempo (antes ou depois da intervenção) e tipo de ensino (P<0.05), demonstrando que a construção do conhecimento sobre o tema foi superior nos alunos expostos a metodologia lúdica, no caso específico usando o jogo educativo quando comparados aos alunos do grupo exposto à metodologia interativa/expositiva. Reforçamos que a AIDS ainda é uma doença sem cura, e que a infecção pelo vírus do HIV afeta a qualidade de vida dos portadores.No entanto o controle da infecção através do uso da medicação antirretroviral pode melhorar significativamente a vida do portador do vírus, levantando questões éticas no convívio social e combatendo o preconceito ao tratar tal infecção; deste modo, incentivamos um maior 12 uso de métodos preventivos a HIV/Aids e ISTs e atitudes responsáveis neste grupo. Mostrar aos alunos as consequências, a realidade e o impacto que o contágio pelo HIV pode exercer na vida de um indivíduo soropositivo e reforçar a importância que o tratamento antirretroviral possui para ampliar a expectativa de vida e diminuir a propagação do vírus para outras pessoas é de suma importância para a saúde pública no Brasil e no Mundo. Article	2019	Tekeste M.; Hull S.; Dovidio J.F.; Safon C.B.; Blackstock O.; Taggart T.; Kershaw T.S.; Kaplan C.; Caldwell A.; Lane S.B.; Calabrese S.K.	Differences in Medical Mistrust Between Black and White Women: Implications for Patient–Provider Communication About PrEP	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2283-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85054004726&doi=10.1007%2fs10461-018-2283-2&partnerID=40&md5=4e64c97510cc8c1fb7ad5e9bf301766c	Pre-exposure prophylaxis (PrEP) is an effective biomedical HIV prevention method. PrEP uptake has been persistently low among US women, particularly Black women, who account for 61% of new HIV diagnoses among women. Further understanding of barriers to Black women accessing PrEP is needed. This 2017 cross-sectional survey study explored race-based differences in PrEP interest and intention among women and the indirect association between race and comfort discussing PrEP with a healthcare provider through medical mistrust. The sample consisted of 501 adult women (241 Black; 260 White) who were HIV-negative, PrEP-inexperienced, and heterosexually active. Black women reported greater PrEP interest and intention than White women. However, Black women expressed higher levels of medical mistrust, which, in turn, was associated with lower comfort discussing PrEP with a provider. Medical mistrust may operate as a unique barrier to PrEP access among Black women who are interested in and could benefit from PrEP. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Terndrup C.; Streed C.G., Jr.; Tiberio P.; Black M.; Davis J.; Apfel A.; Blackstock O.J.; Edelman E.J.; Berkenblit G.	A Cross-sectional Survey of Internal Medicine Resident Knowledge, Attitudes, Behaviors, and Experiences Regarding Pre-Exposure Prophylaxis for HIV Infection	Journal of General Internal Medicine	-	-	-	8848734	10.1007/s11606-019-04947-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85064833841&doi=10.1007%2fs11606-019-04947-2&partnerID=40&md5=8bbe72e0bfc975cc433544abce8071c7	Background: Pre-exposure prophylaxis (PrEP) for HIV is effective, yet many providers continue to lack knowledge and comfort in providing this intervention. It remains unclear whether internal medicine (IM) residents receive appropriate training in PrEP care and if this affects their future practices. Objective: We sought to evaluate the relationship between current IM residents' prior PrEP training and knowledge, comfort, and practice regarding the provision of PrEP. Design and Participants: We created an online survey to assess IM residents' knowledge, attitudes, and behaviors related to PrEP. The survey was distributed among five IM programs across the USA. Key Results: We had a 35% response rate. Of 229 respondents, 96% (n = 220) had heard of PrEP but only 25% (n = 51) had received prior training and 11% (n = 24) had prescribed PrEP. Compared with those without, those with prior training reported good to excellent knowledge scores regarding PrEP (80% versus 33%, p < 0.001), more frequent prescribing (28% versus 7%, p = 0.001), and higher comfort levels with evaluating risk for HIV, educating patients, and monitoring aspects of PrEP (75% versus 26%, 56% versus 16%, and 47% versus 8%, respectively; all p values < 0.0001). While only 25% (n = 51) had received prior training, 75% (n = 103) of respondents reported that training all providers at their continuity clinic sites would improve implementation. Conclusions: We found that prior training was associated with higher levels of self-reported PrEP knowledge, comfort, and prescribing behaviors. Given the significant need for PrEP, IM residents should be trained to achieve adequate knowledge and comfort levels to prescribe it. This study demonstrates that providing appropriate PrEP training for IM residents may lead to an increase in the pool of graduating IM residents prescribing PrEP. © 2019, Society of General Internal Medicine. Institutional	2019	The Council for Treatment Guidelines	HIV-infektsiooni kokkupuute-eelne ja -järgne profülaktika ning HIV-positiivsete isikute ravi	-	-	-	-	NA	NA	https://www.ravijuhend.ee/tervishoiuvarav/juhendid/195/hiv-infektsiooni-kokkupuute-eelne-ja-jargne-profulaktika-ning-hiv-positiivsete-isikute-ravi	HIV is a chronic viral infection that damages the immune system. HIV can be contracted during sexual intercourse or through direct contact with the blood of an infected person (including sharing syringes). The virus can also be transmitted from mother to child during pregnancy, childbirth or breastfeeding (1). The main risk groups for HIV infection are people who inject drugs (IDUs), people involved in prostitution and men who have sex with men (MSM). Heterosexual transmission must also be considered, and many infected people do not belong to any of the usual risk groups (2). Today, it is not possible to cure HIV, the infected person will always be a carrier of the virus, but it is possible to slow down the reproduction of the virus in the body with medicines. Combined antiretroviral therapy (ARV therapy) consisting of different active agents is used. With good treatment compliance, the number of virus copies in a person's blood cannot be determined and they are not infectious to others (treatment = prevention). Since it is not possible to get rid of the virus, it is important to avoid becoming infected with HIV. A pharmacological option for this is post-exposure prophylaxis (PEP). Pre-exposure prophylaxis (PrEP) programs, where people at high risk of infection take ARV drugs to prevent infection, have also been successful in recent years. HIV prevalence among MSM varies from 17% in Brazil and Mexico to 13% in Peru, whereas it is below 0.5% for the general population in each country. Pre-exposure prophylaxis (PrEP) with emtricitabine/tenofovir is being implemented in the context of combination HIV prevention. Reports on willingness to use PrEP among MSM have started to emerge over the last few years. Previously reported factors associated with willingness to use PrEP include awareness, higher sexual risk behavior, and previous sexually transmitted infection. Objective: This study aimed to evaluate the factors associated with willingness to use daily oral PrEP among MSM in 3 Latin American, middle-income countries (Brazil, Mexico, and Peru). Methods: This Web-based, cross-sectional survey was advertised in 2 gay social network apps (Grindr and Hornet) used by MSM to find sexual partners and on Facebook during 2 months in 2018. Inclusion criteria were being 18 years or older, cisgender men, and HIV-negative by self-report. Eligible individuals answered questions on demographics, behavior, and PrEP (awareness, willingness to use, barriers, and facilitators). Multivariable logistic regression modeling was performed to assess the factors associated with willingness to use daily oral PrEP in each country. Results: From a total sample of 43,687 individuals, 44.54% of MSM (19,457/43,687) were eligible and completed the Web-based survey—Brazil: 58.42% (11,367/19,457), Mexico: 30.50% (5934/19,457), and Peru: 11.08% (2156/19,457); median age was 28 years (interquartile range: 24-34), and almost half lived in large urban cities. Most participants were recruited on Grindr (69%, 13,349/19,457). Almost 20% (3862/19,352) had never tested for HIV, and condomless receptive anal sex was reported by 40% (7755/19,326) in the previous 6 months. Whereas 67.51% (13,110/19,376) would be eligible for PrEP, only 9.80% (1858/18,959) of participants had high HIV risk perception. PrEP awareness was reported by 64.92% (12,592/19,396); this was lower in Peru (46.60%, 1002/2156). Overall, willingness to use PrEP was reported by 64.23% (12,498/19,457); it was highest in Mexico (70%, 4158/5934) and lowest in Peru (58%, 1241/2156). In multivariate regression models adjusted for age, schooling, and income in each country, willingness to use PrEP was positively associated with PrEP awareness and PrEP facilitators (eg, free PrEP and HIV testing) and negatively associated with behavioral (eg, concerned by daily pill regimen) and belief barriers (eg, sexual partners may expect condomless sex). Conclusions: In this first cross-country, Web-based survey in Latin America, willingness to use PrEP was found to be high and directly related to PrEP awareness. Interventions to increase awareness and PrEP knowledge about safety and efficacy are crucial to increase PrEP demand. This study provides important information to support the implementation of PrEP in Brazil, Mexico, and Peru. Article	2019	Thomas R.; Skovdal M.; Galizzi M.M.; Schaefer R.; Moorhouse L.; Nyamukapa C.; Maswera R.; Mandizvidza P.; Hallett T.B.; Gregson S.	Improving risk perception and uptake of pre-exposure prophylaxis (PrEP) through interactive feedback-based counselling with and without community engagement in young women in Manicaland, East Zimbabwe: Study protocol for a pilot randomized trial	Trials	-	-	-	17456215	10.1186/s13063-019-3791-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075911816&doi=10.1186%2fs13063-019-3791-8&partnerID=40&md5=aa07757d658b3f4bbb101252d63b181f	Background: HIV incidence in adolescent girls and young women remains high in sub-Saharan Africa. Progress towards uptake of HIV prevention methods remains low. Studies of oral pre-exposure prophylaxis (PrEP) have shown that uptake and adherence may be low due to low-risk perception and ambivalence around using antiretrovirals for prevention. No evidence exists on whether an interactive intervention aimed at adjusting risk perception and addressing the uncertainty around PrEP will improve uptake. This pilot research trial aims to provide an initial evaluation of the impact of an interactive digital tablet-based counselling session, correcting risk perception, and addressing ambiguity around availability, usability, and effectiveness of PrEP. Methods/Design: This is a matched-cluster randomized controlled trial which will compare an interactive tablet-based education intervention against a control with no intervention. The study will be implemented in eight sites. In each site, two matched clusters of villages will be created. One cluster will be randomly allocated to intervention. In two sites, a community engagement intervention will also be implemented to address social obstacles and to increase support from peers, families, and social structures. A total of 1200 HIV-negative young women aged 18-24 years, not on PrEP at baseline, will be eligible. Baseline measures of endpoints will be gathered in surveys. Follow-up assessment at six months will include biomarkers of PrEP uptake and surveys. Discussion: This will be the first randomized controlled trial to determine whether interactive feedback counselling leads to uptake of HIV prevention methods such as PrEP and reduces risky sexual behavior. If successful, policymakers could consider such an intervention in school-based education campaigns or as post-HIV-testing counselling for young people. © 2019 The Author(s). Article	2019	Thomas, Portia D	A Qualitative Exploration of Pre-Exposure Prophylaxis (PrEP) Initiation Decision-Making Among Men Who Have Sex with Men (MSM): "It Definitely was a Process".	Journal of the National Black Nurses Association	-	-	-	0885-6028	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-32176964	Pre-exposure prophylaxis (PrEP) is the first biomedical regimen approved to significantly reduce HIV transmission risk. Men who have sex with men (MSM) living in the South represent one of the most HIV-vulnerable populations; however, PrEP initiation is slow in this demographic. The factors leading to clients' decisions to initiate PrEP are relatively unknown. This study interviewed 14 MSM PrEP clients from 3 Southern states. The analysis revealed that 5 factors were integral to the sample's initiation of PrEP: HIV risk acknowledgment, HIV concern, PrEP understanding, PrEP accessibility, and PrEP consideration. From the analysis, a model emerged conceptualizing the decision-making process of PrEP initiation in this sample. This model is foundational to understanding the factors and their relationships affecting initiation of PrEP and can be used to develop effective interventions to facilitate PrEP initiation in MSM in the United States. Article	2019	Tilchin C.; Schumacher C.M.; Psoter K.J.; Humes E.; Muvva R.; Chaulk P.; Checkley W.; Jennings J.M.	Human Immunodeficiency Virus Diagnosis after a Syphilis, Gonorrhea, or Repeat Diagnosis among Males Including non-Men Who Have Sex with Men: What Is the Incidence?	Sexually Transmitted Diseases	-	-	-	1485717	10.1097/OLQ.0000000000000964	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063014799&doi=10.1097%2fOLQ.0000000000000964&partnerID=40&md5=0755b7cb095f7721f272cfb192afec36	Background The release of the first drug for human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP) in 2012 marked the beginning of a new era of HIV prevention. Although PrEP is highly efficacious, identifying and ultimately increasing uptake among the highest risk male subgroups remains a challenge. Methods Public health surveillance data from 2009 to 2016 was used to evaluate the risk of an HIV diagnosis after a syphilis (ie, primary, secondary, or early latent), gonorrhea, and repeat diagnoses among urban males, including men who have sex with men (MSM) and non-MSM in Baltimore City. Results Of the 1531 males with 898 syphilis diagnoses and 1243 gonorrhea diagnoses, 6.8% (n = 104) were subsequently diagnosed with HIV. Within 2 years, 1 in 10 syphilis or gonorrhea diagnoses were followed by an HIV diagnosis among MSM, and 1 in 50 syphilis or gonorrhea diagnoses were followed by an HIV diagnosis among non-MSM. Among non-MSM with gonorrhea, the rate of HIV incidence was 5.36 (95% confidence interval, 2.37-12.14) times higher in those with (vs. without) a subsequent syphilis diagnosis or gonorrhea diagnosis. Conclusions Local health care providers should offer PrEP to MSM diagnosed with syphilis or gonorrhea and to non-MSM with a previous gonorrhea diagnosis at time of a syphilis or gonorrhea diagnosis. The high proportion and short time to an HIV diagnosis among MSM after a syphilis or gonorrhea diagnosis suggest immediate PrEP initiation. © 2018 American Sexually Transmitted Diseases Association All rights reserved. Article	2019	Tims-Cook Z.	A retrospective assessment of antecedent pre-exposure prophylaxis eligibility of HIV-Positive Women in the South	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2019.0046	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85072154330&doi=10.1089%2fapc.2019.0046&partnerID=40&md5=8ddb9c4320e2a6179004b418f57c4c36	African American women disproportionately endure the predominance of HIV infections among women, especially in the South. HIV pre-exposure prophylaxis (PrEP) is recognized as an effective prevention strategy for individuals at higher risk of HIV acquisition. Accordingly, PrEP is recommended in heterosexually active adult persons who are HIV negative; not in a monogamous relationship with an HIV-negative partner; and infrequently use condoms with a partner who is a bisexual male, HIV positive, or uses recreational intravenous (IV) drugs. Despite PrEP's acceptance among other groups at higher risk of HIV acquisition, studies indicate low use among African American women in the South. It is unclear whether underutilization results from a low perceived risk of HIV infection or from miscalculation of risk by clinicians. To ascertain the fitness of current PrEP indicators to evaluate HIV acquisition risk in heterosexual women, 102 HIV-positive women in Atlanta, GA, were queried about their awareness of and participation in higher risk heterosexual relationship dynamics before their HIV diagnosis. Risk awareness and behaviors were retrospectively assessed to determine whether the same women, now HIV positive, would have been considered for PrEP before their HIV diagnoses. When queried, 66% reported having only one sexual partner, 64% reported having sex ≥4 times with the partner from whom they acquired HIV, and >90% reported no knowledge of their partners' HIV-positive status or bisexual orientation. As demonstrated, heterosexual women with only one sexual partner and limited awareness of their partners' HIV-positive status or bisexual orientation remain at substantial risk of HIV acquisition without suitable risk approximation strategies. © Copyright 2019, Mary Ann Liebert, Inc., publishers 2019. Article	2019	Tolley E.E.; Li S.; Zangeneh S.Z.; Atujuna M.; Musara P.; Justman J.; Pathak S.; Bekker L.-G.; Swaminathan S.; Stanton J.; Farrior J.; Sista N.	Acceptability of a long-acting injectable HIV prevention product among US and African women: findings from a phase 2 clinical Trial (HPTN 076)	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25408	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074072777&doi=10.1002%2fjia2.25408&partnerID=40&md5=0709040df27c2a1be2c12c018a3159c8	Introduction: High HIV incidence and low adherence to daily oral PrEP among women underscore the need for more acceptable and easier to use HIV prevention products. Global demand for injectable contraception suggests that new, long-acting, injectable formulations could meet this need. We examine acceptability of a long-acting injectable PrEP among HIV-uninfected women in Zimbabwe, South Africa and two United States phase 2 trial sites. Methods: Quantitative surveys were administered at the first, fourth and sixth injection visits. Focus group discussions (FGD) were conducted after the sixth injection visit. We compared the acceptability of injectable product attributes, prevention preferences and future interest in injectable PrEP by site and arm and ran longitudinal ordinal logistic regression models to identify determinants of future interest in injectable PrEP. Results: Between April 2015 and February 2017, the trial enrolled 136 (100 African, 36 US) women with a median age of 31 years. Most participants (>75%) rated injectable attributes as very acceptable. While few reported rash or other side effects, 56% to 67% reported injection pain, with nonsignificant differences over time and between arms. During FGDs, participants described initial fear of the injectable and variable experiences with pain. Most US and African participants preferred injectable PrEP to daily oral pills (56% to 96% vs. 4% to 25%). Future interest in using injectable PrEP was associated with acceptability of product attributes and was higher in African than US sites. In FGDs, participants described multiple reasons for trial participation, including a combination of monetary, health-related and altruistic motivations. While associated with future interest in use in univariate models, neither altruistic nor personal motivations remained significant in the multivariate model. Conclusions: This study found that long-acting injectable PrEP is acceptable among African and US women experiencing product use. Acceptability of product attributes better predicted future interest in injectable use than experience of pain. This is reassuring as a single-dose regimen of a different product has advanced to phase 3 trials. Finally, the study suggests that future demand for an injectable PrEP by women may be greater in African than US settings, where the risk of HIV is highest. © 2019 FHI 360. Article	2019	Tomko, Catherine; Park, Ju Nyeong; Allen, Sean T; Glick, Jennifer; Galai, Noya; Decker, Michele R; Katherine HA Footer; Sherman, Susan G	Awareness and Interest in HIV Pre-Exposure Prophylaxis Among Street-Based Female Sex Workers: Results from a US Context	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2018.0182	https://pubmed.ncbi.nlm.nih.gov/30632769/	Pre-exposure prophylaxis (PrEP) has the potential to be an empowering HIV prevention tool among female sex workers (FSW), yet little is known about PrEP awareness and interest in this population. Sex workers and Police Promoting Health in Risky Environments (SAPPHIRE) is a prospective cohort study of street-based FSW in Baltimore, MD. A cross-sectional analysis explored awareness and interest in PrEP among HIV-negative FSW. Multivariable Poisson regressions modeled associations between individual, interpersonal, and structural variables and PrEP awareness and interest. Of n = 232 FSW, 66% were white, half were less than 35 years old, 59% injected drugs daily, and 66% sold sex daily. Only 21% of FSW were aware of PrEP, though 74% were interested. PrEP awareness was associated with experiencing client condom coercion adjusted incidence rate ratio (aIRR) = 0.50, 95% CI: 0.28–0.90 and condomless sex with an intimate partner (aIRR = 0.54, 95% CI: 0.30–0.98). PrEP interest was associated with perceiving PrEP as "very easy" to take (aIRR = 1.91, 95% CI: 1.49–2.45) and moving to an unfamiliar geographic area to sell sex (aIRR = 1.20, 95% CI: 1.04–1.39). Women who had a current gonorrhea or chlamydia infection were less likely to be interested in PrEP (aIRR = 0.75, 95% CI: 0.59–0.95). Though PrEP awareness among FSW is low, there are FSW who are significantly more likely to express interest in PrEP and outreach efforts should target these women. Results suggest that women-controlled HIV prevention methods may be important for reducing incidence among FSW. Article	2019	Too L.; Hailili G.; Zhen C.; Xiaoqing T.; Aijie C.; Zhao Z.; Jianghong D.	The confidence affects willingness to use pre-exposure prophylaxis among msm, based on path analysis	Chinese Journal of Endemiology	-	-	-	20954255	10.3760/cma.j.issn.0254-6450.2019.10.020	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074968572&doi=10.3760%2fcma.j.issn.0254-6450.2019.10.020&partnerID=40&md5=2f184b6a3f2aaa2d7d5bdef494a01735	Objective To analyze the influence of the confidence to pre-exposure prophylaxis (PrEP) on the willingness to use PrEP in men who have sex with men (MSM) by using the path analysis model based on structural equation model approach. Methods A total of 550 MSM were recruited in Urumqi by snowball method and a questionnaire survey was conducted among them. According to the professional knowledge and analysis results of the confidence and willingness to use PrEP, structural equation model (SEM) analysis method was used to construct a path analysis model. Results A total of 513 MSM participated in the survey. The modified path equation model was well fitted, with the modified fitting index as: CFI=0.993, RMSEA<0.00\, and ,4£F/=0.984. The confidence to PrEP had direct influence on the willingness; the degree of influence from sex partners, the attitude of sex partner to PrEP and the positive emotions not only had direct effects on willingness of PrEP use, but also had indirect effects on willingness of PrEP use by affecting the confidence to it; the role in sexual behavior, AIDS severity, HIV prevention behavior had direct effects on willingness of PrEP use. The proportion of HIV infection in the population had no direct effects on willingness of PrEP use, but had indirect effects on willingness of PrEP use by affecting the confidence to it. Conclusions The confidence to PrEP had influence on willingness of PrEP use in MSM, therefore targeted activities can be conducted to improve the confidence and willingness of MSM in taking the PrEP and reducing the risk of HIV infection in MSM. Compared with the traditional multiple regression analysis, the path analysis using the structural equation model could better reveal the mediating effect between the independent variables and dependent variables. © 2019 Chinese Medical Association. Article	2019	Tookes H.; Yao K.; Chueng T.; Butts S.; Karsner R.; Duque M.; Cardenas G.; Feaster D.J.; Doblecki-Lewis S.	Pre-exposure prophylaxis access in federally qualified health centers across 11 United States metropolitan statistical areas	International journal of STD & AIDS	-	-	-	9564624	10.1177/0956462419855178	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068934470&doi=10.1177%2f0956462419855178&partnerID=40&md5=f819d674e364d9c38a1f48df567e2556	Pre-exposure prophylaxis (PrEP) is a promising tool for HIV prevention, but uptake has been slow in key demographics and geographic areas including racial and ethnic minorities. Federally qualified health centers (FQHCs), serving those with heightened risk of contracting HIV, including low-income and minority patients regardless of ability to pay, are potential sites for PrEP delivery. This study aims to determine availability of PrEP at FQHCs in the US. FQHCs in the 11 largest U.S. metropolitan statistical areas (MSAs) were included. The south included Atlanta, Dallas, District of Columbia, Houston, and Miami. Reference MSAs included Boston, Chicago, Los Angeles, New York, Philadelphia, and San Francisco. We randomly selected 360 FQHCs for phone calls in which investigators queried the availability of PrEP for HIV prevention at each center. The study was powered to determine a 10% difference in proportion of clinics with PrEP services by region. We used a bivariate logistic regression to compare cities and regions. The percentage of FQHCs providing PrEP generally was low within this sample, with 0–28.0% offering PrEP services in the southern and 14.0–33.3% in reference metropolitan areas. Overall, 19.3% of clinics sampled indicated that they offered PrEP. Logistic regression did not show any difference between southern and reference regions (p = 0.779). However, the total number of FQHCs was significantly lower in southern metropolitan areas (p = 0.014). FQHCs in all metropolitan areas provided limited access to PrEP. Interventions, including technical assistance to increase PrEP availability in these settings catering to underserved populations, could be beneficial. © The Author(s) 2019.	federally qualified health centers; HIV; men who have sex with men; Pre-exposure prophylaxis; prevention; public health	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Article	2019	Torres T.S.; Konda K.A.; Vega-Ramirez E.H.; Elorreaga O.A.; Diaz-Sosa D.; Hoagland B.; Diaz S.; Pimenta C.; Benedetti M.; Lopez-Gatell H.; Robles-Garcia R.; Grinsztejn B.; Caceres C.; Veloso V.G.	Factors associated with willingness to use pre-exposure prophylaxis in Brazil, Mexico, and Peru: Web-based survey among men who have sex with men	JMIR Public Health and Surveillance	-	-	-	23692960	10.2196/13771	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85077350159&doi=10.2196%2f13771&partnerID=40&md5=a7e8c1e32a2fe3be6365c109cf2d0b67	Background: HIV disproportionally affects key populations including men who have sex with men (MSM). HIV prevalence among MSM varies from 17% in Brazil and Mexico to 13% in Peru, whereas it is below 0.5% for the general population in each country. Pre-exposure prophylaxis (PrEP) with emtricitabine/tenofovir is being implemented in the context of combination HIV prevention. Reports on willingness to use PrEP among MSM have started to emerge over the last few years. Previously reported factors associated with willingness to use PrEP include awareness, higher sexual risk behavior, and previous sexually transmitted infection. Objective: This study aimed to evaluate the factors associated with willingness to use daily oral PrEP among MSM in 3 Latin American, middle-income countries (Brazil, Mexico, and Peru). Methods: This Web-based, cross-sectional survey was advertised in 2 gay social network apps (Grindr and Hornet) used by MSM to find sexual partners and on Facebook during 2 months in 2018. Inclusion criteria were being 18 years or older, cisgender men, and HIV-negative by self-report. Eligible individuals answered questions on demographics, behavior, and PrEP (awareness, willingness to use, barriers, and facilitators). Multivariable logistic regression modeling was performed to assess the factors associated with willingness to use daily oral PrEP in each country. Results: From a total sample of 43,687 individuals, 44.54% of MSM (19,457/43,687) were eligible and completed the Web-based survey-Brazil: 58.42% (11,367/19,457), Mexico: 30.50% (5934/19,457), and Peru: 11.08% (2156/19,457); median age was 28 years (interquartile range: 24-34), and almost half lived in large urban cities. Most participants were recruited on Grindr (69%, 13,349/19,457). Almost 20% (3862/19,352) had never tested for HIV, and condomless receptive anal sex was reported by 40% (7755/19,326) in the previous 6 months. Whereas 67.51% (13,110/19,376) would be eligible for PrEP, only 9.80% (1858/18,959) of participants had high HIV risk perception. PrEP awareness was reported by 64.92% (12,592/19,396); this was lower in Peru (46.60%, 1002/2156). Overall, willingness to use PrEP was reported by 64.23% (12,498/19,457); it was highest in Mexico (70%, 4158/5934) and lowest in Peru (58%, 1241/2156). In multivariate regression models adjusted for age, schooling, and income in each country, willingness to use PrEP was positively associated with PrEP awareness and PrEP facilitators (eg, free PrEP and HIV testing) and negatively associated with behavioral (eg, concerned by daily pill regimen) and belief barriers (eg, sexual partners may expect condomless sex). Conclusions: In this first cross-country, Web-based survey in Latin America, willingness to use PrEP was found to be high and directly related to PrEP awareness. Interventions to increase awareness and PrEP knowledge about safety and efficacy are crucial to increase PrEP demand. This study provides important information to support the implementation of PrEP in Brazil, Mexico, and Peru. © 2021 JMIR Publications Inc. All rights reserved. Article	2019	Torres, Thiago S; Luz, Paula M; De Boni, Raquel B; de Vasconcellos, Mauricio T L; Hoagland, Brenda; Garner, Alex; Moreira, Ronaldo I; Veloso, Valdilea G; Grinsztejn, Beatriz	Factors associated with PrEP awareness according to age and willingness to use HIV prevention technologies: the 2017 online survey among MSM in Brazil.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2019.1619665	https://www.tandfonline.com/doi/full/10.1080/09540121.2019.1619665	Brazil has the largest population of individuals living with HIV/AIDS in Latin America with a disproportional prevalence of infection among men who have sex with men (MSM). This study evaluated PrEP awareness by age (18-24, 25-35, ≥36 years), its associated factors and the willingness to use HIV prevention technologies among MSM using a GSN app in Brazil. Inclusion criteria were ≥18 years-old, cisgender men and HIV-negative serostatus. Of 7242 individuals, 4136 (57%) completed the questionnaire. PrEP awareness was reported by 51% (though lower among MSM aged 18-24 and ≥36 years) and its associated factors were higher family income, most friends with the same sexual orientation, high number of male sexual partners and marijuana use. HIV testing (never vs. at least once) lead to an almost 3-fold increase in the odds of PrEP awareness. High HIV risk perception led to increased PrEP awareness only among MSM aged 18-24 years. A total of 2335 (56%) was willing to use daily oral PrEP. PrEP awareness remains low in Brazil and mobile tools are key strategies to reach MSM and increase awareness of prevention technologies. Community-based interventions could add to online campaigns to reach the most vulnerable, which include young, non-white and lower-income MSM. Article	2019	Torres, Thiago S; Marins, Luana M S; Veloso, Valdilea G; Grinsztejn, Beatriz; Luz, Paula M	How heterogeneous are MSM from Brazilian cities? An analysis of sexual behavior and perceived risk and a description of trends in awareness and willingness to use pre-exposure prophylaxis	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-019-4704-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076987279&doi=10.1186%2fs12879-019-4704-x&partnerID=40&md5=2b64b4bb707de41c3ebafd1041e41a1e	Background: Brazil has the largest population of individuals living with HIV/AIDS in Latin America, with a disproportional prevalence of infection among gays, bisexuals and other men who have sex with men (MSM). Of relevance to prevention and treatment efforts, Brazilian MSM from different regions may differ in behaviors and risk perception related to HIV. Methods: We report on MSM living in 29 different cities: 26 Brazilian state capitals, the Federal District and two large cities in São Paulo state assessed in three web-based surveys (2016-2018) advertised on Grindr, Hornet and Facebook. Using logistic regression models, we assessed the association of risk behavior with HIV perceived risk as well as factors associated with high-risk behavior. Results: A total of 16,667 MSM completed the survey. Overall, MSM from the North and Northeast were younger, more black/mixed-black, of lower income and lower education compared to MSM from the South, Southeast and Central-west. Though 17% had never tested for HIV (with higher percentages in the North and Northeast), condomless receptive anal sex (previous 6 months) and high-risk behavior as per HIV Incidence Risk scale for MSM were observed for 41 and 64%, respectively. Sexual behavior and HIV perceived risk had low variability by city and high-risk behavior was strongly associated with high HIV perceived risk. Younger age, being gay/homosexual, having a steady partner, binge drinking, report of sexually transmitted infection (STI) and ever testing for HIV were associated with increased odds of high-risk behavior. Awareness and willingness to use PrEP increased from 2016 to 2018 in most cities. Conclusions: Overall, MSM socio-demographic characteristics were heterogeneous among Brazilian cities, but similarities were noted among the cities from the same administrative region with a marked exception of the Federal District not following the patterns for the Central-West. Combination HIV prevention is most needed among young men who self-identify as gay/homosexual, report binge drinking or prior STI. © 2019 The Author(s). Article	2019	Tortelli, Brett A; Char, Douglas M; Crane, John S; Powderly, William G; Salter, Amber; Chan, Philip A; Patel, Rupa R	Comfort Discussing HIV Pre-exposure Prophylaxis With Patients Among Physicians in an Urban Emergency Department.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001890	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6331216	Pre-exposure prophylaxis (PrEP), containing tenofovir disoproxil fumarate/emtricitabine, is effective to prevent HIV.1–7 One million adults are estimated to be in need of PrEP and engaging providers that can link at-risk persons into the PrEP continuum of care remains a priority.8–11 Emergency department (ED) physicians encounter at-risk individuals presenting an opportunity for PrEP education and linkage to care.12–15 Studies of PrEP awareness have focused on infectious diseases, HIV and primary care physicians.8,16–20 We assessed awareness and comfort in discussing PrEP with at-risk individuals among ED physicians in Missouri. From February through March 2017, we conducted an anonymous online survey of physicians in the Division of Emergency Medicine at Washington University in St. Louis (See Supplemental Digital Content). Participants were recruited through the department listserve using Qualtrics software (Qualtrics, Provo, UT). Survey development was informed by prior studies regarding provider PrEP awareness.16,21,22 At the time survey, the department had 88 physicians who were faculty, fellows and residents, and there had been no department PrEP education sessions. The study was approved by the Washington University in St. Louis Institutional Review Board. The 26-item questionnaire included physician demographics (i.e., level of training and years having practiced medicine since obtaining a medical degree) and seven topic domains: comfort in discussing HIV risk factors and PrEP with patients, awareness of PrEP, concerns with prescribing PrEP, perceived barriers to discussing PrEP with patients, educational training interest, training modality preference, and department support for training. The majority of question responses used a 5-point Likert scale: 1) strongly agree, 2) somewhat agree, 3) neither agree nor disagree, 4) somewhat disagree, and 5) strongly disagree and were used to create a binary measure of agree (1-2) versus did not agree (3-5) for the analysis. The primary outcome was comfort in discussing PrEP with patients. Comfort was defined as "strongly agree" or "somewhat agree." We assessed having an interest in PrEP educational training using a 3-point scale: 1) not interested, 2) moderately interested, and 3) very interested and defined (1) as "not interested" versus (2-3) as "interested." Training modality preferences included: 1) in-person training, 2) webinar, 3) self-guided online training, 4) written materials, and 5) other. Perceptions of having department support for PrEP training used a 3-point scale: 1) not supportive, 2) moderately supportive, and 3) very supportive and defined (1) as "no support" versus (2-3) as "support." Bivariate analyses were performed between the primary outcome and awareness- and concern-related factors. Multivariable logistic regression was performed to determine awareness- and concern-related predictors of comfort discussing PrEP with patients. Predictors that were significantly associated with comfort discussing PrEP in bivariate analyses were incorporated into the final regression model. Odds ratios (OR) and 95% confidence intervals (CI) are reported. All statistical tests were two-sided and the significance level was set at 0.05. Statistical analyses were performed using SPSS version 24 (IBM Corporation, Chicago, IL). Of 88 adult-trained emergency department physicians contacted, 76.0% completed the survey and were included in analyses. Many (64.2%) were faculty and the median years of practicing medicine were 15 years (interquartile range 10–25 years). Most (79.1%) had previously heard of PrEP to prevent HIV infection, but few (23.9%) reported awareness of the current Centers for Disease Control and Prevention (CDC) PrEP prescribing guidelines7 and only 34.3% were familiar with any current research regarding PrEP safety and efficacy. Providers reported being comfortable discussing intravenous drug use (100.0%) and sexual practices (95.5%) with their patients. However, under half (43.3%) of respondents reported being comfortable discussing PrEP with their patients. Twenty-three percent were aware of local PrEP care referral information for their patients. Concerns with PrEP prescribing included potential medication side effects (89.6%) and the selection for antiretroviral resistance (70.1%). Many (67.2%) reported that non-PrEP strategies should be attempted prior to PrEP initiation and that PrEP prescribing would lead to riskier sexual practices (47.8%). Over half (53.7%) of the providers were concerned that PrEP is not effective in reducing HIV transmission. In bivariate analyses, the comfort of providers discussing PrEP with their patients was associated with awareness of guidelines (P < 0.001),7 familiarity with current research on PrEP safety and efficacy (P < 0.01), awareness of local care referral information (P < 0.001), and the lack of a concern that PrEP was not effective (P < 0.01). When adjusting for the concern that PrEP is not effective, awareness of the guidelines (OR: 5.49; 95% CI: 1.14-26.48) and awareness of care referral information (OR: 6.54; 95% CI: 1.45-29.56) were significantly associated with comfort in discussing PrEP with patients (Table 1). Article	2019	Touger R.; Wood B.R.	A Review of Telehealth Innovations for HIV Pre-Exposure Prophylaxis (PrEP)	Current HIV/AIDS Reports	-	-	-	15483568	10.1007/s11904-019-00430-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85062970477&doi=10.1007%2fs11904-019-00430-z&partnerID=40&md5=d0e1ad113fdeb248ee7a4be234ad1bfa	Purpose of Review: This review summarizes novel interventions that employ technology to improve HIV pre-exposure prophylaxis (PrEP) availability, uptake, and adherence. Recent Findings: Several notable technology-based programs are increasing access to PrEP in unique ways. We identified multiple models for using telehealth to bolster PrEP dissemination and adherence, such as mobile applications that offer PrEP prescribing without an in-person visit, longitudinal distance telementoring for community provider PrEP education and clinical guidance, and electronic consults for PrEP specialist support in the primary care setting. Outcomes data for all of these modalities are limited but show promise. Summary: Technology-based interventions can address gaps in the PrEP care continuum. Future research should assess and compare outcomes, scalability, cost-effectiveness, and sustainability. Costs associated with the creation of new technological tools slow innovation and the field would benefit from a platform for technology sharing. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Tracer, Howard; Jasmin, Wilnise	Screening for HIV Infection and Preexposure Prophylaxis for the Prevention of HIV Infection.	American Family Physician	-	-	-	1532-0650	NA	https://www.aafp.org/pubs/afp/issues/2019/1115/p637.pdf	Nucleoside reverse transcriptase inhibitors (NRTIs) remain a critical component of therapy for HIV-infected patients. The drugs are effective, relatively inexpensive and an important component of antiretroviral therapy (ART), particularly in areas where the introduction of effective therapy has been delayed. They are an essential part of initial therapy for HIV and for prevention of mother-to-child transmission; however, toxicities and resistance may limit their use. The role for pre-exposure prophylaxis (PrEP) to reduce sexual transmission of HIV is still undefined, but this use may have a significant impact on NRTI resistance worldwide, most particularly in areas where subtype C predominates. With increasing prevalence of resistant HIV, the approval of new agents that are effective against resistant virus, and those that use novel cellular targets, are essential. Large studies are now in progress examining the safety and efficacy of NRTI-sparing regimens, but results are not currently available. NRTIs may lose relevance in the not distant future unless steps are put in place to reduce the development and spread of NRTI-resistant viruses, and new NRTIs with minimal toxicity are developed that have a novel resistance profile. This article describes the principal NRTIs, their mechanism of action, and resistance and selected toxicities of the class and of the individual drugs. Article	2019	Traeger, Michael W, MSc; Cornelisse, Vincent J, PhD, MBBS; Asselin, Jason, BSc; Price, Brian, MBA; Roth, Norman J, MBBS; Willcox, Jeff, MBBS; Tee, Ban Kiem, MBBS; Fairley, Christopher K, PhD, MBBS; Chang, Christina C, PhD, MBBS; Armishaw, Jude, BNurs; Vujovic, Olga, MBBS; Penn, Matthew, MBBS; Cundill, Pauline, BM; Forgan-Smith, George, MBBS; Gall, John, PhD, MBBS; Pickett, Claire, MBBS; Lal, Luxi, BPharm; Mak, Anne, BPharm; Spelman, Tim D, MBBS, MSc; Nguyen, Long, MCom; Murphy, Dean A, PhD; Ryan, Kathleen E, PhD; El-Hayek, Carol, MEpi; West, Michael, BA; Ruth, Simon, MSSc; Batrouney, Colin, BA; Lockwood, John T, BN; Hoy, Jennifer F, MBBS; Hellard, Margaret E, PhD, MBBS; Stoové, Mark A, PhD; Wright, Edwina J, PhD, MBBS	Association of HIV Preexposure Prophylaxis With Incidence of Sexually Transmitted Infections Among Individuals at High Risk of HIV Infection: The Journal of the American Medical Association	JAMA - Journal of the American Medical Association	-	-	-	00987484	10.1001/jama.2019.2947	https://pubmed.ncbi.nlm.nih.gov/30964528/	Importance Emerging evidence suggests that risk of bacterial sexually transmitted infections (STIs) increases among gay and bisexual men following initiation of HIV preexposure prophylaxis (PrEP). Objective To describe STI incidence and behavioral risk factors among a cohort of predominantly gay and bisexual men who use PrEP, and to explore changes in STI incidence following PrEP commencement. Design, Setting, and Participants The Pre-exposure Prophylaxis Expanded (PrEPX) Study, a multisite, open-label intervention study, was nested within the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS) clinic network. A total of 4275 participants were enrolled (July 26, 2016–April 1, 2018) in Victoria, Australia. Of these, 2981 enrolled at 5 ACCESS clinics (3 primary care, 1 sexual health, and 1 community-based HIV rapid testing service), had at least 1 follow-up visit, and were monitored until April 30, 2018. Exposures Upon enrollment, participants received daily oral tenofovir disoproxil fumarate and emtricitabine for HIV PrEP, quarterly HIV and STI testing, and clinical monitoring. Main Outcomes and Measures The primary outcome was incidence of chlamydia, gonorrhea, or syphilis. Incidence rates and hazard ratios describing behavioral risk factors of STI diagnosis were calculated. Incidence rate ratios (IRRs), adjusted for change in testing frequency, described changes in STI incidence from 1-year preenrollment to study follow-up among participants with preenrollment testing data (n = 1378). Results Among the 2981 individuals (median age, 34 years interquartile range, 28-42), 98.5% identified as gay or bisexual males, 29% used PrEP prior to enrollment, 89 (3%) withdrew and were censored at date of withdrawal, leaving 2892 (97.0%) enrolled at final follow-up. During a mean follow-up of 1.1 years (3185.0 person-years), 2928 STIs were diagnosed among 1427 (48%) participants (1434 chlamydia, 1242 gonorrhea, 252 syphilis). STI incidence was 91.9 per 100 person-years, with 736 participants (25%) accounting for 2237 (76%) of all STIs. Among 2058 participants with complete data for multivariable analysis, younger age, greater partner number, and group sex were associated with greater STI risk, but condom use was not. Among 1378 participants with preenrollment testing data, STI incidence increased from 69.5 per 100 person-years prior to enrollment to 98.4 per 100 person-years during follow-up (IRR, 1.41 95% CI, 1.29-1.56). After adjusting for testing frequency, the increase in incidence from 1 year preenrollment to follow-up was significant for any STI (adjusted IRR, 1.12 95% CI, 1.02-1.23) and for chlamydia (adjusted IRR, 1.17 95% CI, 1.04-1.33). Conclusions and Relevance Among gay and bisexual men using PrEP, STIs were highly concentrated among a subset, and receipt of PrEP after study enrollment was associated with an increased incidence of STIs compared with preenrollment. These findings highlight the importance of frequent STI testing among gay and bisexual men using PrEP. Theses and Dissertations	2019	Troth, Brian Jonathan	Amour à risques: A Reworking of Risk in the PrEP Era in France	-	-	The Ohio State University	-	NA	NA	http://rave.ohiolink.edu/etdc/view?acc_num=osu1562092704692905	At the crossroads of French Studies, Visual Studies, and Queer theory, my dissertation seeks to confront notions of risk and responsibility to argue that society's perceptions of risk have changed in relation to a pre-AIDS world and the onset of AIDS and that contemporary treatments such as PrEP (Pre-Exposure Prophylaxis) continue to refine our definition of risk. While much recent scholarship has been written about AIDS in the 1980s and 1990s, I would like to address contemporary AIDS narratives that respond to advances in medication and a shift in our understanding of AIDS from a death sentence, to a chronic disease, and now to a preventable illness.In order to explore how gay men's relationship with risk has been articulated in artistic production and has evolved with the availability of PrEP in France, my dissertation confronts cultural production throughout the epidemic. Film and literature analysis of Herve Guibert's work establishes a relationship between taking risks with one's health and the feelings of shame often felt in the early days of the epidemic, while a critical look at Cyril Collard's Les Nuits fauves in tandem with public health campaigns demonstrate how beauty is manipulated in times of epidemic. Engaging with Erik Remes's allows for further nuancing of the question of responsibility, and suggest that the epidemic resulted in a vilification of behavior that was not only deemed risky, but also irresponsible. Finally, I explore contemporary notions of risk through a study of prevention campaigns, film, newspaper articles, and interviews. The HIV/AIDS narrative in contemporary France is one that is marked by new modes of communication, the creation of a digital queer space, and a revisiting of the trauma of AIDS. The first three chapters are in the tradition of medical humanities and film studies approach, and the fourth chapter requires a shift methodology to one that emphasizes cultural studies and oral testimonies, necessitating onsite research with local activists. Theses and Dissertations	2019	Troutman, Jamie	Pre-Exposure Prophylaxis (PrEP) for HIV Prevention: A Mixed-Methods Study of Sexual Risks and Knowledge, Perceptions, and Willingness of PrEP Use Among African American Women in the South	-	-	University of South Carolina	-	NA	NA	https://scholarcommons.sc.edu/etd/5459	There are approximately 1.1 million people living with HIV in United States, with nearly 40,000 new diagnoses annually. Significant regional and racial disparities are associated with HIV diagnoses — with the South experiencing the greatest burden of HIV and African American women accounting for 60% of new diagnoses among women. Pre-exposure prophylaxis (PrEP) has been designated as an effective tool to prevent HIV transmission among individuals who may be at risk of HIV infection. Earlier PrEP research has focused mainly on at-risk groups such as men who have sex with men (MSM). Previous PrEP research involving African American women included mixed-race and mixed-gender populations, took place in larger, urban cities, and were mainly single-method studies. Given the disproportionate burden of HIV in the South and among African American women, further HIV prevention research is needed in this region and with this at-risk population. Therefore, a sequential, mixed-methods study was conducted to 1) examine the sexual behaviors that put African American women, living in the Southeast, at risk of HIV infection and eligible for PrEP and 2) to explore African American women's current knowledge, perceptions, and willingness of PrEP use for HIV prevention. Data were collected from May 2018 – April 2019 from African American women, 18 years of age or older, who were HIV-negative, and resided in the Southeastern United States. Quantitative data were collected from 413 women, through a confidential, self-administered sexual behavior survey. Four focus groups were conducted, with 27 women, to discuss sexual risk behaviors and PrEP for HIV prevention. Quantitative results demonstrate African American women are engaging in sexual risk behaviors that make them eligible for PrEP use, with nearly half of eligible women reporting an interest in potential PrEP use. Predictors of PrEP interest among women included younger age (18-35 years), perceived risk of HIV, receiving or giving money for sex, past experience of sexual assault, and comfort with condom negotiation. Qualitative data analyses revealed major themes around 1) sexual risk behaviors linked to HIV and 2) potential PrEP use for HIV prevention. First, several themes emerged highlighting HIV risk behaviors and multi-level factors that influence risk behaviors. These included: 1) lack of condom use; 2) HIV status, disclosure, and testing; 3) sexual partner sharing; 4) cultural and southern influences; 5) perceived societal worth; and 6) health care system and provider experiences impacting health care seeking. Second, several themes emerged which highlighted African American women's thoughts and likelihood of potential PrEP use. These included: 1) knowledge and awareness of PrEP; 2) perceptions of PrEP; 3) willingness to use PrEP; 4) concerns about PrEP; and 5) recommendations to increase PrEP uptake. Study findings are encouraging of PrEP implementation efforts targeting African American women in the South. It is important that future efforts to increase PrEP uptake be…	Medicine and Health Sciences; Public Health; Public Health Education and Promotion; HIV; African American women; Southern United States; sexual risk behaviors; knowledge of PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Mixed methods
Article	2019	Trujillo, Lindsay; Chapin-Bardales, Johanna; German, Emilio J; Kanny, Dafna; Wejnert, Cyprian	Trends in Sexual Risk Behaviors Among Hispanic/Latino Men Who Have Sex with Men - 19 Urban Areas, 2011-2017.	MMWR Recommendations and Reports	-	-	-	1545-861X	10.15585/mmwr.mm6840a2	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6788398	Correct and consistent condom use and human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP) are protective against sexual transmission of HIV (1,2). The incidence of HIV infection among Hispanic/Latino men who have sex with men (MSM) in the United States is increasing (3). HIV risk among Hispanic/Latino MSM differs based on their place of birth and years of U.S. residence (4). Data from CDC's National HIV Behavioral Surveillance (NHBS)* for 2011-2017 were analyzed to assess changes in sexual risk behaviors among Hispanic/Latino MSM by place of birth and years of U.S. residence. Overall, condomless anal sex during the previous 12 months increased from 63% in 2011 to 74% in 2017, and PrEP use during the previous 12 months increased from 3% in 2014 to 24% in 2017. Regardless of place of birth, nearly 75% of Hispanic/Latino MSM reported condomless anal sex during 2017. However, because of PrEP use, <60% of non-U.S.-born Hispanic/Latino MSM and <50% of U.S.-born Hispanic/Latino MSM reported unprotected anal sex (condomless anal sex and no PrEP use) during 2017. Results indicate that PrEP can be a vital tool for reducing HIV transmission among Hispanic/Latino MSM, especially those who have condomless anal sex. Interventions to prevent HIV acquisition, including increasing PrEP uptake, could address cultural and linguistic needs of Hispanic/Latino MSM, as well as other barriers to prevention of HIV infection typically faced by all MSM. Article	2019	Tugume L.; Muwonge T.R.; Joloba E.N.; Isunju J.B.; Kiweewa F.M.	Perceived risk versus objectively measured risk of HIV acquisition: A cross-sectional study among HIV-negative individuals in Serodiscordant partnerships with clients attending an Urban Clinic in Uganda	BMC Public Health	-	-	-	14712458	10.1186/s12889-019-7929-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075785020&doi=10.1186%2fs12889-019-7929-0&partnerID=40&md5=417394affc261a93545142c7d3b1d1eb	Background: Acceptability of Pre-exposure Prophylaxis (PrEP) could be hampered by low self-perceived risk for HIV acquisition. Moreover, discordance between risk perception and actual risk of HIV acquisition is likely to occur. We assessed congruence between the level of self-perceived and that of objectively scored risk of HIV acquisition among HIV-negative individuals in discordant relationships. Methods: This was a cross-sectional study among a representative sample of HIV-negative adult males and females whose partners were receiving antiretroviral therapy for at least 3 months from the Infectious Diseases Institute Clinic in Kampala, Uganda. Perceived risk was measured based on self-report using a numerical rating scale whereas objective risk was measured using a validated risk score tool. Congruence between perceived risk and objectively scored risk was evaluated using descriptive statistics and validity measures. Incongruence between the two phenomena was further evaluated using univariate and multivariate regression analyses. Results: HIV-negative partners evaluated in this study were mostly male (64%) with a median age of 41 years (IQR 35 to 50). Majority (76.3%) of the partners perceived themselves as low risk for HIV acquisition. Similarly, most (93.8%) were objectively scored as low risk. However, nearly three quarters (72.7%) of partners who were objectively scored as high risk perceived themselves as being at low risk and all were men. The sensitivity and specificity of perceived risk for detecting the objectively measured risk was 27.3 and 76.5% respectively; area under ROC curve = 0.52; 95%CI (0.38, 0.66). The proportion of participants at high risk of HIV acquisition who perceived their risk as low was greater among those whose partners had detectable viral load compared to participants whose partners had undetectable viral load (PR = 0.51; 95%CI 0.29 to 0.90). Conclusion: Incongruence between perceived and objectively measured risk of HIV acquisition does occur especially among individuals whose partners had a detectable viral load. PrEP counselling for serodiscordant couples should focus on explaining the consequence of detectable viral load in the HIV-positive partner on HIV transmission risk. © 2019 The Author(s). Theses and Dissertations	2019	Turner, Deanne E.	Using the Consolidated Framework for Implementation Research to Investigate Daily Pre-exposure Prophylaxis (emtricitabine/tenofovir DF) Implementation via Community-based HIV Testing Sites in Florida	-	-	Florida International University	-	NA	NA	https://digitalcommons.usf.edu/etd/8419 https://digitalcommons.usf.edu/context/etd/article/9616/viewcontent/Turner_usf_0206D_15410.pdf	Background: Pre-exposure prophylaxis (PrEP) is a daily pill that can reduce a person's chances of acquiring HIV. HIV testing and counseling is a critical point during which non-clinical staff could intervene, discuss and/or refer clients for PrEP. However, not all HIV testing/counseling staff take part in PrEP implementation in the same way. This study investigated: 1) the underlying PrEP implementation subgroups of staff who perform HIV testing and 2) PrEP implementation as a function of key constructs from the Consolidated Framework for Implementation Research (CFIR). Methods: This study was a mixed methods concurrent triangulation design, in which qualitative and quantitative data were collected concurrently and data were triangulated during analysis and interpretation. Latent Class Analysis (LCA) was performed using MPlus.v.8 on a sample of 150 HIV testing/counseling staff in Florida. The LCA technique groups participants based on similarities in how they answer a predetermined set of questions (here, five items related to PrEP-implementation behaviors). The final LCA model and corresponding latent classes were determined based upon fit indices and theoretical interpretation. Two generalized linear mixed models were conducted to estimate PrEP implementation as a function of key variables from the CFIR. A total of 22 interviews were completed and data were analyzed thematically. Results: A LCA with four models was conducted–containing 1, 2, 3 or 4 classes, respectively. Based on consideration of fit statistics and theoretical relevance, a 3-class LCA was selected. Class one (labeled "Universal"; 42%; n=62) includes HIV testing/counselors who were PrEP advocates; "Universal" participants were likely to talk about PrEP with clients, regardless of client eligibility, and likely to share physical information about PrEP (e.g. brochures). Class two (labeled "Eligibility Dependent"; 33%; n=48) includes staff who were most likely to discuss PrEP if they believed their client met the indications for PrEP. Staff in Class 3 (labeled "Limited"; 25%; n=37) spoke to clients about PrEP inconsistently. Several variables under the CFIR have a statistically significant association with PrEP implementation among HIV testing staff, including race, sexual orientation, relative priority, and available resources. Qualitative data revealed the importance of available resources, cosmopolitanism, and leadership in PrEP implementation within community-based HIV testing sites. Conclusions: Not all HIV testing and counseling staff discuss PrEP with clients. Some staff differentially discuss PrEP based on eligibility, or inconsistently talk to clients about PrEP. Understanding implementation subgroups can assist in training and program development. Furthermore, understanding the factors that could affect PrEP implementation (e.g. availability of PrEP-related resources) may help organizations to better prepare HIV testing staff to more seamlessly implement PrEP education and referrals. Theses and Dissertations	2019	Tyo, Kevin Michael	Electrospun fibers and nanoparticles for the prevention of sexually transmitted infections.	-	-	University of Louisville	-	NA	NA	https://ir.library.louisville.edu/etd/3344	Human immunodeficiency virus-1 (HIV-1) and herpes simplex virus 2 (HSV-2) affect hundreds of millions of people worldwide, with women disproportionately impacted by these infections. Currently, only oral pre-exposure prophylaxis (PrEP) is approved specifically for the prevention of HIV-1, but is challenged with adverse side effects associated with long-term use. Topical delivery platforms, such as gels and films, deliver agents directly to the female reproductive tract, but are limited in providing transient-release. The technology of polymeric electrospun fibers may serve as alternative topical delivery platform to the female reproductive tract. In these studies, we fabricated electrospun fibers comprised of different polymers or polymer blends that possess different physical attributes and fiber architectures. The goal was to provide sustained-release of agents such as the antiretroviral tenofovir disoproxil fumarate (TDF) and the antiviral lectin, Griffithsin (GRFT). We hypothesized that these delivery platforms would prevent HIV-1 and HSV-2 infections, while retaining the safety and biocompatibility of free agent. To determine the amount of GRFT loading and release from fiber formulations, ELISA was conducted, whereas TDF quantification was performed using absorbance measurements. Next, the in vitro efficacy of composites was assessed in HIV-1 and HSV-2 infectivity assays. From these initial results, multilayered fiber composites, free NPs, and hydrophilic fibers were tested for safety and antiviral efficacy within a murine model. Animal studies were conducted using 5-week-old female BALB/c mice, histology and cytokine expression were evaluated from mouse reproductive tracts and vaginal lavages collected 24 and 72 hr following platform administration. In parallel experiments, mice were administered fibers, followed by a single challenge 4 or 24 hr later with HSV-2 (LD90). Viral progression was monitored for 14 days post viral challenge to evaluate potential infection. Statistical significance for all studies was determined using one-way ANOVA with Bonferroni post hoc test (p < 0.05), while log-ranked post hoc tests were used for antiviral efficacy studies. Future studies will consider encapsulation of multiple antiviral compounds to provide synergetic protection against infection. Predictors of Daily Adherence to HIV Pre-exposure Prophylaxis in Gay/Bisexual Men in the PRELUDE Demonstration Project	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2353-5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058104226&doi=10.1007%2fs10461-018-2353-5&partnerID=40&md5=c5e5c75d86a1ee698b0d98dac36c9651	Adequate adherence to pre-exposure prophylaxis (PrEP) is critical to prevent HIV infection, but accurately measuring adherence remains challenging. We compared two biological blood drug concentrations in plasma and peripheral blood mononuclear cells (PBMC) and two self-reported measures (facilitated recall to clinicians and self-report in online surveys) and identified predictors of daily PrEP adherence among gay and bisexual men (GBM) in their first 12 months on PRELUDE, an open-label, single-arm PrEP demonstration project in New South Wales, Australia. 327 participants were enrolled; 263 GBM attended their 12-month follow-up visit (81% retention). Overall, 91% of blood samples had plasma drug concentrations indicative of taking 7 pills/week, and 99% had protective drug concentrations (≥ 4 pills/week). Facilitated recall to clinicians identified 99% of participants with protective adherence as measured by PBMC drug concentrations. Daily adherence measured by facilitated recall was associated with behavioural practices including group sex (aOR 1.33, 95% CI 1.15–1.53, p < 0.001). Retained participants maintained high adherence to daily PrEP over 12 months, confirmed by four different measures. Facilitated recall to clinicians is a suitable measure for assessing PrEP adherence in populations engaged in care where there is established trust and rapport with patients. Article	2019	Vaitses Fontanari, Anna Martha; Zanella, Gabriel Ibarra; Feijó, Marina; Churchill, Siobhan; Rodrigues Lobato, Maria Inês; Costa, Angelo Brandelli	HIV-related care for transgender people: A systematic review of studies from around the world.	Social Science & Medicine	-	-	-	1873-5347	10.1016/j.socscimed.2019.03.016	https://dx.doi.org/10.1016/j.socscimed.2019.03.016	RATIONALE: Transgender people face unique challenges, such as structural, interpersonal, and individual vulnerabilities to chronic diseases. Stigma and prejudice may hamper their access to health care and prevent their inclusion in the labor market, as well as cause exposition to violence. Labor market exclusion contributes to engagement in survival sex work, which increases HIV infection vulnerability. HIV continuum of care combines HIV prevention (including antiretroviral pre-exposure prophylaxis (PrEP), antiretroviral post-exposure prophylaxis (PEP) and HIV testing) with linkage to care (that is, initiating, maintaining and monitoring antiretroviral therapy). Currently, many studies evaluate the access barriers and facilitators to HIV care for transgender people. OBJECTIVE: The present systematic review aimed to provide a clear summary of the current literature on HIV-related care for transgender men, transgender women and gender diverse people. METHOD: Inclusion criteria were peer-reviewed quantitative studies, published through April 04, 2018, concerning transgender women, transgender men and gender diverse people and HIV-related care, which was any intervention aiming to prevent, treat or alleviate the impact of HIV on these populations. RESULTS: From 6,585 references, 62 articles were included: Three articles had results on PEP, 18 on PrEP, 29 on HIV-testing, 17 on access to health care, and 13 on adherence to treatment. CONCLUSIONS: The present study is the first systematic review evaluating HIV-related care for transgender people. Data collection is still scarce regarding transgender men and gender diverse people. Worldwide, testing for HIV infection does not necessarily enable access to the HIV continuum of care for transgender populations or even guarantee awareness of HIV seropositivity. Article	2019	Valdiserri, Ronald O; Holtgrave, David R	Pre-exposure Prophylaxis for HIV Infection: Preventing Disease or Promoting Sexual Health?	Journal of Community Health	-	-	-	00945145	10.1007/s10900-018-00616-3	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-hiv-infection-preventing/docview/2164908349/se-2?accountid=8113	Practitioners of public health recognize that disease prevention and health promotion occupy the same continuum of activities that are aimed at improving individual and population health. Closely related as they are, however, these two domains are not identical—either in concept or in practice. Their differences owe to the widely-accepted definition of health as a state of "complete physical, mental and social well-being and not merely the absence of disease or infirmity" 1. Namely, while the absence of disease brought about by prevention activities is a laudable goal and an important component of health, it may not be the only condition necessary to achieve and sustain overall health. Article	2019	van de Vijver D.A.M.C.; Richter A.-K.; Boucher C.A.B.; Gunsenheimer-Bartmeyer B.; Kollan C.; Nichols B.E.; Spinner C.D.; Wasem J.; Schewe K.; Neumann A.	Cost-effectiveness and budget effect of pre-exposure prophylaxis for HIV-1 prevention in Germany from 2018 to 2058	Eurosurveillance	-	-	-	1025496X	10.2807/1560-7917.ES.2019.24.7.1800398	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061849430&doi=10.2807%2f1560-7917.ES.2019.24.7.1800398&partnerID=40&md5=c3ac91eb4e4276e22ae503548199f1fb	Background: Pre-exposure prophylaxis (PrEP) is a highly effective HIV prevention strategy for men-whohave- sex-with-men (MSM). The high cost of PrEP has until recently been a primary barrier to its use. In 2017, generic PrEP became available, reducing the costs by 90%. Aim: Our objective was to assess cost-effectiveness and costs of introducing PrEP in Germany. Methods: We calibrated a deterministic mathematical model to the human immunodeficiency virus (HIV) epidemic among MSM in Germany. PrEP was targeted to 30% of high-risk MSM. It was assumed that PrEP reduces the risk of HIV infection by 85%. Costs were calculated from a healthcare payer perspective using a 40-year time horizon starting in 2018. Results: PrEP can avert 21,000 infections (interquartile range (IQR): 16,000-27,000) in the short run (after 2 years scaleup and 10 years full implementation). HIV care is predicted to cost EUR 36.2 billion (IQR: 32.4-40.4 billion) over the coming 40 years. PrEP can increase costs by at most EUR 150 million within the first decade after introduction. Ten years after introduction, PrEP can become cost-saving, accumulating to savings of HIVrelated costs of EUR 5.1 billion (IQR: 3.5-6.9 billion) after 40 years. In a sensitivity analysis, PrEP remained cost-saving even at a 70% price reduction of antiretroviral drug treatment and a lower effectiveness of PrEP. Conclusion: Introduction of PrEP in Germany is predicted to result in substantial health benefits because of reductions in HIV infections. Short-term financial investments in providing PrEP will result in substantial cost-savings in the long term. © 2019, European Centre for Disease Prevention and Control (ECDC). Article	2019	Van Epps P.; Wilson B.M.; Garner W.; Beste L.A.; Maier M.M.; Ohl M.E.	Incidence of HIV in a Nationwide Cohort Receiving Pre-exposure Prophylaxis for HIV Prevention	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000002186	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074742199&doi=10.1097%2fQAI.0000000000002186&partnerID=40&md5=48edcd4ef5d2164b94e14102a10a410b	Background:Cases of HIV, while infrequent, have been reported during tenofovir disoproxil fumarate/emtricitabine use as pre-exposure prophylaxis (PrEP). We describe the incidence of HIV and patterns of PrEP use within the Veterans Health Administration (VHA).Methods:We conducted a retrospective cohort study among persons initiating PrEP in the VHA between July 2012 and April 2016 using national VHA data. We defined time on PrEP and time at risk of HIV exposure as the total time from the first PrEP fill to exhaustion of supply of the final PrEP prescription. We identified incident cases of HIV infection after PrEP initiation based on laboratory data. Medication adherence measures and days without pills were calculated using pharmacy fill data. We used a chart review to determine patient-reported PrEP use around the time of diagnosis.Results:We identified 825 unique patients initiating PrEP; they were 97% men and 67% white, with a mean age of 41 years. Six HIV infections were observed during the study period, yielding an HIV incidence of 0.8 (Poisson exact 95% confidence interval: 0.3 to 1.8) cases per 100 person-years. Two cases occurred during active PrEP use by self-report and perfect adherence based on fill data. Both were infected with viruses containing the M184V mutation. Four additional cases were diagnosed after self-reported discontinuation.Conclusions:HIV infection was rare in a nationwide cohort of PrEP users. Although most of the infections occurred during inconsistent PrEP use, infections during periods of high measured adherence were also observed. These findings highlight the importance of PrEP persistence during periods of risk. © 2019 The Author(s). Published by Wolters Kluwer Health, Inc. Article	2019	Van Obberghen E.K.; Viard D.; Lafeuillade A.; Civiletti A.; Rocher F.; Drici M.-D.	Are current guidelines adapted for patient eligibility to PrEP? A case report	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-019-4239-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068825836&doi=10.1186%2fs12879-019-4239-1&partnerID=40&md5=0dc8d7a9b0c4832b7ce6331a0c2b6a6e	Background: Despite effective antiretroviral therapy developed over the last decade, HIV infection remains a major worldwide public health problem. Recently, a promising preventive treatment has been made available for HIV prophylaxis, PrEP for pre-ExPosure Prophylaxis. Indeed, it was shown to significantly reduce the risk of HIV infection in patients exposed to high risk of infection such as men having sex with men (MSM), heterosexuals and people who inject drugs. Several issues pertaining to PrEP remain uncertain including short and long-term adverse events, drug resistance, risk compensation and resurgence of other sexually transmitted infections. Case presentation: We report a case of a 52-year-old MSM eligible for PrEP as he was exposed to a high risk of HIV infection, presented no clinical symptoms of HIV primary infection and was seronegative for HIV. PrEP therapy was then initiated with fixed association of emtricitabine-tenofovir disoproxil. One month later, HIV tests using two different assays were positive, despite perfect compliance reported by the patient and confirmed by plasma drug level. A retrospective search for plasma viral RNA in the blood sample before PrEP initiation turned out positive. Genotyping and treatment sensitivity performed on sample after one month of PrEP showed a virus resistance to lamivudine and emtricitabine. Similar cases in the literature and pivotal studies have reported HIV infections in patients initiating or undergoing PrEP. These patients where either infected but still seronegative, displaying no clinical symptoms upon enrollment, or became infected during PrEP. Reasons are mainly poor compliance to treatment, resistance to PrEP, and lack of diagnosis before PrEP. Guidelines advocate safe sex behavior before initiation, search for clinical signs of HIV primary infection and two different serologic tests performed with one-month interval. Discussion and conclusions: Our patient newly HIV infected received PrEP as he was still seronegative. Current recommendations fail to screen recently HIV infected, but still seronegative patients who are initiating PrEP. This issue raises strong concerns regarding the lack of adequate selection for eligibility to PrEP and may contribute to exposing partners to HIV infection and select viral mutations. Infection risk could be minimized by search for plasma viral HIV RNA at pre-inclusion, at least for patients suspected of unsafe behaviors such as non-respect of the non-exposure period before PrEP initiation. © 2019 The Author(s). Article	2019	van Vliet, Marjolein M; Hendrickson, Cheryl; Nichols, Brooke E; Boucher, Charles Ab; Peters, Remco Ph; van de Vijver, David Amc	Epidemiological impact and cost-effectiveness of providing long-acting pre-exposure prophylaxis to injectable contraceptive users for HIV prevention in South Africa: a modelling study.	Journal of the International AIDS Society	-	-	-	1758-2652	10.1002/jia2.25427	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6922023	INTRODUCTION: Although pre-exposure prophylaxis (PrEP.) is an efficacious HIV prevention strategy, its preventive benefit has not been shown among young women in sub-Saharan Africa, likely due to non-adherence. Adherence may be improved with the use of injectable long-acting PrEP methods currently being developed. We hypothesize that providing long-acting PrEP to women using injectable contraceptives, the most frequently used contraceptive method in South Africa, could improve adherence to PrEP, result in a reduction of new HIV infections, and be a relatively easy-to-reach target population. In this modelling study, we assessed the epidemiological impact and cost-effectiveness of providing long-acting PrEP to injectable contraceptive users in Limpopo, South Africa. METHODS: We developed a deterministic mathematical model calibrated to the HIV epidemic in Limpopo. Long-acting PrEP was provided to 50% of HIV negative injectable contraceptive users in 2018 and scaled-up over two years. We estimated the number of HIV infections that could be averted by 2030 and the drug price of long-acting PrEP for which this intervention would be cost-effective over a time horizon of 40 years, from a healthcare payer perspective. In the base-case scenario we assumed long-acting PrEP is 75% effective in preventing HIV infections and 85% of infected individuals are on antiretroviral drug therapy (ART) by 2030. In sensitivity analyses we adjusted PrEP effectiveness and ART coverage. Costs between \$519 and \$1119 per disability-adjusted life-year (DALY) averted were considered potentially cost-effective, and <\$519 as cost-effective. RESULTS: Without long-acting injectable PrEP, 224,000 (interquartile range 176,000 to 271,000) new infections will occur by 2030; use of long-acting injectable PrEP could prevent 21,000 (17,000 to 26,000) or 9.8% (8.9% to 10.6%) new HIV infections by 2030 (including 6000 (4000 to 7000) in men). Long-acting PrEP would prevent 34,000 (29,000 to 39,000) or 12,000 (8000 to 15,000) at 75% and 95% ART coverage by 2030 respectively. To be considered potentially cost-effective the annual long-acting PrEP drug price should be <\$16, and/or ART coverage remains at <85% in 2030. CONCLUSIONS: Providing long-acting PrEP to injectable contraceptive users in Limpopo is only potentially cost-effective when long-acting PrEP drug prices are low. If low prices are not feasible, providing long-acting PrEP only to women at high risk of HIV infection will become important. Article	2019	Vaughn, Kendra; Dillon, Patrick J; Kedia, Satish K	Barriers to PrEP uptake: Perspectives of community health workers in the Mid-South region of the United States	Journal of HIV/AIDS & Social Services	-	-	-	15381501	10.1080/15381501.2019.1655512	https://www.proquest.com/scholarly-journals/barriers-prep-uptake-perspectives-community/docview/2311910626/se-2?accountid=8113	Despite its promise, pre-exposure prophylaxis (PrEP) uptake has been slow in the United States with fewer than 100,000 of the 1.1 million Americans considered at substantial risk for HIV currently taking it. Community health workers play a critical role in promoting PrEP awareness and access in their local communities. However, there is currently limited literature that focuses on barriers faced by community health workers providing PrEP services. The present qualitative study draws upon the social ecological model (SEM) to examine barriers to PrEP uptake from the perspective of community health workers in a large Mid-South U.S. city. Study participants identified several barriers at all five levels of the SEM: individual, interpersonal, community, organizational, and policy. The study findings provide viable entry points for multilevel interventions aimed at promoting PrEP uptake. Article	2019	Vuylsteke, Bea; Reynders, Thijs; De Baetselier, Irith; Nitsellinger, Christiana; Crucitti, Tania; Buyze, Jozefien; Kenyon, Chris; Wouters, Kristien; Laga, Marie	Daily and event-driven pre-exposure prophylaxis for men who have sex with men in Belgium: results of a prospective cohort measuring adherence, sexual behaviour and STI incidence.	Journal of the International AIDS Society	-	-	-	1758-2652	10.1002/jia2.25407	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6819946/	1	1	1	1	1	1	1	1	1	INTRODUCTION: Pre-Exposure Prophylaxis (PrEP) is highly effective in reducing the risk for HIV infection among men who have sex with men (MSM), and may have an important impact in slowing down HIV incidence. However, concerns about low medication adherence, increased risk behaviour and reduced condom use when using PrEP. The aim of this study was to assess these factors prospectively among MSM using daily and event-driven PrEP in Belgium. METHODS: An open-label prospective cohort study was conducted from October 2017 to May 2018 at the Institute of Tropical Medicine, in Antwerp, Belgium. At enrolment, MSM at high risk for HIV chose between daily or event-driven PrEP. They were allowed to switch regimens or stop taking PrEP at each of their bi-monthly visits. Data were collected on an electronic case report form, web-based diary and self-administered questionnaire. Screening for HIV and other Sexually Transmitted Infections (STIs) was also performed. RESULTS: Two hundred MSM were followed-up for a total duration of 318 person-years. At month 18, 75.4% of the participants were on daily and 24.6% were on event-driven PrEP. The mean proportion of covered sex acts by PrEP for the complete follow-up period was 91.2% for all participants, 96.5% for daily and 67.0% for event-driven PrEP use. The number of casual and anonymous sex partners was significantly higher for daily users, as compared with event-driven users, but did not change over time. In contrast, the mean proportion of condomless receptive anal intercourse with casual and anonymous partners increased significantly over time (p = 0.001), but was not different between daily and event-driven users (p = 0.1). The incidence of bacterial STIs was 57.9 per 100 person-years (95% CI 43.6 to 75.1). The incidence of gonorrhoea, syphilis and lymphogranuloma venereum was 29.6 per 100 person-years. CONCLUSIONS: Daily and event-driven PrEP are effective and well-adapted HIV prevention tool for MSM in Belgium. Participants adapted daily and event-driven regimens to their own needs and were able to adapt their PrEP adherence to risk exposure. Article	2019	Walmsley, Ben; Gallant, Dan; Naccarato, Mark; Hull, Mark; Smith, Alex; Tan, Darrell Hoi-Sau	The PrEP You Want: A Web-Based Survey of Online Cross-Border Shopping for HIV Prophylaxis Medications.	Journal of Medical Internet Research	-	-	-	1438-8871	10.2196/12076	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6603100/	1	1	1	1	1	1	1	1	1	BACKGROUND: In response to the high cost of HIV pre-exposure prophylaxis (PrEP) medications in Canada, community organizations have created internet-based guides detailing how to legally order generic medications online and travel to collect them in the United States. However, little is known about the patients following these guides. OBJECTIVE: Our primary objective was to measure the proportion of Ontario gay, bisexual, and other men who have sex with men (GBMSM) accessing these online guides who intended to use the border-crossing approach. Our secondary objectives were to explore their demographic characteristics, their completion of the steps in the border-crossing approach, and the barriers they perceived. METHODS: Between July 20, 2017, and May 18, 2018, we administered two online surveys to GBMSM who accessed a border-crossing guide. The first survey was administered to participants at baseline and the second survey was administered to participants on the guide's landing page and a follow-up survey 3 months later. The data were analyzed using descriptive statistics. We used multivariable logistic regression to identify characteristics associated with the intention to use the border-crossing approach. RESULTS: Most of the 141 participants were young (median age 23, interquartile range 22-25 years) and black (79.4%, 112/141). GBMSM who had completed a college or an undergraduate degree (62.4%, 88/141) were common. In addition, 19.9% (28/141) of them reported a total family income less than $30,000 and another 53.9% (76/141) reported income between $30,000 and $60,000. 54.6% (76/141) paid for medications entirely out of pocket. Most participants indicated that they were likely to complete a border-crossing approach: 80.1% (113/141) at baseline and 79.1% (87/110) at follow-up. The characteristics associated with the intention to use the approach included being black (adjusted odds ratio aOR 5.73, 95% CI 2.06-16.01), paying for medications out of pocket (aOR 7.18, 95% CI 3.82-17.04), and having a provider who was thought to be willing to prescribe PrEP (aOR 4.42, 95% CI 1.63-12.41). Comparing baseline and follow-up for the 110 participants who completed both surveys, we found that 11.8% (13/110) of them had used the approach by follow-up. The most commonly used pharmacies were Canadian Discount Pharmacy (7/13, 54%) and Rx Outlet (3/13, 23%). All had ordered medications to that mailbox, whereas only 1.8% (1/110) and 0.9% (1/110) had crossed the border to collect them at baseline and follow-up, respectively. Reported barriers included perceived concerns about the approach's legality (56.0%, 79/141), the security of personal health information (39.0%, 55/141), and the safety of online vendors (38.3%, 54/141). CONCLUSIONS: Despite high interest in pursuing an online border-crossing approach to get PrEP medications, such an approach may not be a viable option for PrEP scale-up among interested GBMSM because of logistical challenges and perceptions of safety and legitimacy. Article	2019	Walsh J.L.	Applying the Information–Motivation–Behavioral Skills Model to Understand PrEP Intentions and Use Among Men Who Have Sex with Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-018-2371-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85058161936&doi=10.1007%2Fs10461-018-2371-3&partnerID=40&md5=5a7b3d5d295e8c3fd0065d2ca6e9ead	Research is needed to determine the strategies for interventions to increase pre-exposure prophylaxis (PrEP) uptake. The Information–Motivation–Behavioral Skills (IMB) model has not been tested for PrEP use among men who have sex with men (MSM). Men and transgender women and men were surveyed at a community event in the Midwest in 2014 (N = 476, 60% White, Mage = 33). New measures assessed PrEP knowledge, attitudes, stigma, descriptive and subjective norms, and intentions, and participants reported on PrEP use. We tested the IMB model for a subsample of HIV-negative MSM and transgender individuals (N = 357) using structural equation modeling. Only 12% of participants used PrEP. New measures performed well and were reliable (α = 0.83–0.94). Structural models generally supported the IMB model knowledge, stigma, and self-efficacy were directly associated with use, and attitudes, stigma, and descriptive norms had indirect effects on use via self-efficacy. The IMB model may be useful when developing PrEP interventions for MSM. © 2018, Springer Science+Business Media, LLC, part of Springer Nature.	1	1	1	1	1	1	1	1	1	HIV prevention; Information–motivation–behavioral skills model; Men who have sex with men; Pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2019	Wang H.; Zhang Y.; Mei Z.; Jia Y.; Lesha S.I.; Zhang J.; Cha Z.; Ding H.; Jiang Y.; Geng W.; Shang H.; Xu J.	Protocol for a multicenter, real-world study of HIV pre-exposure prophylaxis among men who have sex with men in China (ChinaPrEP)	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-019-4355-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070967536&doi=10.1186%2Fs12879-019-4355-y&partnerID=40&md5=3c7fa85b3f8ce40fa4899ab0e0f0b7a1	Background: Pre-exposure prophylaxis (PrEP) is a promising and effective tool to prevent human immunodeficiency virus (HIV) transmission; however, context-specific data to guide optimal implementation are currently lacking in China. This study aims to systematically collect comprehensive, empirical data to determine effective ways to implement PrEP among at-risk men who have sex with men (MSM) in China. Methods: The CHOPrEP project, a real-world study of PrEP use, will recruit 1000 high-risk HIV-negative MSM participants from four cities in China, who will be able to choose between daily or event-driven dosing regimens, according to their preference. Participants will be followed up at months 1, 3, 6, 9, and 12 for PrEP provision, clinical evaluation, laboratory testing (e.g., eurrieulum-tenofovir disoproxil fumarate (FTC/TDF) concentrations, and HIV/sexually transmitted infections), alongside detailed, self-administered online questionnaires regarding sexual behaviors, adherence, and attitudes. Online weekly notes will be used to record pill use and sexual practice. Various measurements will be triangulated to assess adherence, including self-reported adherence, pill count, and drug concentration. A propensity score matching model will be fitted to examine the effectiveness of PrEP use in HIV seroconversion compared with non-PrEP users selected from a local expanding cohort study of HIV-1-negative MSM. Discussion: The CHOPrEP project is the first study of the TDF/FTC combination as PrEP in China, which will provide primary data on PrEP implementation, including the cascade of PrEP use, "real-world" effectiveness, adherence, and safety. The findings have potential to be vital for promoting the integration of PrEP within the portfolio of HIV prevention interventions and developing guidance on PrEP implementation in China. © 2019 The Author(s).	1	1	1	1	1	1	1	1	1	HIV; MSM; Pre-exposure prophylaxis; PrEP	English	United Kingdom	Western and Central Europe and North America	China	Asia and the Pacific	China	Asia and the Pacific	Clinical
Article	2019	Wang, Xinzhe; Nutland, Will; Brady, Michael; Green, Ian; Boffito, Marta; McClure, Myra	Quantification of tenofovir diacoproxil fumarate and emtricitabine in generic pre-exposure prophylaxis tablets obtained from the internet	International journal of STD & AIDS	-	-	-	9566624	10.1177/0956462419841144	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063737363&doi=10.1177%2F0956462419841144&partnerID=40&md5=a2789078bca3c8fd4b8ca52fa1e6c2	In this study, we addressed the recent concerns over the authenticity of generic pre-exposure prophylaxis (PrEP) purchased online by sampling 14 generic PrEPs from different manufacturers and suppliers and assessing tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) content using high-performance liquid chromatography. We confirmed that all the PrEP tablets contained 94.5% to 106.9% of the 300 mg of TDF claimed on the label and 97.3% to 104.4% of the 200 mg FTC claimed on the label. © The Author(s) 2019.	1	1	1	1	1	1	1	1	1	Generic PrEP; HIV prevention; liquid chromatography; quantification; tablet form	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative

Article	2019	Ward, Helen	MO.3 Impact of HIV PrEP on risk compensation and STI epidemiology: a review	Sexually Transmitted Infections	-	-	-	13684973	10.1136/sextrans-2019-sti.26	https://www.proquest.com/scholarly-journals/s03-3-impact-hiv-prep-on-risk-compensation-sti/docview/2256660768/se-2?accountid=8113	Introduction/Even the earliest days of the HIV epidemic there has been a close relationship with other sexually transmitted infections (STI). The shared transmission routes and determinants were reflected in high levels of synergy in the epidemics. Early preventive interventions for HIV – including changes in partner numbers and selection, use of barriers and changes in sexual practices towards safer sex – were infection agnostic, and had a dramatic impact on bacterial STI, with levels of syphilis and gonorrhoea falling to historic lows in some high-income settings. In contrast, many newer technologies for HIV prevention are 'infection specific', leading to the potential for divergent epidemics of HIV and other STIMethod and resultsWe review evidence to date of the impact of PrEP on (a) risk compensation, and (b) STI rates in a range of settings. We synthesise data from earlier systematic reviews, and review the associations between PrEP use and bacterial STIs in six quasi-experimental studies. Detailed results will be presented; briefly, early randomised control trials reported no increase in STIs or changes in sexual practices; more recent studies in low controlled environments such as open-label or demonstration projects have found increases in STIs, but not consistently. Studies of the impact of PrEP on condom use have found no evidence of reduced condom use, but the measurement of condomless sex is not an unintended consequence of PrEP. For decades HIV prevention was limited because many people prefer sex without condoms and there was no technology to do this without the fear of HIV, just as the oral contraceptive pill (OCP) removed the fear of pregnancy for many women. While that may contribute to an increase in STI, as the OCP did, we should see this as an opportunity to argue for renewed investment in STI control programmes and research.DisclosureNo significant relationships.	1	1	1	1	1	1	1	1	1	Epidemics; PrEP; prevention; Risk compensation; epidemiology; Sexually transmitted infection; Human immunodeficiency virus; Pre-exposure prophylaxis; Epidemiology; Prep; Compensation; systematic review; Human immunodeficiency virus--HIV; Medical Sciences--Dermatology And Venereology; Oral contraceptive pill	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Review

Article	2019	Wheeler, Darrell P; Fields, Sheldon D; Benuchamp, Geetha; Chen, Ying Q; Estel, Lynda M; Lea Highnow-Weidman; Christopher Hucks-Ortiz; Kao, Irene; Lucas, Jonathan; Magnus, Marcye; Meyer, Kenneth H; Nelson, Adam E; Hendrix, Craig W; Eaichi Piwowar-Manning; Shoptaw, Steven; Watkins, Phaedrus; C Chauncey Watson; Wilton, Lea	Pre-exposure prophylaxis initiation and adherence among Black men who have sex with men (MSM) in three US cities: results from the HPTN 073 study	Journal of the International AIDS Society	-	-	-	-	NA	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-initiation-adherence-among/docview/2329753449/se-2?accountid=8113	Introduction/Randomized clinical trials have demonstrated the efficacy of antiretroviral pre-exposure prophylaxis (PrEP) in preventing HIV acquisition among men who have sex with men (MSM). However, limited research has examined initiation and adherence to PrEP among MSM. The HPTN 073 study enrolled and followed 200 HIV-uninfected MSM (BMSM) in the United States (US) who are disproportionately represented among new HIV infections and late to care individuals. This research reports on the HIV Prevention Trials Network 073 (HPTN 073) study aimed to examine PrEP initiation, utilization and adherence among Black MSM utilizing the theoretically grounded, culturally informed and client-centered care coordination (CC) model.Methods/Study: The HPTN 073 study enrolled and followed 226 HIV-uninfected Black MSM in three US cities (Seattle, WA; Washington DC; and Chapel Hill, NC) from February 2013 through September 2015. Study participants were offered once daily oral emtricitabine/tenofovir (FTC/TDF) PrEP combined with CC and followed for 48 weeks. Participants were assessed at baseline, weeks 4, 12, 24, 36 and 48 for PrEP uptake, adherence and safety. Multivariable logistic regression was used to identify factors associated with PrEP initiation at week 26 (and point of no return, the study biomedical intervention ended) and adherence to study visits (and study partner was matching significantly associated with a greater likelihood of PrEP initiation (adjusted odds ratio (OR):4.4, 95% confidence interval (CI): 1.7, 11.7). Greater age ((≥25 vs. <25, OR 2.95, 95% CI 1.37, 6.37), perception of having enough money (OR 3.4, 95% CI 1.7 to 7.7) and knowledge of nadir partner taking PrEP before sex (OR 2.22, 95% CI 1.03 to 4.79) were statistically significantly associated with increased likelihood of PrEP adherence at week 26. Annualized HIV incidence was 2.0 (95% CI 2.2 to 7.9) among those who initiated PrEP, compared to 7.7 (95% CI 2.5 to 24.1) among those who did not initiate PrEP (p = 0.18).Conclusions/Results suggest a high level of PrEP initiation among at-risk Black MSM, a group historically characterized as hard to reach. The data support the importance of addressing contextual factors that effect PrEP initiation and adherence, and of additional research on the ultimate benefit of PrEP in HIV prevention among Black MSM.	1	1	1	1	1	1	1	1	1	Counseling; California; Laboratories; HIV prevention; Pre-exposure prophylaxis; Research; Pharmacokinetics; Adherence; Alcohol; Men who have sex with men; Medications; Sexual behavior; Pharmacology; Prophylaxis; Education; Randomization; Exposure; Hair; Age; Correlation analysis; Alcohol use; Human immunodeficiency virus--HIV; Sexually transmitted diseases--STD; Medical Sciences--Communicable Diseases; Health risks; Higher education; Correlation coefficients; Alcoholic beverages	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2019	White, Ellen; Dunn, David T; Desai, Monica; Gafos, Mitzy; Kirwan, Peter; Sullivan, Ann K; Clarke, Amanda; McCormack, Sheena	Predictive factors for HIV infection among men who have sex with men and who are seeking PrEP: a secondary analysis of the PROUD trial	Sexually Transmitted Infections	-	-	-	13684973	10.1136/sextrans-2018-053808	https://www.proquest.com/scholarly-journals/predictive-factors-hiv-infection-among-men-who/docview/2276534084/se-2?accountid=8113	Introduction/Pre-exposure prophylaxis (PrEP) is a highly effective method of HIV prevention for men who have sex with men (MSM). However, uncertainty remains around the optimal eligibility criteria for PrEP, specifically what clinical and demographic risk of HIV should be selected. We aimed to identify factors associated with incident HIV in MSM not on event-driven waitlist trial design that randomised MSM attending participating sexual health centres in England to receive PrEP immediately (IMM) or after a deferred period of 1 year (DEF). This analysis is based on participants who were randomised to the deferral arm, when they did not have access to PrEP. HIV incidence was compared between subgroups defined by baseline characteristics.ResultsOverall, 23 participants acquired HIV infection over 230.1 person-years (PY) follow-up, yielding an incidence rate of 9.9/100 PY (95% CI 5.4 to 11.6). Two highly significant predictors for HIV acquisition were identified. Men with a self-reported diagnosis of syphilis, rectal chlamydia (CT) or rectal gonorrhoea (GC) in the previous 12 months had an incidence of 17.2/100 PY (95% CI 9.7 to 28.5); those reporting receptive anal intercourse without a condom (noRAI) with two or more partners in the previous 3 months had an incidence of 11.6/100 PY (95% CI 7.3 to 21.7). The incidence rate among participants lacking both of these risk factors was 1.1/100 PY (3/87.6, 95% CI 0.03 to 6.4).ConclusionsThe high HIV incidence in PROUD suggests that most participants appropriately judged their need for PrEP. Eligibility criteria for a PrEP programme can therefore be broad, as in the current guidelines. However, a recent history of syphilis or rectal CT/GC, or multiple noRAI partners indicates a high instantaneous risk of HIV infection. MSM with one of these characteristics should be offered PrEP as a matter of urgency.	1	1	1	1	1	1	1	1	1	HIV; Condoms; PrEP; England; MSM; Disease prevention; eligibility criteria; Human immunodeficiency virus--HIV; United States--US; Acquired immune deficiency syndrome--AIDS; Medical Sciences--Dermatology And Venereology; United Kingdom--UK	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Clinical

Article	2019	Whiteley, Laura; Mena, Leandro; Craker, Lacey K; Healy, Meredith Garver; Brown, Larry K	Creating a Theoretically Grounded Gaming App to Increase Adherence to Pre-Exposure Prophylaxis: Lessons From the Development of the Viral Combat Mobile Phone Game.	JMIR Serious Games	-	-	-	-	2291-9279	10.2196/11861	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6456850	BACKGROUND: In the United States, young minority men who have sex with men (MSM) are most likely to become infected with HIV. The use of antiretroviral medications to reduce the risk of acquiring HIV infection (pre-exposure prophylaxis, PrEP) is an efficacious and promising prevention strategy. There have been significant advances regarding PrEP, including the definitive demonstration that PrEP reduces HIV acquisition and the development of clinical prescribing guidelines. Despite these promising events, the practical implementation of PrEP can be challenging. Data show that PrEP's safety and effectiveness could be greatly compromised by suboptimal adherence to treatment, and there is concern about the potential for an increase in HIV risk behavior among PrEP users. Due to these challenges, the prescribing of PrEP should be accompanied by behavioral interventions to promote adherence. OBJECTIVE: This study aimed to develop an immersive, action-oriented iPhone gaming intervention to improve motivation for adherence to PrEP. METHODS: Game development was guided by social learning theory, taking into consideration the perspectives of young adult MSM who are taking PrEP. A total of 20 young men who have sex with men (YMSM; aged 18-35 years) were recruited from a sexually transmitted infection (STI), HIV testing, and PrEP care clinic in Jackson, Mississippi, between October 2016 and June 2017. They participated in qualitative interviews guided by the information-motivation-behavioral skills (IMB) model of behavior change. The mean age of participants was 26 years, and all the participants identified as male. Acceptability of the game was assessed with the Client Service Questionnaire and session evaluation form. RESULTS: A number of themes emerged that informed game development. YMSM taking PrEP desired informational game content that included new and comprehensive details about the effectiveness of PrEP, details about PrEP as it relates to doctors' visits, and general information about STIs other than HIV. Motivational themes that emerged were the desire for enhancement of future orientation; reinforcement of positive influences from partners, parents, and friends; collaboration with health care providers; decreasing stigma; and a focus on personal relevance of PrEP-related medical care. Behavioral skills themes centered around self-efficacy and strategies for adherence to PrEP and self-care. CONCLUSIONS: We utilized youth feedback, IMB, and agile software development to create a multilevel, immersive, action-oriented iPhone gaming intervention to improve motivation for adherence to PrEP. There is a dearth of gaming interventions for persons on PrEP. This study is a significant step in working toward the development and testing of an iPhone gaming intervention to decrease HIV risk and promote adherence to PrEP for YMSM.	cell phone, HIV, young adult, sexual and gender minorities	English	Canada	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2019	Whitfield, Thomas H F; Jones, Stephen S; Wachman, Matthew; Grov, Christian; Parsons, Jeffrey T; Rendina, H Jonathon	The Impact of Pre-Exposure Prophylaxis (PrEP) Use on Sexual Anxiety, Satisfaction, and Esteem Among Gay and Bisexual Men	The Journal of Sex Research	-	-	-	-	00224499	10.1080/00224499.2019.1572064	https://www.proquest.com/scholarly-journals/impact-pre-exposure-prophylaxis-prep-use-on/docview/2305129498/se-2?accountid=8113	Gay and bisexual men (GBM) with heightened fears of human immunodeficiency virus (HIV) acquisition have reported high levels of sexual anxiety and low sexual self-esteem. Similarly, sexual satisfaction has been reported to be lower among some GBM who rely solely on condom use as HIV prevention. We sought to explore whether pre-exposure prophylaxis (PrEP) had an impact on the sexual satisfaction, anxiety, and esteem of GBM. As part of a longitudinal cohort study of 1,071 GBM, participants reported at three time points on PrEP use and completed the Multidimensional Sexual Self-Concept Questionnaire (MSSCQ). A total of 137 GBM began taking PrEP in the 24 months following baseline. Comparing their responses during times before initiating PrEP and after, within adjusted multilevel models, there was a significant decrease in sexual anxiety (B = −0.27, p = 0.03) but no significant changes in sexual esteem or satisfaction. Our findings indicate important psychological improvements resulting from PrEP initiation. Further research should explore the potential for other psychological benefits of PrEP use among GBM. Article	2019	Wilkinson, Anna L; Scott, Nick; Tidhar, Tom; Luong, Phillip; El-Hayek, Carol; Wilson, David P; Fairley, Christopher K; Zhang, Lei; Leslie, David; Roth, Norman; Tee, B K; Hellard, Margaret; Stoové, Mark	Estimating the syphilis epidemic among gay, bisexual and other men who have sex with men in Australia following changes in HIV care and prevention.	Sexual Health	-	-	-	-	1449-8987	10.1071/SH18215	https://dx.doi.org/10.1071/SH18215	Background Syphilis control remains a challenge in many high-income countries, including Australia, where diagnoses are concentrated among gay, bisexual and other men who have sex with men (GBM). The aim of this study is to project the syphilis epidemic among GBM under a range of scenarios. METHODS: A dynamic coinfection model of HIV and syphilis transmission among GBM in Victoria, Australia, was parametrised to test data from clinics in Melbourne and syphilis case notifications in Victoria. Projected outcomes were new syphilis infections between 2018 and 2025 under seven testing and behaviour change scenarios. RESULTS: Among HIV-negative GBM, the model estimated that increasing syphilis testing coverage (69% - 75%) and frequency (~8-monthly - 6-monthly) could prevent 5% and 13% of syphilis cases respectively between 2018 and 2025 compared to the status quo. Among HIV-positive GBM, less syphilis testing due to changes in HIV care increased syphilis cases by 29% between 2018 and 2025 compared to the status quo. Under a scenario of 20% HIV pre-exposure prophylaxis (PrEP) coverage among HIV-negative GBM (and associated increased serodiscordant sex, reduced condom use and increased syphilis testing), syphilis cases were estimated to decrease by 6% among HIV-negative GBM and by 3% among HIV-positive GBM compared to the status quo, driven by increased testing among PrEP users. CONCLUSION: The present study findings support syphilis control policies focusing on increased testing among GBM. Current Australian PrEP guidelines of quarterly syphilis testing are likely to negate any increases in syphilis due to risk compensation occurring with PrEP scale-up. Article	2019	Williamson, Iain; Papaloukas, Periklis; Jaspal, Rusi; Lond, Benjamin	'There's this glorious pill': gay and bisexual men in the English midlands navigate risk responsibility and pre-exposure prophylaxis	Critical Public Health	-	-	-	-	09581596	10.1080/09581596.2018.1497143	https://www.proquest.com/scholarly-journals/theres-this-glorious-pill-gay-bisexual-men/docview/2283161164/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) is currently being trialled for seronegative gay and other men who have sex with men (GMSM) at risk of HIV infection in England. However, research from other countries where PrEP is available shows limited literacy and uptake by GMSM at risk of HIV. We collected focus group data from 18 GMSM (13 HIV- and 5 HIV+) from Leicester, an ethnically diverse city in the English Midlands. Data were analysed using thematic analysis and three themes are presented. The first theme 'I can't get my head around people like that': Representations of PrEP users within and beyond gay communities explores how PrEP users are vilified by some GMSM and the wider media. The second theme, 'There's a culture of anti-trust': PrEP, stigma and the interpersonal politics of HIV disclosure discusses how PrEP influences HIV disclosure and sexual decision-making in casual sero-discordant sexual encounters in a context where seropositive men experienced pervasive HIV stigma and HIV- men were suspicious of HIV+ sexual partners. In the final theme, 'I'm still suspicious': Discourses of doubt and distrust participants voiced concern over the safety of PrEP and the motives of drug companies, healthcare agencies and PrEP activists. We consider these findings through a critical lens of wider theorising around the relationship between public health agencies and GMSM communities and consider the impact of these perspectives on likely engagement with PrEP in an English context. We call for more critically informed and nuanced ways of promoting health and well-being amongst men from these communities. Article	2019	Willie, Tiara C, MA; Stockman, Jamila K, PhD, MPH; Keene, Danya E, PhD; Calabrese, Sarah K, PhD; Alexander, Kamila A, PhD, MPH, RN; Kershaw, Trace S, PhD	Social Networks and Its Impact on Women's Awareness, Interest, and Uptake of HIV Pre-exposure Prophylaxis (PrEP): Implications for Women Experiencing Intimate Partner Violence: JAIDS	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000001935	https://www.proquest.com/scholarly-journals/social-networks-impact-on-womens-awareness/docview/2229638951/se-2?accountid=8113	Background: In the United States, women represent less than 5% of all pre-exposure prophylaxis (PrEP) users. Social networks may promote and/or inhibit women's PrEP awareness, which could influence PrEP intentions. Furthermore, women experiencing intimate partner violence (IPV) may have smaller, less supportive networks, which could deter or have no impact on PrEP care engagement. This study examined associations between network characteristics and women's PrEP awareness, interest, uptake, and perceived candidacy and analyzed IPV as an effect modifier. Setting/Methods: From 2017 to 2018, data were collected from a prospective cohort study of 218 PrEP-eligible women with (n = 94) and without (n = 124) IPV experiences in Connecticut. Women completed surveys on demographics, IPV, social networks, and PrEP care continuum outcomes. Results: Adjusted analyses showed that PrEP awareness related to having more PrEP-aware alters. PrEP intentions related to having more alters with favorable opinions of women's potential PrEP use and a smaller network size. Viewing oneself as an appropriate PrEP candidate related to having more PrEP-aware alters and more alters with favorable opinions of women's potential PrEP use. IPV modified associations between network characteristics and PrEP care. Having members who were aware of and/or used PrEP was positively associated with PrEP care engagement for women without IPV experiences but had either no effect or the opposite effect for women experiencing IPV. Conclusion: Improving PrEP attitudes might improve its utilization among women. Social network interventions might be one way to increase PrEP uptake among many US women but may not be as effective for women experiencing IPV. Article	2019	Wilson, Erin C.; Jalil, Emilia M.; Castro, Cristiane; Martinez Fernandez, Nilo; Kamel, Luciana; Grinsztejn, Beatriz	Barriers and facilitators to PrEP for transwomen in Brazil.	Global Public Health	-	-	-	-	1744-1706 1744-1692	10.1080/17441692.2018.1505933	https://www.tandfonline.com/doi/full/10.1080/17441692.2018.1505933	Pre-exposure prophylaxis (PrEP) is an important biomedical intervention that may help reduce the risk of HIV transmission among transwomen. To date, little research is available to inform interventions to increase uptake and adherence to PrEP among transwomen, especially in places outside the U.S. We conducted a qualitative study in 2015 with 34 adult transwomen in Rio de Janeiro, Brazil and assessed awareness, interest, barriers and facilitators to PrEP uptake and adherence for transwomen. Almost one third of participants had heard of PrEP, and most were interested and thought it would be beneficial for transwomen in their community. Barriers to PrEP included fear of being HIV positive resulting in low HIV testing and concerns about the ability to adhere to a daily PrEP regimen. The most prominent barrier to uptake was past experiences of transgender-identity related discrimination in the universal health care system that reduced willingness to seek PrEP or health care in general. Participants recommended technological solutions to PrEP health education information that could address uptake and adherence. This study informs efforts to increase PrEP use among transwomen in Brazil. Article	2019	Witzel, T Charles; Nutland, Will; Bourne, Adam	What are the motivations and barriers to pre-exposure prophylaxis (PrEP) use among black men who have sex with men aged 18-45 in London? Results from a qualitative study.	Sexually Transmitted Diseases	-	-	-	-	1472-3263	10.1136/sextrans-2018-053773	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6585870	BACKGROUND: Black men who have sex with men (BMSM) have higher HIV incidence and prevalence when compared with other men who have sex with men, despite similar risk profiles. New prevention technologies, including pre-exposure prophylaxis (PrEP), may be effective in responding to these inequalities, provided they are appropriately targeted and acceptable to their intended beneficiaries. This study aims to understand the motivations and barriers of BMSM aged 18-45 to PrEP uptake. METHODS: Twenty-five BMSM recruited through geolocation social networking apps took part in in-depth interviews between April and August 2016. Intersectionality theory was used as an organising principle. Interviews were transcribed verbatim and analysed using a thematic framework analysis. RESULTS: For BMSM with heterogeneous social groups, discussions about sexual health were challenging because of the intersection of ethnic background, family history and religion. This limited conversations about PrEP to gay male friends who often held stigmatising views of condomless anal intercourse. BMSM reported exclusion from gay male spaces (online and offline) which could serve to restrict exposure to PrEP messages. Stereotypes of BMSM intersected with negative conceptions of PrEP users, limiting acknowledgement of PrEP candidacy. For those who had attempted to or successfully accessed it, PrEP was framed as a strategy to mitigate risk and to guard against future stigma associated with HIV infection. DISCUSSION: BMSM operate within a complex set of circumstances related to the intersection of their sexual, ethnic, cultural and religious identities, which shape PrEP acceptability. Interventions which seek to facilitate uptake in this group must be attentive to these. Health promotion and clinical services could seek to facilitate nuanced discussions about the merits of PrEP for those at frequent risk, perhaps while also providing publicly visible PrEP role models for BMSM and other marginalised groups.	risk, pre-exposure prophylaxis, health status disparities, England, sexual and gender minorities	English	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Qualitative
Article	2019	Wolfgang S.; Portinari D.	The PrEP recommendation: The inscribed disease in a healthy body	Social Medicine	-	-	-	-	15577112	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85079664323&partnerID=40&md5=5578bc0130c97f69bc17a9741ef3da73	In July 2014, the World Health Organization (WHO) recommended that all gay men join the "pre exposal medication Truvada" as a valid resource to prevent HIV. The PrEP, prophylaxis consists in taking a combination of antiretroviral medication once a day, in order to prevent HIV infection. The WHO promotion of a policy that recommends all HIV negative gay men to join the PrEP, may be seen, in the context of contemporary biopolitical techniques and strategies, as a form of control and medicalization of homosexual bodies and practices. It´s important to explicit the life-related effects linked to a measure like the PrEP program, considering this as a paradigm shift in HIV/Aids strategies. The shift involves the gradual substitution of the "condom use" recommendations for the use of permanent prophylactic medications, and may be understood as a move away from the abstinence paradigm – sexual behavior control – to a more contemporary form of individual medicalized body biocontrol, as outlined by Foucault in his later texts. This measure also exposes a delicate aspect of the social conduction of the HIV/Aids epidemics: the stigmatization related to the gay community as the ultimate risk group. Affirming that every homosexual should take the PrEP pill, may have the effect of perpetuating the idea that gay men are the main vector of this disease. Among the misconceptions that this may involve are the perpetuation of prejudice related to Aids and gay men, leading heterosexual populations to believe that they are not connected in the epidemic chain. © 2019, Social Medicine Publishing Group. Article	2019	Wong C.S.; Kumar P.A.; Wong C.M.; Choong B.C.H.; Lim O.Z.; Chan Y.Y.; Ibrahim M.A.B.; Chio M.T.; Tan R.K.J.; Chen M.I.	Acceptability of hiv pre-exposure prophylaxis (prep) and opinions on prep service delivery among men who have sex with men in singapore: A qualitative study	AIDS Education and Prevention	-	-	-	-	8999546	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85063954398&partnerID=40&md5=1ab654f8f59146d141e3ed36ed570824	PrEP is effective in preventing HIV transmission among at-risk HIV-negative MSM. A qualitative descriptive study with five focus group discussions (N = 33) involving a purposively recruited sample of Singaporean MSM was conducted from August 2016 to April 2017 to understand local perspectives on potential barriers and motivators to the adoption of PrEP, prior to the implementation of PrEP services in Singapore. Knowledge of PrEP was high, and many viewed PrEP as an attractive alternative to condoms for HIV prevention. Concerns about PrEP included the cost of PrEP and related services, the frequency of PrEP-related clinic visits, fear of side effects, and the stigma associated with using PrEP. Participants felt PrEP was best provided by MSM-friendly providers, and more needed to be done to increase awareness of the effectiveness of PrEP. Access to PrEP for MSM in Singapore has to be affordable, patient-centered, and convenient to maximize the potential benefits of PrEP. © 2019 The Guilford Press. Article	2019	Wong G.N.L.; Fua T.-P.; Pek J.H.	HIV post-exposure prophylaxis in the Emergency Department: a perspective from Singapore	Proceedings of Singapore Healthcare	-	-	-	-	20101058	10.1177/2010105819841391	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85184738567&doi=10.1177%2f2010105819841391&partnerID=40&md5=63f871164e562b30e2ec648e6c66896c	Background: Exposures to human immunodeficiency virus (HIV) commonly arrive at the Emergency Department (ED) for evaluation of transmission risk and the necessity for post-exposure prophylaxis (PEP). PEP aims to prevent HIV after exposure. International recommendations exist to guide eligibility assessment and standardise prescribing practices. Objective: The primary objective was to describe the patient cohort receiving HIV PEP at the ED. The secondary objective was to assess the ED physicians' adherence to the 2005 guidelines provided by US Centers for Disease Control and Prevention for HIV PEP. Methods: This retrospective study identified patients prescribed with PEP after presenting with potential HIV exposure to a tertiary hospital ED in Singapore over 2 years. The exposure type and characteristics, source patient characteristics, indications for PEP, HIV status on presentation and on follow-up were assessed. Institutional guidelines recommended tenofovir/emtricitabine (Truvada) and raltegravir as HIV PEP. Results: Twenty-seven patients received HIV PEP during the study period. The majority (81.5%) presented after occupational exposure, with fresh needlestick injury (44.4%) being the most common cause. Amongst all recipients, PEP was indicated in 22.2% and not in 18.5%. Conclusions: With international guidelines simplifying eligibility assessment and prescribing practices, accurate and evidence-based PEP provision should be implemented at the frontline in the ED. These may be encouraged by enforcement of specific workflows and physician education. © The Author(s) 2019.	emergency; Human immunodeficiency virus; infectious disease; post-exposure prophylaxis	English	Singapore	Asia and the Pacific	Singapore	Asia and the Pacific	Singapore	Asia and the Pacific	Clinical
Article	2019	Wood, Sarah; Gross, Robert; Shea, Judy A; Bauermeister, José A; Franklin, Joshua; Petsis, Danielle; Swyryn, Meghan; Linden Lalley-Chareczko; Koenig, Helen C; Dowshen, Nadia	Barriers and Facilitators of PrEP Adherence for Young Men and Transgender Women of Color	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02502-y	https://www.proquest.com/scholarly-journals/barriers-facilitators-prep-adherence-young-men/docview/2210301840/se-2?accountid=8113	We aimed to discover barriers and facilitators of HIV pre-exposure prophylaxis (PrEP) adherence in young men and transgender women of color who have sex with men (YMSM/TW). Short-term and sustained adherence were measured by urine tenofovir concentration and pharmacy refills, respectively. Optimal adherence was defined as having both urine tenofovir concentration consistent with dose ingestion within 48 h and pharmacy refills consistent with ≥ 4 doses per week use. Participants completed semi-structured interviews exploring adherence barriers and facilitators. Participants (n = 31) were primarily African-American (68%), mean age 22 years (SD: 1.8), and 48% had optimal adherence. Adherence barriers included stigma, health systems inaccessibility, side effects, competing stressors, and low HIV risk perception. Facilitators included social support, health system accessibility, reminders/routines, high HIV risk perception, and personal agency. Our findings identify targets for intervention to improve PrEP adherence in these populations, including augmenting health activation and improving accuracy of HIV risk perception. Resumo alternativo:Nuestro objetivo fue descubrir los obstáculos y facilitadores de la adherencia al profilaxis de pre-exposición al VIH (PrEP) en hombres jóvenes y mujeres transgénero que tienen sexo con hombres (YMSM/TW) y quienes son minorías étnicas. La adherencia, a corto plazo y sostenida, se midió mediante la concentración de tenofovir en la orina y las prescripciones completadas en la farmacia. La adherencia óptima se definió basado en una concentración de tenofovir en la orina consistente con el uso de PrEP en las ultimas 48 horas y prescripciones completadas en la farmacia consistentes con ≥ 4 dosis por semana. Los participantes completaron entrevistas semiestructuradas que exploraron los obstáculos y facilitadores de la adherencia. Los participantes (n = 31) fueron principalmente afroamericanos (68%), con una edad media de 22 años (SD: 1.8) y 48% obtuvieron adherencia óptima. Participantes discutieron varios obstáculos, incluyendo el estigma, acceso limitado a los sistemas de salud, los efectos secundarios asociados a PrEP, competencia con otras prioridades, y la baja percepción del riesgo de VIH. Los facilitadores incluyeron apoyo social, acceso al sistema de salud, recordatorios/rutinas, alta percepción de riesgo de VIH y agencia personal. Nuestros hallazgos identifican oportunidades para mejorar la adherencia al PrEP en estas poblaciones a través de intervenciones, incluyendo la activación de salud y cambios en la percepción del riesgo al VIH en estas comunidades. Article	2019	Wray, Tyler B; Chan, Philip A; Kahler, Christopher W; Simpanen, Erik M; Liu, Tao; Mayer, Kenneth H	Vulnerable Periods: Characterizing Patterns of Sexual Risk and Substance Use During Lapses in Adherence to HIV Pre-exposure Prophylaxis Among Men Who Have Sex With Men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000001914	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6534124	BACKGROUND: Pre-exposure prophylaxis (PrEP) is highly efficacious, but some groups of men who have sex with men may have difficulty adhering to daily dosing. Prevention-effective adherence suggests that PrEP's efficacy depends on adherence at the time of HIV exposure; yet, few studies have examined how exposures (ie, high-risk sex) overlap with periods of consecutive missed PrEP doses. Substance use may also play a role in these vulnerable periods. METHODS: We used digital pill bottles to monitor the daily adherence of 40 PrEP-experienced patients recruited from an outpatient clinic in the Northeastern US over a six-month period. Participants also completed detailed online diaries every 2 weeks during this time that surveyed their sexual behavior and substance use each day. RESULTS: Daily adherence was high overall (M = 83.9%, SD = 18.0%), but 53% (N = 21) had a lapse of > 3 consecutive daily PrEP doses over 6 months. Participants' rate of engaging in high-risk condomless anal sex (CAS) did not differ across lapse days versus continuously adherent days. Alcohol use was not associated with engaging in CAS during a PrEP lapse. However, participants reported engaging in CAS significantly more often during a PrEP adherence lapse on days when they also used stimulant drugs. CONCLUSIONS: Men who have sex with men may have periodic difficulty adhering to PrEP at the specific times when they are at risk. Stimulant drug use could play an important role in increasing HIV risk specifically during adherence lapses. Article	2019	Wray, Tyler B; Luo, Xi; Ke, Jun; Pérez, Ashley E; Carr, Daniel J; Monti, Peter M	Using Smartphone Survey Data and Machine Learning to Identify Situational and Contextual Risk Factors for HIV Risk Behavior Among Men Who Have Sex with Men Who Are Not on PrEP.	Prevention Science	-	-	-	-	1573-6695	10.1007/s11121-019-01019-z	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC10259870	"Just-in-time" interventions (JITs) delivered via smartphones have considerable potential for reducing HIV risk behavior by providing pivotal support at key times prior to sex. However, these programs depend on a thorough understanding of when risk behavior is likely to occur to inform the timing of JITs. It is also critical to understand the most important momentary risk factors that may precede HIV risk behavior, so that interventions can be designed to address them. Applying machine learning (ML) methods to ecological momentary assessment data on HIV risk behaviors can help answer both questions. Eighty HIV-negative men who have sex with men (MSM) who were not on PrEP completed a daily diary survey each morning and an experience sampling survey up to six times per day via a smartphone application for 30 days. Random forest models achieved the highest area under the curve (AUC) values for classifying high-risk condomless anal sex (CAS). These models achieved 80% specificity at a sensitivity value of 74%. Unsurprisingly, the most important contextual risk factors that aided in classification were participants' plans and intentions for sex, sexual arousal, and positive affective states. Findings suggest that survey data collected throughout the day can be used to correctly classify about three of every four high-risk CAS events, while incorrectly classifying one of every five non-CAS days as involving high-risk CAS. A unique set of risk factors also often emerge prior to high-risk CAS events that may be useful targets for JITs. Article	2019	Wu D.; Tao H.; Dai J.; Liang H.; Huang A.; Zhong X.	Study on pre-exposure prophylaxis regimens among men who have sex with men: A prospective cohort study	International Journal of Environmental Research and Public Health	-	-	-	-	16617827	10.3390/ijerph16244996	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076348249&doi=10.3390%2fijerph16244996&partnerID=40&md5=065626f687dce040859dfc573829a6bc	Background: There are limited studies on the medication regimen of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) in China. This study compared the effectiveness of and adherence to two prophylactic HIV medication regimens, which provided evidence and guidance for the application and promotion of the PrEP strategy in the MSM population in China. Methods: We conducted an open, non-randomized, multicenter, parallel, controlled clinical intervention study in western China. Subjects were recruited by convenience sampling at research centers in Chongqing, Guangxi, Xinjiang and Sichuan, China from April 2013 to March 2015, and they were categorized into the daily PrEP, event-driven and blank control groups. Tenofovir disoproxil fumarate (TDF; 300 mg/dose) was administered to subjects in the daily PrEP and event-driven groups, and all subjects were followed up every 12 weeks for 96 weeks. Demographic, behavioral, psychological characteristics and AIDS-related attitudes were assessed using self-completed questionnaires. TDF serum concentrations in subjects in Chongqing and Sichuan were quantified after systematic sampling. Results: Of the 2422 enrolled MSM, 856 were eligible for statistical analysis (PrEP group: 385 and event-driven group: 471); 30 and 32 subjects in daily PrEP and event-driven groups, respectively, were HIV-positive; the incidence of HIV infection was as follows: daily PrEP group, 6.60 cases/100 person-years and event-driven group, 5.57 cases/100 person-years (relative risk (RR) 95% confidence interval (CI) was 0.844 (0.492–1.449)); HIV incidence did not differ significantly when stratified by medication adherence or sites. When the medication adherence rate was ≥80%, the median TDF serum concentrations were 0.458 mg/L and 0.429 mg/L in the daily PrEP, and event-driven groups, respectively (not significant; p > 0.05); Subjects who were in the event-driven PrEP group (OR = 2.152, 95% CI: 1.566–2.957), had fewer male sexual partners in the last two weeks (OR = 0.685, 95% CI: 0.563–0.834), were one year older on average (OR = 1.022, 95% CI: 1.002–1.043), considered that medication kept them safe, were less worried about others knowing they took medicine and were more likely to have high adherence. Conclusions: The efficacies of daily TDF and event-driven TDF use were not significantly different in preventing new infections among HIV-negative MSM. Event-driven TDF use is economical and effective and is worth popularizing. Our results provide evidence for the application and promotion of the PrEP strategy in the MSM population in China. © 2019 by the authors. Licensee MDPI, Basel, Switzerland. Article	2019	Wu Y.; Xie L.; Meng S.; Hou J.; Fu R.; Zheng H.; He N.; Meyers K.	Mapping Potential Pre-Exposure Prophylaxis Users onto a Motivational Cascade: Identifying Targets to Prepare for Implementation in China	LGBT Health	-	-	-	-	23258292	10.1089/lgbt.2018.0256	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85068514657&doi=10.1089%2flgbt.2018.0256&partnerID=40&md5=8fc81c5ff3647a1f03341cb7caee89cd	Purpose: China recently commenced several pre-exposure prophylaxis (PrEP) projects, but little work has characterized potential users. This study describes awareness of, intention to use, and uptake of PrEP in a sample of men who have sex with men (MSM), a key population experiencing high rates of HIV in China. Methods: Through a cross-sectional survey administered to 708 MSM in four cities, we mapped respondents onto a Motivational PrEP Cascade. We conducted bivariable and multivariable analysis to examine factors associated with progression through the Cascade. Results: Among 45.6% of MSM who were PrEP eligible, 36% were in Contemplation, 9% were in PrEParation, 2% were in PrEP Action and Initiation, and none reached Maintenance and Adherence. We found no association between individual risk factors and progression through the Cascade. In multivariable analysis, friends' positive attitudes toward PrEP, more frequent sexually transmitted infection testing, and higher scores on the perceived PrEP benefits scale were positively associated with entering PrEP Contemplation. Having higher condom use self-efficacy was associated with decreased odds of entering PrEP Contemplation. Having sex with men and women in the past 6 months, having heard of PrEP from medical providers, and knowing a PrEP user were positively associated with entering PrEParation. Conclusion: We found a high proportion of MSM who were PrEP eligible and identified several intervention targets to prepare for PrEP introduction in China: community education to increase accurate knowledge, gain-framed messaging for PrEP and sexual health, and provider trainings to build MSM-competent services that can support shared decision-making for PrEP initiation. © 2019, Mary Ann Liebert, Inc., publishers. Article	2019	Wu, Dan; Huang, Wenting; Zhao, Peipei; Li, Chunyan; Cao, Bolin; Wang, Yifan; Stoneking, Shelby; Tang, Weiming; Luo, Zhenzhou; Wei, Chongyi; Tucker, Joseph	A Crowdsourced Physician Finder Prototype Platform for Men Who Have Sex with Men in China: Qualitative Study of Acceptability and Feasibility.	JMIR Public Health and Surveillance	-	-	-	-	2369-2960	10.2196/13027	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6913768	BACKGROUND: Men who have sex with men (MSM), including both gay and bisexual men, have a high prevalence of HIV and sexually transmitted infections (STIs) in China. However, healthcare seeking behaviors and engagement in clinical services among MSM are often suboptimal. Global evidence shows that embedding online HIV or sexual health services into gay social networking applications holds promise for facilitating higher rates of healthcare utilization among MSM. We developed a prototype of a gay-friendly health services platform, designed for integration within a popular gay social networking app (Blued) in China. OBJECTIVE: The purpose of this study was to evaluate the acceptability of the platform and ask for user feedback through focus group interviews with young MSM in Guangzhou and Shenzhen, cities in Southern China. METHODS: The prototype was developed through an open, national crowdsourcing contest. Open crowdsourcing contests solicit community input on a topic in order to identify potential improvements and implement creative solutions. The prototype included a local, gay-friendly, STI physician finder tool and online psychological consulting services. Semistructured focus group discussions were conducted with MSM to ask for their feedback on the platform, and a short survey was administered following discussions. Thematic analysis was used to analyze the data in NVivo, and we developed a codebook based on the first interview. Double coding was conducted, and discrepancies were discussed with a third individual until consensus was reached. We then carried out descriptive analysis of the survey data. RESULTS: A total of 34 participants attended four focus group discussions. The mean age was 27.3 years old (SD 4.6). A total of 32 (94%) participants obtained at least university education, and 29 (85%) men had seen a doctor at least once before. Our survey results showed that 24 (71%) participants had interest in using the online health services platform and 25 (74%) thought that the system was easy to use. Qualitative data also revealed that there was a high demand for gay-friendly healthcare services which could help with care seeking. Men felt that the platform could bridge gaps in the existing HIV or STI service delivery system, specifically by identifying local gay-friendly physicians and counselors, providing access to online physician consultation and psychological counseling services, creating space for peer support, and distributing pre-exposure prophylaxis and sexual health education. CONCLUSIONS: Crowdsourcing can help develop a community-centered online platform linking MSM to local gay-friendly HIV or STI services. Further research on developing social media-based platforms for MSM and evaluating the effectiveness of such platforms may be useful for improving sexual health outcomes.	gay-friendly doctors, social media, crowdsourcing, prototype evaluation, men who have sex with men, China	English	Canada	Western and Central Europe and North America	China	Asia and the Pacific	China	Asia and the Pacific	Qualitative
Article	2019	Xie, Lu; Wu, Yumeng; Meng, Siyan; Hou, Jianhua; Fu, Rong; Huang, Zheng; He, Na; Wang, Min; Meyers, Kathrine	Risk Behavior Not Associated with Self-Perception of PrEP Candidacy: Implications for Designing PrEP Services	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02587-5	https://www.proquest.com/scholarly-journals/risk-behavior-not-associated-with-self-perception/docview/2252713455/se-2?accountid=8113	In a study of sexually-active HIV-negative men who have sex with men (MSM) in China, we compared behavioral indication for pre-exposure prophylaxis (PrEP) based on risk criteria to self-perception of PrEP candidacy (SPC) and explored factors associated with SPC. Of 708 MSM surveyed, 323 (45.6%) were behaviorally-indicated for PrEP, among whom 42.1% self-perceived as appropriate PrEP candidates. In a multivariable model we found no association between sexual behavior nor HIV risk perception and SPC but found that higher perceived benefits of PrEP, increased frequency of HIV testing, and low condom use self-efficacy were positively-associated with SPC. In a sub-analysis restricted to MSM behaviorally-indicated for PrEP, relationship-factors were also significant. Our findings suggest that PrEP implementers should look beyond risk criteria to consider shared decision-making tools that support individuals to assess whether they are appropriate PrEP candidates based on their existing HIV prevention strategies, sexual health goals, and relationship dynamics. Article	2019	Yang C.; Krishnan N.; Painter J.E.; Latkin C.	The Association Between Disclosure of Same Sex Behavior to Healthcare Providers and PrEP Awareness Among BMSM in Baltimore	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02401-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85060353960&doi=10.1007%2fs10461-019-02401-2&partnerID=40&md5=f92e204e13cdbe610a4360ad46e8d467	The goal of this study was to explore the association between disclosure of same sex behavior to a healthcare provider and PrEP awareness in a sample of 192 Black MSM in Baltimore. After adjusting for age, education, sexual identity and employment status, we observed a trend of greater PrEP awareness among Black MSM who disclosed same sex behaviors to healthcare providers (adjusted odds ratio = 2.24, p = 0.08). This study provides new evidence of potential benefit of disclosure of same sex behavior to healthcare providers for awareness of new HIV biomedical interventions. Findings highlight the need to support patient–provider communication on sexual behaviors and PrEP with key populations at risk of HIV. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Yang H.; Li J.; Patel S.K.; Palmer K.E.; Devlin B.; Rohan L.C.	Design of poly(Lactic-co-glycolic acid) (plga) nanoparticles for vaginal co-delivery of griffithsin and dapivirine and their synergistic effect for hiv prophylaxis	Pharmaceutics	-	-	-	-	19994923	10.3390/pharmaceutics11040184	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85070204454&doi=10.3390%2fpharmaceutics11040184&partnerID=40&md5=8bdd326f324dbee0d6ccf924428b0db2	Long-acting topical products for pre-exposure prophylaxis (PrEP) that combine antiretrovirals (ARVs) inhibiting initial stages of infection are highly promising for prevention of HIV sexual transmission. We fabricated core-shell poly(lactide-co-glycolide) (PLGA) nanoparticles, loaded with two potent ARVs, griffithsin (GRFT) and dapivirine (DPV), having different physicochemical properties and specifically targeting the fusion and reverse transcription steps of HIV replication, as a potential long-acting microbicide product. The nanoparticles were evaluated for particle size and zeta potential, drug release, cytotoxicity, cellular uptake and in vitro bioactivity. PLGA nanoparticles, with diameter around 180–200 nm, successfully encapsulated GRFT (45% of initially added) and DPV (70%). Both drugs showed a biphasic release with initial burst phase followed by a sustained release phase. GRFT and DPV nanoparticles were non-toxic and maintained bioactivity (IC50 values of 0.5 nM and 4.7 nM, respectively) in a cell-based assay. The combination of drugs in both unformulated and encapsulated forms showed strong synergistic drug activity at 1:1 ratio of IC50 values. This is the first study to co-deliver a protein (GRFT) and a hydrophobic small molecule (DPV) in PLGA nanoparticles as microbicides. Our findings demonstrate that the combination of GRFT and DPV in nanoparticles is highly potent and possess properties critical to the design of a sustained release microbicide. © 2019 by the authors. Article	2019	Yankellow I.; Yingling C.T.	Nonoccupational Postexposure Prophylaxis: An Essential Tool for HIV Prevention	Journal for Nurse Practitioners	-	-	-	-	15554155	10.1016/j.nurpra.2019.09.003	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073830639&doi=10.1016%2fj.nurpra.2019.09.003&partnerID=40&md5=0b55afe8f01daaa7df1344bbb39e49cc	Previous progress of antiretroviral HIV prevention efforts focusing on preexposure prophylaxis (PrEP) and treatment as prevention (TasP) has plateaued in recent years. Until prevention efforts expand, nonoccupational postexposure prophylaxis (nPEP) is another antiretroviral intervention that people can use after a potential HIV exposure to reduce their risk of infection and should be offered in outpatient settings as a way to prevent new HIV infections and bridge people to future prevention, like PrEP. The purpose of this article is to equip nurse practitioners with the information to develop a practice-level program to deliver nPEP to patients in need of urgent HIV prevention. © 2019 Elsevier Inc. Article	2019	Yap P.K.; Loo Xin G.L.; Tan Y.Y.; Chellian J.; Gupta G.; Liew Y.K.; Collet T.; Dua K.; Chellappan D.K.	Antiretroviral agents in pre-exposure prophylaxis: emerging and advanced trends in HIV prevention	Journal of Pharmacy and Pharmacology	-	-	-	-	223573	10.1111/jphp.13107	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85066504978&doi=10.1111%2fjphp.13107&partnerID=40&md5=f7b8e43053a1b837064cb7f01d9861c7	Objectives: Antiretroviral agents (ARVs) have been the most promising line of therapy in the management of human immunodeficiency virus (HIV) infections. Some of these ARVs are used in the pre-exposure prophylaxis (PrEP) to suppress the transmission of HIV. Prophylaxis is primarily used in uninfected people, before exposure, to effectively prevent HIV infection. Several studies have shown that ART PrEP prevents HIV acquisition from sexual, blood and mother-to-child transmissions. However, there are also several challenges and limitations to PrEP. This review focuses on the current antiretroviral therapies used in PrEP. Key findings: Among ARVs, the most common drugs employed from the class of entry inhibitors are maraviroc (MVC), which is a CCR5 receptor antagonist. Other entry inhibitors like emtricitabine (FTC) and tenofovir (TFV) are also used. Rilpivirine (RPV) and dapivirine (DPV) are the most common drugs employed from the Non-nucleoside reverse transcriptase inhibitor (NNRTIs) class, whereas, tenofovir disoproxil fumarate (TDF) is primarily used in the Nucleoside Reverse Transcriptase Inhibitor (NRTIs) class. Cabotegravir (CAB) is an analog of dolutegravir, and it is an integrase inhibitor. Some of these drugs are also used in combination with other drugs from the same class. Summary: Some of the most common pre-exposure prophylactic strategies employed currently are the use of inhibitors, namely entry inhibitors, non-nucleoside reverse transcriptase inhibitors, nucleoside reverse transcriptase inhibitors, integrase and protease inhibitors. In addition, we have also discussed on the adverse effects caused by ART in PrEP, pharmacoeconomics factors and the use of antiretroviral prophylaxis in serodiscordant couples. © 2019 Royal Pharmaceutical Society	antiretroviral; human immunodeficiency virus; pre-exposure prophylaxis; prevention; prophylaxis	English	United Kingdom	Western and Central Europe and North America	Malaysia	Asia and the Pacific	Malaysia	Asia and the Pacific	Review
Article	2019	Yavuz, Burcin; Morgan, Jessica L; Herrera, Carolina; Harrington, Kristin; Perez-Ramirez, Bernardo; LiWang, Patricia J; Kaplan, David L	Sustained release silk fibroin discs: Antibody and protein delivery for HIV prevention.	Journal of Controlled Release	-	-	-	-	1873-4995	10.1016/j.jconrel.2019.03.001	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6538278	With almost 2 million new HIV infections worldwide each year, the prevention of HIV infection is critical for stopping the pandemic. The only approved form of pre-exposure prophylaxis is a costly daily pill, and it is recognized that several options will be needed to provide protection to the various affected communities around the world. In particular, many at-risk people would benefit from a prevention method that is simple to use and does not require medical intervention or a strict daily regimen. We show that silk fibroin protein can be formulated into insertable discs that encapsulate either an antibody (IgG) or the potent HIV inhibitor 5P12-RANTES. Several formulations were studied, including silk layering, water vapor annealing and methanol treatment to regulate the protein cargo and impact the release kinetics over weeks. In the case of IgG, high concentrations were released over a short time using water vapor annealing, with more sustained results with the use of water vapor annealing and layering during device fabrication. For 5P12-RANTES, sustained release was obtained for 31â days using water vapor annealing. Further, we show that the released inhibitor 5P12-RANTES was functional both in vitro and in ex vivo colorectal tissue. This work shows that silk fibroin discs can be developed into formidable tools to prevent HIV infection. Article	2019	Yeung, Howa; Luk, Kevin M.; Chen, Suephy C.; Ginsberg, Brian A.; Katz, Kenneth A.	Dermatologic care for lesbian, gay, bisexual, and transgender persons: Epidemiology, screening, and disease prevention.	Journal of the American Academy of Dermatology	-	-	-	-	1097-6787 0190-9622	10.1016/j.jaad.2018.02.045	https://pubmed.ncbi.nlm.nih.gov/30744875/	Lesbian, gay, bisexual, and transgender (LGBT) persons face important health issues relevant to dermatologists. Men who have sex with men (MSM) are at higher risk of certain infectious diseases, including HIV, syphilis and other sexually transmitted diseases (STDs), methicillin-resistant Staphylococcus aureus infections, and invasive meningococcal disease, and might be at higher risk of non-infectious conditions, including skin cancer. Recommendations for preventive health care, including screening for HIV and other STDs, sexual health-related vaccinations, and HIV pre-exposure prophylaxis, differ for MSM compared with non-MSM. Women who have sex with women experience disparities in STDs, including chlamydia and HPV. Transgender patients have unique, and often unmet, dermatologic needs during gender transition (also called gender affirmation), related to hormonal therapy and gender-affirming surgery. Familiarity with LGBT health issues and disease-prevention guidelines can enable dermatologists to provide medically appropriate and culturally competent care to LGBT persons.	*Homosexuality, Male; Humans; Male; Female; Practice Guidelines as Topic; HIV; *Transgender Persons; bisexual; gay; transgender; sexually transmitted diseases; LGBT; *Homosexuality, Female; cross-sex hormone; dermal fillers; dermatology; Dermatology/*methods; gender affirmation; indoor tanning; lesbian; sexual minority; Sexually Transmitted Diseases/*diagnosis/*epidemiology/prevention & control; skin cancers; Skin Diseases/*diagnosis/*epidemiology/prevention & control	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review

Article	2019	Younger J.; Raboud J.; Szadkowski L.; Harrigan R.; Walmsley S.; Bayoumi A.M.; Klein M.B.; Cooper C.; Burchell A.N.; Loutfy M.; Hull M.; Wong A.; Thomas R.; Hogg R.; Montaner J.; Tsoukas C.; Antoniou T.	Tenofovir and emtricitabine resistance among antiretroviral-naive patients in the Canadian Observational Cohort Collaboration: Implications for PrEP	Antiviral Therapy	-	-	-	-	13596535	10.3851/IMP3302	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85071701271&doi=10.3851%2fIMP3302&partnerID=40&md5=2d78453efb9261a20f35e088c225e1d2	Background: The real-world effectiveness of pre-exposure prophylaxis (PrEP) may be influenced by circulating HIV strains resistant to either tenofovir or emtricitabine. Yet, few studies have examined rates of resistance to these drugs in clinical settings. Methods: We conducted a retrospective cohort study of antiretroviral-naive participants in the Canadian Observational Cohort collaboration who initiated antiretroviral therapy between 2006 and 2014. In separate analyses, we determined the prevalence of pretherapy resistance and cumulative incidence of follow-up resistance to tenofovir and emtricitabine. We used multivariable proportional hazards models to examine associations between baseline variables and the development of resistance. Results: We studied 6,622 antiretroviral-naive participants initiating therapy, of whom 5,428 (82.0%) had a baseline resistance test. Baseline resistance to tenofovir and emtricitabine was observed in 83 (1.5%) and 21 (0.4%) patients, respectively. Among patients without baseline resistance, the cumulative incidence of resistance to tenofovir and emtricitabine 5 years following treatment initiation was 0.0070 (95% CI 0.0046, 0.0095) and 0.033 (95% CI 0.028, 0.038), respectively. Following multivariable analysis, a baseline viral load ≥100,000 copies/ml was associated with emergence of tenofovir (hazard ratio HR 2.88; 95% CI 1.35, 6.15) and emtricitabine (HR 2.27; 95% CI 1.64, 3.15) resistance. Initiating an integrase inhibitor-based regimen and CD4+ T-cell count below 200 cells/mm3 were also associated with resistance to each drug. Conclusions: We observed a low prevalence of baseline resistance and a low incidence of emergence of resistance to tenofovir and emtricitabine among antiretroviral-naive patients in routine clinical care. © 2019 International Medical Press 1359-6535 (print) 2040-2058 (online)	NA	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Clinical
Article	2019	Zablotska, Iryna B; Vaccher, Stefanie J; Bloch, Mark; Carr, Andrew; Foster, Rosalind; Grulich, Andrew E; Guy, Rebecca; McNulty, Anna; Ooi, Catriona; Pell, Catherine; Poynten, Isobel M; Prestage, Garrett; Ryder, Nathan; Templeton, David	High Adherence to HIV Pre-exposure Prophylaxis and No HIV Seroconversions Despite High Levels of Risk Behaviour and STIs: The Australian Demonstration Study PrELUDE.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-018-2290-3	https://dx.doi.org/10.1007/s10461-018-2290-3	PrELUDE study evaluated daily pre-exposure prophylaxis (PrEP) in high-risk individuals in Australia. This open-label, single-arm study tested participants for HIV/STI and collected behavioural information three-monthly. We report trends over 18 months in medication adherence, side-effects, HIV/STI incidence and behaviour. 320 gay/bisexual men (GBM), 4 women and 3 transgender participants, followed on average 461 days, reported taking seven pills/week on 1,591 (88.5%) occasions and 4-6 pills/week on 153 (8.5%) occasions. No HIV infections were observed. STI incidence was high and stable, while gonorrhoea infections declined from 100.0 to 25.8/100 person-years between 6 and 15 months (p < 0.001). The number of HIV-positive and unknown-status sex partners, and condomless anal intercourse, significantly increased. In this high-risk cohort of mainly GBM, increases in risk behaviours and high STI incidence were not accompanied by HIV infections due to high adherence to daily PrEP. The study informed policy and further PrEP implementation among Australian GBM. Article	2019	Zarwell M.; Ransome Y.; Barak N.; Gruber D.; Robinson W.T.	PrEP indicators, social capital and social group memberships among gay, bisexual and other men who have sex with men	Culture, Health & Sexuality	-	-	-	-	13691058	10.1080/13691058.2018.1563912	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85061099693&doi=10.1080%2f13691058.2018.1563912&partnerID=40&md5=1adf926687302fa5263d997276840a5e	Efforts to reduce HIV among gay, bisexual and other men who have sex with men include increasing awareness and uptake of pre-exposure prophylaxis (PrEP). Social capital may facilitate engagement in HIV prevention. Membership of social groups including chosen families (i.e. friends as family relationships)–one potential indicator of social capital–may be protective against HIV risk and infection. In this cross-sectional quantitative study, we examined social capital items and social group membership in association with PrEP outcomes. In 2014, the New Orleans arm of the National HIV Behavioral Surveillance recruited 353 HIV-negative men, of whom 46% identified as Black, Latino or Other Race and 54% as Non-Hispanic White, using venue-based sampling to complete a structured survey. Multivariable logistic regression models tested the relations between social group membership and social capital with PrEP indicators. Men who reported community group participation were more likely to be aware of PrEP compared to those who did not. Men in chosen families associated with a family name were least likely to be aware of and willing to take PrEP compared to those not in any other social groups. Social group membership is a potential social capital indicator for assessing HIV prevention among men. © 2019, © 2019 Informa UK Limited, trading as Taylor & Francis Group.	bisexual; gay; men; PrEP; social capital	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Article	2019	Zhabokritsky, Alex; Nelson, LaRon E; Tharao, Wangari; Husbands, Winston; Su, Tang Zhang; Nanhoe, Thomas-Persaud, Jamie; Baidoobonso, Shamara; Kaul, Rupert	Barriers to HIV pre-exposure prophylaxis among African, Caribbean and Black men in Toronto, Canada	PLOS One	-	-	-	-	1932-6203	NA	https://pubmed.ncbi.nlm.nih.gov/30925582/	Single-tablet combination emtricitabine/tenofovir is highly effective as HIV pre-exposure prophylaxis (PrEP). Scale-up efforts have targeted men who have sex with men (MSM), but patterns of racial disparities in HIV and PrEP use suggest that other populations may benefit. Black men are disproportionately affected by HIV in Toronto and may benefit from PrEP implementation in this priority population. ACB men from Toronto, Canada were recruited in community settings by peers. Participants completed a detailed socio-behavioural questionnaire. Biological samples were collected and tested for sexually transmitted infections. Willingness to accept PrEP was assessed in relation to actual and self-perceived risk of acquiring HIV, as well as demographic and behavioural variables. 426 ACB men were included in the analysis. ACB MSM were more likely to accept PrEP than ACB men only reporting sex with women (MSW; 50.0% vs. 21.6%). The most common reasons for PrEP non-acceptance were concerns regarding side effects and low self-perceived risk. PrEP acceptance was lowest among younger men (12.5%) and those born in Canada (13.2%). Men with a high self-perceived HIV risk were more likely to accept PrEP (81.3% vs. 22.7% of men with a low self-perceived risk), but only 25.4% of men who were defined as being at high-risk, self-identified themselves as such. Most ACB MSW were unlikely to accept PrEP, largely due to low self-perceived HIV risk, but PrEP acceptance among ACB MSM was similar to other contemporaneous Toronto MSM communities. PrEP acceptance was particularly low among younger ACB men and those born in Canada. Tailored strategies will be needed to effectively implement PrEP in Toronto ACB communities. Article	2019	Zhang C., McMahon J., Fiscella K., Przybyla S., Brakemeier A., Lofthus N., Liu Y.	HIV Pre-Exposure Prophylaxis Implementation Cascade among Health Care Professionals in the United States: Implications from a Systematic Review and Meta-Analysis	AIDS Patient Care and STDs	-	-	-	-	1087-2914	10.1089/apc.2019.0119	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85076339654&doi=10.1089%2Fapc.2019.0119&partnerID=40&md5=4948a6aa6310f0a328b17867b68fc3a1	Although pre-exposure prophylaxis (PrEP) has been approved for primary HIV prevention for individuals aged 18 years or older since 2012, PrEP utilization has been suboptimal. To understand trends in PrEP provision from the health care providers' perspective, we systematically assessed each specific stage along the PrEP implementation cascade (i.e., awareness, willingness, consideration, and prescription) among health care professionals (HCPs) in the United States. Between June and December 2018, we conducted a systematic review of published studies on this topic. A total of 26 eligible studies were identified, and 14 studies with 2,419 HCPs were included in the meta-analysis. Pooled prevalence of PrEP awareness was 69% (95% confidence interval [CI] = 55–80%), willingness to prescribe PrEP was 66% (95% CI = 54–77%), PrEP consultation was 37% (95% CI = 25–51%), and prescription provision was 24% (95% CI = 17–32%). Subgroup analyses revealed that PrEP provision among HCPs was lower in the south, but has been improving annually nationwide. Infectious disease specialists odds ratio (OR) = 4.04, 95% CI = 1.12–5.28; compared with primary care providers and advanced practice registered nurses/physician assistants (OR = 1.51, 95% CI = 1.09–2.09; compared with physicians) had higher odds of prescribing PrEP. Barriers and facilitators regarding optimal PrEP implementation were embedded within individual, dyadic, social, and structural levels. This meta-analysis has comprehensively examined the trend and pattern of PrEP implementation among HCPs. To achieve optimal implementation of the PrEP cascade in the United States, tailored training and programs need to be provided to HCPs. © 2019, Mary Ann Liebert, Inc.	health care professionals; meta-analysis; PrEP implementation cascade; systematic review; United States	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2019	Zhang C., McMahon J.; Simmons J.; Brown L.L.; Nash R.; Liu Y.	Suboptimal HIV Pre-exposure Prophylaxis Awareness and Willingness to Use Among Women Who Use Drugs in the United States: A Systematic Review and Meta-analysis	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-019-02573-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069493324&doi=10.1007%2Fs10461-019-02573-x&partnerID=40&md5=5743ca9410dc02d538b2b2ce1167b3	In the United States (U.S.), more than 12 million women reported illicit drug use in the past month. Drug use has been linked to increased risk for HIV, but little is known about the uptake of HIV pre-exposure prophylaxis (PrEP) to prevent HIV among women who use drugs (WWUD). Following the PRISMA guideline, we conducted a multi-database literature search to assess engagement along the PrEP care continuum among WWUD in the U.S. Seven studies with a total of 755 women were included in the review: 370 (49%) Black, 126 (16.7%) Hispanics, and 239 (34.3%) White. Employing random-effect models, data indicate 20.6% (95% CI 8.7%, 32.4%) of WWUD were aware of PrEP, and 46.2% (95% CI 32.2%, 60.2%) of those aware were also willing to use PrEP. Across dissimilar study limitations, our findings suggest there may be potential to increase PrEP uptake among WWUD, but efforts must first concentrate on improving PrEP awareness among this population. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Zhang L.; Peng P.; Wu Y.; Ma X.; See N.N.; Huang X.; Wu H.; Markowitz M.; Meyers K.	Modelling the Epidemiological Impact and Cost-Effectiveness of PrEP for HIV Transmission in MSM in China	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-018-2205-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85049382626&doi=10.1007%2Fs10461-018-2205-3&partnerID=40&md5=1f0e9935fdd533cb4a4c849d02209bb3	Risk of HIV infection is high in Chinese MSM, with an annual HIV incidence ranging from 3.41 to 13.7/100 person-years. Tenofovir-based PrEP is effective in preventing HIV transmission in MSM. This study aims to assess the cost-effectiveness of PrEP implementation among MSM in China. We developed a dynamic model to project the lifetime HIV infections averted by PrEP, the number of infections, deaths, and disability-adjusted life years (DALY) averted. We also provide an estimate of the incremental cost-effectiveness ratio (ICER) and the cost per DALY averted of the intervention. Without PrEP, there will be 1.1–3.0 million new infections and 0.7–2.1 million HIV-related deaths in the next two decades. Moderate PrEP coverage (50%) would prevent 0.17–0.32 million new HIV infections. At Yunnan's current price in China, daily oral PrEP costs $46.013–52,000 per DALY averted and is not cost-effective; on-demand Truvada reduces ICER to $25,857–27,830 per DALY averted, marginally cost-effective; daily generic tenofovir-based regimens further reduce ICER to $3675–8963, wholly cost-effective. The cost of daily oral Truvada PrEP regimen would need to be reduced by half to achieve cost-effectiveness and realize the public health good of preventing hundreds of thousands of HIV infections among MSM in China. © 2018, Springer Science+Business Media, LLC, part of Springer Nature. Article	2019	Zhang, Helen L; Murthy, Bhavini; Johnston, Barbara; Morthley, Marissa; Wu, Jiewei; Samsa, Gregory P; Sohn, Arlene C; McKellar, Melvin S	Public Awareness of HIV Pre-Exposure Prophylaxis in Durham, North Carolina: Results of a Community Survey.	North Carolina Medical Journal	-	-	-	-	0029-2559	10.18043/ncm.80.1.7	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC9079027/	BACKGROUND Adoption of HIV pre-exposure prophylaxis (PrEP) remains limited among populations at greatest risk for HIV acquisition. This study aims to assess awareness of PrEP among individuals in Durham, North Carolina, which has one of the highest rates of HIV diagnoses in the state. METHOD In 2015-2016, we administered a survey including questions to assess PrEP awareness to individuals at multiple venues throughout Durham, North Carolina. RESULTS A total of 139 community respondents were surveyed. The majority were male (66%) and black/African American (75%); 21% were Hispanic. There were an estimated 53 men who have sex with men (MSM), of which 18 (33%) were black MSM and 34 years of age. Overall, only 53/138 (38%) respondents were aware of PrEP. Awareness was reported among 33/52 (63%) MSM respondents, 29/46 (63%) black MSM, and 10/17 (59%) black MSM 24 years of age. In multivariate analysis, non-heterosexual orientation, health-insured status, and prior HIV testing were significantly associated with PrEP awareness. Ninety-four (68%) of 137 respondents reported prior HIV testing.CONCLUSIONS Limitations include non-random sampling and limited sample size. Despite these limitations, this study is one of the largest surveys of PrEP awareness in the southeastern United States. Our findings demonstrate a low overall awareness of PrEP in Durham, North Carolina, indicating that expanded outreach is necessary to increase public awareness and encourage adoption of PrEP among all demographics at risk for HIV. Article	2019	Zhao, ZZ; Jones, J; Sanders, R; Gladfelter, G; Mcdonald, S; Reed, C; Castellanos, J; Fellon, G; Morley, K; Campbell, E; Myer, D; Jones, T; Rothman, R; Hsieh, YH	EMERGENCY DEPARTMENT (ED)-BASED HIV PRE-EXPOSURE PROPHYLAXIS (PREP) REFERRAL PROGRAM - USING EDS AS A PORTAL FOR PREP SERVICES	Sexually Transmitted Infections	-	-	-	-	1368-4973	10.1136/sextrans-2019-sti.537	https://sti.bmj.com/content/95/Suppl_1/A213.1	Background U.S. Emergency Departments (EDs) serve many patients at high risk for HIV and could serve as a portal of entry for pre-exposure prophylaxis (PrEP). We conducted a pilot study to determine feasibility and acceptability of PrEP referral from the ED. Methods From late December 2018 to March 2019, a pilot PrEP referral program was integrated into an established HIV/STI screening program in an urban U.S. ED with HIV seroprevalence of 6%. Patients were eligible if they were aged 18-64 years, had a negative HIV test during the previous 12 months and tested HIV-negative, or a negative HIV test during the current ED visit. The PrEP referral program was implemented by HIV/STI program staff and clinicians. Patients who were approached by convenience sampling based on staff availability. HIV risk and interest in PrEP referral was assessed through an electronic survey based on CDC PrEP guidelines. Patients expressing interest in PrEP were referred to PrEP peer navigators from the adult infectious disease specialty clinic and positive clinic. Referrals, scheduled and completed appointments, and PrEP initiation were collected. Results In this ongoing program, 298 ED patients were screened, 162 approached and 89 (55%) took the survey. 68 (42%) were categorized as high-risk and eligible for PrEP referral. Of these 68 patients, 36 (53%) accepted PrEP referral, 15 (22%) were successfully contacted by phone with additional 21 (31%) pending for follow-up calls, six (9%) were scheduled for appointments, and two (3%) completed an appointment. Conclusion Our preliminary findings demonstrate a high interest for PrEP referral and comparable PrEP care cascade outcomes in high-risk ED patients indicating that implementation of an ED-based PrEP referral program is feasible and acceptable and could serve as an important portal for PrEP care. Barriers along the PrEP care continuum to better engage and retain patients should be addressed as a future direction. Article2	2019	Zheng Z.-W.; Qiu J.-L.; Gu J.; Xu H.-F.; Cheng W.-H.; Hao C.	Preexposure prophylaxis comprehension and the certainty of willingness to use preexposure prophylaxis among men who have sex with men in China	International journal of STD & AIDS	-	-	-	-	9564624	10.1177/0956462418783142	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85053193111&doi=10.1177%2F0956462418783142&partnerID=40&md5=6d0b92dfc0b44d2f9703f7c2f2bbd1f4	Preexposure prophylaxis (PrEP) is not available in China and the willingness to use PrEP among Chinese men who have sex with men (MSM) is not clear. The aim of this study was to better understand the association between PrEP comprehension and the willingness to use PrEP under varying conditions among MSM. An online survey investigating personal characteristics, PrEP comprehension, and PrEP willingness among MSM was conducted. A third of respondents (36.2%, 196 out of 541) reported that they would like to use PrEP. Compared with MSM who had a high-level comprehension, MSM with a high level were more likely to report clear choices: a willingness or unwillingness to use PrEP (82.4% versus 65.7%, p <0.01). Among 350 MSM willing to use PrEP or uncertain about uptake, those with a high level of PrEP comprehension were more likely to use PrEP daily (adjusted odds ratio: AOR = 1.72, 95% confidence interval: 1.04–2.88), and to take it either daily or when sexually active (AOR = 2.72 or 2.37). A high level of PrEP comprehension is a key factor in urging MSM to use PrEP under varying conditions. Our findings call attention to the need for health education to improve PrEP comprehension. © The Author(s) 2018. Article	2019	Zhu, Yifan; Di, Chongzhi; Chen, Yang Qing	Clustering functional data with application to electronic medication adherence monitoring in HIV prevention trials.	Statistics in Biosciences	-	-	-	-	1867-1764 1867-1772	10.1007/s12561-019-09232-8	https://pubmed.ncbi.nlm.nih.gov/31695010/	Maintaining high medication adherence is essential for achieving desired efficacy in clinical trials, especially prevention trials. However, adherence is traditionally measured by self-reports that are subject to reporting bias/error and intervention/placebo differential reporting/error. Recently, electronic medication adherence devices have been adopted in several HIV pre-exposure prophylaxis prevention-mirror events. Recently, electronic medication adherence devices have been adopted in several HIV pre-exposure prophylaxis prevention-mirror events. Electronic devices are capable of collecting objective, frequent, and timely drug adherence data. The device opening signals generated by such devices are often represented as regularly or irregularly spaced discrete functional data, which are then summarized into adherence profiles for each study participant. We propose a functional clustering approach to identify subgroups of study participants based on these functional data. Functional data are smoothed functional data. Parametric mixture models with changepoints, as well as several non-parametric and semi-parametric functional clustering approaches are developed and applied to the smoothed adherence data. Simulation studies were conducted to evaluate finite sample performances, on the choices of tuning parameters in the pre-processing step as well as the relative performance of different clustering algorithms. We applied these methods to the HIV Prevention Trials Network(HPTN) 068 study for identifying subgroups with distinct adherence behavior over the study period. Article	2019	Zimba, Chifundo; Mamun, Seesmee; Rosenberg, Nora E; Willwood Munthi; Mwesemba, Oliver; Dunda, Wezzie; Phanga, Tweniwhite; Chibwe, Kasapo F; Matenga, Tukesi; Freyhem, Kellie; Schreible, Leah; Nwalika, Bellington; Chi, Benjamin H	The landscape for HIV pre-exposure prophylaxis during pregnancy and breastfeeding in Malawi and Zambia: A qualitative study	PLOS One	-	-	-	-	NA	10.1371/journal.pone.0223487	https://www.proquest.com/scholarly-journals/landscape-hiv-pre-exposure-prophylaxis-during/docview/2300990110/se-2?accountid=14113	High HIV incidence rates have been observed among pregnant and breastfeeding women in sub-Saharan Africa. Oral pre-exposure prophylaxis (PrEP) can effectively reduce HIV acquisition in women during these periods; however, understanding of its acceptability and feasibility in antenatal and postpartum populations remains limited. To address this gap, we conducted in-depth interviews with 90 study participants in Malawi and Zambia. Participants were pregnant women, breastfeeding women, male partners, and key informants. Data were analyzed using manual thematic coding. Salient themes related to PrEP. As a public health intervention, PrEP was not well-known among patients and healthcare workers; however, when it was described, most participants, male counterparts, and key informants were receptive. Concerns about safety and adherence were raised, highlighting two critical areas for community outreach. The feasibility of introducing PrEP into antenatal services was also a concern, especially if introduced within already strained health systems. Support for PrEP varied among policymakers in Malawi and Zambia, reflecting the ongoing policy discussions in their respective countries. Implementing PrEP during the pregnancy and breastfeeding periods will require addressing barriers at the individual, facility, and policy levels. Multi-level approaches should be considered in the design of new PrEP programs for antenatal and postpartum populations. Article	2019	Zimmermann H.M.L.; Eshtiaun S.W.; Achterbergh R.C.A.; Schim van der Loeff M.F.; Prins M.; de Vries H.J.C.; Hoornenborg E.; Davidovich U.	Motives for choosing, switching and stopping daily or event-driven pre-exposure prophylaxis – a qualitative analysis	Journal of the International AIDS Society	-	-	-	-	17582652	10.1002/jia2.25389	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85073173324&doi=10.1002%2Fjia2.25389&partnerID=40&md5=45ed1728d0e29203c53ddf3a06fd3648	Introduction: In settings where both daily and event-driven pre-exposure prophylaxis (PrEP) are offered to men who have sex with men (MSM), a clear understanding of the motives to choose between the different dosing regimens can facilitate more effective PrEP implementation. We therefore studied the motives for choosing for, switching between, and stopping daily or event-driven PrEP. Methods: We used data (August 2015-June 2017) from the prospective, longitudinal, open-label Amsterdam PrEP demonstration study, in which daily (dPrEP) and event-driven PrEP (edPrEP) were offered to 374 HIV-negative MSM and two transgender persons. Participants self-selected the preferred PrEP regimen at baseline and could switch regimens at three-monthly follow-up visits. We measured motives for choosing PrEP regimen at baseline and for switching and stopping PrEP at follow-up visits. Open- and closed-end items were combined and qualitatively analysed. Results: Choices of PrEP-regimens were determined by personal and contextual factors, involving the perceived self-efficacy concerning adherence, the risk context, and the anticipated impact of PrEP on physical and mental health. Participants who preferred dPrEP because of the anticipated better adherence and the fear of side-effects relating to edPrEP-ingestions. Moreover, dPrEP was perceived to be more effective than edPrEP. Motives to choose edPrEP were the avoidance of unnecessary PrEP-ingestions, the lower costs, and the lower impact on sexual pleasure. Switches from edPrEP to dPrEP were mainly motivated by the perceived risk context, and choices relied on the perceived effectiveness of dPrEP. Switches from dPrEP to edPrEP were mainly motivated by the anticipated impact on sexual pleasure, and choices relied on perceived adherence. Changes in the eleven factors, such as changing risk perceptions, changing relationships or changing physical conditions, resulted in switching regimens. Choices to stop PrEP were related to lower sexual risk, adherence issues and side-effects. Conclusions: The great diversity of motives illustrates the importance of offering a choice of PrEP-regimens. In counselling of MSM starting PrEP, choices for PrEP-regimens may be addressed as a continuum of flexible and changeable options over time. This may help individuals choose the PrEP-regimen that best fits their current sexual context, priorities and personal capabilities and therefore will be more easily adhered to. © 2019 The Authors. Article	2019	Zucker, Jason; Carnevale, Caroline; Richards, Paul; Slowikowski, Jacek; Borza, Alexander; Gottlieb, Felix; Vakkor, Isabelle; Hyden, Christel; Okrokov, Susan; Cobalt, Alwyn; Gordon, Peter; Schnoes,Erik; Magdalena E	Predictors of Disengagement in Care for Individuals Receiving Pre-exposure Prophylaxis (PrEP).	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000002054	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8576954/	BACKGROUND: HIV pre-exposure prophylaxis (PrEP) reduces incident HIV infections, but efficacy depends on adherence and retention, among other factors. Substance use disorders, unmet mental health needs, and demographic factors are associated with nonadherence in HIV-infected patients; we studied whether these affect PrEP retention in care. METHODS: To investigate potential risk factors disengagement in a comprehensive HIV prevention program, we conducted a retrospective cohort analysis of individuals starting tenofovir-emtricitabine between January 1, 2015, and December 30, 2017. The primary outcome was adherence to the initial 3-visit schedule after PrEP initiation. RESULTS: The cohort was predominantly African American (23%) and Hispanic (46%). Race, ethnicity, substance use, mental health conditions, and housing instability were not associated with PrEP retention. Age was significantly associated with PrEP retention: each year of age at birth, transition from post-exposure prophylaxis (PEP) to PrEP, feeling that they could benefit from PrEP, or participating in mental health services were associated with increased retention. Overall, retention in HIV preventative care at the first follow-up visit (68%) and third follow-up visit (35%) after PrEP initiation was low. CONCLUSION: Clinic services and ancillary services (such as mental health) may facilitate retention in care. In this study, select social and behavioral determinants of health were not found to be related to retention. Focused investigation of reasons for dropout may elucidate the challenges to maintaining individuals in PrEP care and direct resource allocation to those in greatest need. Article	2020	Abo-Khaled, Suhe; Dent, Jennes; Tot, Michelle; Dandachi, Dima	Are We Proscribing Enough HIV Pre-Exposure Prophylaxis in Missouri?: A Cross-Sectional Study at University of Missouri Health Care.	Missouri Medicine	-	-	-	-	0026-6620	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7722142/	Despite the proven efficacy and safety of HIV pre-exposure prophylaxis (PrEP), it remains underutilized. PrEP use among Missouri providers has increased as the rate of new HIV infections grows statewide, placing their risk for Missouri and Urban Crescent (UC) patients. Recent guidelines by the Centers for Disease Control and Prevention (CDC) identify Missouri as at-risk for an HIV outbreak; we seek to characterize HIV testing practices and PrEP knowledge and use among Missouri healthcare providers.	The study has been approved by the University of Missouri Institutional review board. Article	2020	Achieng, AE; Owiti, E	SOCIOECONOMIC INEQUALITY IN HIV PREVENTION AMONGST FEMALE SEX WORKERS: A CROSS-SECTIONAL ANALYSIS OF ORAL PRE-EXPOSURE PROPHYLAXIS IN RURAL KENYA	Value in Health	-	-	-	-	1098-3015	10.1016/j.jval.2020.04.471	https://www.valueinhealthjournal.com/article/S1098-3015%2820%2930193-8/fulltext	Objectives: HIV and AIDS remain a major public health and economic burden to Kenya. The prevalence among the general-population has been decreasing, however, it remains very high at an average of 30% among female sex workers (FSWs). The sex trade is unlawful in Kenya and FSWs operate illegally without business protection increasing risk of sexual exploitation and abuse. The Government of Kenya offers FSWs Oral Pre-exposure prophylaxis (PrEP) free of charge to reduce the risk of HIV infection. Socioeconomic inequalities contribute to disparities in the uptake of health services, with the rich accessing more care than the poor. The objective of this study was to estimate socioeconomic inequality in PrEP use among FSWs in rural Kenya. Methods: Using a structured questionnaire, 479 HIV negative FSWs were sampled and data on their socioeconomic and demographic status collected. Average marginal effects was used to estimate the determinants of PrEP use by FSWs. Concentration curves and Erreygers CI were used to estimate inequality in PrEP use among FSWs in rural Kenya. Results: Of the 479 HIV Negative FSWs (median age 26y), 297 (62%) reported ever using PrEP. PrEP uptake was highest amongst those aged over 24 years (66%), formerly and currently married (54%), with less than 2 children (85%), unemployed (54%), above secondary education (61%), town residence (52%), and those in the richest wealth quintile (26%). Overall, PrEP use was concentrated among the wealthy FSWs (CI=0.224, p<0.01). Conclusions: The findings shows socioeconomic inequality in oral PrEP uptake, hence the need to target poor and vulnerable FSWs as the distribution of PrEP. Secondly, the government needs to consider linking social protection interventions and PrEP use to improve its uptake. Article	2020	Adriaenssens, Jeroen; Hompes, Thierry; Gianfrancesco, Fabrizio; Arnon, Jacob; Geusens, Nathalie; Spinnewijn, Jan; Sturtewagen, Yves; Van Den Eede, Frank	Experiences and choices of women using antenatal dydrogesterone: results of a pregnancy exposure registry and survey	The European Journal of Contraception & Reproductive Health Care	-	-	-	-	1362-5187	10.3109/13625187.2012.715381	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3518696/	OBJECTIVES: To estimate HIV prevalence and associated risk factors among men who have sex with men (MSM) in Dar es Salaam, Tanzania following the implementation of the national comprehensive package of HIV interventions for key populations (CHIP). DESIGN: A cross-sectional survey using respondent-driven sampling. SETTING Dar es Salaam, Tanzania's largest city. PARTICIPANTS: Men who occasionally or regularly have sex with another man, aged 18 years and above and living in Dar es Salaam city at least 6 months preceding the study. PRIMARY OUTCOME MEASURE: HIV prevalence was estimated using RDS-Analyst. Risk factors were analysed using multivariable logistic regression. RESULTS: Between January 1, 2015, and December 30, 2017. The study. The weighted HIV prevalence was 8.3% (95% CI 6.5%-10.8%) as compared with 22.2% (95% CI: 16.7%-28.4%) observed in a similar survey in 2014. Half of the participants had had sex with more than two partners in the month preceding the survey. Among those who had engaged in transactional sex, 80% had used a condom during last anal sex with a paying partner. Participants aged 25 and above had four times higher odds of being infected than those aged 15-19 years. HIV infection was associated with multiple sexual partnerships (adjusted OR/AOR, 3.0; 95% CI: 1.8-12.0), not having used a condom during last sex with non-paying partner (AOR, 4.1; 95% CI: 1.4-7.8) and ever having engaged in group sex (AOR, 3.4; 95% CI: 1.7-3.6). CONCLUSION: HIV prevalence among MSM in Dar es Salaam has decreased by more than a half over the past 5 years, coinciding with implementation of the CHIP. It is nonetheless two times as high as that of men in the general population. To achieve the 2-10 goals, behavioural change interventions and roll-out of new intervention measures such as pre-exposure prophylaxis are urgently needed. Article	2020	Aghaindi, Amenah; Hempel, Amanda; Hezenkleiya, Amde; Clifford-Rashotte, Matthew; Tan, Darryl H S; Bogoch, Isaac I	HIV postexposure prophylaxis-in-pocket: long-term follow-up of individuals with low-frequency, high-risk HIV exposures.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0000000000002441	https://dx.doi.org/10.1097/QAD.0000000000002441	BACKGROUND HIV postexposure prophylaxis and postexposure prophylaxis are two major biomedical HIV prevention modalities. The utility of these prevention tools for individuals with infrequent high-risk HIV exposures remains uncertain. HIV postexposure prophylaxis-in-pocket (PEP) may be an effective HIV prevention tool in such situations. Here, we present long-term follow-up of a cohort of patients initiated on PEP for HIV prevention. METHODS: We retrospectively evaluated clinical characteristics of patients initiated on PEP as a primary HIV prevention tool between 1 January 2010 to 31 May 2019 at the Toronto General Hospital HIV Prevention Clinic and St. Michael's Hospital HIV Clinic, both in Toronto, Canada. Patients were referred for consideration of a biomedical HIV prevention modality. Individuals with a low frequency of high-risk exposures to HIV were initiated on PEP after counselling, and were followed at regular intervals. Demographic and clinical data was collected with a standardized form. RESULTS: In total, 79 patients were initiated on PEP as a primary HIV prevention modality and followed for a mean duration of 14.8 months combining for a total of 97.3 patient-years. Twenty-one (26.6%) patients used their PEP, and 32 courses of PEP were taken during the study period. Transitions between HIV prevention modalities included 13 (16.5%) patients who transitioned from PrEP to PEP, and 12 (12.6%) patients who transitioned from PEP to PrEP. No HIV seroconversions were detected during the course of this study. CONCLUSION: PEP is helpful HIV prevention modality for individuals with a low frequency of high-risk HIV exposures. Article	2020	Allen, Sean T; O'Rourke Allison; White, Rebecca Hamilton; Smith, Katherine C; Weir, Brian; Lucas, Gregory M; Sherman, Susan G; Grieb, Suzanne M	Barriers and Facilitators to PrEP Use Among People Who Inject Drugs in Rural Appalachia: A Qualitative Study	AIDS and Behavior	-	-	-	-	1090-7165	10.1007/s10461-019-02767-3	https://www.proquest.com/scholarly-journals/barriers-facilitators-prep-use-among-people-who-inject/docview/2402240754/se-2?accountid=14113	The opioid crisis has increased risks for injection drug use-associated HIV outbreaks in rural communities throughout the United States. Existing research has examined pre-exposure prophylaxis (PrEP) utilization among people who inject drugs (PWID); however, no studies have been conducted to explore barriers and facilitators of PrEP use among rural PWID in Appalachia. We conducted qualitative interviews with PWID (n = 40) in two rural counties in West Virginia to explore barriers and facilitators of PrEP use. Among our participants, the majority (68.8%) had never heard of PrEP. Upon learning about PrEP, most participants expressed willingness to use it. Rural PWID described several factors that may impede PrEP utilization (e.g., housing instability; forgetting to take PrEP). Participants also identified practical strategies to support sustained PrEP utilization, such as integrating PrEP services into venues PWID access. This research provides important insights into the barriers and facilitators of PrEP utilization among rural PWID. Article	2020	Amith, Muhammad Tuan; Cui, Licong; Roberts, Kirk; Tao, Cui	Towards an ontology-based medication conversational agent for PrEP and PEP.	Proc Conf Assoc Comput Linguist Meet	-	-	-	-	0736-587X	10.18653/v1/2020.nlpmc-1.5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7606882/	HIV (human immunodeficiency virus) can damage a human's immune system and cause Acquired Immunodeficiency Syndrome (AIDS) which could lead to severe outcomes, including death. While HIV infections have decreased over the last decade, there is still a significant population where the infection permeates. PrEP and PEP are two proven preventive measures introduced that involve periodic dosage to stop the onset of HIV infection. However, the adherence rates for this medication is low in part due to the lack of information about the medication. There exist several communication barriers that prevent patient-provider communication from happening. In this work, we present our ontology-based method for automating the communication of this medication that can be deployed for live conversational agents for PrEP and PEP. This method facilitates a model of automated conversation between the machine and user can also answer relevant questions. Article	2020	Anjum, R; Lakshmi, PK		Dolutegravir sodium loaded solid lipid nanoparticles: A vaginal drug delivery system for pre-exposure prophylaxis of HIV	Journal of Research in Pharmacy	-	-	-	-	2630-4244	10.35333/jrp.2020.203	https://jrpsharm.com/abstract.php?lang=en&id=918	The objective of this study was to formulate dolutegravir sodium an antiretroviral drug into topical (vaginal) semisolid solid lipid nanoparticle gel formulation using a rapid, economical one step process. Solid lipid nanoparticles formulations were prepared using solvent injection method combined with sonication, using different types of lipids (e.g. Phosphocholin 80H, Phospholipon 90H and Soy lecithin) and surfactants (Poloxamer 407, Poloxamer 188, and Tween 80). The SLN gel was formed in one step process using poloxamer 407 & water forming aqueous phase and micro acid & phospholipon 80H in ethanol forming lipid phase. The lipid phase was injected into aqueous phase forming a creamy gel at 70 degrees C. Hence it does not require any gelling agent. It was optimized using a systematic approach of design of experiments. The formulation was evaluated for particle size, polydispersity index, zeta potential, flux, entrapment efficiency and results were found to be 455 nm, 0.431, -26.6 mv, 43.7 +/- 0.12 mm, 85.3 +/- 0.12 % and 0.9 +/- 0.12 % respectively. The in vitro release study was carried out using Franz diffusion cell and the release was found to be 90.3 +/- 0.12 % in 24 hours which followed Higuchi release mechanism. The release exponent 'n' of the Korsmeyer equation indicates the Fickian diffusional drug release. The ex vivo vaginal study of F2 formulation showed 64.89% of tissue deposition which was 16 times more than the pure drug. This study concluded that the dolutegravir sodium, a sustained release solid lipid nanoparticle gel may have increased vaginal deposition and might show site targeted effect.	vaginal delivery; FORMULATION; Dolutegravir sodium; gel; solid lipid nanoparticles; solvent injection method	English	India	Asia and the Pacific	India	Asia and the Pacific	India	Asia and the Pacific	Clinical
Article	2020	Annequin M.; Villes V.; Delobre R.M.; Alain T.; Morel S.; Malcheb D.; Schmidt A.J.; Veber A.; Rojo-Castro D.		Are PrEP services in France reaching all those exposed to HIV who want to take PrEP? MSM respondents who are eligible but not using PrEP (IMIS 2017)	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2020.1739219	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85082849574&doi=10.1080%2F09540121.2020.1739219&partnerID=40&md5=e55d8787fcc5305f9181268	Pre-exposure prophylaxis (PrEP) is fully reimbursed by the French health insurance system since 2016. However, uptake of PrEP is slower than expected and little is known about men who have sex with men (MSM) who are eligible for PrEP according to French guidelines, but not using it. This study aims to (1) assess and describe MSM that are eligible to PrEP but not using it, and (2) identify potential individual and structural barriers of PrEP uptake among eligible MSM who are aware and intend to take PrEP. Data from IMIS-2017, a cross-sectional internet survey among gay, bisexual, and other MSM, were used. MSM who are eligible for PrEP according to French guidelines, but not using it, were compared to MSM who are using PrEP and to MSM who are not using PrEP. Among 2231 non-PrEP users, 24.2% were eligible to PrEP and 15.2% were eligible, aware and intended to take PrEP. Compared to MSM who are not using PrEP are mostly younger, students, less "out", living in small cities, using condoms more frequently but still with low self-efficacy regarding safe sex and more distant from preventive health care and information than PrEP users. Despite free PrEP availability in France, results suggest that PrEP is not fully accessible and that there is a need to increase PrEP demand and decentralize PrEP delivery. Article	2020	Antoni, Guillemette; Tremblay, Cécile; Delsuguere, Constance; Charreau, Isabelle; Cua, Eric; Rojas Castro, Daniela; Raffi, François; Chas, Julie; Hoktan, Thomas; Spire, Bruno; Capitant, Catherine; Cotte, Laurent; Meyer, Laurence; Molina, Jean-Michel		On-demand pre-exposure prophylaxis with tenofovir disoproxil fumarate plus emtricitabine among men who have sex with men with low frequent sexual intercourse: a post-hoc analysis of the ANRS IPERGAY trial.	The Lancet HIV	-	-	-	-	2352-3018	https://dx.doi.org/10.1016/S2352-3018(19)30341-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7406871/	BACKGROUND: ANRS IPERGAY found that on-demand pre-exposure prophylaxis (PrEP) with oral tenofovir disoproxil fumarate plus emtricitabine was associated with an 86% relative reduction of HIV-1 incidence compared with placebo among men who have sex with men at high risk of HIV. We aimed to investigate whether on-demand PrEP was similarly effective among individuals with lower exposure to HIV risk. METHODS: Participants in the ANRS IPERGAY trial were randomly assigned to receive PrEP (fixed-dose combination of 300 mg tenofovir disoproxil fumarate and 200 mg emtricitabine per pill) or placebo. The primary endpoint was the diagnosis of HIV-1 infection. PM uptake was assessed by prespecified secondary analyses of the trial's efficacy and safety. Structural equation modelling analysis showed that the awareness of PrEP related knowledge and concerning about PrEP utilization in MSM played a direct positive role in their self-efficiency of using PrEP, and the effect coefficients were 0.31 and 0.29 respectively. Moreover, the awareness of PrEP related knowledge also indirectly affected the self-efficiency of using PrEP by concerning about PrEP utilization in MSM. The mixed model analysis demonstrated that the utilization of PrEP can improve the self-efficacy of using PrEP (OR=5.55), which increased by 0.14 times with the increase of 1 score of the awareness of PrEP related knowledge and concern about using PrEP respectively. In addition, this survey found that in the participants, the main concerns about using PrEP were side effects, HIV prevention effect and its expense, accounting for 61.1% (H01625), 60.1% (U74322) and 53.2% (U51322), respectively. Most participants hoped to obtain PrEP services from CDC, MSM social organizations and internet, accounting for 75.6% (A70422), 65.4% (467422), and 63.8% (J97422), respectively. Conclusions MSM showed different degree of high need but low utilization of PrEP services. Low awareness of PrEP related knowledge, concerns about the prevention effect, side effects and expense of PrEP as well as self-disinterestion were the factors hindering the use of PrEP in MSM. It is necessary to establish a suitable PrEP service model to meet the needs for PrEP in MSM. © 2020 Chinese Medical Association. All rights reserved. Article	2020	Arnie S.; Operario D.; Zhihua Z.; Yue Z.; Xiaofang Z.; Cui Y.; Zeller N.; Pan G.; Jun W.; Yehuan S.; Hongbo Z.		Needs of pre-exposure prophylaxis for HIV infection and related barriers among men who have sex with men	Chinese Journal of Endemiology	-	-	-	-	20954255	10.3760/cma.j.issn.0254-6450.2020.02.012	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85084460606&doi=10.3760%2Fcma.j.issn.0254-6450.2020.02.012&partnerID=40&md5=e8054c971ca4b2b873adeef1f3cd9be2	BACKGROUND: ANRS IPERGAY trial is registered with ClinicalTrials.gov, NCT01473472. OPINIONS: 400 participants who were randomly assigned to receive PrEP (n=199) or placebo (n=201) between Feb 22, 2012, and Oct 17, 2014, were included in this analysis. 270 participants had at least one period of less frequent sexual intercourse with high PrEP adherence during the study, representing 134 person-years of follow-up and 33% of the total study follow-up. During these periods, participants in both groups reported a median of 5·9 (IQR 2·8–10·0) episodes of sexual intercourse per month and used a median of 9·5 (6·0–13·0) pills per month. Six HIV-1 infections were diagnosed in the placebo group (HIV incidence of 9·2 per 100 person-years; 95% CI 3·4–20·1) and none were diagnosed in the tenofovir disoproxil fumarate plus emtricitabine arm (HIV incidence of 0 per 100 person-years; 0·5–8·4; p=0·013), with a relative reduction of HIV incidence of 100% (95% CI 38–100). INTERPRETATION: A choice between daily or on-demand PrEP regimens could be offered to men who have sex with men who have less frequent sexual intercourse. Article	2020	Arnie S.; Operario D.; Zhihua Z.; Yue Z.; Xiaofang Z.; Cui Y.; Zeller N.; Pan G.; Jun W.; Yehuan S.; Hongbo Z.		Identification of adolescent girls and young women for targeted HIV prevention: a new risk scoring tool in KwaZulu Natal, South Africa.	Scientific Reports	-	-	-	-	2045-2322	10.1038/s41598-020-69842-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7406871/	Objective To understand the actual needs for the pre-exposure prophylaxis (PrEP) for HIV infection and the factors hindering PrEP utilization in men who have sex with men (MSM). Methods Participants were recruited by using MSM social application software Blued 6.5.0 and through MSM peer referral, sample size was 600. An electronic questionnaire survey was conducted anonymously with guidance of investigators via "Questionnaire Star" platform. The contents of the survey included demographic characteristics of the participants, the awareness of PrEP related knowledge, willingness and concerns about using PrEP, actual need for PrEP and self-efficacy of using PrEP. Results A total of 622 MSM completed the survey, of whom 56.4% (351/622) and 4.3% (27/622) ever heard of and received PrEP, respectively. The need assessment of PrEP showed that 47.2% (418/622) of the participants had actual needs for PrEP and 21.2% (132/622) used PrEP with good self-efficacy. Structural equation modelling analysis showed that the awareness of PrEP related knowledge and concerning about PrEP utilization in MSM played a direct positive role in their self-efficiency of using PrEP, and the effect coefficients were 0.31 and 0.29 respectively. Moreover, the awareness of PrEP related knowledge also indirectly affected the self-efficiency of using PrEP by concerning about PrEP utilization in MSM. The mixed model analysis demonstrated that the utilization of PrEP can improve the self-efficacy of using PrEP (OR = 5.55), which increased by 0.14 times with the increase of 1 score of the awareness of PrEP related knowledge and concern about using PrEP respectively. In addition, this survey found that in the participants, the main concerns about using PrEP were side effects, HIV prevention effect and its expense, accounting for 61.1% (H01625), 60.1% (U74322) and 53.2% (U51322), respectively. Most participants hoped to obtain PrEP services from CDC, MSM social organizations and internet, accounting for 75.6% (A70422), 65.4% (467422), and 63.8% (J97422), respectively. Conclusions MSM showed different degree of high need but low utilization of PrEP services. Low awareness of PrEP related knowledge, concerns about the prevention effect, side effects and expense of PrEP as well as self-disinterestion were the factors hindering the use of PrEP in MSM. It is necessary to establish a suitable PrEP service model to meet the needs for PrEP in MSM. © 2020 Chinese Medical Association. All rights reserved. Theses and Dissertations	2020	Arndt, Elisabeth; Hunt, Linda		The Ambiguity of HIV Risk in Pre-Exposure Prophylaxis (PrEp) Administration in New York	-	-	Michigan State University	-	NA	NA	https://www.proquest.com/dissertations-theses/ambiguity-hiv-risk-pre-exposure-prophylaxis-prep/docview/2630974796/se-2?accountid=9113	"Risk" has become a ubiquitous concept in American healthcare settings, drawing both on objective biostatistics and on subjective, morally-charged interpretations. In particular, past epidemiological categorizations of a patient's identity or behavior – like their race or sexual practices – as "risk factors" for contracting HIV has promoted the sociocultural interpretation of HIV risk and stigmatized individuals in those groups. Nonetheless, with the advent of the pharmacologic Pre-Exposure Prophylaxis (PrEP) to prevent HIV transmission, such epidemiological categories of HIV risk are being even more broadly applied. The first medication used for PrEP was Truvada (emtricitabine and tenofovir disoproxil fumarate), an antiretroviral manufactured by the pharmaceutical giant Gilead Sciences that was first approved by the FDA in 2004 to treat HIV-positive patients and then approved again in 2012 as PrEP to prevent HIV infection in HIV-negative patients. Currently, the indications for PrEP prescription are imprecisely defined, leaving it to the discretion of healthcare providers to decide who is a candidate for the medication based on their perceptions of a patient's risk for contracting HIV. Providers' perceptions of HIV risk have been conceptualized in basic, these concepts may be influenced by the intersection of public health agencies and healthcare corporations, and by their pre-set for health and patients in the clinical setting.In this dissertation, I examine the concepts of HIV risk that come into play in the administration of PrEP, considering how these concepts are understood by individual health professionals who prescribe as well as how such representations may align with the goals of healthcare corporations and public health agencies. Using ethnographic research techniques, I construct the perspectives of HIV-negative patients identified as candidates for PrEP, HIV- positive patients, and health professionals administering PrEP to capture how they may understand HIV "risk" and PrEP's role in treating it. I conducted the fieldwork for this dissertation in a New York community health center network that provides PrEP and HIV services to diverse patient populations. I interviewed patients, clinic administrators, social workers, public health workers, and pharmaceutical industry members; observed clinical interactions; reviewed medical charts; and analyzed HIV prevention advertisements, publications, and guidelines. Based upon these collected data, I found that the discourse surrounding HIV risk is ambiguous. PrEP diverts and crystallizes this ambiguity, and structured risk (embedded healthcare structures identifying certain people as "at risk") is a reflective "model of" and constructive "model for" this process in a top-down direction. In doing so, I draw attention to the social significance of the pharmaceuticalization of risk by showing how pharmaceutical marketing can impact how risk is conceptualized, communicated, and experienced. Article	2020	Arrington-Sanders, Renata; Hailey-Fair, Kimberly; Witte, Andrea; Cox, Travis; Galea, Noye; Brooks, Darryle; Castillo, Marne; Dowshen, Nadia; Trexler, Constance; D'Angelo, Lawrence J; Kwiat, Jennafer; Beyrer, Chris; Morgan, Anthony; Celentano, David		Providing unique support for health study among young black and latinx men who have sex with men and young black and latinx transgender women living in 3 urban cities in the united states: Protocol for a couch-based mobile-enhanced randomized control trial	JMIR Research Protocols	-	-	-	-	19298748	10.2196/17269	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85092750988&doi=10.2196%2F17269&partnerID=40&md5=5b9ce8bc2e0b5c377fe0a9c9c133fad6	Background: The US National HIV/AIDS Strategy 2020 calls for increasing access to care, improving outcomes of people living with HIV, and targeting biomedical prevention efforts, including access to pre-exposure prophylaxis (PrEP) in communities where HIV is most heavily concentrated. The cities of Baltimore, Maryland (MD), Washington, DC, and Philadelphia, Pennsylvania (PA) are disproportionately burdened by high rates of new cases of HIV infection, with high prevalence among young Black and Latinx men who have sex with men (YMSMM) and young Black and Latinx transgender women (YBLTW) aged 15-24 years. Objective: This study aims (1) to identify and recruit YBLMM and YBLTW who are at risk or living with HIV in Baltimore, MD; Philadelphia, PA; and Washington, DC, using social media platforms; (2) to engage them in a couch-based, mobile-enhanced, randomized control trial (RCT) to increase PrEP uptake and adherence and linkage to and successful engagement in care for those living with HIV; PrEP, and substance use treatment care; access the HIV care and prevention continuum. A URL-Atlanta cities. The study protocol was approved by the institutional review board on October 20, 2019. Methods: This study uses a multiphase mixed methods design. The first phase is a formative, qualitative research with focus group discussions and key informant interviews. The second phase consists of creating the study platform and delivering the intervention. The third phase includes 2 embedded randomized controlled trials (RCTs), where participants complete a baseline computer-assisted self-interview survey, rapid HIV testing, and eligible youth enroll in parallel status-dependent RCTs that randomize the participant to 1 of 2 study arms: MEI with coach or SOC. Participants are asked to complete a web-based survey and provide biologic specimens (HIV-1 RNA viral load) or HIV-1 antibody test and urine drug screen at baseline and at 3, 6, and 12 months, and an exit interview at 18 months. Results: A formative qualitative research was conducted in February 2017 and May 2018, and this led to further refinement of recruitment and study methods. Aim 1 recruitment began in September 2017 with enrollment completed in May 2019. Aim 2 began recruitment in September 2019 and ended in March 2020. Aim 3 began in April 2020 and ended in August 2020. There were 36 (22.4%) HIV-positive sex study-suppressed (cmv 2) and 125 (77.6%) high-risk HIV-negative (cmv 3). Conclusions: This study lays the foundation for significant efforts to engage these vulnerable populations in care and services provided to YBLMSM and YBLTW in the United States by providing rigorous scientific evidence outlining approaches and strategies that improve the uptake and engagement of YBLMSM and YBLTW in the HIV treatment and prevention continuum. © 2020 Journal of Plant Nutrition and Fertilizer. HIV preexposure prophylaxis with tenofovir disoproxil fumarate/emtricitabine and changes in kidney function and tubular health	AIDS	-	-	-	-	2699370	10.1097/QAD.0000000000002456	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85087084222&doi=10.1097%2FQAD.0000000000002456&partnerID=40&md5=5b9ce8bc2e0b5c377fe0a9c9c133fad6	Objective:To evaluate the effects of HIV preexposure prophylaxis (PrEP) with tenofovir disoproxil fumarate (TDF)/emtricitabine (FTC) on kidney function and kidney tubular health.Design:The Incisive Profilaxia Pre-Exposición open-label extension (iPrEx-OLE) study enrolled former PrEP trial participants to receive open-label TDF/FTC. This study included 123 iPrEx-OLE participants who demonstrated PrEP adherence.Methods:We compared estimated glomerular filtration rate calculation using serum creatinine (eGFRcr), serum cystatin C (eGFRcys), and in combination (eGFRcr-cys), and panel of 14 urine biomarkers reflecting kidney tubular health before and 6 months after PrEP initiation.Results:At baseline, mean eGFRcr, eGFRcys, and eGFRcr-cys were 108.3, 105.0, and 111.1 ml/min per 1.73 m2, respectively. Six participants (4.9%) had eGFRcr less than 90 ml/min per 1.73 m2. After 6 months of TDF/FTC, mean eGFRcr, eGFRcys, and eGFRcr-cys were 106.3, 104.2, and 109.3 ml/min per 1.73 m2. The 6%-8% decrease in eGFRcr was similar to that observed in the placebo arm of the iPrEx trial. Urine concentrations of 13 of 14 urine biomarkers, whereas clusterin, beta-2-microglobulin and β2-microglobulin increased by 22.7%–95% (5.1.8–34.7%) and 14.1%–95% (5.–8.1 to 30.4%), whereas clusterin, beta-2-microglobulin and monocyte chemoattractant protein-1 decreased by -35.7%–95% (5.–53.0 to -17.3%) and -15.0%–95% (5.–21.0 to 4.2%), respectively. Ten of the 14 urine biomarkers, including albumin, had estimated changes of less than 12% with wide confidence intervals.Conclusion:Six months of PrEP with TDF/FTC was associated with decreases in eGFRcr and eGFRcys. We also observed for the first time changes in four of 14 urine biomarkers reflecting kidney tubular health. These findings demonstrate that PrEP has direct effects on eGFR and the proximal tubule. © 2020 Lippincott Williams and Wilkins. Article	2020	Ashford C.; Morris M.; Powell A.		Barebuck Sex in the Age of Preventative Medication: Rethinking the 'Harms' of HIV Transmission	Journal of Criminal Law	-	-	-	-	220183	10.1177/0022018320974904	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85097297104&doi=10.1177%2F0022018320974904&partnerID=40&md5=dc1f1f830ccf6d1e1d7a2920bbe2c497	The experiences of people living with HIV have been transformed over recent years. Advances in medical science have made the virus a manageable chronic condition, while eliminating the risk of onward transmission for those with access to treatment, something referred to as 'TasP' (treatment as prevention) or U=U (undetectable equals untransmittable). Most controversially, the availability of PrEP (pre-exposure prophylaxis), alongside PEP (post-exposure prophylaxis), through the NHS has created the conditions for condomless sexual encounters to take place without the fear of HIV transmission associated with previous decades. Despite this, the criminal law has continued to frame HIV in terms of personal responsibility and bodily autonomy within the dominant narratives of danger, disease, and out-dated science. Doctrinal law has failed to keep pace with social and scientific change. Therefore, in this article, we provide a re-examination of the criminal issues relating to HIV transmission within this new landscape, arguing that it necessitates a shift in attitude, policy and doctrine. We specifically argue that HIV transmission does not meet the appropriate harm threshold to constitute GBH and that if criminal law is ultimately about preventing or regulating harm, the ongoing criminalisation of HIV transmission is counter to that aim. © The Author(s) 2020. Article	2020	Bahn, Sabine C; Lester, Cody; Gigante, Rebecca; Mayo, Ashley J; Reel, Christine Tagliaferri; Soto-Torres, Lydia; Palanesi-Phillips, Theshi; Migoli, Nyawaka M; Hiller, Shawn; Barnes, Jared M		Implementation of a fidelity monitoring process to assess delivery of an evidence-based adherence counseling intervention in a multi-site biomedical HIV prevention study.	AIDS Care	-	-	-	-	1360-0451	10.1080/09540121.2019.1709614	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7332290/	Background: We conducted a systematic review and meta-analysis (CRD42019170755) to quantify the impact of oral tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) on bone mineral density (BMD) and the risk of osteoporosis, low bone mass and fractures, among people taking it as pre-exposure prophylaxis (PrEP), HIV treatment and HBV treatment. Methods: We searched MEDLINE and EMBASE for randomised controlled trials published from 1997–2018 reporting BMD outcomes, low bone mass and/or fractures in treatment-naive patients taking contraceptives with or without TDF for 48 + 4 weeks. We pooled outcomes using DerSimonian random-effects models. Results: Our search yielded 5,178 abstracts, representing 3,845 articles, with 25 meeting the inclusion criteria. TDF was associated with greater decreases in BMD than did comparators in the lumbar spine (pooled mean difference (MD) -1.26%, 95% CI -1.61, -0.91%, I2 = 0%, 4 studies) and hip (pooled mean difference (MD) -1.73%, 95% CI -2.08, -1.42%, I2=16%, 4 studies). Increased risk: MD -1.26%, 95% CI -2.21, -0.30%, I2 = 87%) in comparison to those not taking TDF. Eight studies reported on incident osteoporosis or low bone mass, with variable results. Pooled results from five PrEP studies showed that TDF was not associated with increased fractures compared with no PrEP (RR=1.12, 95% CI=0.752, 1.74, I2=24%). Conclusions: TDF caused greater decreases in BMD than did comparators when used for all three indications and the magnitude of this decrease was larger for HBV treatment compared with PrEP. Fractures were not increased among PrEP patients. The clinically significant BMD decline caused by TDF and current expansion of PrEP use suggest attention to the adverse bone effects of TDF will increase in importance.	counseling, fidelity, motivational interviewing, HIV, Africa	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review

Article	2020	BARBOSA, ANA KARINA PINTO		PROFILAXIA PRÉ-EXPOSIÇÃO AO HIV (PrEP): ADESÃO, EVENTOS ADVERSOS, COMPORTAMENTO SEXUAL E INFECÇÕES SEXUALMENTE TRANSMISSÍVEIS	-	-	Universidade de Pernambuco	-	NA	NA	-	Tenofovir/emtricitabina (TDF/FTC) tem sido usado como profilaxia pré-exposição (PrEP) na prevenção da infecção pelo HIV. A PrEP é uma ferramenta de prevenção eficaz, como demonstrado em ensaios clínicos e estudos pós-comercialização clínica, e foi incorporada aos sistemas públicos de saúde do Brasil em dezembro de 2017. O presente estudo é uma coorte prospectiva que incluiu 239 usuários de PrEP acompanhados ao longo de 10 meses em uma capital do nordeste brasileiro. Os dados foram coletados a partir da plataforma de prontuários eletrônicos de usuários de PrEP disponibilizada pelo ministério da saúde do Brasil. Durante o período de seguimento, verificou-se uma boa retenção dos usuários no serviço (80%) e boa adesão à medicação (90%). Quase metade dos usuários (49%) experimentou algum evento adverso, embora poucos leves e transitórios, tenha sido após início da profilaxia. Houve uma redução significativa no clearance de creatinina (p=0,001), de 104,9 mL/min para 83,5 mL/min, no entanto não foi necessária a descontinuação da medicação. Ao longo do estudo, não houve alteração no número de parceiros sexuais, mas o uso de preservativos nas relações sexuais diminuiu (p=0,001). Houve um aumento não significativo da incidência de sífilis (p=0,08) e diminuição de 50% no relato de uma e sintomas de infecções sexualmente transmissíveis. Não houve casos de infecção pelo HIV entre os usuários da PrEP. Article	2020	Bardon, Ashley R; Siemsz, Jane M; Layman, Leif M; Stickler, Joanne D; Drain, Paul K		Perspectives on the utility and interest in a point-of-care urine tenofovir test for adherence to HIV pre-exposure prophylaxis and antiretroviral therapy: an exploratory qualitative assessment among U.S. clients and providers.	AIDS Research and Therapy	-	-	-	-	1742-6405	10.1186/s12981-020-00308-w	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7361228/	BACKGROUND: Real-time, objective measures of adherence to antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) are needed to better assess adherence levels and to expedite clinical response for those with suboptimal adherence. Point-of-care tenofovir (POC-TFV) testing has been proposed as a solution to facilitate real-time antiretroviral adherence monitoring, but little is known about how health care providers, people living with HIV (PLWH) receiving ART, and people receiving PrEP will perceive POC-TFV testing. METHODS: We conducted an exploratory qualitative study to assess perceptions and interest in the utility of a hypothetical urine-based POC-TFV testing from potential end users. We conducted three focus group discussions (FGDs) among 17 PLWH receiving ART and four individuals receiving PrEP, as well as eight in-depth interviews (IDIs) with health care providers in the Seattle area and presented participants with a hypothetical urine-based POC-TFV test. FGDs and IDIs were audio recorded, transcribed, coded, and analyzed to describe emerging themes. RESULTS: Overall, study participants demonstrated broad support for a point-of-care urine tenofovir test. Participants most commonly described POC-TFV testing as motivating (n = 17/21) and enabling patients during the PrEPa. However, all PLWH participants would not receive POC-TFV testing if separated by their POC-TFV. Participants identified several key factors that would influence the acceptability and uptake of POC-TFV testing, including ease of use, test accuracy, and test availability. Participants' perceptions were equally divided—half suggested POC-TFV testing would be valuable, particularly for people receiving PrEP, while half indicated the test would have little benefit for most individuals receiving ART or PrEP in the U.S. All providers agreed that POC-TFV test results could be beneficial for assessing discrepancies in viral load results and self-reported adherence among PLWH. The study also revealed that a low-cost, non-urine-based POC-TFV test with a long-term limit of detection would be preferred over the hypothetical urine-based test. CONCLUSIONS: Our findings indicate POC-TFV testing may be beneficial for routine, clinic-based adherence monitoring, particularly for individuals receiving PrEP or for PLWH with persistent viremia or following recent ART initiation. These findings should also be used to formulate a target product profile for a POC-TFV test and to guide further developments in tools for objective antiretroviral adherence monitoring. Article	2020	Birnbaum, Kate; Meise, Sindy; Hughey, Allison B.; Hettema, Anita; Birnbaumen, Till W.; McMahon, Shannon A.		"We know this will be hard at the beginning, but better in the long term": understanding PrEP uptake in the general population in Eswatini.	AIDS Care	-	-	-	-	1360-0451	10.1080/09540121.2019.1653437	https://www.tandfonline.com/doi/full/10.1080/09540121.2019.1653437?rfrdoiact	Information regarding HIV pre-exposure prophylaxis (PrEP) for the general population is largely lacking, because the majority of PrEP demonstration projects have focused on key populations. This qualitative study examines barriers and facilitators to PrEP uptake and adherence among the general population in Eswatini, where PrEP is offered through public-sector primary-care clinics. We analysed 108 semi-structured in-depth interviews with healthcare workers (n = 26), stakeholders (n = 30), and clients who initiated, continued, declined or discontinued PrEP (n = 50). Some healthcare workers and stakeholders feared that PrEP would reduce condom use and cause drug resistance, while some clients feared possible side effects and the reaction of family members when learning of PrEP use. At the same time, respondents across all groups valued that PrEP could be taken without partner knowledge or consent, and that PrEP was available via public sector clinics. Clients felt that PrEP relieved the fear of HIV infection and thus bolstered enjoyment during sex. Overall, respondents described the general population approach to PrEP delivery as enabling and life-improving, despite the above concerns. Respondents recommended to create community PrEP promotion and delivery, gain community leaders' approval and understanding of PrEP, shorten the PrEP initiation process, and target men and adolescent girls. Article	2020	Baron, Deborah; Scorgie, Fiona; Ramokin, Lethabo; Khoza, Nombili; Schuttman, Jennifer; Stangl, Anne; Harvey, Sheila; Delany-Moretlwe, Sinead	"You talk about problems until you feel fine": South African adolescent girls' and young women's narratives on the value of HIV prevention peer support clubs.	BMC Public Health	-	-	-	-	-	1471-2458	10.1186/s12889-020-09115-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7328960/	BACKGROUND: Daily oral pre-exposure prophylaxis (PrEP) can reduce HIV infection in adolescent girls and young women if used consistently during periods of risk. The EMPOWER study evaluated peer-based clubs incorporating an empowerment curriculum offered to adolescent girls and young women (16-24 years) in South Africa and Tanzania for adherence support. METHODS: Using oral in-depth interviews (n = 33), we assessed the benefits and challenges of club attendance among 13 EMPOWER participants in the Johannesburg site who were randomised to clubs. We used a summary matrix of coded data to support a narrative, case-based analysis. Four case studies are presented. RESULTS: Club participants reported benefits such as increased self-esteem and self-efficacy, reduced isolation, and greater insight into gender-based violence and strategies to address it. Day-to-day PrEP adherence was not the only topic discussed in clubs; participants also appreciated the safe space for sharing problems (such as relationship conflict and PrEP stigma) and found interactive exercises helpful in improving partner communication. CONCLUSIONS: Findings support the use of peer-based clubs using a structured empowerment approach, which may offer valuable PrEP initiation support to adolescent girls and young women in settings with high HIV and gender-based violence prevalence. Article	2020	Barp, Luiz Fernando Greiner; Mágredo, Myriam Raquel	O reaparecimento da homossexualidade masculina nas estratégias de prevenção da infecção por HIV: reflexões sobre a implementação da PrEP no Brasil	Physis	-	-	-	-	-	0103-7331	10.1590/s0103-73312020300319	http://www.scielo.br/scielo.php?script=sci_arttext&pid=S0103-73312020000300403	Resumo Este trabalho toma como ponto de partida o texto de Nestor Perlongher, intitulado "O desaparecimento da homossexualidade", que descreve um ressurgimento da identidade homossexual masculine com o surgimento da aids e propõe uma nova leitura a partir da implementação da profilaxia pré-exposição ao HIV (PrEP) pelo sistema público de saúde no Brasil. Distribuída a partir de início de 2018 e considerada como uma das mais novas medidas de prevenção ao HIV/aids, a PrEP se configura como um expoente antirretroviral de seu contínuo direcionado aos sujeitos que não foram infectados pelo vírus. Tomando como referência empírica o Protocolo Clínico de Diretrizes Terapêuticas para PrEP, identificamos como, a partir da oração de risco, a droga possibilita o retorno da homossexualidade aos consultórios médicos e, mais do que isso, opera como objeto discursivo de problematizações de caráter sanitário e social. Diante disso, a PrEP produz uma nova categoria de homossexual, atrelada a tecnologias disciplinares e biopolíticas, que se apoiam na individualização e responsabilização dos indivíduos pelo cuidado de si.	homossexualidade; HIV; PrEP; risco; individualização	Portuguese	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Qualitative
Article	2020	Barreto, Victor Hugo Souza	Responsabilidade, consentimento e cuidado. Ética e moral nos limites da sexualidade	Sexualidad, Salud y Sociedad	-	-	-	-	-	-	https://doi.org/10.1590/1984-6487.sess.2020.35.10.e	https://www.scielo.br/j/sess/a/H56KzLPKtWwQm9Qbq7HJ8Ny/	En este artículo tengo la intención de presentar algunos de los resultados de una investigación posdoctoral, en la que sugal grupos virtuales y reuniones cara a cara de interlocutores que eran expertos en prácticas sexuales consideradas "de riesgo", como el sexo a pelo, en eventos exclusivos para hombres cisgéneros. El objetivo aquí es analizar un cierto régimen de racionalidad sexo-moral que, en respuesta a la preocupación de afirmar que estas prácticas sexuales portan de valores tales como "responsabilidad", "consentimiento" y "cuidado". En la dinámica observada, estos valores se (re) construyen y describen a través del cruce de diferentes vectores, como drogas y medicamentos, además de varios tensores libidinales. Se trata de la producción de contextual de estas conceptos y se relacionan con las políticas actuales de prevención pública que pretenden abordar en el artículo.	bareback; prevención; riesgo; PrEP; HIV/Aids	Portuguese	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Qualitative
Article	2020	Bartovská, Z; Zlámal, M; Jánská, P; Holubb, M	Pre-exposure prophylaxis, a new approach for HIV prevention: experience from the HIV Center of the Military University Hospital Prague	Epidemiologie und Mikrobiologie Immunology	-	-	-	-	-	1210-7913	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-32326714	AIMS: To present our experience with pre-exposure prophylaxis (PrEP) at the HIV Center of the Military University Hospital Prague, to characterize a set of PrEP candidates, to assess the efficiency and safety of PrEP and to measure the incidence of sexually transmitted diseases (STDs) in the studied cohort. MATERIAL AND METHODS: In total, 86 PrEP candidates (98 men who have sex with men and one woman) were screened during an 18-month period. An initial examination included acquiring a history, performing a physical examination, screening for STDs (syphilis, gonorrhea, chlamydia) and other HIV risk factors and final function tests. RESULTS: In total, 81 candidates (in the cohort of 99 candidates) received PrEP. During the course of the 18-month period, nine of the clients were newly infected with HIV, and no side effects of PrEP were observed. The incidence of HIV was 3.7 per 100 person-years (PY) in the cohort and 1.2 per 100 PY in the PrEP group. The incidence of STDs was 19.2 per 100 PY and 6.2 per 100 PY, respectively. Ten clients contracted an STD during the monitoring period. CONCLUSIONS: Experience amassed at the HIV Center of the Military University Hospital Prague over an 18-month period documented the demand for PrEP, assessed PrEP efficacy, indicated good tolerance and suggested that PrEP played a role in the decline in the HIV incidence in the Czech Republic. In addition, several new HIV cases and cases of other asymptomatic STDs were also detected. Article	2020	Baruch, R; Cuadra, S M; Arellano, J; Sánchez, D; Ortega, D V; Arredondo, A	Pre-exposure prophylaxis and its implications in Mexico: notions of men who have sex with men.	Sexual Health	-	-	-	-	-	1449-8987	10.1071/SH18193	https://dx.doi.org/10.1071/SH18193	Background The aim of this study was to analyse ideas regarding pre-exposure prophylaxis (PrEP) for the prevention of HIV among groups of men who have sex with men in Mexico for future implementation in health services. METHODS: During 2015, 54 people participated in four focus groups in three Mexican cities. Issues related to challenges for uses and barriers of PrEP were explored. RESULTS: In contrast with other qualitative studies, which emphasised problems with relationships with other people for PrEP use or access to key populations, Mexican participants focused their concerns around the public health services organisation. PrEP is too expensive and the health services have no resources, which will affect services and result in discrimination. Participants identified possible stigmatisation related to prejudices of medical providers who do not approve the decreased use of condoms. As a potential solution, participants suggested that the Mexican Government could negotiate a lower cost for PrEP and public health services could provide the medication, with periodical review of the arrangements by civil organisations. CONCLUSION: In the current context of the new Mexican government, it is necessary to explore public politics focused on negotiating with pharmaceutical companies on the costs of the PrEP, coordinating public services with groups within civil society and strengthening policies and actions to reduce stigma and discrimination. Article	2020	Batista, Amanda Trajano; Saldanha, Ana Aleyde Worbe; Furtado, Francisca Marina Freire	Vantagens e desvantagens percebidas pelas populações chaves no uso da profilaxia pré-exposição	Medicina (Ribeirão Preto. Online)	-	-	-	-	-	0104-3269	NA	http://pepsic.bvsalud.org/scielo.php?script=sci_arttext&pid=S0104-32692020000200002	Para entender o impacto da Profilaxia Pré-Exposição - PrEP na prevenção do HIV, além dos dados de eficácia clínica, precisamos compreender as crenças que subjazem a aceitabilidade da PrEP, uma vez que, para ser segura e eficaz é importante, que exista um interesse com as necessidades e preocupações dos usuários. Assim, o objetivo deste estudo é analisar as crenças comportamentais quanto às vantagens e desvantagens do uso da PrEP. A amostra foi composta por 33 participantes de quatro populações-chaves que já utilizam a PrEP, sendo contactados de forma online. Como instrumento de coleta utilizou-se um questionário on-line, com questões de caracterização sociodemográfica e questões abertas sobre as crenças comportamentais. Os dados foram analisados por meio da técnica de análise de conteúdo temática, respaldada na análise qualitativa pelo software IRAMUTEQ. Emergiram três classes temáticas: 1) Dois em um só comprimido; 2) Não uso da preservativo, 3) Diminuir a contaminação; 4) Diminuir as ISTs; 5) Autonomia na prevenção. Já em relação às desvantagens, obtivemos os 95 cenários: 1) Efeitos colaterais, 2) Não eficácia, 3) Não uso do preservativo, 4) Foco no HIV, 5) Tomar diariamente a PrEP. A análise das crenças possibilitou a identificação dos fatores que podem influenciar positivamente ou negativamente a adesão de comportamentos quanto às vantagens e desvantagens do uso da PrEP. Assim, espera-se que os resultados desta pesquisa possam contribuir para que a utilização e a PrEP, assim contactados de forma online. Article	2020	Bauer, R; Nettey, E; Paintsil, C; Capitani, C; Cua, E; Elion, N; Fossati, J; Paikoti, G; Chadau, C; Etienne, C; Doré, V; Meyer, L; Molina, JM	Coverage of Sex Acts by Event-Driven Pre-exposure Prophylaxis: a Sub-Study of the ANRS IPERGAY Trial	AIDS and Behavior	-	-	-	-	-	-	10.1007/s10461-020-02990-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7529156/	We assessed the coverage of sex acts by event-driven pre-exposure prophylaxis (ED-PrEP) over a 2-month period in 54 participants in the open label phase of the ANRS Ipergay trial. Participants received an electronic monitoring system device to record bottle openings. Self-questionnaires collected daily information on PrEP intake and sexual behavior. Intake was estimated through visual inspection and counts. Full coverage of sex acts was defined as at least one pill taken both within 24 h before and within 48 h following sex. There was a strong correlation (r = − 0.92) between the number of bottle openings and returned pills. Of 1,827 sex acts reported, 1,744 (95.5%) were covered by ED-PrEP, 1,712 (93.7%) were fully covered, and 32 (1.8%) were not covered by any sexual activity. Out of the 154 reported receptive anal sex acts, 93% were condomless among them, PrEP coverage was high (97%) among those practicing daily PrEP and 82% among those using ED-PrEP. Article	2020	Bauermeister J.A.; Downs J.S.; Krakower D.S.	PrEP Product Acceptability and Dual Process Decision-Making Among Men Who Have Sex with Men	Current HIV/AIDS Reports	-	-	-	-	-	15483568	10.1007/s11904-020-00497-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85083420568&doi=10.1007%2fs11904-020-00497-z&partnerID=40&md5=2955ba559ed5c6162c523611c4c8f61b	Purpose of Review: Advances in short- and long-acting pre-exposure prophylaxis (PrEP) technologies have incentivized the need to understand how individuals make trade-offs and competing decisions regarding PrEP modalities. The purpose of this review was to examine how researchers have conceptualized and measured attributes that are either intuitive and emotional (System 1) or deliberative and cognitive (System 2) to conjoint analysis or discrete choice experiments focused on diverse PrEP technologies among men who have sex with men (MSM). Recent Findings: Across the 9 reviewed studies, a consistent theme was the importance of inclusion criteria, if included oral PrEP, 3 included topical rectal microbicides, 4 included PrEP injectables, and 1 study focused on an HIV prevention vaccine. Studies have not used uniform metrics, making comparisons difficult. Summary: Future research should leverage the PrEP Product Acceptability and Dual Process Model to guide the development of measures that can be used to compare PrEP products to all groups. Prevention products will need to be developed and promoted to reflect that diversity. Given that PrEP technologies have been actively informed by System 2 attributes, efforts to integrate System 1 attributes into ongoing and future PrEP choice experiments are pivotal to advance PrEP acceptability research and interventions to support their implementation. © 2020, Springer Science+Business Media, LLC, part of Springer Nature. Article	2020	Baum, Marc M; Ramirez, Christina M; Moss, John A; Gunawardana, Manjula; Bobseth, Michael; Galley, Philippe A	Highly synergistic drug combination prevents vaginal HIV infection in humanized mice.	Scientific Reports	-	-	-	-	-	2045-2322	10.1038/s41598-020-69937-5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7400648/	The HIV-1 epidemic remains an urgent global health concern. Young women are disproportionately at risk of acquiring the virus. A range of highly effective, female-controlled, discrete vaginal products therefore is needed to help curb the epidemic. Oral tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) are effective in HIV-1 pre-exposure prophylaxis (PrEP) and form a promising basis for a vaginal product. Here, we evaluate TDF and FTC in combination with the broadly neutralizing antibody VRC01-N using a highly reproducible humanized mouse model. The agents were vaginally dosed individually and in combination, and the efficacy of HIV-1 prevention was analyzed using the established, quantitative, incidence-effect model. Surprisingly, the triple combination showed a high degree of synergism, unprecedented for in vivo HIV-1 PrEP, leading to a possible fivefold dose reduction for some of the agents. Vaginal administration of the TDF-FTC-VRC01-N combination holds significant promise for HIV-1 PrEP. Article	2020	Bauman, Laurie J; Mellins, Claude Ann; Kiltzman, Robert	Whether to Waive Parental Permission in HIV Prevention Research Among Adolescents: Ethical and Legal Considerations.	Journal of Law, Medicine & Ethics	-	-	-	-	-	1748-720X	10.1177/1073110520917010	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8365764/	Critical ethical questions arise concerning whether studies among adolescents of new behavioral and biomedical HIV preventive interventions such as Pre-Exposure Prophylaxis (PrEP) should obtain parental permission. This paper examines the relevant regulations and ethical guidance concerning waivers of parental permission, and arguments for and against such waivers. Proponents of such waivers may argue that adolescent decision-making is "too immature" and that parents always have rights to decide how to protect their children. Yet requiring parental permission may put adolescents at risk, and/or limit adolescents' opportunities to benefit from HIV prevention research. Waivers of parental permission should be granted only when adolescents are at minimal risk, and when adequate protections should be adopted for adolescents who consent for themselves, e.g., assuring adolescent privacy and confidentiality, screening for capacity to consent, and identifying adolescents who are at elevated risk from study participation. We also present a series of specific areas for future research to design tools to help make these assessments, and to inform researcher and IRB decisions. These recommendations can help ensure that research is conducted that can aid adolescents at risk for HIV, while minimizing risks and preserving those individuals' rights as much as possible. Article	2020	Bavinton B.R.; Grulich A.E.; Broady T.; Keen P.; Mao L.; Patel P.; Chan C.; Prestage G.P.; Holt M.	Increases in HIV Testing Frequency in Australian Gay and Bisexual Men are Concentrated Among PrEP Users: An Analysis of Australian Behavioural Surveillance Data, 2013–2018	AIDS and Behavior	-	-	-	-	-	10907165	10.1007/s10461-020-02826-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85081811653&doi=10.1007%2fs10461-020-02826-0&partnerID=40&md5=f0f9d150fd2383b5a4b5d91327f6a3	Increasing HIV testing frequency in gay and bisexual men (GBM) is critical to reducing the time between HIV infection and diagnosis. Using anonymous national behavioural surveillance data (2013–2018) from 43,753 surveys of Australian GBM, we examined HIV testing frequency trends and factors differentiating PrEP-users, non-PrEP-users reporting two or more tests in the previous year, and non-PrEP-users reporting less frequent testing. The proportion tested at least annually increased from 64.4% in 2013 to 70.9% in 2018 (p-trend < 0.001), and from 73.9% to 84.6% among the 31.4% of men classified as higher-risk. Among higher-risk men, having two or more tests in the previous year increased from 48.0% to 69.2% (p-trend < 0.001). Among higher-risk non-PrEP-users, it increased from 47.2% to 54.9% (p-trend < 0.001); however, there was a decrease since 2016 (p-trend < 0.001). Among PrEP-users, it increased from 82.1% in 2013 to 97.3% in 2018 (p-trend < 0.001). Non-PrEP-using higher-risk men having less frequent tests reported lower risk than PrEP-users and non-PrEP-using men reporting two or more tests in the previous year. However, recent risk behaviour was not uncommon: nearly half reported condomless anal sex with casual partners, methamphetamine use, or STI diagnosis. Increasing HIV testing frequency is important for PrEP-users, but also for other higher-risk men who have sex with casual partners. Efforts are needed to encourage frequent testing and PrEP use among non-PrEP-users who are at higher-risk. © 2020, Springer Science+Business Media, LLC, part of Springer Nature. Article	2020	Bosch, Lauren B; Reidy, Emma; Mares, Rachel; Johnson, Amy K; Landsman, Peter; Phillips, Gregory; Stonehouse, Patrick; Greene, George J	Application of a Multisite Empowerment Evaluation Approach to Increase Evaluation Capacity Among HIV Services Providers: Results From Project Pride in Chicago.	AIDS Education and Prevention	-	-	-	-	-	1943-2755	10.1521/aeap.2020.32.2.137	https://dx.doi.org/10.1521/aeap.2020.32.2.137	In 2015, the Centers for Disease Control and Prevention (CDC) funded Project PrIDE, a national initiative to implement and evaluate demonstration projects to increase PrEP uptake among HIV-negative individuals and to re-engage HIV-positive individuals in HIV care. Our team served as the Evaluation Center for Project PrIDE organizations in Chicago and used an empowerment evaluation (EE) approach to enhance evaluation capacity at these organizations. To evaluate our approach, we assessed organizations' evaluation capacity and engagement in technical assistance and capacity building activities in 2016 and 2018. Respondents who self-reported higher engagement with the Evaluation Center and who spent a greater number of hours engaged with our evaluators experienced greater increases in evaluation capacity and in the application of evaluation skills to practice. Empowerment evaluation is a promising approach that can be successfully applied to increase the evaluation capacity of organizations that collect health HIV prevention and service outcomes. Article	2020	Buyze, Jozefien; Nöstlinger, Christiana; Kenyon, Chris; Colebunders, Robert; Laga, Marie	Syndemics and the PrEP Cascade: Results from a Sample of Young Latino Men Who Have Sex with Men	Archives of Sexual Behavior	-	-	-	-	-	40002	10.1007/s10508-019-01476-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074596642&doi=10.1007%2fs10508-019-01476-7&partnerID=40&md5=a03bfb01eac49e4c4b4b5bed5570f2	Young Latino men who have sex with men (MSM) are a highly vulnerable population for HIV infection. Pre-exposure prophylaxis (PrEP) is a novel biomedical HIV prevention tool that may aid in reducing the disparity in HIV incidence among Latino MSM. However, PrEP use has been disproportionally low among Latino MSM and, therefore, identifying barriers along the PrEP continuum of care (the 'PrEP cascade') would provide insight into how to best deploy PrEP interventions. Syndemics theory is a prominent framework employed in HIV prevention; however, to date, no known studies have applied this theory to PrEP. Thus, the aim of the current study was to explore the associations between syndemics and the PrEP cascade, including the degree to which psychosocial and structural syndemic conditions are related to the PrEP cascade. Participants were 151 young Latino MSM (M age = 24 years; SD = 3) residing in San Diego, California, who completed a battery of online self-report measures. Results indicated high levels of syndemic indicators and varying levels of engagement across the PrEP cascade. As syndemic indicators increased, the odds of engagement across the PrEP cascade were significantly lowered. Psychosocial and structural syndemic factors accounted for unique variance in the PrEP cascade. Results highlight the need for combination interventions that address both psychosocial and structural barriers to PrEP use and prevalence among young Latino MSM. © 2019, Springer Science+Business Media, LLC, part of Springer Nature. Article	2020	Bucquet, Valentine; Nouaman, Marcelle; Placy, Mélanie; Masumbuko, Jean-Marie; Arsenu, Camille; Kouame, Soh; Danel, Christine; Eholie, Serge Paul; Lemarrec, Joseph	Increases in HIV Testing Frequency in Australian Gay and Bisexual Men are Concentrated Among PrEP Users: An Analysis of Australian Behavioural Surveillance Data, 2013-2018	HIV Open	-	-	-	-	-	2044-6055	10.1136/bmjopen-2018-025508	https://www.proquest.com/scholarly-journals/brief-report-hormonal-contraception-usethe/docview/2455541141/se-2?accountid=8113	Objectives: To evaluate whether hormonal contraceptive use among cisgender women is associated with differences in pharmacokinetic (PK) parameters of a long-acting injectable formulation of the integrase strand transfer inhibitor, cabotegravir (CAB-LA). Design: This is a secondary analysis of 50 cisgender women enrolled in HPTN 077, a phase 2a multicentre study that enrolled HIV-uninfected, low-risk individuals in Malawi, Brazil, South Africa, and the United States. Methods: Participants received 4-week daily oral cabotegravir lead-in, followed by CAB-LA 800 mg injection every 12 weeks (cohort 1) or 600 mg every 8 weeks (after 4 week initial intervals) (cohort 2), over 41 weeks. Participants were followed 32–76 weeks subsequent to their last injection. Generalised estimating equations and linear regression were used to evaluate differences in CAB-LA PK parameters (peak concentration, trough concentration, area under the curve, apparent terminal half-life, and time to lower limit of quantification) and self-reported hormonal contraceptive method by type (oral, injectable, implants, and other), controlling for body mass index and cohort. Results: Compared to women reporting no hormonal contraception (n = 6), oral contraceptive use (n = 18) was associated with lower CAB-LA peak concentration but was not associated with differences in other PK parameters. No other hormonal contraceptive type (injectable, implants, and other) was associated with significant differences in CAB-LA PK parameters. Conclusion: Although oral contraceptive use was associated with differences in CAB-LA peak concentration, no differences were observed in other PK parameters, suggesting that this association is not likely to be clinically significant. However, these data highlight the need for further research exploring potential drug–drug interactions between CAB-LA and hormonal contraceptives.	pharmacokinetics; Contraception; Integrase; Cabotegravir; Pharmacology; Injection; Body mass; Parameters; Secondary analysis; Hormonal contraception; Injectable; Oral contraceptives; Drug interactions; Lead-in; Drug–drug interactions; Implants; Birth control; Human immunodeficiency virus--HIV; Medical Sciences--Communicable Diseases; Health risks; Body mass index; Body size; Contraceptives; Women	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

The purpose of our study was to understand the training needs of clinicians who do not prescribe PrEP. From September 2017 to January 2018, qualitative interviews were conducted with providers from 10 clinics in Uganda (N = 20). Thematic analysis revealed four themes: three emphasized the temporal nature of training requirements and one identified training preferences of providers. Study findings suggest that clinicians require specific information in order to integrate PrEP into their practice. Training needs may change as PrEP programs mature. © 2020, © 2020 Taylor & Francis Group, LLC.	health care providers; HIV prevention; pre-exposure prophylaxis; qualitative research; training	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2020	Bursztyn L.; Wilson K.; Aidoo-Frimpong G.; Przybyla S.	Presenting HIV pre-exposure prophylaxis: A qualitative analysis of health care provider training needs	Journal of HIV/AIDS & Social Services	-	-	-	-	-	15381501	10.1080/15381501.2020.1712291	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85074259768&doi=10.1080%2f15381501.2020.1712291&partnerID=40&md5=944bc46d91954b0f0ea0f50aa2556de5f	Co-formulated tenofovir disoproxil plus emtricitabine is highly effective as pre-exposure prophylaxis for HIV. It is suitable for men who have sex with men, for heterosexual sex and for people who use intravenous drugs where there is a risk of HIV infection. Pre-exposure prophylaxis is one pill per day and can be prescribed by all medical practitioners and nurse practitioners via the Pharmaceutical Benefits Scheme. It is best prescribed in a three-monthly program with regular monitoring for patient adherence, safety, HIV and other sexually transmitted infections. Prophylaxis is well-tolerated but requires monitoring for kidney toxicity and low bone density. © 2020 SPS MedicineWise. Article	2020	Bossert S.; Mountjoy S.; Ehrenzer S.; Bauermeister J.	State-level discrimination policies and his pre-exposure prophylaxis adoption efforts in the US	Health Affairs	-	-	-	-	-	2782715	10.1377/hlthaff.2020.00242	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85091501694&doi=10.1377%2fhlthaff.2020.00242&partnerID=40&md5=3ca46a63c0425c9bd2a1b8052c24dd9f	Pre-exposure prophylaxis (PrEP) is a drug regimen recommended for anyone at high risk of getting HIV to prevent them from being infected. Little research exists on how state-level policies might be related to differential PrEP uptake across the United States. To better understand the associations between state-level policies and PrEP uptake, we examined HIV criminalization, nondiscrimination laws for sexual and gender minorities, Medicaid expansion, Ryan White funding, and sociodemographic characteristics in relation to the PrEP-to-need ratio, a measure of PrEP uptake. Using a cross-sectional design, we analyzed data from all fifty states, Washington, D.C., and Puerto Rico (all of which we categorize as states here) regarding policy, socioeconomic factors, and PrEP-to-need ratio in 2018. States with HIV criminalization laws had lower PrEP-to-need ratio, and states with more nondiscrimination laws for sexual and gender minorities had higher PrEP-to-need ratio. We found no association between Medicaid expansion and PrEP-to-need ratio. Our findings suggest that structural factors, including state-level policies, are associated with PrEP uptake. Our study provides important insights into how laws concerning HIV and sexual and gender minorities might protect against discrimination and subvert fear and stigma, given the potential impact of these policies on HIV prevention. © 2020 Project HOPE— The People-to-People Health Foundation, Inc. Theses and Dissertations	2020	Bonett, Stephen; Bauermeister, José	Towards Equity in Prep: Social Networks, Structural Factors, and Engagement with the Prep Continuum among Young Sexual and Gender Minorities in the United States	-	-	-	-	University of Pennsylvania	-	no	NA	https://www.proquest.com/dissertations-theses/towards-equity-prep-social-networks-structural/docview/2446708770/se-2?accountid=8113	The HIV epidemic has disproportionately affected young people, racial/ethnic minorities, and sexual and gender minorities. These inequities have significant implications for the health and wellbeing of young queer and transgender people of color. Pre-exposure prophylaxis (PrEP) is a safe and efficacious biomedical prevention modality that could dramatically reduce the number of new HIV infections. However, efforts to extend access to PrEP to those who stand to benefit the most, including young people, racial/ethnic minorities, and sexual/gender minorities, have fallen short. In this dissertation, I adopt an ecological model of HIV risk and prevention to contextualize health-related behaviors within the socio-structural environment that young people inhabit and identify factors relevant to engagement with PrEP. First, I used a systematic literature review to summarize and synthesize the existing body of literature on social networks as a factor in racial disparities in HIV among sexual minority men. In this review, I found that social network factors and structural factors are driving racial disparities in HIV and suggested that these same forces may underlie the inequities in PrEP uptake. To explore how network and structural factors are associated with progress along the PrEP continuum, I performed secondary analyses of two datasets related to social and sexual networks, economic vulnerability, HIV risk, and PrEP engagement among young sexual/gender minorities. I found that engagement with PrEP among young racial/ethnic minorities continues to lag behind engagement for adult White gay men. Additionally, I found that economic vulnerability was associated with lower PrEP engagement and that insurance status was a consistent correlate of engagement. Young people who perceived that their peers, both in social and sexual networks, were using PrEP had greater knowledge and more favorable attitudes toward PrEP. Finally, I conducted a community-engaged study of PrEP use and persistence to explore the potential of PrEP as a tool for health equity as to be realized. Efforts to address inequities in HIV burden and PrEP uptake should aim to improve economic conditions for marginalized young people and bolster the capacity of social networks to promote PrEP engagement through community-engaged and peer-led interventions. Article	2020	Bórquez, Annick; Rich, Katherine; Farrell, Michael; Degenhardt, Louisa; McKetin, Rebecca; Tran, Lucy T; Cepeda, Javier; Silva-Santisteban, Alfonso; Kouba, Kellka; Cáceres, Carlos F; Kelly, Sherrie; Aliss, Frederick L; Martin, Natasha K	Integrating HIV pre-exposure prophylaxis and harm reduction among men who have sex with men and transgender women to address intersecting harms associated with stimulant use: a modelling study.	Journal of the International AIDS Society	-	-	-	-	-	1758-2652	10.1002/jia2.25495	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7305611/	INTRODUCTION: Among men who have sex with men (MSM) and transgender women (TW), stimulant use is high and has been associated with an increased risk of HIV infection, suicide and cardiovascular disease (CVD) mortality. We used epidemic modelling to investigate these intersecting health harms among MSMTW in Lima, Peru and assess whether they could be mitigated by prioritizing HIV pre-exposure prophylaxis (PrEP) for stimulant-using MSMTW. METHODS: We developed a dynamic model of HIV, stimulant use and CVD among MSMTW in Lima. We used it to incorporate stimulant use and increased HIV risk, suicide and CVD mortality. Among 6% to 24% of MSMTW using stimulants (mostly cocaine), we modelled an increased risk of unprotected anal sex (RR = 1.35 95%CI: 1.17 to 1.57) obtained from local data, and increased risk of suicide (SMR = 6.26 95%CI: 2.84 to 13.80) and CVD (SMR = 1.83 95%CI: 0.39 to 8.57) mortality associated with cocaine use based on a global systematic review. We estimated the proportion of health harms occurring among MSMTW who use stimulants in the next year (01/2020-01/2021) due to stimulant use, and its impact (01/2020-01/2030) of: (1) PrEP prioritization for stimulant-using MSMTW compared to random allocation, and (2) integrating PrEP with a theoretical intervention halving stimulant-associated risk. RESULTS: MSMTW in Lima will experience high HIV incidence, suicide and CVD mortality (1.6/100 py, and 0.03/100 py, 0.3/100 py respectively) in 2020. Despite stimulant using MSMTW comprising an estimated 9.5% (95%CI: 7.8 to 11.5) of all MSMTW, in the next year, 11% 95%CI (i.e. 2.5% to 97.5% percentile) 10% to 12%) of new HIV infections, 29% (95%CI: 18% to 80%) of suicides and 15% (95%CI: 12% to 18%) of CVD deaths among MSMTW will be due to stimulant use. Over 10 years, 17% (95%CI: 14% to 20%) of HIV infections, 29% (95%CI: 18% to 80%) of suicides and 15% (95%CI: 12% to 18%) of CVD deaths among MSMTW will be due to stimulant use. Prioritizing PrEP to stimulant-using MSMTW could reduce new HIV infections by 29% (95%CI: 18% to 37%), suicide deaths by 14% (95%CI: 5% to 27%) and CVD deaths by 3% (95%CI: 0% to 16%) over a decade. CONCLUSIONS: MSMTW who use stimulants experience a disproportionate burden of health harms. Prioritizing PrEP based on stimulant use, in addition to sexual behaviour/gender identity criteria, could increase its impact. Integrated substance use, harm reduction, mental health and HIV care among MSMTW is needed. Article	2020	Bowring, Anna L; Ampt, Frances H; Schwartz, Sherrie; Stoové, Mark A; Luchters, Stanley; Baird, Stefan; Hellard, Margaret	HIV pre-exposure prophylaxis for female sex workers: ensuring women's family planning needs are not left behind.	Journal of the International AIDS Society	-	-	-	-	-	1758-2652	10.1002/jia2.25442	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7029561/	INTRODUCTION: Female sex workers (FSWs) experience overlapping burdens of HIV, sexually transmitted infections and unintended pregnancy. Pre-exposure prophylaxis (PrEP) is highly efficacious for HIV prevention. It represents a promising strategy to reduce HIV acquisition risks among FSWs specifically given complex social and structural factors that challenge consistent condom use. However, the potential impact on unintended pregnancy has garnered little attention. We discuss the potential concerns and opportunities for PrEP to positively or negatively impact the sexual and reproductive health and rights of FSWs. DISCUSSION: PrEP may increase FSWs' vulnerability to unintended pregnancy through multiple pathways, including condom displacement, sexual risk compensation and reducing health and social effects for FSWs, including consequences of unsafe abortion and financial impacts affecting subsequent risk-taking. It is possible that PrEP could negatively impact condom and other contraceptive use among FSWs due to condom substitution, normalization, external pressures or PrEP provision by single-focus services. There are limited empirical data available to assess the impact of PrEP on pregnancy rates in real-life settings. However, pregnancy rates are relatively high in PrEP trials and modelling suggests a potential two-fold increase in condomless sex among FSWs on PrEP, which, given low use of non-barrier contraceptive methods, would increase rates of unintended pregnancy. Opportunities for integrating family planning with PrEP and HIV services may circumvent these concerns and support improved SRHR. Synergies between PrEP and family planning could promote uptake and maintenance for both interventions. Integrating family planning into FSW-focused community-based HIV services is likely to be the most effective model for improving access to non-barrier contraception among FSWs. However, barriers to integration, such as provider skills and training and funding mechanisms, will require addressing. CONCLUSIONS: As PrEP is scaled up among FSWs, there is growing impetus to consider integrating family planning services with PrEP delivery in order to better meet the diverse SRHR needs of FSWs and to prevent unintended consequences. Programme monitoring combined with research can close data gaps and mobilize adequate resources to deliver comprehensive SRHR services respectful of all women's rights.	sex workers, Pre-Exposure Prophylaxis (PrEP), contraception, unplanned pregnancy, HIV infections	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Review
Article	2020	Bradshaw, Daniel; Vasylyeva, Tetyana I; Davis, Chris; Pybus, Oliver G; Thézé, Julien; Thomson, Emma C; Martinello, Marianne; Matthews, Gail V; Bulteel, Ruth; Gilleece, Yvonne; Cooke, Graham S; Page, Emma E; Waters, Laura; Nelson, Mark	Transmission of hepatitis C virus in HIV-positive and PrEP-using MSM in England.	Journal of Viral Hepatitis	-	-	-	-	-	1365-2893	10.1111/jvh.13286	https://dx.doi.org/10.1111/jvh.13286	We sought to characterize risk factors and patterns of HCV transmission amongst men who have sex with men (MSM). MSM with recently acquired HCV (AHCV) were prospectively recruited (Aline cohort?) between January and September 2017. Clinical data and risk behaviours were identified and blood obtained for HCV whole genome sequencing. Phylogenetic analyses were performed, using sequences from this cohort and two other AHCV cohorts, to identify transmission clusters. Sixteen (40.0%) men in the aline cohort were HIV-negative MSM. HIV-negative MSM were younger than HIV-positive MSM (median 31 vs 39 years, P = .001) and 7 (43.8%) were PrEP in the previous year. Phylogenetic analysis identified 3 clusters containing 5 HIV-negative MSM. Within clusters, sequences from HIV-negative MSM were interspersed with those from HIV-positive MSM. Estimated transmission dates ranged from 17, 17.5?) years before diagnosis. Sequences from 3 HIV-negative MSM were found in the UCL cohort, 2 of whom had UK?CV. Three were in the UCL cohort and 1 in the clinic cohort and 34 from other AIDV cohorts; 67 (90.4%) clustered with 0.008?0.1 other sequence. There were 7 clusters of 2?7 sequences; 6 clusters contained HIV-negative and HIV-positive MSM and 1 cluster only HIV-positive MSM. Four of these clusters were of larger clusters first described in 2007. PrEP using MSM are at risk of HCV, sharing similar risk factors to HIV-positive MSM. Phylogenetics highlights that PrEP-using and HIV-positive MSM are involved in the same HCV transmission networks. Few men demonstrated HCV awareness and risk reduction strategies should be expanded. Article	2020	Brakenridge A.; Walters S.M.; Crean H.F.; Stephenson R.; McMahon J.M.	Pre-exposure Prophylaxis Use Among Men Who Have Sex with Men Experiencing Partner Violence	AIDS and Behavior	-	-	-	-	-	10907165	10.1007/s10461-020-02788-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85078213180&doi=10.1007%2fs10461-020-02788-2&partnerID=40&md5=6e4ca5947ea1b2fc497d6c4f3977f4a	Intimate partner violence (IPV) significantly increases HIV risk among MSM. Pre-exposure prophylaxis (PrEP) may provide MSM experiencing IPV an option for self-protection from HIV without requiring condom negotiation or compromising safety. This study examined relationships among various forms of IPV (physical, emotional, monitoring, controlling, and sexual) and PrEP awareness, willingness, and use (ever and current) participating in a cross-sectional, internet-based survey. Participants reported IPV rates during the prior 6 months that were consistent with prior research (physical violence, 23.3%; emotional violence, 36.3%; monitoring, 41.1%; controlling, 25.3%; forced sex, 20.0%). Forced sex and emotional IPV were negatively associated with PrEP use in our sample; in contrast, controlling was positively associated with PrEP use. We suggest clinical HIV screenings among MSM seeking PrEP, as well as PrEP-focused interventions that explicitly address IPV. © 2020, Springer Science+Business Media, LLC, part of Springer Nature. Article	2020	Brakenridge A.; Zhang C.; McMahon J.M.	Associations Between Relationship Power and Pre-Exposure Prophylaxis (PrEP) Use Among Men Who Have Sex With Men	AIDS and Behavior	-	-	-	-	-	10907165	10.1007/s10461-019-02733-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85075213036&doi=10.1007%2fs10461-019-02733-1&partnerID=40&md5=47ac6eb47255619e77184ac6753f3bc	Few studies have attempted to understand relationship-level factors impacting PrEP utilization among men who have sex with men (MSM). This study examined associations between relationship power and PrEP use among HIV-MSM participating in a cross-sectional, Internet-based survey. The results of our analysis indicate that decision-making dominance was associated with PrEP use among MSM, but the association between relationship control/overall relationship power and PrEP use was inconclusive. Furthermore, when examining specific types of decision-making dominance, equal and greater decision-making dominance was associated with greater odds of PrEP awareness, willingness, and use, while lesser decision-making dominance was not. Our findings suggest that the presence of decision-making dominance related to condom use/sexual initiation and PrEP use were inconclusive. This study suggests that the presence of egalitarian relationships—as well as other relationship-level determinants—should be an essential component of biobehavioral interventions targeting this population. © 2019, Springer Science+Business Media, LLC, part of Springer Nature	HIV prevention; MSM; Pre-exposure prophylaxis; PrEP; Relationship power	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Quantitative
Article	2020	Brant A.R.; Dhillon P.; Hull S.; Coleman M.; Ye P.P.; Lotke P.S.; Fokas J.; Scott R.K.	Integrating HIV Pre-Exposure Prophylaxis into Family Planning Care: A RE-AIM Framework Evaluation	AIDS Patient Care and STDs	-	-	-	-	-	10872914	10.1089/apc.2020.0004	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85085909674&doi=10.1089%2fapc.2020.0004&partnerID=40&md5=257e94aa6698ff6b9bc1b859da2d3f6c	We aimed to systematically evaluate the feasibility of integrating HIV prevention services, including pre-exposure prophylaxis (PrEP), into a family planning setting in a high-prevalence community. We used the RE-AIM Framework (Reach, Efficacy, Adoption, Implementation, Maintenance) to evaluate the integration of HIV prevention services into a family planning clinic over 6 months. Before the integration, PrEP was not offered. We implemented a staff training program on HIV PrEP. We determined the proportion of women presenting to the clinic who were screened, eligible for, and initiated PrEP through chart review. We assessed staff comfort with PrEP pre- and post-integration. We compared planned and actual implementation, interviewed staff to determine barriers and facilitators, and identified systems adaptations. We assessed maintenance of PrEP after the study concluded. There were 640 clinical encounters for 515 patients; the rate of HIV counseling and PrEP screening was 50%. The rate was 10% in the first month and 4% in the last month. Of 32 women eligible for PrEP, 20 initiated PrEP (63%). Staff comfort with PrEP increased from baseline to 6 months post-integration. Staff identified many women requested partners' permission to take PrEP. Uptake was motivated by high perceived HIV risk, and beliefs that PrEP use supported life goals. PrEP was often discontinued due to disenchantment of partnerships/changing risk, unsupportive partners/peers, or early side effects/pill burden. Despite high perceived risks and interest, PrEP was received with muted ambitiousness because of its associations with HIV/ART and stigmatized behaviors. Delivery models that promote youth access, frame messaging on wellness and goals, and foster partner and peer support may facilitate uptake among young people.	family planning; HIV prevention; implementation; PrEP; women	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Review
Article	2020	Brinkley-Rubinstein L.; Crowley C.; Montgomery M.C.; Peterson M.; Zidar N.; Martin R.; Clarke J.; Dubey M.; Chan P.A.	Internet and Knowledge of HIV Pre-Exposure Prophylaxis in a Unified Jail and Prison Setting	Journal of Correctional Health Care	-	-	-	-	-	10783458	10.1177/1078345819897405	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85081660496&doi=10.1177%2f1078345819897405&partnerID=40&md5=5f2959944b4b03b1adf87c2c356b1576	Pre-exposure prophylaxis (PrEP) may be an effective approach to prevent HIV among people who are currently incarcerated or who have been recently released from incarceration. However, awareness and interest in PrEP are largely unknown in this population. This study assessed 417 incarcerated men's lifetime HIV risk engagement and gauged their interest and willingness to take PrEP. Twenty percent reported ever injecting drugs and 4% ever having sex with a man without a condom. 80% had never heard of PrEP. Men White men had heard of PrEP, but higher percentages of men of color were interested in learning more about PrEP and willing to take PrEP to prevent HIV. Future interventions should focus on PrEP education and uptake among individuals who are incarcerated. © The Author(s) 2020. Article	2020	Broady, Timothy R; Bavinton, Benjamin R; Mao, Limin; Prestage, Garrett; Holt, Martin	Australian Gay and Bisexual Men Who Use Condoms, PrEP or Rarely Practise HIV Risk Reduction with Casual Sex Partners: An Analysis of National, Behavioural Surveillance Data, 2017-2018.	AIDS and Behavior	-	-	-	-	-	1573-3254	10.1007/s10461-020-02928-9	https://dx.doi.org/10.1007/s10461-020-02928-9	Recent accounts in the scientific literature of PrEP implementation in Australia have widened the range of HIV prevention strategies available to gay men. This paper aims to quantify the use of different risk reduction strategies and compare characteristics of men who rarely use any strategies with those who regularly use condoms or PrEP. Using national cross-sectional data from the Gay Community Periodic Survey in Australia, comparisons were made between regular condom users (37.1% of participants), PrEP users (30.1%), and men who infrequently used any risk reduction strategies (12.4%). The proportion of gay and bisexual men reporting infrequent use of HIV risk reduction strategies has decreased in recent years. These men reported less frequent high-risk sexual practices than PrEP users and also reported less recent HIV testing than either PrEP or condom users. Men who infrequently use HIV risk reduction strategies should be encouraged to test for HIV more regularly and to utilise prevention strategies that align with their infrequent high-risk behaviour. Article	2020	Brooks, Ronald A; Landrian, Amanda; Lozelle, Gabriele; Gebon, Frank H; Liu, Hongbo; Chen, Ying-Tung	Predictors of Awareness, Accessibility and Acceptability of Pre-exposure Prophylaxis (PrEP) Among English- and Spanish-Speaking Latino Men Who have Sex with Men in Los Angeles, California	Journal of Immigrant and Minority Health	-	-	-	-	-	1557-1920	10.1007/s10903-019-00955-w	https://dx.doi.org/10.1007/s10903-019-00955-w	Uptake of pre-exposure prophylaxis (PrEP) among Latino men who have sex with men (LMSM) remains low. We examined awareness, accessibility, acceptability and use of PrEP among LMSM. LMSM were recruited using social/sexual networking apps. Multiple Logistic regressions identified significant predictors of PrEP awareness, accessibility and acceptability. Among 276 participants, only 6% reported PrEP use. Only 37% were aware of PrEP. Awareness was significantly lower among Spanish- (OR = 0.39, 95% CI: 0.19–0.80) than English-dominant LMSM. In multivariate logistic regressions, a lower likelihood of PrEP awareness was associated with lower level education, whereas a higher likelihood was associated with lower level education, whereas a higher likelihood of PrEP accessibility was associated with lower level education and undocumented status. A lower likelihood of PrEP acceptability was associated with an income of $15,001–30,000, whereas a higher likelihood was associated with lower level education and reporting 6–10 or over 10 sexual partners. PrEP promotion targeting Latino MSM should be expanded for those with lower levels of education and those who are undocumented. Article	2020	Card, Kiffer G; Fournier, Anabelle Bernard; Sorge, Justin T; Morgan, Jeffrey; Grace, Daniel; Ham, David; Lachowsky, Nathan J; Trussler, Terry	Substance use patterns and awareness of biomedical HIV prevention strategies among sexual and gender minority men in Canada.	AIDS Care	-	-	-	-	-	1360-0451	10.1080/09540121.2020.1719026	https://dx.doi.org/10.1080/09540121.2020.1719026	Sexual and gender minority men (SGMM) who use drugs are frequently cited as at-risk for HIV. Fortunately, biomedical prevention can greatly reduce transmission, provided individuals are aware of and interested in the uptake of these strategies. We examined associations between substance use patterns and biomedical prevention among SGMM in Canada. Latent class analysis identified patterns of substance use. Demographic-adjusted logistic regression models assessed the associations between latent classes and key biomedical prevention indicators. Among 669 participants living with HIV (PLWH) and 7,184 participants without, substance use classes characterized "limited" (48.0%; infrequent/low use of drugs), "extensive" (21.9%; alcohol, cannabis, club drugs, and ecstasy/analogues), "club" (2.2%; ecstasy, club drugs, and psychedelics), "acs" (4.8%; alcohol, crystal methamphetamine, GHB, poppers, and erectile drugs), "prescription" (11.0%; alcohol and prescription drugs), and "polydrug" (11.1%; most drugs) use. HIV-negative men in the "prescription" and "acs" substance use classes were more likely to know about the preventative benefits of HIV treatment. All non-"limited use" HIV-negative men were more likely to report interest in taking pre-exposure prophylaxis (PrEP). For PLWH, substance use patterns were not associated with detectable viral loads or treatment awareness. While PLWH exhibited high levels of undetectability and treatment awareness regardless of substance use classes, a variety of substance use patterns were associated with increased awareness, interest, and uptake of biomedical HIV-negative participants. Article	2020	Carillon, Séverine; Gallardo, Lucille; Lisard, Françoise; Chakvetadze, Catherine; Varel, Jean-Paul; Cros, Agnès; Molina, Jean-Michel; Slama, Laurence	Perspectives of injectable long-acting antiretroviral therapies for HIV treatment or prevention: understanding potential users' ambivalences.	AIDS Care	-	-	-	-	-	1360-0451	10.1080/09540121.2020.1742869	https://dx.doi.org/10.1080/09540121.2020.1742869	Recent clinical trial data showed that injectable long-acting antiretroviral treatment (LA-ART) every four or eight weeks could become an alternative option for HIV treatment or prevention. The purpose of our study was to explore perceptions and potential users' points of views of this new mode of administration through individuals' therapeutic itinerary and their singular history with ART. Between 2018 and 2019, a qualitative study was conducted in two University Hospitals in Paris, France. In-depth interviews were conducted with 15 virologically controlled People Living with HIV (PLWH) and 11 men on pre-exposure prophylaxis (PrEP) for at least six months. Interviews, focused on the daily experiences with ART, were recorded, transcribed, and analyzed using thematic content analysis. Collected discourses were heterogeneous and revealed ambivalences. Participants' perceptions were presented as ambivalent, between potential benefits and risks, and burdens. It revealed the complexity of each individual relationship to their HIV treatment or PrEP, leading to balance the injectable LA-ART popularly reported within clinical trials. The new mode of administration may be a suitable alternative for some PLWH and PrEP users, a "simplification" compared to the oral route. It opens a window for "sustainable" ART-treatment according to individuals' lives. Essay	2020	Carnevale, Caroline; Zucker, Jason; Bocsa, Alexander; Northland, Bianka; Castro, Jonathan; Molina, Emma; Richards, Paul; Dominguez, Jose; George, William; Cobali, Alwyn; Okrahn, Susan; Gordon, Peter; Subnaczyk, Magdalena E	Engaging a Predominantly Latina Community in HIV Prevention: Laying the Groundwork for Pre-exposure Prophylaxis and HIV Sexual Health Programs.	Journal of the Association of Nurses in AIDS Care	-	-	-	-	-	1552-6917	10.1097/JNC.0000000000000121	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8013179/	Thanks to advances in HIV prevention and treatment, such as pre-exposure prophylaxis (PrEP) and treatment as prevention, the overall number of new HIV infections in the United States decreased from 2005 to 2017 (Centers for Disease Control and Prevention, 2018). Despite the overall decrease in HIV cases, certain groups, such as young adults and racial/ethnic minorities remain disproportionately affected. In 2017, Latinos made up 26% of new HIV diagnoses in the United States (Centers for Disease Control and Prevention, 2018). Among Latinos, young Latina women (ages 13–24 years) accounted for 64% of new HIV diagnoses in New York City (New York City Department of Health and Mental Hygiene, 2017). Almost two-third (64.9%) of new HIV diagnoses in NYC were in Black and Latino men who have sex with men (MSM)(New York City Department of Health and Mental Hygiene, 2018). Factors contributing to high rates of HIV include poverty, stigma, substance use, and mental health issues (Pellowski, Kalichman, Matthews, & Adler, 2013). Successful sexual health programs must address these social and behavioral determinants of health. Article	2020	Carter, Gregory; Woodward, Brennan	The Relationship Between Perception of HIV Susceptibility and Willingness to Discuss PrEP With a Health Care Provider: A Pilot Study	American Journal of Men's Health	-	-	-	-	-	1557-9883	10.1177/1557988320919661	https://www.proquest.com/scholarly-journals/relationship-between-perception-hiv/docview/2428119298/se-2?accountid=8113	HIV continues to be a significant public health concern and despite recent reductions in new HIV diagnoses, certain demographics continue to be disproportionally affected. Men who have sex with other men (MSM) account for the largest percentage of new HIV diagnoses; however, 24% of new diagnoses can be attributed to male-to-female sex, highlighting the need to explore the HIV epidemic beyond the MSM community. The purpose of this study was to explore the relationship between HIV susceptibility and willingness to discuss pre-exposure prophylaxis (PrEP) with a health care provider among a sample of men living in the United States (n = 377). Men who had an increased perception of HIV susceptibility were significantly more likely to feel comfortable discussing PrEP with a health care provider. Men who distinguish themselves to be at increased risk of acquiring HIV were significantly more likely to report having either insertive or receptive condomless anal intercourse within the previous 3 months, while men who reported condomless vaginal intercourse perceived low HIV susceptibility. Never being screened for HIV was significantly associated with a perception of low HIV susceptibility compared to those men who had been screened in the previous year. Understanding how men perceive HIV susceptibility and engage with HIV prevention may help to improve HIV prevention efforts such as PrEP. Editorial	2020	Castilla, J	Profilaxis antiretroviral preexposición de la infección por el virus de la inmunodeficiencia humana (VIH)	Semergen	-	-	-	-	-	1138-3593	10.1016/j.semerg.2020.02.004	https://www.elsevier.es/es-revista-medicina-familia-semergen-40-articulo-profilaxis-antiretroviral-preexposicion-infeccion-por-S1138359320300599	Desde 1996 se han sucedido avances muy importantes en la terapia antirretroviral frente a la infección por el virus de la inmunodeficiencia humana (VIH)1. Hay suficiente evidencia de que las personas infectadas por el VIH que mantienen un buen control de su carga viral, prácticamente no son contagiosas2,3. Este contexto parecería alimes para un progresivo y rápido control de la transmisión sexual del VIH en la población. Sin embargo, esto no está ocurriendo, porque otros factores están operando en dirección opuesta. Los métodos barrera han dejado de ser una medida preventiva aceptada por una parte importante de la población, y la frecuencia de prácticas sexuales de riesgo y la incidencia de infecciones de transmisión sexual se han disparado4,5. Editorial	2020	Castillo-Mancilla, Jose R.	Adherence to Antiretroviral Therapy and Pre-exposure Prophylaxis: TARGETing the Ideal Measure.	Clinical Infectious Diseases	-	-	-	-	-	1537-6591	10.1093/cid/ciz651	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7201407/	While the current medications available for antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) are potent, effective, and safe, they remain dependent on durable adherence to achieve therapeutic success [1–3]. However, an accurate, reproducible, generalizable, and readily available method to quantify adherence that can be used as a gold standard in clinical practice and research settings remains elusive. Different subjective (eg, self-report) and objective (eg, pharmacologic) adherence measures have been developed, validated, and applied in research studies and clinical practice in recent years, but they all have limitations [4–6]. Subjective measures are inexpensive and easy to implement but tend to overestimate adherence, while others are objective and quantitative, but are expensive and not widely accessible. Thus, the quest for novel methods that can overcome some of these barriers continues. Article	2020	Castor, Delivette; Meyers, Kathrine; Allen, Shannon	The only way is up: priorities for implementing long-acting antiretrovirals for HIV prevention and treatment.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0000000000000601	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6903331	PURPOSE OF REVIEW: Long-acting HIV treatment and prevention (LAHTP) can address some of the achievement gaps of daily oral therapy to bring us closer to achieving Joint United Nations Programme on HIV/AIDS Fast-track goals. Implementing these new technologies presents individual-level, population-level, and health systems-level opportunities and challenges. RECENT FINDINGS: To optimize LAHTP implementation and impact, decision-makers should define and gather relevant data to inform their investment case within the existing health systems context. Programmatic observations from scale-up of antiretroviral therapy, oral preexposure prophylaxis, voluntary medical male circumcision, and family planning offer lessons as planning begins for implementation of LAHTP. Additional data intelligence should be derived from formative studies, pragmatic clinical trials, epidemiologic and economic modeling of LAHTP. Key implementation issues that need to be addressed include optimal communication strategies for demand creation; target setting; logistics and supply chain of commodities needed for LAHTP delivery; human resource planning; defining and operationalizing monitoring and evaluating metrics; integration into health systems. SUMMARY: Successful LAHTP implementation can bolster treatment and prevention coverage levels if implementation issues outlined above are proactively addressed in parallel with research and development so that health systems can more rapidly integrate new technologies as they gain regulatory approval. Theses and Dissertations	2020	CASTRO, CLARISSE DE GUSMAO	Sociedade Civil e a Política da Profilaxia Pré-Exposição ao HIV no Brasil	-	-	Fundação Oswaldo Cruz	-	-	NA	https://sucupira.capes.gov.br/sucupira/public/consultas/coleta/trabalhoConclusao/viewTrabalhoConclusao.jsf?popup=true&id_trabalho=10048353	O estudo tem como objetivo descrever como se deu a interação da sociedade civil durante o processo de implementação da PrEP no Brasil. Para isso, foi proposto um estudo qualitativo exploratório, dividido em revisão de escopo e entrevistas semiestruturadas. Na revisão de escopo o estudo produziu dois levantamentos. O primeiro, realizado em bases de dados científicas, que possibilitou a classificação dos 51 artigos selecionados e o mapeamento de atores, espaços e documentos presentes nos artigos. No segundo, realizado nas páginas de internet oficiais de 6 organizações da sociedade civil, foi possível encontrar 57 publicações, entre boletins, cartilhas, impressos e notas de posicionamento. As entrevistas semiestruturadas realizadas com atores do governo, da sociedade civil organizada e pesquisadores, possibilitaram o registro cronológico da incorporação da PrEP no Brasil, utilizando as fases do ciclo de política para ajudar na organização do objeto de estudo. O estudo concluiu que a sociedade civil organizada esteve em interação nos espaços de consulta e decisão tanto na esfera governamental quanto da pesquisa clínica. Essa interação teve diferenças no engajamento entre os movimentos sociais, e se deu por meio de promoção de debates e campanhas, de difusão e translação de informações, de ações de pressão ao governo, além de colaboração e monitoramento das pesquisas clínicas e de ações do governo. O estudo ainda conclui que, o acesso à PrEP pelas populações mais vulneráveis precisa ser ampliado, e que a estrutura do serviço de saúde (falta de profissionais, dependência de médicos para prescrição, estigma, preconceito e moralidade no atendimento), a falta de vontade política de implementar à PrEP em estados e municípios, e as dificuldades financeiras e estruturais de ONGs, ainda são grandes barreiras. Article	2020	Cattaneo D.; Gervasoni C.; Vinti P.; Baldelli S.; Fusi M.; Zagato D.; De Bona A.; Suardi E.; Bossolasco S.; Ancona G.; Rossotti R.; Cernuschi M.	A comparison of tenofovir predose concentrations in generic pre-exposure prophylaxis formulations: A short communication	Therapeutic Drug Monitoring	-	-	-	1634356	10.1097/FTD.0000000000000756	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85088520835&doi=10.1097%2fFTD.0000000000000756&partnerID=40&md5=1ac40f0b7e8b6bfd229c720c5174e7de	Background:There is extensive evidence to show that pre-exposure prophylaxis (PrEP) using tenofovir disoproxil fumarate (TDF)-based formulations dramatically reduces the risk of HIV acquisition among individuals without HIV infection. Here, the authors aim to compare tenofovir plasma predose concentrations in subjects taking PrEP daily versus on demand and using different TDF-based generic formulations.Methods:Subjects providing informed signed consent for the measurement of tenofovir plasma levels were included in the study. Predose drug concentrations were stratified according to PrEP administration and the type of TDF-based formulation. The control group consisted of patients with HIV infection who were matched for renal function and were administered branded TDF that was not combined with boosted-antiretroviral drugs.Results:The study consisted of 100 subjects (mean age, 39 ± 10 years; body weight, 77 ± 11 kg). A wide distribution in tenofovir predose concentrations was observed, with values ranging from 17 to 297 ng/mL (coefficient of variation 77%). No significant differences were noted in tenofovir predose concentrations between subjects who were administered PrEP daily (n = 75) or on demand (n = 25) 94 (35-255) versus 104 (37-287) ng/mL; P = 0.476. Comparable tenofovir predose concentrations were found between patients with HIV infection (n = 220) who were administered branded TDF and those without HIV infection who were treated with 5 different generic TDF-based formulations with generics-to-branded ratios. These were always within the range of 80%-125% and were used to define bioequivalence.Conclusions:The marketed generic formulations of TDF delivered tenofovir plasma predose concentrations comparable with those delivered by branded formulations. © 2020 Lippincott Williams and Wilkins. Article	2020	Cazorla-Luna, Raúl; Notario-Pérez, Fernando; Martín-Illana, Araceli; Bedoya, Luis-Miguel; Tamayo, Aitana; Rubio, Juan; Ruiz-Caro, Roberto; Veiga, María-Dolores	Development and In Vitro/Ex Vivo Characterization of Vaginal Mucoadhesive Bilayer Films Based on Ethylcellulose and Biopolymers for Vaginal Sustained Release of Tenofovir.	Biomacromolecules	-	-	-	1526-4602 1525-7797	10.1021/acs.biomac.0c00249	https://pubs.acs.org/doi/10.1021/acs.biomac.0c00249	Young women in sub-Saharan Africa have the highest risk of human immunodeficiency virus (HIV) acquisition through sexual contact of all groups. Vaginal controlled release of antiretrovirals is a priority option for the prevention of sexual transmission of the virus in women. In this manuscript, bilayer films were prepared based on ethylcellulose and a natural polymer (xanthan or tragacanth gum) plasticized with glycerol and tributylcitrate for tenofovir-controlled release. The mechanical properties and microstructure of the blank films were characterized by texture analysis, Fourier transform infrared spectroscopy, and scanning electron microscopy. The loaded films were evaluated in simulated vaginal fluid through release and swelling studies and ex vivo mucoadhesion assessments. The results show that the preparation method produced bilayer films with adequate mechanical properties. The contribution of both layers allowed the sustained release of tenofovir and a mucoadhesion time of up to 360 h. The toxicity of the materials was evaluated in three cell lines of vaginal origin. The films constituted by ethylcellulose and xanthan gum in a 2:1 proportion (EX2-D) showed the longest mucoadhesion time, with 15 days of tenofovir-controlled release, zero toxicity, and optimal mechanical properties. These films are therefore a promising option for offering women a means of self-protection against the sexual transmission of HIV. Article	2020	Celum C.; Baeten J.	PrEP for HIV Prevention: Evidence, Global Scale-up, and Emerging Options	Cell Host and Microbe	-	-	-	19313128	10.1016/j.chom.2020.03.020	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85082872914&doi=10.1016%2fj.chom.2020.03.020&partnerID=40&md5=ccd8cf858ae7ea257a80e247ace68ffb	Antiretroviral pre-exposure prophylaxis (PrEP) for the prevention of HIV infection was demonstrated to be efficacious and safe earlier this decade from pivotal studies using oral emtricitabine-tenofovir disoproxil fumarate. Regulatory approval and normative guidance, now for almost 70 countries worldwide, has followed. Demonstration projects have shown high uptake and population-level HIV reductions, highlighting the need for simplifying delivery and reducing current barriers to access and persistence. A portfolio of additional, next-generation PrEP formulations, currently under testing, if effective, will offer users choice and likely increase coverage and impact. © 2020; Antiretroviral pre-exposure prophylaxis (PrEP) for HIV prevention has been shown to be a safe and effective measure for population-level HIV reductions. In this Commentary, Celum and Baeten make a case for PrEP and highlight strategies that take lessons learned from the first decade of PrEP to increase delivery and effect. © 2020	NA	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2020	Celum C.; Morton J.F.; Myers L.; Gill K.; Bekker L.-G.; Stein G.; Thomas K.K.; Duyver M.; van der Straten A.; McConnell M.; Aunger R.; Curtis V.; de Witt Huberts J.; Van Damme L.; Baeten J.M.	Evaluation of a behavior-centered design strategy for creating demand for oral PrEP among young women in Cape Town, South Africa	Gates Open Research	-	-	-	25724754	10.12688/gatesopenres.13103.1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85086272713&doi=10.12688%2fgatesopenres.13103.1&partnerID=40&md5=49eb8e68c5e8c27a4b45fe844dcd1da0	Background: There is an urgent need to find effective interventions that reduce young South African women's vulnerability to HIV, and pre-exposure prophylaxis (PrEP) is highly effective when taken consistently. As national programs in Africa launch PrEP programs for young women, it is critical to understand how to effectively create awareness, stimulate interest, and increase uptake of PrEP. Methods: Behavior-centered design (BCD) guided the development of a PrEP social marketing campaign for young women. Ethnographic observations, in-depth interviews, and focus-group discussions with young South African women informed the content and design of a 90-second PrEP demand creation video and two informational brochures. A short survey was administered to young women at their homes after watching a video to evaluate PrEP interest. Of 800 households with a 16-25-year-old female identified from a Cape Town township census, 320 women in these households viewed the video and completed a survey about the video and their interest in PrEP. Results: In focus groups, young women from the township preferred local characters and messaging that was empowering, simple, and motivational. From the household survey of young women who viewed the video, most reported interest in learning more about PrEP (67.7% 'definitely interested' and 9.4% 'somewhat interested') and taking PrEP (56.4% 'definitely interested' and 12.5% 'somewhat interested'). Factors significantly associated with interest in taking PrEP were having a primary partner with whom they regularly have sex (80.0% vs. 65.2% without a primary partner; adjusted odds ratio (AOR)=3.1, 95% CI: 1.3, 7.0) and being in a sexual partnership for <6 months (86.8% vs. 68.5% for >12 months; AOR=3.0, 95% CI: 1.2, 7.3). Conclusions: A positively framed PrEP demand creation video generated high interest in PrEP among young South African women, particularly among women with a primary partner and a shorter-term relationship. Article	2020	Celum C.L.; Gill K.; Morton J.F.; Stein G.; Myers L.; Thomas K.K.; McConnell M.; van der Straten A.; Baeten J.M.; Duyver M.; Mendel E.; Naidoo K.; Dallimore J.; Wiesner L.; Bekker L.-G.	Incentives conditioned on tenofovir levels to support PrEP adherence among young South African women: a randomized trial	Journal of the International AIDS Society	-	-	-	17582652	10.1002/jia2.25636	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85096752550&doi=10.1002%2fjia2.25636&partnerID=40&md5=9456a7564e4f490596ccb0f7e8799872	Introduction: HIV incidence remains high among African adolescent girls and young women (AGYW), who would benefit from pre-exposure prophylaxis (PrEP). Strategies to increase PrEP adherence and persistence need to be evaluated in African AGY, including incentives conditional on high adherence. Methods: The 3Ps for Prevention Study was a 12-month prospective cohort of 200 women ages 16 to 25 initiating PrEP in South Africa from 2017 to 2018. Participants received retrospective feedback about drug levels at Months 1, 2 and 3; half was randomized to receive a 200 Rand shopping voucher ($13 US) at Months 2, 3 and 4, conditioned on high intracellular tenofovir diphosphate (TFV-DP) levels in dried blood spots (≥500 fmol/punch at Month 1, ≥700 fmol/punch at Months 2 and 3). The primary analysis was intention-to-treat, comparing the proportion with high PrEP adherence (≥700 fmol/punch) at Month 3 by randomized group, based on 100% efficacy among men who have sex with men. Results: Median age of the 200 women was 19 years (interquartile range IQR 17, 21); 86% had a primary sexual partner. At Month 3, the mean TFV-DP level was 822 fmol/punch (SD 522) in the incentive group and 689 fmol/punch (SD 546) in the control group (p = 0.11). Forty-five (56%) of 85 women in the incentive group and 35 (41%) of 85 women in the control group had TFV-DP levels ≥700 fmol/punch (RR 1.35; 95% CI 0.98, 1.86; p = 0.067), which declined to 8% and 5% in the incentive and control groups at Month 12 (no significant difference by arm). 44% refilled PrEP without gaps, 14% had a gap of ≥3 weeks in coverage subsequently restarted PrEP and 54% accepted at the final dispensing visit at Month 9. No new HIV infections were observed after PrEP initiation. Conclusions: Among South African AGYW initiating PrEP, drug levels indicated high PrEP adherence in almost half of women at Month 3, with a non-statistically significant higher proportion with high adherence among those in the incentive group. Over half persisted with the 12-month PrEP programme although high adherence declined after Month 3. Strategies to support PrEP adherence and persistence and longer-acting PrEP formulations are needed. © 2020 The Authors. Article	2020	Cempaka, Rissa; Wardhani, Brigitta; Sawitri, Anak Agung Sagung; Januraga, Pande Putu; Bavinton, Benjamin	PrEP Use Awareness and Interest Cascade among MSM and Transgender Women Living in Bali, Indonesia.	Tropical Medicine and Infectious Disease	-	-	-	2414-6366	10.3390/tropicalmed5040158	https://www.mdpi.com/2414-6366/5/4/158	Indonesia has not implemented HIV pre-exposure prophylaxis (PrEP) despite global calls for its scale-up, and there is limited information about attitudes towards PrEP among its potential users. We aim to present a PrEP cascade among men who have sex with men (MSM) and transgender women (known locally as "waria") in Denpasar, Bali, from a cross-sectional survey with 220 HIV-negative MSM/waria recruited from one clinic in Denpasar. Only 16.4% of participants had heard of PrEP before. From first-to-last steps included in the cascade, we found 77.3% (170/220) of participants were classified with HIV high risk, 75.9% (129/170) perceived themselves as being at high risk, 81.4% (105/129) expressed interest in using PrEP, 78.1% (82/105) were willing to do PrEP procedures, 48.8% (40/82) were willing to pay 500,000-600,000 IDR, and only two participants had ever been on PrEP before (5.0% of those willing to pay and 0.9% of the total sample). Multivariate logistic regression analysis showed that self-perception of high HIV risk was lower among older age groups (p < 0.001 among 30-39; p = 0.002 among > 40) and higher among participants with multiple sex partners (p = 0.016). Interest in using PrEP was lower among participants with high social engagement as MSM/waria (p = 0.002) and was higher among participants with multiple sex partners (p = 0.020) and inconsistent condom use (p = 0.011). This study has shown a significantly low level of PrEP awareness among its participants and decreases in interest in PrEP use due to procedure and cost. It suggested that an appropriate PrEP campaign is needed if PrEP is going to be introduced in Indonesia. Article	2020	Cerqueira N.B.; Vasconcelos R.; Carlo Hojilla J.; Kallás E.G.; Avelino-Silva V.I.	Attitudes and Knowledge about Human Immunodeficiency Virus Pre-Exposure Prophylaxis among Brazilian Infectious Disease Physicians	AIDS Research and Human Retroviruses	-	-	-	8892229	10.1089/aid.2019.0281	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85097210765&doi=10.1089%2faid.2019.0281&partnerID=40&md5=d20a09b42119205bdb670ac02e53b391	The objective was to describe levels and predictors of knowledge, attitudes, and willingness to prescribe pre-exposure prophylaxis (PrEP) among Brazilian Infectious Disease (ID) Physicians. The design was a cross-sectional study. We collected information on demographics and attitudes/knowledge about PrEP using an anonymous electronic survey. Willingness to prescribe PrEP, fear of adherence issues, and concerns about risk compensation were addressed in three case vignettes that varied by a single characteristic (i.e., by gender identity, drug use, and socioeconomic status) randomly assigned to physicians. Three hundred seventy ID physicians responded to the survey. Although most identified as informed/well informed about PrEP (75%) and believed PrEP availability to be necessary (38%), concerns with adherence (49%), side effects (38%), risk compensation (28%), and increase in sexually transmitted infection incidence (38%) were raised. We found no statistically significant differences in willingness to prescribe PrEP and concerns about risk compensation across the three case vignettes. ID physicians who declared having a religion reported more concerns about risk compensation compared to those self-identified as atheists (72% vs. 46%, p <.001). Most Brazilian ID physicians reported a positive attitude toward PrEP. Patients' gender identity, drug use, and socioeconomic status were not associated with willingness to prescribe PrEP. However, ID physicians who declared having a religion were more frequently concerned about risk compensation among PrEP users, suggesting that personal beliefs can influence PrEP implementation. © Copyright 2020, Mary Ann Liebert, Inc.	attitudes; health knowledge; HIV infections; implementation science; practice; pre-exposure prophylaxis	English	United States	Western and Central Europe and North America	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Quantitative
Theses and Dissertations	2020	Chadwick, Caleb	A New Era of HIV: Psychology's Contributions to the Epidemic and Development of the Pre-Exposure Prophylaxis Determinants Scale	-	-	Georgia State University	-	NA	https://doi.org/10.57709/15996927	https://scholarworks.gsu.edu/cps_diss/137	By 1991, the Human Immunodeficiency Virus (HIV) had claimed more than 250,000 lives in the United States (US; Chadwick, Zelaya & DeBlaere, 2017). That same year, the first clinical trials began to test the effectiveness of Antiretroviral Treatment (ART) to combat the virus (HIV.gov, 2017). By 1995, HIV/AIDS became the leading cause of death among Americans age 25-44 (Zuninga et al., 2008), becoming a modern epidemic of unprecedented proportions, particularly among sexual minority men. Over time, treatments for HIV improved in their scope and effectiveness, leading to our modern conceptualization of HIV as a chronic illness, rather than a terminal disease. Pre-exposure prophylaxis (PrEP) is a recently developed primary medical prevention method for HIV. Although clinical trials have demonstrated promising results in terms of efficacy, little is known regarding the attitudes of individuals most likely to benefit from PrEP treatment (e.g. sexual minority men). As such, the proposed study aims to address this gap in the research literature by contributing a psychological perspective on HIV and PrEP. Specifically, Chapter 1 provides a systematic literature review of the flagship psychological journals associated with subfields within the discipline (e.g. counseling psychology, men and masculinity issues, sexual orientation diversity) uniquely suited to contribute expertise relevant to the HIV epidemic. Chapter 2 proposes to develop a scale measuring the psychosocial determinants of PrEP utilization. Based on the extant literature, four factors are proposed for the PrEP Determinants (PrEP-D) scale, including knowledge about PrEP, stigma, treatment attributes, and perceived effectiveness. Results of exploratory and confirmatory factor analyses using data collected from a sample of sexual minority men suggest the presence of four factors in the PrEP-D scale, consistent with the themes identified in the literature. The study also provides initial evidence of internal consistency, reliability, and construct validity. Article	2020	Chakrapani V.; Shunmugam M.; Rawat S.; Baruah D.; Nelson R.; Newman P.A.	Acceptability of HIV Pre-Exposure Prophylaxis among Transgender Women in India: A Qualitative Investigation	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2019.0237	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85079352589&doi=10.1089%2fapc.2019.0237&partnerID=40&md5=8516be7a4adb669269ce15271d3b8eca	Despite high HIV prevalence among transgender women (TGW) in India, there is limited exploration of pre-exposure prophylaxis (PrEP) acceptability. With PrEP licensure pending, we conducted six focus group discussions (FGDs) with diverse TGW (n = 36), and eight key informant interviews with community leaders and physicians, in Mumbai and Chennai. Data were explored using framework analysis guided by the Theoretical Framework of Acceptability. FGD participants' mean age was 26.1 years (SD = 4.8); two-thirds engaged in sex work. TGW reported low PrEP awareness, with moderate acceptability once PrEP was explained. Population-specific facilitators of PrEP acceptability included its perceived effectiveness in the context of challenges to condom use in serodiscordant relationships and forced sex encounters. PrEP was considered especially appropriate for TGW sex workers; however, barriers were anticipated in the context of hierarchical hijra (indigenous trans identity) kinship networks and gurus' (masters) potential negative reactions to PrEP use by their chelas (disciples). Positive attitudes toward high efficacy and potential covert use were tempered by TGW's concerns about high costs and adherence challenges living with parents or primary partners, and TGW sex workers' unpredictable schedules. Anticipated interactions with feminizing hormones, visible side effects, and PrEP-related stigma within TGW communities emerged as opportunity costs. PrEP implementation for TGW in India should promote comprehensive information on side effects and potential interactions with feminizing hormones, provide free or subsidized PrEP, and highlight the advantages of added protection in sex work and forced sexual encounters. Meaningful engagement with TGW kinship networks can encourage positive transgender community norms on PrEP use and mitigate multifaceted stigma. © Copyright 2020, Mary Ann Liebert, Inc., publishers 2020. Article	2020	Chan C.; Broady T.R.; Bavinton B.R.; Mao L.; Prestage G.P.; Holt M.	Assessing the HIV Prevention Needs of Young Gay and Bisexual Men in the PrEP Era: An Analysis of Trends in Australian Behavioural Surveillance, 2014–2018	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-020-02797-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85078126804&doi=10.1007%2fs10461-020-02797-2&partnerID=40&md5=94fda10c62046a1600673a92e2a6a559	Data from repeated, national behavioural HIV surveillance was used to identify similarities and differences between young gay and bisexual men (YGBM) aged 16–24 (n = 1608) and older GBM aged 25–49 (n = 6266), in order to quantify risks and identify gaps in HIV prevention. Trend analyses from 2014 to 2018 are also reported. While there were similar rates of condomless anal intercourse with casual partners in both age groups, YGBM had lower rates of HIV testing and PrEP use but also fewer male partners. Our results suggest most YGBM have lower HIV risk than older GBM but a minority merit enhanced testing and prevention efforts. © 2020, Springer Science+Business Media, LLC, part of Springer Nature. Article	2020	Chan, Stephanie S; Chappel, Andre R; Maddox, Karen E Joynt; Hoover, Karen W; Huang, Ya-Lin A; Zhu, Weiming; Cohen, Stacy M; Klein, Pamela W; De Lew, Nancy	Pre-exposure prophylaxis for preventing acquisition of HIV: A cross-sectional study of patients, prescribers, uptake, and spending in the United States, 2015-2016.	PLOS Medicine	-	-	-	1549-1676	10.1371/journal.pmed.1003072	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7147726	BACKGROUND: In 2015, there were approximately 40,000 new HIV diagnoses in the United States. Pre-exposure prophylaxis (PrEP) is an effective strategy that reduces the risk of HIV acquisition; however, uptake among those who can benefit from it has lagged. In this study, we 1) compared the characteristics of patients who were prescribed PrEP with individuals newly diagnosed with HIV infection, 2) identified the specialties of practitioners prescribing PrEP, 3) identified metropolitan statistical areas (MSAs) within the US where there is relatively low uptake of PrEP, and 4) reported median amounts paid by patients and third-party payors for PrEP. METHODS AND FINDINGS: We analyzed prescription drug claims for individuals prescribed PrEP in the Integrated Dataverse (IDV) from Symphony Health for the period of September 2015 to August 2016 to describe PrEP patients, prescribers, relative uptake, and payment methods in the US. Data were available for 75,839 individuals prescribed PrEP, and findings were extrapolated to approximately 101,000 individuals, which is less than 10% of the 1.1 million adults for whom PrEP was indicated. Compared to individuals with newly diagnosed HIV infection, PrEP patients were more likely to be non-Hispanic white (45% versus 26.2%), older (25% versus 19% at ages 35-44), male (94% versus 81%), and not reside in the South (30% versus 52% reside in the South).Using a ratio of the number of PrEP patients within an MSA to the number of newly diagnosed individuals with HIV infection, we found MSAs with relatively low uptake of PrEP were concentrated in the South. Of the approximately 24,000 providers who prescribed PrEP, two-thirds reported primary care as their specialty. Compared to the types of payment methods that people living with diagnosed HIV (PLWH) used to pay for their antiretroviral treatment in 2015 to 2016 reported in the Centers for Disease Control and Prevention (CDC) HIV Surveillance Special Report, PrEP patients were more likely to have used commercial health insurance (80% versus 35%) and less likely to have used public healthcare coverage or a publicly sponsored assistance program to pay for PrEP (12% versus 45% for Medicaid). Third-party payors covered 95% of the costs of PrEP. Overall, we estimated the median annual per patient out-of-pocket spending on PrEP was approximately US$72. Limitations of this study include missing information on prescription claims of patients not included in the database, and for those included, some patients were missing information on patient diagnosis, race/ethnicity, educational attainment, and income (34%-36%). CONCLUSIONS: Our findings indicate that in 2015-2016, many individuals in the US who could benefit from being on PrEP were not receiving this HIV prevention medication, and those prescribed PrEP had a significantly different distribution of characteristics from the broader population that is at risk for acquiring HIV. PrEP patients were more likely to pay for PrEP using commercial or private insurance, whereas PLWH were more likely to pay for their antiretroviral treatment using publicly sponsored programs. Addressing the affordability of PrEP and otherwise promoting its use among those with indications for PrEP represents an important opportunity to help end the HIV epidemic. Article	2020	Chandler, Cristian J; Bukowski, Leigh A; Matthews, Derrick D; Hawk, Mary E; Markovic, Nina; Stall, Ronald D; Egan, James E	Understanding the impact of a syndemic on the use of pre-exposure prophylaxis in a community-based sample of behaviorally PrEP-eligible BMSM in the United States	AIDS Care	-	-	-	09540121	10.1080/09540121.2019.1659921	https://www.proquest.com/scholarly-journals/understanding-impact-syndemic-on-use-pre-exposure/docview/2383466532/se-2?accountid=8113	HIV Pre-Exposure Prophylaxis (PrEP) has shown great promise in reducing HIV transmission among affected populations; however, PrEP uptake among Black men who have sex with men (BMSM) has stalled. This study compares BMSM using PrEP and BMSM at risk for HIV not using PrEP based on differences in behavior, psychosocial conditions and the presence of a syndemic (n = 1,411). BMSM reporting PrEP use were significantly more likely to report three of five HIV risk behaviors and three of four psychosocial conditions. Odds of reporting PrEP use increased as the number of psychosocial conditions increased such that BMSM with three psychosocial conditions (AOR = 5.65, 95% CI: 3.17, 10.08) and four conditions (AOR = 18.34, 95% CI: 5.01, 67.20) demonstrated significantly greater odds of PrEP use compared to BMSM reporting one or less conditions. While BMSM at greatest risk are using PrEP, strategies are still needed for men at varying risk levels.
