Article	2001	Van Rompay KK, McChesney MB, Aguirre NL, Schmidt KA, Bischofberger N, Marthas ML	Two Low Doses of Tenofovir Protect Newborn Macaques against Oral Simian Immunodeficiency Virus Infection	The Journal of Infectious Diseases	-	-	-	1537-6613	https://doi.org/10.1086/322781	https://academic.oup.com/jid/article-abstract/184/4/429/808643?redirectedFrom=fulltext	Simple affordable interventions are needed to reduce vertical human immunodeficiency virus (HIV) transmission in developing countries. The efficacy of 2 low doses (4 mg/kg, subcutaneously) or 1 high dose (30 mg/kg, subcutaneously) of the reverse-transcriptase inhibitor 9-[2-(phosphonomethoxy)propyl]adenine (PMPA; tenofovir) to protect newborn macaques against simian immunodeficiency virus (SIV) infection was investigated. Thirteen newborn macaques were inoculated orally with virulent SIVmac251. The 4 placebo-treated animals (group A) became persistently infected. Groups B and C (n=4 in each group) received 2 4-mg/kg doses of PMPA, either 4 h before and 20 h after (group B) or 1 and 25 h after SIV inoculation (group C). One animal (group D) received a single 30-mg/kg dose of PMPA 1 h after SIV inoculation. Despite evidence of an initial transient infection, 3 group B animals, 2 group C animals, and the group D animal were SIV negative and seronegative at ages 19–23 months. Immune activation with recall antigens or pharmacologic immunosuppression with corticosteroids failed to reactivate viral replication. These data suggest that 1 or 2 doses of PMPA may protect human newborns against intrapartum HIV infection	hiv, adrenal corticosteroids, glucocorticoids, antigens, newborn, macaca, simian immunodeficiency virus, vaccination, therapeutic immunosuppression, natural immunosuppression, infections, mineralocorticoids, viruses, tenofovir	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2002	Van Rompay KK, Schmidt KA, Lawson JR, Singh R, Bischofberger N, Marthas ML	Topical administration of low-dose tenofovir disoproxil fumarate to protect infant macaques against multiple oral exposures of low doses of simian immunodeficiency virus	The Journal of Infectious Diseases	-	-	-	1537-6613	https://doi.org/10.1086/344360	https://academic.oup.com/jid/article-abstract/186/10/1508/832180?redirectedFrom=fulltext	Simian immunodeficiency virus (SIV) infection of infant macaques is a useful animal model to determine whether topical (oral) administration of antiviral compounds to the nursing infant could reduce human immunodeficiency virus transmission through breast-feeding. The reverse-transcriptase inhibitor tenofovir was selected because of previous demonstrations that systemic drug levels are effective in preventing SIV infection. To mimic the multiple exposures to virus during breast-feeding, 14 infant macaques were fed 15 low doses of SIVmac251 without chemical restraint. Six animals were treated with placebo, and 2 groups of 4 animals received oral topical doses of tenofovir disoproxil fumarate (DF; equivalent to 0.037 mg of tenofovir/day). About half the animals of each group became infected. In a subsequent study, 2 oral inoculations of 4 juvenile macaques with a mixture of tenofovir DF and SIVmac251 induced persistent infection. Topical administration of low doses of tenofovir DF did not protect against oral SIV infection	exposure, administration, topical, antiviral agents, breast feeding, child, infant, macaca, animal model, simian immunodeficiency virus, vaccination, infections, viruses, tenofovir, hiv transmission	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2003	Joel E. Gallant, Stanley Deresinski	Tenofovir Disoproxil Fumarate	Clinical Infectious Diseases	-	-	-	1537-6591	https://doi.org/10.1086/378068	https://academic.oup.com/cid/article/37/7/944/422616	Tenofovir disoproxil fumarate (tenofovir DF) is a bioavailable prodrug of tenofovir, a potent nucleotide analogue reverse-transcriptase inhibitor with activity against human immunodeficiency virus (HIV) and hepatitis B virus. It is administered as a single 300-mg tablet once daily. It was approved for the treatment of HIV infection on the basis of data from clinical trials demonstrating activity in treatment-experienced patients, and it was subsequently shown to be effective when used as a component of initial therapy. Tenofovir DF is active against some nucleoside-resistant strains of HIV. However, cross-resistance is associated with multiple thymidine analogue mutations that include 41L or 210W. The signature mutation is the K65R mutation, which causes variable loss in susceptibility to tenofovir DF, didanosine, and abacavir. Tenofovir DF has been well tolerated in clinical trials with durations of follow-up up to 96 weeks. It is associated with more-favorable lipid profiles than stavudine and has not been associated with the mitochondrial toxicity attributed to other nucleoside analogues.	mutation, didanosine, stavudine, tenofovir, hiv, infections	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2003	Youle M, Wainberg MA	Pre-exposure chemoprophylaxis (PREP) as an HIV prevention strategy	Journal of the International Association of Physicians in AIDS Care	-	-	-	1545-1097	https://doi.org/10.1177/154510970300200302	https://journals.sagepub.com/doi/abs/10.1177/154510970300200302	Chemoprophylaxis may be a prevention strategy for the sexual transmission of human immunodeficiency virus (HIV). Evidence suggests that condom use has waned with the availability of antiretroviral medication, at least in some resource-rich settings. Barrier methods of HIV prevention have inherent problems, and the potential for failure. Microbicide research has focused primarily on male-to-female transmission. Analogous to post-exposure prophylaxis, HIV prevention may be achieved by pre-exposure prophylaxis in some settings. Research in this potential strategy may be rewarding. Article	2005	Mills, Edward; Rachlis, Beth; Wu, Ping; Wong, Elaine; Wilson, Kumanan; Singh, Sonal	Media reporting of tenofovir trials in Cambodia and Cameroon	BMC International Health and Human Rights	-	-	-	1472-698X	10.1186/1472-698X-5-6	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1242229/	BACKGROUND: Two planned trials of pre-exposure prophylaxis tenofovir in Cambodia and Cameroon to prevent HIV infection in high-risk populations were closed due to activist pressure on host country governments. The international news media contributed substantially as the primary source of knowledge transfer regarding the trials. We aimed to characterize the nature of reporting, specifically focusing on the issues identified by media reports regarding each trial. METHODS: With the aid of an information specialist, we searched 3 electronic media databases, 5 electronic medical databases and extensively searched the Internet. In addition we contacted stakeholder groups. We included media reports addressing the trial closures, the reasons for the trial closures, and who was interviewed. We extracted data using content analysis independently, in duplicate. RESULTS: We included 24 reports on the Cambodian trial closure and 13 reports on the Cameroon trial closure. One academic news account incorrectly reported that it was an HIV vaccine trial that closed early. The primary reasons cited for the Cambodian trial closure were: a lack of medical insurance for trial related injuries (71%); human rights considerations (71%); study protocol concerns (46%); general suspicions regarding trial location (37%) and inadequate prevention counseling (29%). The primary reasons cited for the Cameroon trial closure were: inadequate access to care for seroconverters (69%); participants not sufficiently informed of risks (69%); inadequate number of staff (46%); participants being exploited (46%) and an unethical study design (38%). Only 3/23 (13%) reports acknowledged interviewing research personnel regarding the Cambodian trial, while 4/13 (30.8%) reports interviewed researchers involved in the Cameroon trial. CONCLUSION: Our review indicates that the issues addressed and validity of the media reports of these trials is highly variable. Given the potential impact of the media in formulation of health policy related to HIV, efforts are needed to effectively engage the media during periods of controversy in the HIV/AIDS epidemic. Article	2006	Gaym, Asheber	Microbicides-emerging essential pillars of comprehensive HIV/AIDS prevention	Ethiopian Medical Journal	-	-	-	0014-1755	NA	https://pubmed.ncbi.nlm.nih.gov/17370443/#full-view-affiliation-1	A quarter century old and still going strong, the HIV/AIDS pandemic is already the deadliest and longest lasting plague in mankind's recorded history. Reportedly among the weakest of the viruses, HIV's survival instincts have relied on extreme adaptability at the molecular and virologic levels on its part. In addition, it has preyed on certain prevalent weaknesses on the part of its host (human society) - extreme poverty; gender bias; lack of education and high prevalence of STIs- to prolong its lethal grip on humanity for as long as possible. This astounding adaptability is evident by the tremendous geographic, gender, mode of transmission and age shifts it has displayed over its now respectably long history. From localized epidemics in localities in the developed world at its onset, it has gravitated and now firmly entrenched itself selecting Sub-Saharan Africa as the epicenter of its global scourge. From a disease of men having sex with men (MSMs) at its inception, it has undergone a gender shift with a definite and alarming "feminization" or as Kofi Annan put it, has the "Face of a woman". From a demonstrable prevalence, concentrating in adults, it has chillingly shifted to being an infection that affects predominantly younger age groups and adolescents. And from its early homosexual and injection drug use transmission modes it has shifted to a predominantly heterosexual transmission for the majority of new infections. Behavioral modifications (health education towards safe sexual practices and VCT provision and utilization); correct and consistent use of male and female condoms; control of sexually transmitted diseases and strategies to prevent mother to child transmission (PMTCT) are effective methods of HIV/AIDS prevention. Their effectiveness has been demonstrated by their ability to contain the epidemic in countries that have successfully implemented them. Of questionable value in prevention but gaining momentum in accumulating data proving their effectiveness in HIV prevention are strategies including male circumcision; PEP (post-exposure prophylaxis); PREP (pre-exposure prophylaxis) and provision of ante-retroviral therapy to all who are in need. Experiences in prevention efforts in resource-poor settings over the last two decades have indicated that the traditional ABC model (abstinence, being faithful to one's partner and condom use) are inadequate in controlling HIV in those settings. Well-known biologic vulnerabilities in women as well as socio-economic, cultural and gender bias towards women, stand in the way of effective implementation of the available prevention strategies. It has become increasingly evident that as part of a comprehensive HIV prevention strategy, a female-controlled method of prevention is crucial for the eventual control of the epidemic in Africa. To this end, efforts to develop a "microbicide"- a topical agent that can be applied vaginally by women to protect themselves from infection; and a product that they can use without the necessary consent of their partner - have been gathering momentum over the last decade. At present, nearly sixty potential microbicides are in the development pipeline. Of these six are in the last (phase III) effectiveness trials that precede drug licensing. There is a general belief in the scientific community that an effective microbicidal agent for HIV prevention might be available in the next five to seven years. Lack of finance and ethical issues in conducting research are delaying rapid development of an effective agent. Ethiopia has been largely left out of research efforts towards microbicides development. It is essential that cognizance of this emerging HIV prevention strategy by health care professionals and the general public be developed in order to avoid undue delays in effective utilization once an effective agent becomes part of our HIV prevention arsenal. Article	2006	Liu, Albert Y; Grant, Robert M; Buchbinder, Susan P	Preexposure Prophylaxis for HIV: Unproven Promise and Potential Pitfalls	JAMA - Journal of the American Medical Association	-	-	-	00987484	10.1001/jama.296.7.863	https://www.proquest.com/scholarly-journals/preexposure-prophylaxis-hiv-unproven-promise/docview/211450981/se-2?accountid=8113	An estimated 11,000 new human immunodeficiency virus (HIV) infections occur worldwide per day and approximately 4 million individuals are infected with HIV per year. Although behavior change has likely led to substantial reductions in HIV incidence in some populations and risk-reduction counseling will likely remain the cornerstone of HIV prevention programs, new HIV prevention strategies are urgently needed to further reduce incident infections. Preexposure chemoprophylaxis (PrEP) has emerged as a promising new biomedical strategy for preventing HIV infection, and clinical trials are planned or under way to evaluate the safety and efficacy of this approach. Because many antiretroviral drugs are licensed in the United States, PrEP could become available for use as a prevention tool more quickly than other experimental prevention strategies, such as an HIV vaccine. Article	2007	Landovitz, Raphael J.	Recent efforts in biomedical prevention of HIV.	Topics in Antiviral Medicine	-	-	-	1542-8826	NA	https://pubmed.ncbi.nlm.nih.gov/17598929/	Despite major advances in HIV treatment and progress in distribution of antiretroviral therapy in the developing world, staggering rates of new HIV infections persist. Innovative approaches to prevention of transmission are needed. Recent data have confirmed previous observational studies that demonstrated a substantial reduction in acquisition risk with male circumcision and microbicide technology experienced a setback with the early termination of a large-scale vaginal microbicide trial of cellulose sulfate. Limited data from one trial of pre-exposure prophylaxis was not able to validate nor refute efficacy. This article summarizes a presentation on biomedical prevention of HIV infection made by Raphael J. Landovitz, MD, at an International AIDS Society-USA Continuing Medical Education course in Los Angeles in March 2007. Article	2007	MacQueen, Kathleen M.; Karim, Quarraisha Abdool	Practice brief: adolescents and HIV clinical trials: ethics, culture, and context.	The Journal of the Association of Nurses in AIDS Care	-	-	-	1055-3290	10.1016/j.jana.2007.01.002	https://www.sciencedirect.com/science/article/abs/pii/S1055329007000039	One quarter of HIV infections globally occur among young people 15 to 24 years of age, and more than half of all new infections are in people younger than 25 years. Clearly, there is a need to identify and implement effective HIV prevention strategies among at-risk teens. Some of the most effective options for slowing the epidemic are biomedical, and several promising methods are in development, including microbicides, vaccines, and preexposure prophylaxis (PREP, or the daily use of antiretrovirals to prevent the acquisition of HIV). There is widespread reluctance to enroll minors in such biomedical prevention trials because of concerns about vulnerability related to physical maturity, experiential maturity, and diminished autonomy as well as legal and social challenges that vary across and within nations. However, excluding minors from trials removes an important opportunity to evaluate the effectiveness, acceptability, and safety of innovative interventions under the best conditions for identifying and resolving potential problems. The challenges of including minors in HIV prevention trials are highlighted through the example of one rural South African community that has been particularly devastated by the HIV epidemic. Article	2007	Macqueen, Kathleen M; Johnson, Laura; Alleman, Patty; Akumatey, Betty; Lawoyin, Taiwo; Nyiama, Tiburce	Pregnancy prevention practices among women with multiple partners in an HIV prevention trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-17667340	BACKGROUND: Women enrolled in microbicide and pre-exposure prophylaxis (PrEP) HIV prevention trials are not allowed to continue use of study products when pregnant because of fetal safety concerns. High pregnancy rates among women in trials can undermine statistical measures of safety and effectiveness. METHODS: Women enrolled in a PrEP trial in Ghana, Nigeria, and Cameroon had an overall pregnancy rate of 52 per 100 person-years of observation. In-depth interviews were conducted with 67 women who were asked to describe any changes made in their pregnancy prevention practices after enrolling in the trial. RESULTS: Most women (n = 44, 65%) reported changing pregnancy prevention practices after enrolling in the trial. Twice as many reported using condoms for pregnancy prevention after enrollment (n = 56, 84%) than before (n = 27, 40%). Cluster analysis identified site-specific patterns. Nigerian women tended to report using condoms for dual protection before and after trial enrollment. Cameroonian women tended to rely on natural methods before and after trial enrollment. Ghanaian women tended to switch from hormonal methods to condoms. CONCLUSIONS: The role of condoms in HIV prevention trials must not be diminished. Their use-effectiveness for contraception is likely too low for microbicide and PrEP trial needs, however. HIV prevention trials with women should be appropriately staffed to provide effective contraceptive counseling and, if needed, direct provision of contraceptives. This must be done without undermining women's reproductive rights. Article	2007	Paxton, Lynn A; Hope, Tony; Jaffe, Harold W	Pre-exposure prophylaxis for HIV infection: what if it works?	The Lancet	-	-	-	01406736	10.1016/S0140-6736(07)61053-8	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-hiv-infection-what-if/docview/199060388/se-2?accountid=8113	Anecdotal reports are already circulating, of physicians prescribing tenofovir to patients at high risk of HIV infection, and of unregulated use of the drug at venues such as sex clubs and circuit parties.20 Even those who would provide pre-exposure prophylactic treatment, such as doctors and other healthcareproviders are unsure about appropriate indications.21 If present trials show efficacy of tenofovir (or tenofovir and emtricitabine) against HIV transmission, the pressure for immediate approval for prevention will be great. In studies of individuals with HIV taking combination antiretroviral therapy, this mutation was detected in 3-2% of people over 96 weeks of follow-up.22 Small phase 1 studies of tenofovir monotherapy in people with HIV did not show development of any drug resistance mutations with up to 28 days of treatment, but in macaques infected with simian immunodeficiency virus, ultrasensitive resistance tests showed rapid development of K65R in those with high viral loads given high doses of tenofovir.21 The K65R mutation also causes some resistance to other nucleoside reverse transcriptase inhibitors and increased susceptibility to zidovudine. Article	2007	Peterson L, Taylor D, Roddy R, Belai G, Phillips P, Nanda K, Grant R, Clarke EE, Doh AS, Ridzon R, Jaffe HS, Cates W	Tenofovir disoproxil fumarate for prevention of HIV infection in women: a phase 2, double-blind, randomized, placebo-controlled trial	PLoS Clin Trials	-	-	-	NA	10.1371/journal.pctr.0020027	https://journals.plos.org/plosclinicaltrials/article?id=10.1371/journal.pctr.0020027	Objectives: The objective of this trial was to investigate the safety and preliminary effectiveness of a daily dose of 300 mg of tenofovir disoproxil fumarate (TDF) versus placebo in preventing HIV infection in women. Design: This was a phase 2, randomized, double-blind, placebo-controlled trial. Setting: The study was conducted between June 2004 and March 2006 in Tema, Ghana; Douala, Cameroon; and Ibadan, Nigeria.Participants: We enrolled 936 HIV-negative women at high risk of HIV infection into this study.Intervention: Participants were randomized 1:1 to once daily use of 300 mg of TDF or placebo.Outcome measures: The primary safety endpoints were grade 2 or higher serum creatinine elevations (>2.0 mg/dl) for renal function, grade 3 or 4 aspartate aminotransferase or alanine aminotransferase elevations (>170 U/l) for hepatic function, and grade 3 or 4 phosphorus abnormalities (<1.5 mg/dl). The effectiveness endpoint was infection with HIV-1 or HIV-2.Results: Study participants contributed 428 person-years of laboratory testing to the primary safety analysis. No significant differences emerged between treatment groups in clinical or laboratory safety outcomes. Study participants contributed 476 person-years of HIV testing to the primary effectiveness analysis, during which time eight seroconversions occurred. Two were diagnosed in participants randomized to TDF (0.86 per 100 person-years) and six in participants receiving placebo (2.48 per 100 person-years), yielding a rate ratio of 0.35 (95% confidence interval = 0.03-1.93), which did not achieve statistical significance. Owing to premature closures of the Cameroon and Nigeria study sites, the planned person-years of follow-up and study power could not be achieved.Conclusion: Daily oral use of TDF in HIV-uninfected women was not associated with increased clinical or laboratory adverse events. Effectiveness could not be conclusively evaluated because of the small number of HIV infections observed during the study. Article	2008	Denton, Paul W; Estes, Jacob D; Sun, Zhifeng; Othieno, Florence A; Wei, Bangdong L; Wege, Anja K; Powell, Daniel A; Payne, Deborah; Haase, Ashley T; Garcia, J Victor	Antiretroviral pre-exposure prophylaxis prevents vaginal transmission of HIV-1 in humanized BLT mice.	PLOS Medicine	-	-	-	1549-1676	10.1371/journal.pmed.0050016	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2194746/	BACKGROUND: Worldwide, vaginal transmission now accounts for more than half of newly acquired HIV-1 infections. Despite the urgency to develop and implement novel approaches capable of preventing HIV transmission, this process has been hindered by the lack of adequate small animal models for preclinical efficacy and safety testing. Given the importance of this route of transmission, we investigated the susceptibility of humanized mice to intravaginal HIV-1 infection. METHODS AND FINDINGS: We show that the female reproductive tract of humanized bone marrow-liver-thymus (BLT) mice is reconstituted with human CD4+ T and other relevant human cells, rendering these humanized mice susceptible to intravaginal infection by HIV-1. Effects of HIV-1 infection include CD4+ T cell depletion in gut-associated lymphoid tissue (GALT) that closely mimics what is observed in HIV-1-infected humans. We also show that pre-exposure prophylaxis with antiretroviral drugs is a highly effective method for preventing vaginal HIV-1 transmission. Whereas 88% (7/8) of BLT mice inoculated vaginally with HIV-1 became infected, none of the animals (0/5) given pre-exposure prophylaxis of emtricitabine (FTC)/tenofovir disoproxil fumarate (TDF) showed evidence of infection (Chi square = 7.5, df = 1, p = 0.006). CONCLUSIONS: The fact that humanized BLT mice are susceptible to intravaginal infection makes this system an excellent candidate for preclinical evaluation of both microbicides and pre-exposure prophylactic regimens. The utility of humanized mice to study intravaginal HIV-1 transmission is particularly highlighted by the demonstration that pre-exposure prophylaxis can prevent intravaginal HIV-1 transmission in the BLT mouse model. Article	2008	Gay, Cynthia L; Cohen, Myron S	Antiretrovirals to prevent HIV infection: pre- and postexposure prophylaxis.	Current Infectious Disease Reports	-	-	-	1523-3847	10.1007/s11908-008-0052-5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3567919/	More than 3 million people are now receiving antiretroviral therapy (ART) worldwide. Currently, the indications for ART depend primarily on CD4 count, blood viral burden, and clinical signs and symptoms suggesting advanced HIV disease. However, interest is increasing in ART's preventive potential. Postexposure prophylaxis following both occupational and nonoccupational exposure to HIV is the standard-of-care in many settings. Observational and ecologic studies suggest that ART administered to HIV-infected people reduces transmission within serodiscordant couples. Pre-exposure prophylaxis to prevent HIV infection is a potentially safe and intermittent intervention for very high-risk people, and clinical trials to evaluate this preventive strategy are underway. The prevention benefits of ART may begin to affect the decision of when to start therapy and add a much-needed strategy to current HIV prevention efforts. Article	2008	Guest, Greg; Shattuck, Dominick; Johnson, Laura; Akumatey, Betty; Clarke, Edith Essie Kekawo; Chen, Pai-Lien; MacQueen, Kathleen M	Changes in sexual risk behavior among participants in a PrEP HIV prevention trial.	Sexually Transmitted Diseases	-	-	-	1537-4521	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-19051397	BACKGROUND: One of the concerns raised regarding the introduction of any new HIV-prevention measure, such as PrEP, is the potential for risk disinhibition or sexual risk compensation. The oral tenofovir HIV prevention trial has been the subject of international discussion in this regard. METHODS: This article maps the changes in sexual risk behavior among women participating in the oral tenofovir HIV prevention trial in Ghana. Content-driven, thematic analysis was carried out on qualitative data obtained from in-depth interviews with study participants. Growth curve analysis was the primary method used to document trends over time in self-reported sexual behavior collected monthly. RESULTS: Overall, the study found that sexual risk behavior did not increase during the trial. Number of sexual partners and rate of unprotected sex acts decreased across the 12-month period of study enrollment. Certain subgroups of women, however, exhibited different growth curves. Data indicate that the HIV prevention counseling associated with the trial was effective. CONCLUSIONS: Counseling during the trial was effective. Different types of counseling and messaging may be needed for different subgroups within a population. These findings also have implications for required sample sizes for future HIV prevention trials where seroconversion is the main outcome. Article	2008	Klasse, Per Johan; Shattock, Robin; Moore, John P.	Antiretroviral Drug–Based Microbicides to Prevent HIV-1 Sexual Transmission	Annual Review of Medicine	-	-	-	0066-4219	10.1146/annurev.med.59.061206.112737	https://doi.org/10.1146/annurev.med.59.061206.112737	The development of a vaginal (and perhaps a rectal) microbicide would be of major benefit for slowing the global spread of human immunodeficiency virus type 1 (HIV-1). A microbicide is a gel or related device that, when inserted vaginally or rectally, acts to prevent infection of a woman or a man by HIV-1 during sexual intercourse. A practical microbicide must be not only effective, safe, and user-friendly but also economically affordable in the developing world. To date, the performance of microbicide candidates in efficacy trials has been disappointing, but next-generation concepts now in or approaching clinical trials offer improved prospects for efficacy. The most plausible approaches involve topical application of antiretroviral agents with specific activity against HIV-1, compounds similar to drugs used to treat HIV-1 infection. How these inhibitors are applied may also be critical, with sustained-release formulations and vaginal ring delivery systems now becoming a high priority.	entry inhibitors, reverse transcriptase inhibitors, sustained-release formulations, topical application, vaginal rings	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2008	Liu, Albert Y; Kittredge, Pravina V; Vittinghoff, Eric; Raymond, H Fisher; Ahrens, Katherine; Matheson, Tim; Hecht, Jennifer; Klausner, Jeffrey D; Buchbinder, Susan P	Limited knowledge and use of HIV post- and pre-exposure prophylaxis among gay and bisexual men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-18340656	BACKGROUND: Post-exposure prophylaxis (PEP) is currently recommended after certain high-risk exposures, and pre-exposure prophylaxis (PrEP) is undergoing evaluation in clinical trials. Media reports have suggested substantial levels of community PrEP use despite its unproven effectiveness. METHODS: We conducted a cross-sectional survey of 1819 HIV-uninfected gay/bisexual men in California to assess PEP and PrEP awareness and use. RESULTS: Overall, 47% reported PEP awareness and 4% ever used PEP. Men who were older than 25 years of age (odds ratio OR = 2.2, 95% confidence interval CI: 1.5 to 3.1), were white (OR = 2.2, 95% CI: 1.6 to 3.0), had an annual income >$100,000 (OR = 2.0, 95% CI: 1.2 to 3.4), self-identified as gay/homosexual (OR = 2.4, 95% CI: 1.4 to 4.3), and had unprotected anal sex (OR = 1.8, 95% CI: 1.3 to 2.3) or sex under the influence of a drug (OR = 2.0, 95% CI: 1.5 to 2.7) were more likely to be aware of PEP, whereas speed users (OR = 0.6, 95% CI: 0.4 to 0.9) were less likely to be aware of PEP. Only 16% reported PrEP awareness, and <1% ever used PrEP. Unprotected anal sex (OR = 1.6, 95% CI: 1.1 to 2.3) and sex under the influence of a drug (OR = 1.5, 95% CI: 1.0 to 2.2) were associated with PrEP awareness. CONCLUSIONS: PEP awareness and use were modest and PrEP use was rare among gay/bisexual men in California. Although PrEP is not currently recommended, community education on the availability of PEP is suggested. Article	2008	Nodin, N.; Carballo-Diéguez, A.; Ventuneac, A. M.; Balan, I. C.; Remien, R.	Knowledge and acceptability of alternative HIV prevention bio-medical products among MSM who bareback.	AIDS Care	-	-	-	0954-0121	10.1080/09540120701449096	https://pubmed.ncbi.nlm.nih.gov/18278621/	Condom use is the best available strategy to prevent HIV infection during sexual intercourse. However, since many people choose not to use condoms in circumstances in which HIV risk exists, alternatives to condom use for HIV prevention are needed. Currently there are several alternative bio-medical HIV-prevention products in different stages of development: microbicides, vaccines, post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP). Seventy-two men who have sex with men (MSM) who took part in a study on Internet use and intentional condomless anal intercourse were asked about these four products during a semi-structured interview. The questions explored knowledge and acceptability of all the products and willingness to participate in microbicide and vaccine trials. Qualitative analysis of the data suggests that these men had virtually no knowledge of PrEP, very limited knowledge of microbicides, some information about PEP and considerably more knowledge about vaccines. Reactions towards the products were generally positive except for PrEP, for which reactions were polarized as either enthusiastic or negative. With the exception of PrEP, many men expressed willingness to use the products in the future. Most men would be willing to participate in trials for microbicides and vaccines if given basic reassurances. Concerns over negative side effects and preoccupation with possible infection were some of the motives given for non-willingness to participate in a vaccine trial. These results should inform the development of future trials of biomedical prevention products. Article	2008	Selemogo, Mpho	HIV pre-exposure prophylaxis trials: socio-economic and ethical perspectives for sub-Saharan Africa.	African Journal of AIDS Research	-	-	-	1608-5906	10.2989/AJAR.2008.7.2.10.527	https://dx.doi.org/10.2989/AJAR.2008.7.2.10.527	The advent of HIV pre-exposure prophylaxis (PrEP) as a HIV-prevention strategy has received optimistic support among HIV researchers. However, discourse on PrEP trials has tended to be dominated by the disputes arising between some activist groups and researchers about the research methodologies. Instead, this paper discusses other issues oftentimes neglected in discussions relating to PrEP trials. Specifically, I focus on the possible ethical implications and the potential impact of sub-Saharan Africa's socio-economic conditions on the promised benefits of PrEP trials for the region and the continent. I argue that the concept of PrEP as a affordable and practical HIV-prevention intervention presents challenges and questions that urgently need addressing as we await results from several ongoing trials. If research is undertaken with no plans on how the results of specific trials can render actual HIV-prevention-benefits - especially for the world's poor - then such endeavours risk being merely information-acquiring ventures. Article	2008	Vissers, Debby C J; Voeten, Hélène A C M; Nagelkerke, Nico J D; Habbema, J Dik F; de Vlas, Sake J	The impact of pre-exposure prophylaxis (PrEP) on HIV epidemics in Africa and India: a simulation study.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0002077	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2367053/	BACKGROUND: Pre-exposure prophylaxis (PrEP) is a promising new HIV prevention method, especially for women. An urgent demand for implementation of PrEP is expected at the moment efficacy has been demonstrated in clinical trials. We explored the long-term impact of PrEP on HIV transmission in different HIV epidemics. METHODOLOGY/PRINCIPAL FINDINGS: We used a mathematical model that distinguishes the general population, sex workers and their clients. PrEP scenarios varying in effectiveness, coverage and target group were modeled in the epidemiological settings of Botswana, Nyanza Province in Kenya, and Southern India. We also studied the effect of condom addition or condom substitution during PrEP use. Main outcome was number of HIV infections averted over ten years of PrEP use. PrEP strategies with high effectiveness and high coverage can have a substantial impact in African settings. In Southern India, by contrast, the number of averted HIV infections in different PrEP scenarios would be much lower. The impact of PrEP may be strongly diminished or even reversed by behavioral disinhibition, especially in scenarios with low coverage and low effectiveness. However, additional condom use during low coverage and low effective PrEP doubled the amount of averted HIV infections. CONCLUSIONS/SIGNIFICANCE: The public health impact of PrEP can be substantial. However, this impact may be diminished, or even reversed, by changes in risk behavior. Implementation of PrEP strategies should therefore come on top of current condom campaigns, not as a substitution. Article	2009	Clauson, Kevin A; Polen, Hyla H; Joseph, Shine A; Zapantis, Antonia	Role of the pharmacist in pre-exposure chemoprophylaxis (PrEP) therapyfor HIV prevention	Pharmacy Practice	-	-	-	1886-3655	NA	https://scielo.isciii.es/scielo.php?pid=S1885-642X2009000100002&script=sci_abstract&tlng=en	With a global estimate of 2.5 million new infections of HIV occurring yearly, discovering novel methods to help stem the spread of the virus is critical. The use of antiretroviral chemoprophylaxis for preventing HIV after accidental or occupational exposure and in maternal to fetal transmission has become a widely accepted method to combat HIV. Based on this success, pre-exposure chemoprophylaxis (PrEP) is being explored in at-risk patient populations such as injecting drug users, female sex workers and men who have sex with men. This off-label and unmonitored use has created a need for education and intervention by pharmacists and other healthcare professionals. Pharmacists should educate themselves on PrEP and be prepared to counsel patients about their means of obtaining it (e.g. borrowing or sharing medications and ordering from disreputable Internet pharmacies). They should also be proactive about medication therapy management in these patients due to clinically important drug interactions with PrEP medications. Only one trial exploring the safety and efficacy of tenofovir as PrEP has been completed thus far. However, five ongoing trials are in various stages and two additional studies are scheduled for the near future. Unfortunately, studies in this arena have met with many challenges that have threatened to derail progress. Ethical controversy surrounding post-trial care of participants who seroconvert during studies, as well as concerns over emerging viral resistance and logistical site problems, have already halted several PrEP trials. Information about these early trials has already filtered down to affected individuals who are experimenting with this unproven therapy as an 'evening before pill'. The potential for PrEP is promising; however, more extensive trials are necessary to establish its safety and efficacy. Pharmacists are well-positioned to play a key role in helping patients make choices about PrEP, managing their therapy, and developing policy with an eye towards the future (AU)	Acquired Immunodeficiency Syndrome; Chemoprevention; United States. Article	2009	Mimiaga, Matthew J; Case, Patricia; Johnson, Carey V; Safren, Steven A; Mayer, Kenneth H	Preexposure antiretroviral prophylaxis attitudes in high-risk Boston area men who report having sex with men: limited knowledge and experience but potential for increased utilization after education.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	10.1097/QAI.0b013e31818d5a27	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2659469/	BACKGROUND: Preexposure prophylaxis (PrEP) could protect individuals engaging in repeated high-risk behaviors from HIV infection. Understanding the demographic and behavioral predictors of intent-to-use PrEP may prove useful to identify clinical trial participants. METHODS: In 2007, 227 HIV-uninfected men who report having sex with men (MSM) recruited through modified respondent-driven sampling completed an interviewer-administered survey assessing prior PrEP use and awareness, future intent-to-use PrEP, demographics, sexual risk, psychosocial variables, and drug/alcohol use. Bivariate and multivariable logistic regression procedures examined predictors of intent-to-use PrEP. RESULTS: Mean age of participants was 41 (SD = 9.1); 54% were nonwhite. One participant reported prior off-label PrEP use (medication obtained from his HIV-infected brother). Nineteen percent had heard of PrEP, whereas 74% reported intent-to-use PrEP if available after being educated about its potential. In multivariable analysis controlling for age and race/ethnicity, significant predictors of intent-to-use PrEP included the following: less education odds ratio (OR) = 7.7; P = 0.04, moderate income (OR = 13.0; P = 0.04), no perceived side effects from taking PrEP (OR = 3.5; P = 0.001), and not having to pay for PrEP (OR = 4.2; P = 0.05). DISCUSSION: Many New England MSM indicated an interest in using PrEP after learning about its potential, particularly if they could obtain PrEP at no expense and if PrEP had no side effects. Less educated MSM and those who knew less about PrEP and antiretroviral therapy before entering the study were more open to using antiretroviral therapy for prevention once they had received some information suggesting its potential value. Findings suggest that careful educational messages are necessary to ensure appropriate PrEP use if clinical trials reveal partial efficacy. Article	2009	Paltiel, A David; Freedberg, Kenneth A; Scott, Callie A; Schackman, Bruce R; Losina, Elena; Wang, Bingxia; Seage, George R; Sloan, Caroline E; Sax, Paul E; Walensky, Rochelle P	HIV preexposure prophylaxis in the United States: impact on lifetime infection risk, clinical outcomes, and cost-effectiveness.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1086/597095	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2876329/	BACKGROUND: The combination of tenofovir and emtricitabine shows promise as HIV preexposure prophylaxis (PrEP). We sought to forecast clinical, epidemiologic, and economic outcomes of PrEP, taking into account uncertainties regarding efficacy, the risks of developing drug resistance and toxicity, behavioral disinhibition, and drug costs. METHODS: We adapted a computer simulation of HIV acquisition, detection, and care to model PrEP among men who have sex with men at high risk of HIV infection (i.e., 1.6% mean annual incidence of HIV infection) in the United States. Base-case assumptions included 50% PrEP efficacy and monthly tenofovir-emtricitabine costs of $753. We used sensitivity analyses to examine the stability of results and to identify critical input parameters. RESULTS: In a cohort with a mean age of 34 years, PrEP reduced lifetime HIV infection risk from 44% to 25% and increased mean life expectancy from 39.9 to 40.7 years (21.7 to 22.2 discounted quality-adjusted life-years). Discounted mean lifetime treatment costs increased from $81,100 to $232,700 per person, indicating an incremental cost-effectiveness ratio of $298,000 per quality-adjusted life-year gained. Markedly larger reductions in lifetime infection risk (from 44% to 6%) were observed with the assumption of greater (90%) PrEP efficacy. More-favorable incremental cost-effectiveness ratios were obtained by targeting younger populations with a higher incidence of infection and by improvements in the efficacy and cost of PrEP. CONCLUSIONS: PrEP could substantially reduce the incidence of HIV transmission in populations at high risk of HIV infection in the United States. Although it is unlikely to confer sufficient benefits to justify the current costs of tenofovir-emtricitabine, price reductions and/or increases in efficacy could make PrEP a cost-effective option in younger populations or populations at higher risk of infection. Given recent disappointments in HIV infection prevention and vaccine development, additional study of PrEP-based HIV prevention is warranted. Article	2009	Reuter, S; Meyer, D; Knechten, H; Oette, M; Mitrenga, D; Rockstroh, J; Fätkenheuer, G; Häussinger, D	Pre-exposure prophylaxis in HIV--a vision or soon a reality?	Deutsche Medizinische Wochenschrift	-	-	-	1439-4413	10.1055/s-0029-1243064	https://dx.doi.org/10.1055/s-0029-1243064	Condom use is propagated as the most efficient measure to prevent HIV-transmission. For several reasons, condoms are NOT ALWAYS used or misapplied during sexual intercourse. Therefore, alternative preventive measures through intake of antiretroviral drugs before sexual intercourse with a (presumably) HIV-positive person are being considered, so called Pre-Exposure Prophylaxis (PrEP). In animal models the efficacy of HIV-PrEP was shown for Tenofovir alone or in combination with Emtricitabine). Several clinical studies are currently being conducted in different HIV-risk groups on various continents. First results from these studies are anticipated for the year 2010. In case of proven efficacy for HIV-PrEP, our health system would face a large interdisciplinary challenge. It would be a difficult task to define the appropriate recipients. Measures would have to be taken to limit possible misuse of antiretroviral drugs, due to the negative consequences with development of resistance, adverse events and illegal trading. It is already evident that HIV-PrEP will not provide absolute protection, nor will it replace other preventive strategies. However, if used cautiously, HIV-PrEP might be established as a useful supplement in the prevention of HIV. Paramount questions from the fields of epidemiology, behavioural science, logistics, health politics and ethics should be answered in advance. Article	2009	Rosengarten, Marsha; Michael, Mike	The performative function of expectations in translating treatment to prevention: the case of HIV pre-exposure prophylaxis, or PrEP.	Social Science & Medicine	-	-	-	1873-5347	10.1016/j.socscimed.2009.07.039	https://dx.doi.org/10.1016/j.socscimed.2009.07.039	This paper is about expectations of oral PrEP, 'a pill a day' HIV pre-exposure prophylaxis that could be the first systemic form of HIV prevention for sexual or needle stick exposures. If found safe and effective--a difficult criteria to establish and, as such, is central to this paper--PrEP has the potential to significantly alter HIV prevention, well ahead of a vaccine or topical microbicide. Hence, despite uncertainty about PrEP's viability, the potential significance of its impact on the HIV field requires early planning. In order to address this potentiality, we use a methodological approach drawn from the sociology of expectations to examine interviews with United States-based scientific stakeholders in the trialing of PrEP. We identify how PrEP is anticipated as both stable object and process involving multiple contingencies. These divergent conceptions enable us to illuminate a range of social, cultural, ethical, pharmaceutical and medical possibilities understood to potentially arise with PrEP. Further, they lead us to propose that the multiple contingencies that enact PrEP as an emergent entity offer scope for rethinking PrEP and, more broadly, the challenges of HIV prevention. Article	2009	Sarazin, V; Milsom, P	Potential synergies between HIV vaccines, microbicides and pre-exposure prophylaxis	Retrovirology	-	-	-	1742-4690	10.1186/1742-4690-6-S3-P223	https://retrovirology.biomedcentral.com/articles/10.1186/1742-4690-6-S3-P223	Background The Canadian HIV Vaccine Initiative (CHVI) is a five-year initiative between the Government of Canada and the Bill & Melinda Gates Foundation, and represents a significant Canadian contribution to the Global HIV Vaccine Enterprise. The CHVI is part of Canada's long-term and comprehensive approach to addressing HIV/AIDS at home and abroad, including the development of new prevention technologies (NPTs). In support of this, the CHVI explored the close relationship between HIV vaccines, microbicides and pre-exposure prophylaxis (PrEP). Methods A discussion paper was commissioned to identify potential linkages and opportunities for collaborative efforts among the three NPTs in the context of the CHVI's four program areas: discovery and social research; clinical trial capacity building and networks; pilot-scale manufacturing facility for clinical trial lots; policy and regulatory issues, and; community and social dimensions. Information was gathered through document review of academic and grey literature. Results There are many common issues/challenges to advancing the development of new NPTs and significant opportunities for collaborative efforts among these NPT fields, including sustainability of funding and clinical trial capacity. The report also noted the importance of positioning HIV vaccines as part of an overall prevention strategy, and that taking advantage of synergies between NPTs could provide the best opportunity to advance the NPT development agenda. Conclusion It is not known which technology will be available first or the timelines for availability. However, it is increasingly recognized by Canadian and global HIV stakeholders that NPTs need to be part of a comprehensive HIV prevention agenda to increase the chances of successfully responding to the HIV/AIDS epidemic in the future. Canada has recognized the importance of including NPTs in a broad HIV prevention framework currently in development. Article	2009	van de Vijver, David A M C; Derdelinckx, Inge; Boucher, Charles A B	Circulating HIV type 1 drug resistance will have limited impact on the effectiveness of preexposure prophylaxis among young women in Zimbabwe.	Journal of Infectious Diseases	-	-	-	0022-1899	10.1086/597804	https://dx.doi.org/10.1086/597804	BACKGROUND: Preexposure prophylaxis (PrEP) with antiretroviral drugs may prevent transmission of human immunodeficiency virus (HIV). Our objective was to predict whether PrEP, in the presence of circulating drug resistance, will reduce the risk of infection with HIV. METHODS: We used risk equations to calculate the monthly risk of infection with HIV before and after the introduction of PrEP. Uncertainty and sensitivity analyses were performed for 2 ranges of PrEP effectiveness (40%-60% and 60%-80%). Circulating drug resistance was assumed to reduce the effectiveness of PrEP by 50%-90% and the transmissibility of HIV by 0%-30%. Parameter ranges were chosen for women 17-29 years of age from publications on HIV in Manicaland in Zimbabwe. RESULTS: PrEP would decrease the median risk of HIV transmission by 21%-33% (effectiveness of PrEP, 40%-60% and 60%-80%). If 50% of HIV strains are drug resistant, then the median risk reduction would be 19%-26% if drug-resistant strains were less transmissible than wild-type HIV and 12%-19% if they were equally transmissible. The risk would increase if condoms were frequently replaced with PrEP. Use of PrEP for sexual acts for which no protection is currently used would be beneficial. CONCLUSION: The public health impact of PrEP will depend on its effectiveness and on risk behavior. Circulating drug resistance will have only a small impact on the effectiveness of PrEP.	hivdrug resistancezimbabwehiv infectionsrisk reductionpre-exposure prophylaxis	English	United States	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Quantitative

Article	2010	Adams, MA; Smith, D	Attitudes and Program Preferences Regarding Preexposure Prophylaxis (PrEP) Among Young Adults at Risk for HIV	International Journal of Qualitative Methods	-	-	-	1609-4069	10.1521/aeap.2012.24.5.408	https://pubmed.ncbi.nlm.nih.gov/23016502/	We elicited attitudes about, and service access preferences for, daily oral antiretroviral pre-exposure prophylaxis (PrEP) from urban, African-American young men and women, ages 18-24 years, at risk for HIV transmission through their sexual and drug-related behaviors participating in eight mixed-gender and two MSM-only focus groups in Atlanta, Georgia. Participants reported substantial interest in PrEP associated with its perceived cost, effectiveness, and ease of accessing services and medication near to their homes or by public transportation. Frequent HIV testing was a perceived benefit. Participants differed about whether risk-reduction behaviors would change, and in which direction; and whether PrEP use would be associated with HIV stigma or would enhance the reputation for PrEP users. This provides the first information about the interests, concerns, and preferences of young adult African Americans that can be used to inform the introduction of PrEP services into HIV prevention efforts for this critical population group. Article	2010	Charurat, Man; Oyegunle, Modupe; Benjamin, Renata; Habib, Abdulrazaq; Eze, Emeka; Ele, Prince; Ibanga, Iquo; Ajayi, Samuel; Eng, Maria; Mondal, Prosanta; Gebi, Usman; Iwu, Emilia; Etiebet, Mary-Ann; Abimiku, Alash'le; Dakum, Patrick; Farley, John; Blattner, William	Patient retention and adherence to antiretrovirals in a large antiretroviral therapy program in Nigeria: a longitudinal analysis for risk factors.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0010584	https://pmc.ncbi.nlm.nih.gov/articles/PMC2868044/	BACKGROUND: Substantial resources and patient commitment are required to successfully scale-up antiretroviral therapy (ART) and provide appropriate HIV management in resource-limited settings. We used pharmacy refill records to evaluate risk factors for loss to follow-up (LTFU) and non-adherence to ART in a large treatment cohort in Nigeria. METHODS AND FINDINGS: We reviewed clinic records of adult patients initiating ART between March 2005 and July 2006 at five health facilities. Patients were classified as LTFU if they did not return >60 days from their expected visit. Pharmacy refill rates were calculated and used to assess non-adherence. We identified risk factors associated with LTFU and non-adherence using Cox and Generalized Estimating Equation (GEE) regressions, respectively. Of 5,760 patients initiating ART, 26% were LTFU. Female gender (p < 0.001), post-secondary education (p = 0.03), and initiating treatment with zidovudine-containing (p = 0.004) or tenofovir-containing (p = 0.05) regimens were associated with decreased risk of LTFU, while patients with only primary education (p = 0.02) and those with baseline CD4 counts (cell/ml(3)) >350 and <100 were at a higher risk of LTFU compared to patients with baseline CD4 counts of 100-200. The adjusted GEE analysis showed that patients aged <35 years (p = 0.005), who traveled for >2 hours to the clinic (p = 0.03), had total ART duration of >6 months (p<0.001), and CD4 counts >200 at ART initiation were at a higher risk of non-adherence. Patients who disclosed their HIV status to spouse/family (p = 0.01) and were treated with tenofovir-containing regimens (p < or = 0.001) were more likely to be adherent. CONCLUSIONS: These findings formed the basis for implementing multiple pre-treatment visit preparation that promote disclosure and active community outreaching to support retention and adherence. Expansion of treatment access points of care to communities to diminish travel time may have a positive impact on adherence. Article	2010	Chirenje, Z Mike; Marrazzo, Jeanne; Parikh, Urvi M	Antiretroviral-based HIV prevention strategies for women.	Expert Review of Anti-Infective Therapy	-	-	-	1744-8336	10.1586/eri.10.79	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4381115	Almost three decades have elapsed since researchers identified HIV as the cause of AIDS, with current estimates from UNAIDS that 33.4 million adults were living with HIV/AIDS in 2008. Two-thirds of this burden of disease is in Sub-Saharan Africa, and 60% of those infected are women. The disease still remains incurable and current prevention strategies including abstinence, male/female condom use and male circumcision are only partially effective. New strategies to curb the epidemic are urgently needed. Scientists are diligently exploring HIV prevention methods that are safe, effective and affordable. These new biological interventions include oral pre-exposure prophylaxis using oral antiretroviral (ARV) drugs, ARV treatment in HIV-infected persons to reduce transmission and topical ARV-based microbicide formulations.	antiretroviral agents, biological plausibility, chemoprophylaxis, post-exposure prophylaxis, pre-exposure prophylaxis, topical microbicides	English	United Kingdom	Western and Central Europe and North America	Zimbabwe	Eastern and Southern Africa	Zimbabwe	Eastern and Southern Africa	Review
Article	2010	Denton, Paul W; Krisko, John F; Powell, Daniel A; Mathias, Melissa; Kwak, Youn Tae; Martinez-Torres, Francisco; Zou, Wei; Payne, Deborah A; Estes, Jacob D; Garcia, J Victor	Systemic administration of antiretrovirals prior to exposure prevents rectal and intravenous HIV-1 transmission in humanized BLT mice.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0008829	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2809117	Successful antiretroviral pre-exposure prophylaxis (PrEP) for mucosal and intravenous HIV-1 transmission could reduce new infections among targeted high-risk populations including discordant couples, injection drug users, high-risk women and men who have sex with men. Targeted antiretroviral PrEP could be particularly effective at slowing the spread of HIV-1 if a single antiretroviral combination were found to be broadly protective across multiple routes of transmission. Therefore, we designed our in vivo preclinical study to systematically investigate whether rectal and intravenous HIV-1 transmission can be blocked by antiretrovirals administered systemically prior to HIV-1 exposure. We performed these studies using a highly relevant in vivo model of mucosal HIV-1 transmission, humanized Bone marrow/Liver/Thymus mice (BLT). BLT mice are susceptible to HIV-1 infection via three major physiological routes of viral transmission: vaginal, rectal and intravenous. Our results show that BLT mice given systemic antiretroviral PrEP are efficiently protected from HIV-1 infection regardless of the route of exposure. Specifically, systemic antiretroviral PrEP with emtricitabine and tenofovir disoproxil fumarate prevented both rectal (Chi square = 8.6, df = 1, p = 0.003) and intravenous (Chi square = 13, df = 1, p = 0.0003) HIV-1 transmission. Our results indicate that antiretroviral PrEP has the potential to be broadly effective at preventing new rectal or intravenous HIV transmissions in targeted high risk individuals. These in vivo preclinical findings provide strong experimental evidence supporting the potential clinical implementation of antiretroviral based pre-exposure prophylactic measures to prevent the spread of HIV/AIDS.	animal model; ART treatment; global strategies; HIV pandemic; prevention; vaccine development; RHESUS MACAQUES; ANTIRETROVIRAL THERAPY; PREEXPOSURE PROPHYLAXIS; DOUBLE-BLIND; HUMANIZED BLT MICE; INJECTION-DRUG USERS; NEUTRALIZING ANTIBODIES; EFFECTIVE HIV VACCINE; HISTONE DEACETYLASE INHIBITORS; STRUCTURE-BASED DESIGN	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2010	Frew, Paula M.; Archibald, Matthew; Diallo, Dazon Dixon; Hou, Su-I.; Horton, Takeia; Chan, Kayshin; Mulligan, Mark J.; del Rio, Carlos	An extended model of reasoned action to understand the influence of individual- and network-level factors on African Americans' participation in HIV vaccine research.	Prevention Science	-	-	-	1573-6695 1389-4986	10.1007/s11121-009-0162-9	https://pubmed.ncbi.nlm.nih.gov/20012200/	In the United States, the number and proportion of HIV/AIDS cases among black/African Americans continue to highlight the need for new biomedical prevention interventions, including an HIV vaccine, microbicide, or new antiretroviral (ARV) prevention strategies such as pre-exposure prophylaxis (PrEP) to complement existing condom usage, harm reduction methods, and behavioral change strategies to stem the HIV epidemic. Although black/African Americans are disproportionately impacted by HIV/AIDS, their participation in HIV clinical research continues to have unique challenges. We theorize that interaction among multilevel factors creates ideal alignment for minority participation in HIV clinical studies. Thus, we initially set out to test an extended model of reasoned action with 362 participants to understand the interplay of sociopsychological and network-level considerations influencing minority participation in HIV prevention research efforts. In this study, we linked the intrapersonal dimensions of attitudes, beliefs, and normative concerns to community-level components, appraisal of involvement with the clinical research organization, an entity which operates within a networked structure of community partner agencies, and identification with coalition advocacy aims. Various participatory outcomes were explored including involvement in future HIV vaccine community functions, participation in community promotion of HIV vaccine research, and community mobilization. Three-stage least squares estimates indicated similar findings across three models. Significant effects demonstrate the importance of positive attitudes toward HIV vaccine research, favorable health research beliefs, perceived social support for participation, HIV/AIDS issue engagement, and perceived relevance of the clinical research site's mission and values. Identification of these nuanced pathway effects provides implications for tailored community program development. Article	2010	García-Lerma, J Gerardo; Cong, Mian-er; Mitchell, James; Youngpairoj, Ae S; Zheng, Qi; Masciotra, Silvina; Martin, Amy; Kuklenyik, Zsuzsanna; Holder, Angela; Lipscomb, Jonathan; Pau, Chou-Pong; Barr, John R; Hanson, Debra L; Otten, Ron; Paxton, Lynn; Folks, Thomas M; Heneine, Walid	Intermittent prophylaxis with oral truvada protects macaques from rectal SHIV infection.	Science Translational Medicine	-	-	-	1946-6242	10.1126/scitranslmed.3000391	https://dx.doi.org/10.1126/scitranslmed.3000391	HIV continues to spread globally, mainly through sexual contact. Despite advances in treatment and care, preventing transmission with vaccines or microbicides has proven difficult. A promising strategy to avoid transmission is prophylactic treatment with antiretroviral drugs before exposure to HIV. Clinical trials evaluating the efficacy of daily treatment with the reverse transcriptase inhibitors tenofovir disoproxil fumarate (TDF) or Truvada (TDF plus emtricitabine) are under way. We hypothesized that intermittent prophylactic treatment with long-acting antiviral drugs would be as effective as daily dosing in blocking the earliest stages of viral replication and preventing mucosal transmission. We tested this hypothesis by intermittently giving prophylactic Truvada to macaque monkeys and then exposing them rectally to simian-human immunodeficiency virus (SHIV) once a week for 14 weeks. A simple regimen with an oral dose of Truvada given 1, 3, or 7 days before exposure followed by a second dose 2 hours after exposure was as protective as daily drug administration, possibly because of the long intracellular persistence of the drugs. In addition, a two-dose regimen initiated 2 hours before or after virus exposure was effective, and full protection was obtained by doubling the Truvada concentration in both doses. We saw no protection if the first dose was delayed until 24 hours after exposure, underscoring the importance of blocking initial replication in the mucosa. Our results show that intermittent prophylactic treatment with an antiviral drug can be highly effective in preventing SHIV infection, with a wide window of protection. They strengthen the possibility of developing feasible, cost-effective strategies to prevent HIV transmission in humans. Article	2010	García-Lerma, J Gerardo; Paxton, Lynn; Kilmarx, Peter H; Heneine, Walid	Oral pre-exposure prophylaxis for HIV prevention.	Trends in Pharmacological Sciences	-	-	-	1873-3735	10.1016/j.tips.2009.10.009	https://pubmed.ncbi.nlm.nih.gov/19963288/	In the absence of an effective vaccine, HIV continues to spread worldwide, emphasizing the need for new biomedical interventions to limit its transmission. Appreciation of the challenges that HIV has to face to initiate an infection mucosally has spurred interest in evaluating the use of antiretroviral drugs to prevent infection. Recent animal studies using macaques or humanized mice models of mucosal transmission of SIV or HIV have shown that daily or intermittent pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) can exploit early virus vulnerabilities and effectively prevent establishment of infection. These preclinical findings have fueled interest in evaluating the safety and efficacy of PrEP in humans. We provide an overview of the rationale behind PrEP and discuss the next steps in PrEP research, including the need to better define the ability of current drugs to reach and accumulate in mucosal tissues and protect cells that are primary targets during early HIV infection. Article	2010	Golub, Sarit A; Kowalczyk, William; Weinberger, Corina L; Parsons, Jeffrey T	Preexposure prophylaxis and predicted condom use among high-risk men who have sex with men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0b013e3181e19a54	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2908204	OBJECTIVES: Preexposure prophylaxis (PREP) is an emerging HIV prevention strategy; however, many fear it may lead to neglect of traditional risk reduction practices through behavioral disinhibition or risk compensation. METHODS: Participants were 180 HIV-negative high-risk men who have sex with men recruited in New York City, who completed an Audio Computer Assisted Self Interview-administered survey between September 2007 and July 2009. Bivariate and multivariate logistic regression models were used to predict intention to use PREP and perceptions that PREP would decrease condom use. RESULTS: Almost 70% (n = 124) of participants reported that they would be likely to use PREP if it were at least 80% effective in preventing HIV. Of those who would use PREP, over 35% reported that they would be likely to decrease condom use while on PREP. In multivariate analyses, arousal/pleasure barriers to condom use significantly predicted likelihood of PREP use (odds ratio = 1.71, P < 0.05) and risk perception motivations for condom use significantly predicted decreased condom use on PREP (odds ratio = 2.48, P < 0.05). DISCUSSION: These data provide support for both behavioral disinhibition and risk compensation models and underscore the importance of developing behavioral interventions to accompany any wide-scale provision of PREP to high-risk populations. Article	2010	Golub, Sarit A; Operario, Don; Gorbach, Pamina M	Pre-exposure prophylaxis state of the science: empirical analogies for research and implementation.	Current HIV/AIDS Reports	-	-	-	1548-3576	10.1007/s11904-010-0057-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2938422	Pre-exposure prophylaxis (PrEP) has the potential to become a powerful biomedical approach to HIV prevention; however, its success depends on behavioral and social factors that may determine its appropriate use. This article is designed to facilitate interdisciplinary empirical analogies relevant to PrEP implementation, reviewing behavioral and social science findings that may provide lessons critical to the success of PrEP as a biomedical-behavioral prevention strategy. As we prepare for the dissemination of new biomedical approaches to HIV prevention, integrating the state of the science across disciplines may result in innovative strategies for implementation that can enhance their success. Article	2010	Grant, RM; Lama, JR; Anderson, PL; McMahan, V; Liu, AY; Vargas, L; Goicochea, P; Casapía, M; Guanira-Carranza, JV; Ramirez-Cardich, ME; Montoya-Herrera, O; Fernández, T; Veloso, VG; Buchbinder, SP; Chariyalertsak, S; Schechter, M; Bekker, LG; Mayer, KH; Kallás, EG; Amico, KR; Mulligan, K; Bushman, LR; Hance, RJ; Ganoza, C; Defechereux, P; Postle, B; Wang, FR; McConnell, JJ; Zheng, JH; Lee, J; Rooney, JF; Jaffe, HS; Martinez, AI; Burns, DN; Glidden, DV; iPrEx Study Team	Preexposure Chemoprophylaxis for HIV Prevention in Men Who Have Sex with Men.	New England Journal of Medicine	-	-	-	0028-4793	10.1056/NEJMoa1011205	https://pubmed.ncbi.nlm.nih.gov/21091279/	Background: Antiretroviral chemoprophylaxis before exposure is a promising approach for the prevention of human immunodeficiency virus (HIV) acquisition. Methods: We randomly assigned 2499 HIV-seronegative men or transgender women who have sex with men to receive a combination of two oral antiretroviral drugs, emtricitabine and tenofovir disoproxil fumarate (FTC-TDF), or placebo once daily. All subjects received HIV testing, risk-reduction counseling, condoms, and management of sexually transmitted infections. Results: The study subjects were followed for 3324 person-years (median, 1.2 years; maximum, 2.8 years). Of these subjects, 10 were found to have been infected with HIV at enrollment, and 100 became infected during follow-up (36 in the FTC-TDF group and 64 in the placebo group), indicating a 44% reduction in the incidence of HIV (95% confidence interval, 15 to 63; P=0.005). In the FTC-TDF group, the study drug was detected in 22 of 43 of seronegative subjects (51%) and in 3 of 34 HIV-infected subjects (9%) (P<0.001). Nausea was reported more frequently during the first 4 weeks in the FTC-TDF group than in the placebo group (P<0.001). The two groups had similar rates of serious adverse events (P=0.57). Conclusions: Oral FTC-TDF provided protection against the acquisition of HIV infection among the subjects. Detectable blood levels strongly correlated with the prophylactic effect. Article	2010	Izzo, I; Albini, L; Calabresi, A; Motta, D; Bellagamba, R; Fezza, R; Narciso, P; Sighinolfi, L; Maggi, P; Foca, E; Mendeni, M; Manili, L; Magoni, M; Carosi, G; Quiros-Roldan, E; Torti, C	A magnifying glass onto renal function and serum lipid evolutions after tenofovir (TDF) and emtricitabine (FTC) in combination with atazanavir/ritonavir (ATV/r) versus efavirenz (EFV) as first-line HAART (the INCA trial)	Journal of the International AIDS Society	-	-	-	NA	NA	https://pmc.ncbi.nlm.nih.gov/articles/PMC3113092/	Background: Measures of glomerular filtration rate (GFR) showed discordant results. CKD-EPI creatinine formula resulted more accurate than other equations in subjects with normal or mildly decreased renal function in the general population and cystatin C could be even a more sensitive measure. As for lipids, lipoprotein subfractions were suggested to be more informative on the cardiovascular risk than the commonly used cholesterol subfractions, with protection conferred especially by HDLp-small (Baker et al. JID 2010). Prospective evaluation of all these markers upon initiation of standard HAART regimens is lacking. We conducted a small, intensive, randomized study in naive HIV-infected patients comparing TDF/FTC+ATV/r versus TDF/FTC+EFV as first-line therapy for these novel markers. Methods: Antiretroviral-naive HIV-infected patients, recruited from 4 centers in Italy (Brescia, Rome, Ferrara, Bari), were randomized to ATV/r or EFV standard doses, in combination with fixed-dose TDF/FTC. Patients had to have creatinine clearance>50 ml/min. Outcome measures included serum creatinine and cystatin C levels and derived eGFRs corrected for body surface area. Lipoprotein particle size and concentration were estimated using an NMR spectroscopy method at Kochen-Hunter Lab, Germany. Results 91 patients were randomized (48 ATV/r, 43 EFV; 80% males; mean age 43 years; 4 patients class C; mean CD4 + 283/mm3, SD: 119/mm3). No significant differences were found between the two arms at baseline, but for some lipids (total cholesterol: mean 173 mg/dL ATV/r vs. 156 mg/dL EFV; p=0.04; HDL-cholesterol: 44 mg/dL vs. 38 mg/dL; p=0.007; HDLp: 36 mg/dL vs. 32 mg/dL; p=0.02). At baseline, a correlation between CKD-EPI creatinine and CKD-EPI cystatin C was found (R2=0.51; p<0.0001). Through CKD-EPI creatinine formula, we detected a significant decrease in eGFR from baseline to week 48 in patients, receiving ATV/r (-4.8233 mL/min/m2; p=0.002) but not in those receiving EFV. Greater GFR reductions were found with CKD-EPI cystatin C than with CKD-EPI creatinine not only in the ATV/r arm up to week 48 (-15.1388 mL/ min/m2; p<0.0001), but also in the EFV arm from baseline to week 24 (-7.2233 mL/min/m2; p=0.04). As for lipids, cholesterol subfractions increased more after EFV than after ATV/r: mean increase from baseline to week 48 was 44.15 mg/dL vs. 15.51; p=0.002 for total cholesterol, 32.4 mg/dL vs. 12.47 mg/dL; p=0.007 for LDL cholesterol, 9.31 mg/dL vs. 2.13 mg/dL; p=0.002 for HDL cholesterol. Total/HDL cholesterol ratio remained stable in both arms. As for lipoprotein subfractions, total HDLp increased more after EFV than after ATV/r (11.97 mg/dL vs. 7.97 mg/dL; p=0.03), but HDLp-small increased significantly in both arms, without statistical differences between the two (1.71 mg/dL vs. 1.86 mg/ dL). Conclusions: Patients receiving TDF in combination with ATV/r had greater decline in renal function than those receiving TDF plus EFV, although eGFR decrease was small in both arms. Interestingly, CKD-EPI cystatin C appeared to be a stricter measure. As for lipids, EFV induced greater LDL cholesterol increases but the risk appeared to be counteracted by greater increase of both HDLcholesterol and HDLp, even though HDLp-small increased similarly in the two arms. We suggest that these novel measures provide additional information so as to better characterize the toxicity profiles of the antiretroviral regimens. Theses and Dissertations	2010	Kandathil, Sonia M.	Women initiated solutions for HIV prevention (WISH study): factors associated with intentions to use microbicides and Tenofovir	-	-	Oregon State University	-	NA	NA	http://hdl.handle.net/1957/15454	With women comprising nearly 50% of HIV/AIDS infections globally, the development of new woman-initiated HIV prevention methods has become a public health imperative. To date, the female condom and the diaphragm are the only woman-initiated prevention methods available on the consumer market. Recent research has focused on two HIV/AIDS prevention technologies undergoing clinical trials: microbicides and tenofovir (PrEP). Both are being touted as female-initiated HIV/AIDS prevention technologies that women can use covertly, without a partner's knowledge, to improve their odds in protecting themselves against HIV. Use of these new technologies will not only depend on their effectiveness, but on women's willingness to use these products. This cross-sectional study used an integrative conceptual model that included both intrapersonal and interpersonal constructs to explore factors associated with women's intentions to use. Three hundred and forty-eight high-risk women in Toronto, Canada completed self-administered questionnaires (SAQs). Results were remarkably consistent across relationship types and prevention methods examined in the study, with 60% of the women intending to use microbicides and tenofovir. Women who perceived themselves to be at greater risk for STIs, had greater microbicide self-efficacy, and more positive perceptions of microbicides were more likely to intend to use microbicides. Women with ≤ grade 12 education, greater sexual and HIV risk, greater tenofovir self-efficacy and more positive perceptions of tenofovir were more likely to intend to use tenofovir. When asked which method they preferred, 66% preferred pre-exposure prophylaxis (PrEP). Women, who had previously used a barrier method for contraception, had greater microbicide self-efficacy and more positive perceptions of microbicides were less likely to prefer tenofovir. Women, who had used hormonal methods for contraception, had greater tenofovir self-efficacy and more positive perceptions of tenofovir were more likely to prefer tenofovir. Findings have important implications including assisting researchers in the development and refinement of these products and consumer analysts in the development of marketing strategies that highlight method attributes women perceive positively. Findings will also help health care providers identify women who would potentially use these products and assist women in developing confidence in their ability to effectively use such methods. Article	2010	Kim, Susan C; Becker, Stephen; Dieffenbach, Carl; Hanewall, Blair S; Hankins, Catherine; Lo, Ying-Ru; Mellors, John W; O'Reilly, Kevin; Paxton, Lynn; Roffenbender, Jason S; Warren, Mitchell; Piot, Peter; Dybul, Mark R	Planning for pre-exposure prophylaxis to prevent HIV transmission: challenges and opportunities.	Journal of the International AIDS Society	-	-	-	1758-2652	10.1186/1758-2652-13-24	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2914050	There are currently several ongoing or planned trials evaluating the efficacy of pre-exposure prophylaxis (PrEP) as a preventative approach to reducing the transmission of HIV. PrEP may prove ineffective, demonstrate partial efficacy, or show high efficacy and have the potential to reduce HIV infection in a significant way. However, in addition to the trial results, it is important that issues related to delivery, implementation and further research are also discussed. As a part of the ongoing discussion, in June 2009, the Bill & Melinda Gates Foundation sponsored a Planning for PrEP conference with stakeholders to review expected trial results, outline responsible educational approaches, and develop potential delivery and implementation strategies. The conference reinforced the need for continued and sustained dialogue to identify where PrEP implementation may fit best within an integrated HIV prevention package. This paper identifies the key action points that emerged from the Planning for PrEP meeting. Theses and Dissertations	2010	Kokolo, Madzouka B	HIV oral pre-exposure prophylaxis (PrEP) trials: A systematic review and systematic ethics appraisal	-	-	University of Ottawa	-	NA	http://dx.doi.org/10.20381/ruor-19385	http://dx.doi.org/10.20381/ruor-19385	BACKGROUND. Pre-exposure prophylaxis (PrEP) is an experimental HIV prevention approach whereby antiretroviral pills are used before anticipated exposure. It is unclear how ethical considerations have been addressed by investigators. METHODS. A systematic review of PrEP controlled prospective studies was conducted. Pre-determined data items were extracted from registries, protocols, reports, and consent forms. Study characteristics, methods, and ethics considerations were synthesized. RESULTS. Among sixteen studies included, twelve involved resource-limited countries. Quality scores were generally high and overall risk of bias was low. Considerations for social value were the least reported whereas considerations for the fair selection of study population were the most reported. More ethics considerations tend to be reported with time. No meta-analysis was performed, as few data were available. CONCLUSION. As critical as clinical data generation is for scientific progress, ethics should be monitored and adequately reported, lest lack of consideration for key principles be uncovered after the facts. Theses and Dissertations	2010	Louissaint, Nicolette Alexandrea	Quantitation of human immunodeficiency virus (HIV) surrogate and tenofovir distribution in the gastrointestinal and female genital tracts	-	-	The Johns Hopkins University	-	NA	NA	http://pqdtopen.proquest.com/#viewpdf?dispub=3410202	Drugs for pre-exposure prophylaxis (PrEP) of HIV infection are being developed as an adjunctive measure to prevent sexual HIV transmission. HIV transmission and drug distribution in both female genital (FGT) and gastrointestinal (GI) tracts must be considered during development, as both vaginal and anal intercourse are critical for transmission. The goal of this dissertation was to determine the distribution of viral surrogates and an anti-HIV drug in the GI and FGT. The distribution of radiolabeled HIV surrogates in areas exposed to HIV after sex was quantified in the distal colon (four men) and the female genital tract (seven women). Both studies used noninvasive imaging and direct mucosal sampling to examine the distribution of radiolabeled HIV surrogates in the lumen and tissues of these compartments. Single-photon emission computed tomography/computed tomography analysis of radiotracer distribution revealed that the surrogates distributed similarly. In the GI, the highest concentration of radioactivity was in the rectosigmoid colon. In the FGT it was the pericervical region. In all tissue biopsies, less than 2% of CD4 cells were radiolabeled. Tenofovir (TFV) was studied first in a single dose study and in a steady-state study in HIV-infected patients, to describe distribution of the drug and its active moiety, tenofovir diphosphate (TFV-DP). In the single dose study, blood and peripheral blood mononuclear cells (PBMCs) were collected post-dosing and analyzed for drug. Data analysis reveals a C_{max} of 60.527 ng/mL TFV at 2.24 h, and biphasic decay. Intracellular TFV-DP has a C_{max} of 20.07 and 19.47 fmol/10⁶ cells for the subjects. In the steady-state study, cell subsets from mucosal tissue and blood were isolated to analyze TFV-DP from HIV-positive subjects on regimens that included TDF. The median TFV-DP concentration were 143.7 fmol/10⁶ epithelial cells, 572.0 fmol/10⁶ CD4 T-helper cells, and 223.5 fmol/10⁶ monocyte/macrophages. In blood, the median TFV-DP concentrations were 26.3 fmol/10⁶ CD4 T-helper cells and 41.2 fmol/10⁶ monocyte/macrophages. In summary, this work developed methods to quantify HIV surrogate and drug distribution and clearance in sexually receptive tissue compartments. Combining these methods can advance more thoughtfully by designing a drug to outdistance and outlast HIV in the sites of sexual transmission. Article	2010	Mack, Natasha; Robinson, Elizabeth T; MacQueen, Kathleen M; Moffett, Jill; Johnson, Laura M	The exploitation of "Exploitation" in the tenofovir prep trial in Cameroon: Lessons learned from media coverage of an HIV prevention trial.	Journal of Empirical Research on Human Research Ethics	-	-	-	1556-2646	10.1525/jer.2010.5.2.3	https://dx.doi.org/10.1525/jer.2010.5.2.3	media coverage influences how clinical trials are perceived internationally and in communities where trials occur, affecting recruitment, retention, and political support for research. We conducted a discourse analysis of news coverage from 2004-2005 of a trial in Cameroon on oral PrEP for HIV prevention, to identify messages, communication techniques, and sources of messages that were amplified via media. We identified two parallel discourses: one on ethical concerns about the Cameroon trial, and a second, more general "science exploitation" discourse concerned with the potential for trials with vulnerable participant populations to be conducted unethically, benefiting only wealthy populations. Researchers should overtly address exploitation as an integral, ongoing component of research, particularly where historical or cultural conditions set the stage for controversy to emerge. Article	2010	Matthews, Lynn T; Baeten, Jared M; Celum, Connie; Bangsberg, David R	Periconception pre-exposure prophylaxis to prevent HIV transmission: benefits, risks, and challenges to implementation.	AIDS	-	-	-	1473-5571	10.1097/QAD.0b013e32833bedeb	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3773599	HIV-serodiscordant couples face complicated choices between fulfilling reproductive desire and risking HIV transmission to their partners and children. Sexual HIV transmission can be dramatically reduced through artificial insemination and sperm washing; however, most couples cannot access these resources. We propose that periconception pre-exposure prophylaxis (PrEP) could offer an important, complementary therapy to harm reduction counseling programs that aim to decrease HIV transmission for couples who choose to conceive. In this paper, we describe the potential benefits of periconception PrEP and define critical points of clarification prior to implementation of PrEP as part of a reproductive health program. We consider sexual transmission risk, current risk reduction options, PrEP efficacy, cost, adherence, resistance, fetal toxicity, and impact of PrEP counseling on entry into health services. We address PrEP in the context of other periconception HIV-prevention strategies, including antiretroviral treatment of the HIV-infected partner. We conclude that, should PrEP prove safe and efficacious in ongoing trials, periconception PrEP may offer a useful approach to minimize risk of HIV transmission for individuals of reproductive age in HIV-endemic countries. Article	2010	Neff, C Preston; Ndolo, Thomas; Tandon, Apurva; Habu, Yuichiro; Akkina, Ramesh	Oral pre-exposure prophylaxis by anti-retrovirals raltegravir and maraviroc protects against HIV-1 vaginal transmission in a humanized mouse model.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0015257	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3006206	Sexual HIV-1 transmission by vaginal route is the most predominant mode of viral transmission, resulting in millions of new infections every year. In the absence of an effective vaccine, there is an urgent need to develop other alternative methods of pre-exposure prophylaxis (PrEP). Many novel drugs that are currently approved for clinical use also show great potential to prevent viral sexual transmission when administered systemically. A small animal model that permits rapid preclinical evaluation of potential candidates for their systemic PrEP efficacy will greatly enhance progress in this area of investigation. We have previously shown that RAG-hu humanized mouse model permits HIV-1 mucosal transmission via both vaginal and rectal routes and displays CD4 T cell loss typical to that seen in the human. Thus far systemic PrEP studies have been primarily limited to RT inhibitors exemplified by tenofovir and emtricitabine. In these proof-of-concept studies we evaluated two new classes of clinically approved drugs with different modes of action namely, an integrase inhibitor raltegravir and a CCR5 inhibitor maraviroc as potential systemically administered chemo-prophylactics. Our results showed that oral administration of either of these drugs fully protects against vaginal HIV-1 challenge in the RAG-hu mouse model. Based on these results both these drugs show great promise for further development as orally administered PrEPs. Article	2010	Poynten, I. M.; Jin, F.; Prestage, G. P.; Kaldor, J. M.; Imrie, J.; Grulich, A. E.	Attitudes towards new HIV biomedical prevention technologies among a cohort of HIV-negative gay men in Sydney, Australia.	HIV Medicine	-	-	-	1468-1293 1464-2662	10.1111/j.1468-1293.2009.00777.x	https://pubmed.ncbi.nlm.nih.gov/20015220/	OBJECTIVES: The aim of the study was to explore the awareness of rectal microbicides, the use of pre-exposure prophylaxis (PREP) and the willingness to participate in biomedical HIV prevention trials in a cohort of HIV-negative gay men. METHODS: In a community-based cohort study, HIV-negative homosexually active men in Sydney, Australia were questioned about awareness of rectal microbicides, use of PREP, and willingness to participate in trials of such products. Predictors of awareness and willingness to participate were analysed by logistic regression. Use of PREP was examined prospectively. RESULTS: Overall, 14% had heard of rectal microbicides. Older (P=0.05) and university-educated men (P=0.001) were more likely to have knowledge of rectal microbicides. Almost one-quarter (24%) of men reported that they were likely/very likely to participate in rectal microbicide trials. Among those men with definite opinions on participation, awareness of rectal microbicides was significantly associated with unwillingness to participate odds ratio (OR) 0.78, 95% confidence interval (CI) 0.65-0.93, P=0.007. Willingness to participate in trials using antiretroviral drugs (ARVs) to prevent HIV infection was reported by 43% of men, and was higher among those who reported unprotected anal intercourse (UAI) with HIV-positive partners (OR 1.88, 95% CI 0.99-3.56). There was no evidence of current PREP use. CONCLUSIONS: This study demonstrates that Australian gay men have had little experience with PREP use and rectal microbicides. About half would be willing to consider participation in trials using ARVs to prevent HIV infection. Extensive community education and consultation would be required before PREP or rectal microbicides could be trialled in populations of gay Australian men. Article	2010	Pretorius, Carel; Stover, John; Bollinger, Lori; Bacaër, Nicolas; Williams, Brian	Evaluating the cost-effectiveness of pre-exposure prophylaxis (PrEP) and its impact on HIV-1 transmission in South Africa.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0013646	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2974638	BACKGROUND: Mathematical modelers have given little attention to the question of how pre-exposure prophylaxis (PrEP) may impact on a generalized national HIV epidemic and its cost-effectiveness, in the context of control strategies such as condom use promotion and expanding ART programs. METHODOLOGY/PRINCIPAL FINDINGS: We use an age- and gender-structured model of the generalized HIV epidemic in South Africa to investigate the potential impact of PrEP in averting new infections. The model utilizes age-structured mortality, fertility, partnership and condom use data to model the spread of HIV and the shift of peak prevalence to older age groups. The model shows that universal PrEP coverage would have to be impractically high to have a significant effect on incidence reduction while ART coverage expands. PrEP targeted to 15-35-year-old women would avert 10%-25% (resp. 13%-28%) of infections in this group and 5%-12% (resp. 7%-16%) of all infections in the period 2014-2025 if baseline incidence is 0.5% per year at 2025 (resp. 0.8% per year at 2025). The cost would be $12,500-$20,000 per infection averted, depending on the level of ART coverage and baseline incidence. An optimistic scenario of 30%-60% PrEP coverage, efficacy of at least 90%, no behavior change among PrEP users and ART coverage less than three times its 2010 levels is required to achieve this result. Targeting PrEP to 25-35-year-old women (at highest risk of infection) improves impact and cost-effectiveness marginally. Relatively low levels of condom substitution (e.g., 30%) do not nullify the efficacy of PrEP, but reduces cost-effectiveness by 35%-40%. CONCLUSIONS/SIGNIFICANCE: PrEP can avert as many as 30% of new infections in targeted age groups of women at highest risk of infection. The cost-effectiveness of PrEP relative to ART decreases rapidly as ART coverage increases beyond three times its coverage in 2010, after which the ART program would provide coverage to more than 65% of HIV(+) individuals. To have a high relative cost-effective impact on reducing infections in generalized epidemics, PrEP must utilize a window of opportunity until ART has been scaled up beyond this level. Article	2010	Rohan, Lisa C; Moncla, Bernard J; Kunjara Na Ayudhya, Ratiya Pamela; Cost, Marilyn; Huang, Yunda; Gai, Fang; Billitto, Nicole; Lynam, J D; Pryke, Kara; Graebing, Phillip; Hopkins, Nicole; Rooney, James F; Friend, David; Dezzutti, Charlene S	In vitro and ex vivo testing of tenofovir shows it is effective as an HIV-1 microbicide.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0009310	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2824823	BACKGROUND: Tenofovir gel has entered into clinical trials for use as a topical microbicide to prevent HIV-1 infection but has no published data regarding pre-clinical testing using in vitro and ex vivo models. To validate our findings with on-going clinical trial results, we evaluated topical tenofovir gel for safety and efficacy. We also modeled systemic application of tenofovir for efficacy. METHODS AND FINDINGS: Formulation assessment of tenofovir gel included osmolality, viscosity, in vitro release, and permeability testing. Safety was evaluated by measuring the effect on the viability of vaginal flora, PBMCs, epithelial cells, and ectocervical and colorectal explant tissues. For efficacy testing, PBMCs were cultured with tenofovir or vehicle control gels and HIV-1 representing subtypes A, B, and C. Additionally, polarized ectocervical and colorectal explant cultures were treated apically with either gel. Tenofovir was added basolaterally to simulate systemic application. All tissues were challenged with HIV-1 applied apically. Infection was assessed by measuring p24 by ELISA on collected supernatants and immunohistochemistry for ectocervical explants. Formulation testing showed the tenofovir and vehicle control gels were >10 times isosmolar. Permeability through ectocervical tissue was variable but in all cases the receptor compartment drug concentration reached levels that inhibit HIV-1 infection in vitro. The gels were non-toxic toward vaginal flora, PBMCs, or epithelial cells. A transient reduction in epithelial monolayer integrity and epithelial fracture for ectocervical and colorectal explants was noted and likely due to the hyperosmolar nature of the formulation. Tenofovir gel prevented HIV-1 infection of PBMCs regardless of HIV-1 subtype. Topical and systemic tenofovir were effective at preventing HIV-1 infection of explant cultures. CONCLUSIONS: These studies provide a mechanism for pre-clinical prediction of safety and efficacy of formulated microbicides. Tenofovir was effective against HIV-1 infection in our algorithm. These data support the use of tenofovir for pre-exposure prophylaxis. Article	2010	Rudy, BJ; Kapogiannis, BG; Lally, MA; Gray, GE; Bekker, LG; Krogstad, P; McGowan, I	Youth-Specific Considerations in the Development of Preexposure Prophylaxis, Microbicide, and Vaccine Research Trials	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	10.1097/QAI.0b013e3181e3a922	https://pubmed.ncbi.nlm.nih.gov/20571421/	Preventing HIV infection in adolescents and young adults will require a multimodal targeted approach, including individual-directed behavioral risk reduction, community-level structural change, and biomedical interventions to prevent sexual transmission. Trials testing biomedical interventions to prevent HIV transmission will require special attention in this population due to the unique psychosocial and physiologic characteristics that differentiate them from older populations. For example, microbicide research will need to consider acceptability, dosing requirements, and coinfection rates that are unique to this population. Preexposure prophylaxis studies also will need to consider potential unique psychosocial issues such as sexual disinhibition and acceptability as well as unique pharmacokinetic parameters of antiretroviral agents. Vaccine trials also face unique issues with this population, including attitudes toward vaccines, risks related to false-positive HIV tests related to vaccine, and different immune responses based on more robust immunity. In this article, we will discuss issues around implementing each of these biomedical prevention modalities in trials among adolescents and young adults to help to guide future successful research targeting this population.	vaccines; PrEP; microbicides; adolescents; biomedical HIV prevention; TENOFOVIR DISOPROXIL FUMARATE; ANTIRETROVIRAL THERAPY; CLINICAL-TRIALS; DOUBLE-BLIND; HUMAN-IMMUNODEFICIENCY-VIRUS; SEXUAL RISK BEHAVIOR; VAGINAL GEL; youth; IMMUNE RECONSTITUTION; HIV-INFECTED CHILDREN; THYMIC FUNCTION	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2010	Sanders, Eduard J.; Thiong'o, Alexander N.; Okuku, Haile Selassie; Mwambi, John; Priddy, Frances; Shafi, Juma; de Vries, Henry; McClelland, R. Scott; Graham, Susan M.	High prevalence of Chlamydia trachomatis and Neisseria gonorrhoeae infections among HIV-1 negative men who have sex with men in coastal Kenya.	Sexually Transmitted Infections	-	-	-	1472-3263 1368-4973	10.1136/sti.2010.043224	https://pubmed.ncbi.nlm.nih.gov/20656722/	OBJECTIVES: To assess the burden of Chlamydia trachomatis (CT) and Neisseria gonorrhoeae (NG) in high-risk HIV-1 negative men who have sex with men (MSM) in Africa. METHODS: Before the start of a pre-exposure prophylaxis trial, HIV-1 negative volunteers were screened for sexually transmitted infection (STI) including CT and NG, using a highly sensitive and specific nucleic acid amplification test. Samples positive for CT by Aptima testing, were evaluated for the presence of lymphogranuloma venereum (LGV) serovars using an in-house PCR assay. All men were asked to submit a urine specimen, and all had a rectal swab collected by a clinician. Men were asked if they had dysuria, urethral or rectal discharge, or rectal pain. RESULTS: 43 HIV-1 negative MSM were screened, of whom 13 reported sex with men only; the majority (27/43) reported sex work. One volunteer had dysuria and another, rectal pain. Eleven MSM (26%, 95% CI 14% to 41%) had infections with either or both pathogens. Homosexual men had a higher prevalence of any infection than bisexual men (46% vs 17%, p=0.04), and all cases of rectal infections, including one with CT, two with NG and two with CT/NG co-infection. All patients with CT were negative for LGV. One patient with a rectal NG infection reported rectal pain. CONCLUSIONS: A remarkably high burden of STI infection was found among HIV-1 negative MSM. Most (12/13) infections, including three of four rectal NG infections, were subclinical. These findings suggest that high-risk MSM will benefit from effective STI screening in Kenya. Article	2010	Schneider, John A; Dandona, Rakhi; Pasupneti, Shravani; Lakshmi, Vemu; Liao, Chuanhong; Yeldandi, Vijay; Mayer, Kenneth H	Initial commitment to pre-exposure prophylaxis and circumcision for HIV prevention amongst Indian truck drivers.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0011922	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2912853	Studies of HIV prevention interventions such as pre-exposure prophylaxis (PREP) and circumcision in India are limited. The present study sought to investigate Indian truck-drivers initial commitment to PREP and circumcision utilizing the AIDS Risk Reduction Model. Ninety truck-drivers completed an in-depth qualitative interview and provided a blood sample for HIV and HSV-2 testing. Truck-drivers exhibited low levels of initial commitment towards PREP and even lower for circumcision. However, potential leverage points for increasing commitment were realized in fear of infecting family rather than self, self-perceptions of risk, and for PREP focusing on cultural beliefs towards medication and physicians. Cost was a major barrier to both HIV prevention interventions. Despite these barriers, our findings suggest that the ARRM may be useful in identifying several leverage points that may be used by peers, health care providers and public health field workers to enhance initial commitment to novel HIV prevention interventions in India. Article	2010	Supervie, Virginie; García-Lerma, J Gerardo; Heneine, Walid; Blower, Sally	HIV, transmitted drug resistance, and the paradox of preexposure prophylaxis.	Proceedings of the National Academy of Sciences	-	-	-	1091-6490	10.1073/pnas.1006061107	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2901470	The administration of antiretrovirals before HIV exposure to prevent infection (i.e., preexposure prophylaxis; PrEP) is under evaluation in clinical trials. Because PrEP is based on antiretrovirals, there is considerable concern that it could substantially increase transmitted resistance, particularly in resource-rich countries. Here we use a mathematical model to predict the effect of PrEP interventions on the HIV epidemic in the men-who-have-sex-with-men community in San Francisco. The model is calibrated using Monte Carlo filtering and analyzed by constructing nonlinear response hypersurfaces. We predict PrEP interventions could substantially reduce transmission but significantly increase the proportion of new infections caused by resistant strains. Two mechanisms can cause this increase. If risk compensation occurs, the proportion increases due to increasing transmission of resistant strains and decreasing transmission of wild-type strains. If risk behavior remains stable, the increase occurs because of reduced transmission of resistant strains coupled with an even greater reduction in transmission of wild-type strains. We define this as the paradox of PrEP (i.e., resistance appears to be increasing, but is actually decreasing). We determine this paradox is likely to occur if the efficacy of PrEP regimens against wild-type strains is greater than 30% and the relative efficacy against resistant strains is greater than 0.2 but less than the efficacy against wild-type. Our modeling shows, if risk behavior increases, that it is a valid concern that PrEP could significantly increase transmitted resistance. However, if risk behavior remains stable, we find the concern is unfounded and PrEP interventions are likely to decrease transmitted resistance. Article	2010	Underhill, Kristen; Operario, Don; Mimiaga, Matthew J; Skeer, Margie R; Mayer, Kenneth H	Implementation science of pre-exposure prophylaxis: preparing for public use.	Current HIV/AIDS Reports	-	-	-	1548-3576	10.1007/s11904-010-0062-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3012127	As efficacy trials of antiretroviral pre-exposure prophylaxis (PrEP) continue, a growing literature has begun anticipating the potential challenges of implementing PrEP for HIV prevention. These efforts coincide with a shift toward combination interventions for preventing HIV, which integrate biomedical, behavioral, and structural components. The optimal implementation of PrEP would exemplify this combination model, incorporating not only PrEP drugs, but also HIV testing, safety screening, behavioral interventions addressing adherence and risk behavior, and long-term monitoring. Efforts to plan for PrEP implementation therefore present an opportunity to advance the science of implementation and delivery in HIV prevention, in order to better address the challenges of scaling up combination approaches. We review the published and unpublished literature on PrEP implementation, organizing themes into five categories: scientific groundwork, regulatory and policy groundwork, stakeholder and infrastructure groundwork, delivery, and long-term monitoring. The lessons from PrEP planning can benefit the scale-up of future combination interventions. Essay	2010	Underhill, Kristen; Operario, Don; Skeer, Margie; Mimiaga, Matthew; Mayer, Ken	Packaging PrEP to Prevent HIV: An Integrated Framework to Plan for Pre-Exposure Prophylaxis Implementation in Clinical Practice.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/qai.0b013e3181e8efe4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3058525	Antiretroviral pre-exposure prophylaxis (PrEP) drugs may be partially effective for preventing HIV transmission. In anticipation of clinical trial results, behavioral HIV prevention scientists have begun examining possible challenges in the implementation of PrEP in clinical practice or community settings. These efforts have acknowledged the need to supplement PrEP drug delivery with risk-reduction counseling and ongoing HIV testing, and we suggest that an even wider range of clinical, diagnostic, behavioral, and monitoring services will be necessary to support PrEP as a population-level HIV prevention strategy. This Commentary offers an integrated structure for optimizing PrEP delivery in clinical practice, which includes five components: 1) PrEP drugs; 2) safety screening and repeated HIV testing; 3) behavioral interventions to facilitate PrEP initiation, maintain adherence, and minimize risk compensation; 4) the development of strategies to engage PrEP users and the healthcare system over the long term; and 5) population-level monitoring. We provide a brief overview of each component and highlight adaptations of this five-part package for implementation. Attempts to plan for scale-up without explicitly addressing non-pharmaceutical elements may overlook critical implementation needs, barriers, and facilitators. Article	2010	van de Vijver, David A M C; Boucher, Charles A B	The risk of HIV drug resistance following implementation of pre-exposure prophylaxis.	Current Opinion in Infectious Diseases	-	-	-	-	1473-6527	10.1097/QCO.0b013e3283f1d6	https://dx.doi.org/10.1097/QCO.0b013e3283f1d6	PURPOSE OF REVIEW: Results of trials determining if pre-exposure prophylaxis (PrEP) with antiretroviral drugs prevents transmission of HIV are expected soon. Tenofovir and emtricitabine--currently evaluated as PrEP--are popular in treatment of HIV. Drug resistance could, therefore, be critical in the use of PrEP. We review the literature regarding risks associated with drug resistance owing to PrEP. RECENT FINDINGS: Few studies addressed the issue of drug resistance to tenofovir and/or emtricitabine. Studies in HIV-1-infected individuals followed small numbers of patients for a short time. Studies in macaques were well designed, but used SHIV, which has an attenuated course of infection. The available information suggests that the probability of emergence of drug resistance is small. Infections that occurred despite use of PrEP had reduced peak viremia, which could reduce HIV transmissibility. Mathematical modeling suggests that, although transmitted drug resistance may under some circumstances increase with use of PrEP, the benefit of reduced HIV incidence greatly outweighs the increase in drug resistance. SUMMARY: Limited information is available on drug resistance and PrEP. Nevertheless, current knowledge should, therefore, be combined in daily practice. Surveillance of drug resistance is recommended in areas where PrEP is used. Patients that become infected despite use of PrEP should be closely monitored for virological failure.	-drug resistance, emtricitabine, HIV, pre-exposure prophylaxis, tenofovir	English	United Kingdom	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Review
Article	2010	van Griensven, Frits; Thienkrua, Warunee; Sukwicha, Wichuda; Wimonsate, Wipas; Chaikummao, Suppaporn; Varangrat, Anchalee; Mock, Philip A	Sex frequency and sex planning among men who have sex with men in Bangkok, Thailand: implications for pre- and post-exposure prophylaxis against HIV infection.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1186/1758-2652-13-13	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2873546/	BACKGROUND: Daily HIV antiretroviral pre-exposure prophylaxis (PrEP) is being evaluated in clinical trials among men who have sex with men (MSM). However, daily PrEP may not be congruent with episodic sexual behaviour. We describe sex frequency and sex planning among MSM in Bangkok, Thailand, and explore the acceptability of daily versus episodic PrEP. METHODS: Data were collected through a cross-sectional survey in a cohort of HIV-negative MSM in Bangkok, Thailand. Chi-squared test was used to compare reports of sex on different weekdays; logistic regression was used to identify predictors of sex frequency and sex planning. RESULTS: Of 823 MSM (with a mean age of 28.3 years), 86% reported having sex on two days per week or less, and 65% reported their last sex to have been planned. Sex on the weekend (approximately 30%) was more often reported than sex on weekdays (approximately 23%). In multivariate analysis, use of alcohol, erectile dysfunction drugs, group sex, sex with a foreigner, having had selling sex, and a history of HIV testing were associated with having sex on three days or more per week. Being aged 22 to 29 years, not identifying as homosexual, having receptive anal intercourse, and not engaging in group sex were associated with unplanned sex. CONCLUSIONS: Intermittently dosed PrEP (as opposed to daily) may be a feasible HIV prevention strategy and should be considered for evaluation in clinical trials. Risk factors for sex frequency and sex planning may help to identify those in need for daily PrEP and those who may not be able to take a timely pre-exposure dose. Article	2010	Veronese, Fulvio; Turpin, Jim A.; Fauci, Cindra	Beyond 2010: Gaps, Challenges, and Priorities for the Future of Preclinical HIV Preexposure Prophylaxis (PrEP): Summary of the October 20-21, 2009 Workshop	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/aid.2010.0136	https://www.liebertpub.com/doi/10.1089/aid.2010.0136	Abstract A two-day symbol Beyond 2010: Gaps, Challenges, and Priorities for the Future of Preclinical HIV Pre-Exposure Prophylaxis (PrEP) was sponsored by the Division of AIDS (DAIDS) of the National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), on October 20-21, 2009, in Bethesda, Maryland. The objective of the workshop was to identify the main gaps in current knowledge, challenges, and priorities for the establishment of a PrEP preclinical pipeline and to also provide guidance for future directions of the Adult and DAIDS preclinical research in this area. The 2-day workshop, through various presentations and breakout group discussions, specifically addressed four main topics that will be critical in identifying and advancing the next generation of PrEP candidates for clinical testing. The topics were (1) drug discovery, (2) pharmacokinetics (PK) and pharmacodynamics (PD), (3) animal models, and (4) delivery systems for prolonged activity. We report here a summary of the presentations and highlights of salient discussion topics from this workshop. Article	2011	Abbas, Uzma L; Hood, Gregory; Wetzel, Arthur W; McKee, John W	Factors influencing the emergence and spread of HIV drug resistance arising from rollout of antiretroviral pre-exposure prophylaxis (PrEP).	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0018165	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3078189/	BACKGROUND: The potential for emergence and spread of HIV drug-resistance from rollout of antiretroviral (ARV) pre-exposure prophylaxis (PrEP) is an important public health concern. We investigated determinants of HIV drug resistance prevalence after PrEP implementation through mathematical modeling. METHODOLOGY: A model incorporating heterogeneity in age, gender, sexual activity, HIV transmission, natural history of infection, ARV treatment and resistance was developed. Rollout of PrEP was projected for 10 years in populations with different growth rates. PRINCIPAL FINDINGS: Analyses suggest that the prevalence of HIV drug resistance is influenced most by the extent and duration of inadvertent PrEP use in individuals already infected with HIV. Other key factors affecting drug resistance prevalence include the persistence time of transmitted resistance and the duration of inadvertent PrEP use in individuals who become infected on PrEP. From uncertainty analysis, the median overall prevalence of drug-resistance at 10 years was predicted to be 9.2% (interquartile range 6.9%-12.2%). An optimistic scenario of 75% PrEP efficacy, 80% coverage of the susceptible population, and 5% inadvertent PrEP use predicts a rise in HIV drug resistance prevalence to only 2.5% after 10 years. By contrast, in a pessimistic scenario of 25% PrEP efficacy, 15% population coverage, and 25% inadvertent PrEP use, resistance prevalence increased to over 40%. CONCLUSIONS: Inadvertent PrEP use in previously infected individuals is the major determinant of HIV drug resistance prevalence arising from PrEP. Both the rate and duration of inadvertent PrEP use are key factors. PrEP rollout programs should include routine monitoring of HIV infection status to limit the spread of drug resistance.	The potential for emergence and spread of HIV drug resistance from rollout of antiretroviral (ARV) pre-exposure prophylaxis (PrEP) is an important public health concern. We investigated determinants of HIV drug resistance prevalence after PrEP implementation through mathematical modeling. Journal of Pharmaceutical Sciences	-	-	-	-	1520-6017 0022-3549	10.1002/jps.22529	https://pubmed.ncbi.nlm.nih.gov/21437910/	The objective of this study is to engineer polylysine-heparin functionalized solid lipid nanoparticles (SLNs) for the use of a vaginal microbicide delivery template for HIV prevention. The SLNs are prepared using a modified phase-inversion technique followed by a layer-by-layer deposition method. The Box–Behnken experimental design is used to analyze the influence of three factors ($X1$) = bovine serum albumin concentration, $X2$) = pH of the aqueous phase, and $X3$) = lipid amount) on the particle mean diameter (PMD) measured by dynamic light scattering (DLS). Tenofovir is used as a model anti-HIV microbicide. The SLNs are also characterized for morphology, zeta potential (ζ), percent drug encapsulation efficiency (EE%), and cytotoxicity on a human vaginal epithelial cell line by electron microscopy, DLS, high-performance liquid chromatography, and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay, respectively. The $X1$, $X2$, and $X3$ factors are found to significantly affect the PMD, EE%, and ζ value of the SLNs. The produced SLNs appear monodisperse and exhibit a platelet-like shape with respective PMD, EE%, and ζ value of 153 nm, 8.3%, and −51 mV. These SLNs intended to be administered topically have the potential to enhance cellular uptake of hydrophobic microbicides and endonuzase the virus during the HIV-AIDS infection process, possibly leading to more effective prevention of the disease transmission. Article	2011	Anderson, Peter L; Kiser, Jennifer J; Gardner, Edward M; Rower, Joseph E; Meditz, Amie; Grant, Robert M	Pharmacological considerations for tenofovir and emtricitabine to prevent HIV infection.	Journal of Antimicrobial Chemotherapy	-	-	-	-	1460-2091	10.1093/jac/dkq487	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3030966/	The use of antiretroviral medications in HIV-negative individuals as pre-exposure prophylaxis (PrEP) is a promising approach to prevent HIV infection. Tenofovir disoproxil fumarate (TDF) and emtricitabine exhibit desirable properties for PrEP including: favourable pharmacokinetics that support infrequent dosing; few major drug-drug or drug-food interactions; an excellent clinical safety record; and pre-clinical evidence for efficacy. Several large, randomized, controlled clinical trials are evaluating the safety and efficacy of TDF and emtricitabine for this new indication. A thorough understanding of variability in drug response will help determine future investigations in the field and/or implementation into clinical care. Because tenofovir and emtricitabine are nucleos(t)ide analogues, the HIV prevention and toxicity effects may be influenced by host genetic polymorphisms in drug transporters, metabolizing enzymes and cellular kinases. Additionally, factors within the female reproductive tract, which include drug penetration into relevant tissues and cell types, sex-chronicity/pharmacogenetics, gender, cellular activation state and appropriate episodic or chronicity dosing strategies based on pharmacokinetic principles. The current state of knowledge in these areas is summarized and the future utility of intracellular pharmacokinetics/pharmacodynamics for the PrEP field is discussed. Article	2011	Arlotne, Harkaitz; Buergaren, Maialen; Camino, Xabier; Iribarren, José Antonio	Prevención de la transmisión del VIH (vertical, ocupacional y no ocupacional) / Prevention of HIV transmission (vertical, occupational and non-occupational)	Enfermedades Infecciosas y Microbiología Clínica	-	-	-	-	1578-1852 0213-005X	10.1016/j.eimc.2011.05.006	https://www.sciencedirect.com/science/article/pii/S021300511001098	In these almost thirty years since the epidemic of HIV infection strategies have been developed to decrease the transmission risk when a non-infected person comes into contact with HIV. One of the key landmarks was the discovery that viremia was shown to reduce the risk of HIV infection by sexual transmission from 25% to 8% when given from the second trimester on. In incomplete effectiveness, the high total cost of pregnancy, during pregnancy and for several weeks in the newborn. These strategies have been subsequently perfected until achieving vertical transmission rates less than 1%. Almost at the same time, strategies have been developed in an attempt to reduce the risk of transmission of infection after occupational accidents and, in the last few years prophylaxis after non-occupational exposure has been a field of particular concern. From its first post year several experiments on pre-exposure prophylaxis have been published, which are generating an intense debate on o applicability. In this article, we analyze the state of the art in the prevention of vertical transmission and occupational and non-occupational prophylaxis, from a perspective of applying this in the developed world. We also review the published data on pre-exposure prophylaxis. Article	2011	Bourguet, A; Gomez, G B; Cucerres, C F; Segura, E R; Grant, R M; Garnett, G P; Hallett, T B	The potential impact of pre-exposure prophylaxis for HIV prevention among Men who Have Sex with Men (MSM) in Lima, Peru	Sexually Transmitted Infections	-	-	-	-	13684973	10.1136/sextrans-2011-050119.2	https://www.sciencedirect.com/science/article/pii/S021300511001098	Background HIV Pre-exposure prophylaxis (PrEP), the use of antiretroviral drugs by those HIV uninfected individuals to prevent HIV infection, recently demonstrated effectiveness in preventing acquisition in a high risk population of men who have sex with men (MSM). There is a need to understand if and how PrEP can be used cost-effectively. This study examines the programmatic implications of the iPrEX trial, the first demonstration of PrEP effectiveness, in a setting of high HIV incidence among MSM in Lima, Peru. Methods We developed a dynamic, stochastic, individual-based model representing the HIV epidemic among Men who Have Sex with Men (MSM) and transgender people in Lima, Peru as a test-case. It considers differential infectiousness by stage, including the impact of antiretroviral treatment and different sexual practices, such as partnerships type and sexual positioning. The model was used to investigate the population-level impact, cost, and cost-effectiveness of PrEP under a range of implementation strategies, and to develop possible strategies by which PrEP could be implemented. Results The epidemiological impact of PrEP is largely driven by programme characteristics: coverage, prioritisation strategy and time to scale up as well as individual's adherence behaviour. If PrEP is prioritised to key groups, it could be a cost-effective way to avert infection and save lives (up to 8% less new infections with 5% coverage). Across all our scenarios the estimated highest cost per DALY gained (US$22755) is below the WHO recommended threshold for cost-effective interventions for the region (<US$8400 DALY gained) see Abstract LBO1-2 Figure 1 . The impact of PrEP is reduced if those on PrEP decrease condom use, especially if the program has low coverage; but only extreme behavioural changes (>50% reduction in condom use) would result in PrEP increasing the number of HIV infections. Conclusions PrEP can be a cost-effective intervention due to its incomplete effectiveness, its high total cost of pregnancy during attainable coverage levels. Conclusions This study quantifies the epidemic and financial implications of different programmatic scenarios. While the implementation of a strategic PrEP intervention has potentially important financial implications (a substantial expenditure would likely be required to generate significant reductions in incidence), PrEP among vulnerable populations could be a cost-effective option comparable to currently available interventions for Men who Have Sex with Men (MSM) populations. Article	2011	Brooks, RA; Kaplan, RL; Lafser, E; Landovitz, RJ; Lee, SJ; Leibowitz, AA	Motivators, concerns, and barriers to adoption of preexposure prophylaxis for HIV prevention among gay and bisexual men in HIV-serodiscordant male relationships	AIDS Care	-	-	-	-	0954-0121	10.1080/09540121.2011.554528	https://pubmed.ncbi.nlm.nih.gov/21478147/	The purpose of this study was to identify factors that may facilitate or impede future adoption of preexposure prophylaxis (PrEP) for HIV prevention among gay and bisexual men in HIV-serodiscordant couples. Using a community-based participatory research approach, we conducted 30 in-depth interviews with HIV-seronegative partners in male couples in which the partner living with HIV was receiving care from a community-based clinic in Los Angeles, CA. A modified grounded theory approach was employed to identify major themes relating to future adoption of PrEP by this population. Motivators for adoption were protection against HIV infection, less concern and fear regarding HIV transmission, the opportunity to engage in unprotected sex, and endorsements of PrEP's effectiveness. Concerns and barriers to adoption included the cost of PrEP, short-and long-term side effects, adverse effects if intermittent use or discontinuing PrEP, and accessibility of PrEP. The findings suggest the need for a carefully planned implementation program along with educational and counseling interventions in the dissemination of an effective PrEP agent. Article	2011	Chariyalertsak, Suwat; Kosachunhanun, Nutthapol; Saekhiro, Pongpun; Sonpuspa, Rutchanok; Wongthanee, Amika; Chariyalertsak, Chonlisa; Visuttaratana, Surasing; Beyrer, Chris	HIV incidence, risk factors, and motivation for biomedical intervention among gay, bisexual men, and transgender persons in Northern Thailand.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0024295	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3168497/	BACKGROUND: HIV prevalence among men who have sex with men (MSM) and transgender (TG) persons is high and increasing in Chiang Mai, northern Thailand. OBJECTIVES: To describe demographic, socioeconomic, sexual behavior and HIV incidence in a MSM/TG HIV prevention trials among gay and bisexual MSM and TG presenting for HIV testing (VCT) and pre-screening for the iPrEx pre-exposure prophylaxis (PrEP) trial. METHODS: Between December 2006 and March 2008, 1,251 MSM/TG were enrolled in a cohort study. Participants were followed every 6 months for up to 24 months. Risk factors for seroconversion were determined using Poisson regression. RESULTS: A total of 551 MSM/TG were enrolled. The mean age was 25.6 years. HIV prevalence among MSM was 4.0%, and overall was 12.9% (71/551), 16.5% among gay men, 9.5% among TG, and 8.9% among BS. Consistent use of condoms was low, 33.3% in insertive anal sex and 31.9% in receptive anal sex. Interest in participation was high, 86.1% for PrEP, 69.7% for HIV vaccine trials, but 29.9% for circumcision. HIV was independently associated with being gay identified, aOR: 2.8, p = 0.017 and with being aged 25-29, aOR 2.7, p = 0.027. Among repeat testers, HIV incidence was 8.2/100 PY, 95% CI, 3.7/100PY to 18.3/100PY. CONCLUSION: HIV risks and rates varied by self-reported sexual orientation and gender identity. HIV was associated with sexual practices, age, and being gay-identified. These are populations are in need of novel prevention strategies and willing to participate in prevention research. Article	2011	Chen, Nadine E.; Meyer, Jaimie P.; Springer, Sandra A.	Advances in the prevention of heterosexual transmission of HIV/AIDS among women in the United States.	Infectious Disease Reports	-	-	-	-	2036-7430 2036-7449	10.4081/idr.2011.e6	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3567593/	Despite recent advances in testing and treatment, the incidence of HIV/AIDS in the United States has remained stagnant with an estimated 56,300 new infections every year. Women account for an increasing proportion of the epidemic. The vulnerability of women to HIV stems from both increased biologic susceptibility to heterosexual transmission and also the social, economic, and structural disadvantages they experience. Women who are young, women with a history of incarceration, and victims of intimate partner violence are disproportionately affected by HIV. Prevention strategies for women include: women who are young, women with a history of incarceration, and victims of intimate partner violence. Although behavioral approaches to HIV prevention may be effective, pragmatic implementation is often difficult, especially for women who lack sociocultural capital to negotiate conditions with their male partners. Recent advances in HIV prevention show promise in terms of female-initiated interventions. These notably include female condoms, non-specific vaginal microbicides, and antiretroviral oral and vaginal pre-exposure prophylaxis. In this review, we will present evidence in support of these new female-initiated interventions while also emphasizing the importance of advocacy and the political support for these scientific advances to be successful. Article	2011	Cong, Mian-ce; Youngquist, Ar S.; Aung, Wutyi; Sharma, Sunite; Mitchell, James; Dobard, Charles; Hewitte, Walid; Garcia-Lerma, J. Gerardo	Generation and mucosal transmissibility of emtricitabine- and tenofovir-resistant SHIV162P3 mutants in macaques.	Virology	-	-	-	-	1096-0341 0042-6822	10.1016/j.virol.2011.01.038	https://pubmed.ncbi.nlm.nih.gov/21334708/	Transmission of drug-resistant HIV has been widely documented. We generated tenofovir (TFV)- and emtricitabine (FTC)-resistant SHIV162P3 mutants that can be used to investigate the transmission efficiency of drug-resistant viruses and their impact on the efficacy of pre-exposure prophylaxis. Both SHIV162p3(M184V) and SHIV162p3(K65R) replicated in vitro at high titers. Drug resistance profiles were similar to those seen in HIV. Virus infectivity to vitro quantacle assays were 4- and 10-fold lower in SHIV162p3(M184V) and SHIV162p3(K65R), compared to a concurrently grown SHIV162p3, respectively. Mucosal transmissibility studies using a repeat low-dose macaque model of rectal and vaginal transmission showed that both mutants were able to efficiently infect macaques only after the dose was increased 10-fold over the dose of SHIV162p3. Thus, the K65R and M184V mutations reduced the transmissibility of macaques suggest that the reduction in fitness due to M184V and K65R decreases virus transmissibility, and identify in vitro infectivity parameters that associate with mucosal transmissibility. Article	2011	Halkett, Timothy B; Baeten, Jared M; Hoffton, Renee; Barnabas, Ruanne; de Bruyn, Guy; Cremin, Ida; Delany, Sinead; Garnett, Geoffrey P; Grey, Glenda; Johnson, Leigh; McIntyre, James; Rees, Helen; Celum, Connie	Optimal uses of antiretrovirals for prevention in HIV-1 serodiscordant heterosexual couples in South Africa: a modelling study.	PLOS Medicine	-	-	-	-	1549-1676	10.1371/journal.pmed.1001123	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3219611/	BACKGROUND: Antiretrovirals have substantial promise for HIV-1 prevention, either as antiretroviral treatment (ART) for HIV-1-infected persons to reduce infectiousness, or as pre-exposure prophylaxis (PrEP) for HIV-1-uninfected persons to reduce the probability of infection. The optimal use of these agents in populations with HIV-1 HIV-1 serodiscordant couples in long-term partnerships (one member is infected and the other is uninfected) are a priority for prevention interventions. Earlier ART and PrEP might both reduce HIV-1 transmission in this group, but the merits and synergies of these different approaches have not been analyzed. METHODS AND FINDINGS: We constructed a mathematical model to examine the impact and cost-effectiveness of different strategies, including earlier initiation of ART and/or PrEP, for HIV-1 prevention for serodiscordant couples. Although the cost of PrEP is high, the cost per infection averted is significantly offset by future savings in lifelong treatment, especially among couples with multiple partners, low condom use, and a high risk of transmission. In some situations, highly effective PrEP could be cost-saving overall. To keep couples alive and without a new infection, providing PrEP to the uninfected partner could be at least as cost-effective as initiating ART earlier in the infected partner, if the annual cost of PrEP is ~40% of the annual cost of ART and PrEP is >70% effective. CONCLUSIONS: Strategic use of PrEP and ART could substantially reduce HIV-1 transmission in serodiscordant couples. Providing PrEP to the uninfected partner can be as cost-effective as delivery of ART and PrEP, and couples' behaviours and preferences will be critical for optimizing the use of antiretrovirals for HIV-1 prevention. Article	2011	Hart, Christopher H; Eron, Joseph J; Cohen, Myron S	Pre-exposure prophylaxis and antiretroviral resistance: HIV prevention at a cost?	Clinical Infectious Diseases	-	-	-	-	1537-6591	10.1093/cid/cir684	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3246407/	Pre-exposure prophylaxis (PrEP), the use of antiretrovirals (ARVs) by human immunodeficiency virus (HIV)-uninfected individuals to prevent acquisition of the virus during high-risk sexual encounters, enjoyed its first 2 major successes with the Centre for the AIDS Programme of Research in South Africa (CAPRISA) 004 and the Pre-Exposure Prophylaxis Initiative (iPrEx). These successes were buoyed by additional positive results from the TDF2 and Partners PrEP trials. Although no seroconverters in either arm of CAPRISA developed resistance to tenofovir, 2 participants in iPrEx with undetected, seronegative acute HIV infection were randomized to receive daily oral tenofovir-emtricitabine and resistance to emtricitabine was later discovered in both men. A similar case in the TDF2 study resulted in resistance to both ARVs. These cases prompted us to examine existing literature on the nature of resistance mutations elicited by ARVs used for PrEP. Here, we discuss the impact of signature mutations selected by PrEP, how rapidly these emerge with daily ARV exposure, and the individual-level and public health consequences of ARV resistance. Article	2011	Jespers, Vicky; Francis, Susanna C; van de Wijgert, Janneke; Crucitti, Tania	Methodological issues in sampling the local immune system of the female genital tract at the context of HIV prevention trials.	American Journal of Reproductive Immunology	-	-	-	-	1600-0897	10.1111/j.1600-0897.2010.00938.x	https://dx.doi.org/10.1111/j.1600-0897.2010.00938.x	The spread of HIV continues unabated in the most vulnerable populations of the world. HIV prevention methods, such as a vaginal microbicide, a mucosal vaccine, pre-exposure prophylaxis or a vaccine, are urgently needed. The female genital tract (FGT) is the site of HIV acquisition and the local immune system plays a crucial role in the outcome of HIV exposure and the early pathogenesis of HIV. Above all, these products should be proven to be safe and not negatively disturb the local immune system in a way that facilitates or enhances heterosexual transmission of HIV. HIV specific and non-specific cellular and humoral local vaginal immunity must be assessed in clinical trials when testing prevention products for safety or efficacy. A proven, well-documented and standardized sampling strategy will provide high quality data to be able to assess both safety and local immune responses. In this paper, we will discuss methods for vaginal immunology sampling in the context of clinical trials. Article	2011	Katsidzira, Leolin; Hakim, James G.	HIV prevention in southern Africa: why we must reassess our strategies?	Tropical Medicine & International Health (TM & IH)	-	-	-	-	1365-3156 1360-2276	10.1111/j.1365-3156.2011.02807.x	https://pubmed.ncbi.nlm.nih.gov/21668592/	Southern Africa continues to shoulder a disproportionate burden of the HIV epidemic with the number of new infections outstripping treatment initiation two- to threefold. Current prevention strategies have had a limited impact on the trajectory of the epidemic so far. The history of HIV prevention research is dominated by failed approaches, but recent developments have provided reason for hope. These include the successful male circumcision outcomes in trials in South Africa, Kenya and Uganda, the recent protective outcome of a tenofovir vaginal gel trial in South Africa and the proof that pre-exposure prophylaxis with oral combination tenofovir/emtricitabine can work in men. The latter positive outcome has however been shattered by the early closure of FEM-PrEP for futility. The challenge now is on how to best integrate emerging prevention methods with established strategies, recognising that some of the older methods have never been scaled up to saturation level. Article	2011	Kelesidis, Theodoros; Landovitz, Raphael J	Preexposure prophylaxis for HIV prevention.	Current HIV/AIDS Reports	-	-	-	-	1548-3576	10.1007/s11904-011-0078-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3269441	Reducing the incidence of HIV remains one of our greatest public health challenges. However, there is growing optimism that preexposure prophylaxis (PrEP) could have a major impact on preventing incident HIV infection. Recently presented data on the use of oral PrEP in men who have sex with men (MSM) have provided proof-of-principle for this strategy. Additional clinical trials are evaluating whether PrEP provides similar protection to risk groups other than MSM, such as heterosexual persons and injection drug users. Still unanswered questions include optimal dosing strategies, long-term safety, maximizing adherence and minimizing costs, addressing drug resistance in the face of PrEP failure, optimizing access, and assessing effects on risk behavior. Future implementation will be guided by the results of clinical trials in progress. This article provides a review of the data on the potential strengths and limitations of PrEP as an HIV prevention strategy, identifies challenges to implementation of this approach, and outlines knowledge gaps. Article	2011	Kersh, Ellen N; Adams, Debra R; Youngpairoj, Ae S; Luo, Wei; Zheng, Qi; Cong, Mian-er; Aung, Wutyi; Mitchell, James; Otten, Ron; Hendry, R Michael; Heneine, Walid; McNicholl, Janet; Garcia-Lerma, J Gerardo	T cell chemo-vaccination effects after repeated mucosal SHIV exposures and oral pre-exposure prophylaxis.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0019295	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3082568	Pre-exposure prophylaxis (PrEP) with anti-viral drugs is currently in clinical trials for the prevention of HIV infection. Induction of adaptive immune responses to virus exposures during anti-viral drug administration, i.e., a "chemo-vaccination" effect, could contribute to PrEP efficacy. To study possible chemo-vaccination, we monitored humoral and cellular immune responses in nine rhesus macaques undergoing up to 14 weekly, low-dose SHIV(SF162P3) rectal exposures. Six macaques concurrently received PrEP with intermittent, oral Truvada; three were no-PrEP controls. PrEP protected 4 macaques from infection. Two of the four showed evidence of chemo-vaccination, because they developed anti-SHIV CD4(+) and CD8(+) T cells; SHIV-specific antibodies were not detected. Control macaques showed no anti-SHIV immune responses before infection. Chemo-vaccination-induced T cell responses were robust (up to 3,940 SFU/10(6) PBMCs), predominantly central memory cells, short-lived (≤22 weeks), and appeared intermittently and with changing specificities. The two chemo-vaccinated macaques were virus-challenged again after 28 weeks of rest, after T cell responses had waned. One macaque was not protected from infection. The other macaque concurrently received additional PrEP. It remained uninfected and T cell responses were boosted during the additional virus exposures. In summary, we document and characterize PrEP-induced T cell chemo-vaccination. Although not protective after subsiding in one macaque, chemo-vaccination-induced T cells warrant more comprehensive analysis during peak responses for their ability to prevent or to control infections after additional exposures. Our findings highlight the importance of monitoring these responses in clinical PrEP trials and suggest that a combination of vaccines and PrEP potentially might enhance efficacy. Article	2011	Koblin, Beryl A; Mansergh, Gordon; Frye, Victoria; Tieu, Hong Van; Hoover, Donald R; Bonner, Sebastian; Flores, Stephen A; Hudson, Sharon M; Colfax, Grant N	Condom-use decision making in the context of hypothetical pre-exposure prophylaxis efficacy among substance-using men who have sex with men: Project MIX.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0b013e31822b76d2	https://dx.doi.org/10.1097/QAI.0b013e31822b76d2	OBJECTIVE: To examine condom-use decision making in the context of hypothetical pre-exposure prophylaxis (PrEP) efficacy among men who have sex with men who use alcohol and other substances during sex. METHODS: Substance-using men who have sex with men were recruited in 4 US cities for a behavioral intervention trial. Three groups were defined as follows: men who indicated that to not use a condom for receptive/insertive unprotected anal intercourse (UAI) while using PrEP, PrEP would need to be: (1) "almost always or always" effective (high efficacy); (2) effective "at least half the time or more but not almost always or always" (mid-range efficacy corresponding to recent PrEP trial results); (3) effective "less than half the time" (low efficacy). The mid-range efficacy group was compared with the low-efficacy group (as the reference) and to the-high efficacy group (as the reference). RESULTS: Among 630 men who never used PrEP, 15.2% were in the mid-range efficacy group for receptive UAI and 34.1% in the mid-range efficacy group for insertive UAI. Scores on difficulty communicating about safer sex while high were significantly higher in the mid-range efficacy group compared with each of the other groups for both receptive and insertive UAI. Men who seemed to be differentiating PrEP use by anal sex role also scored higher on communication difficulties, although scoring lower on condom intentions. CONCLUSIONS: Communication about safer sex while under the influence of alcohol or other substances and condom intentions are important factors to consider for HIV prevention interventions for PrEP users. Article	2011	Koh, Yasuhiro; Haim, Hillel; Engelman, Alan	Identification and characterization of persistent intracellular human immunodeficiency virus type 1 integrase strand transfer inhibitor activity.	Antimicrobial Agents and Chemotherapy	-	-	-	-	1098-6596 0066-4804	10.1128/AAC.01064-10	https://pubmed.ncbi.nlm.nih.gov/21060108/	Pharmacokinetic and pharmacodynamic considerations significantly impact infectious disease treatment options. One aspect of pharmacodynamics is the postantibiotic effect, classically defined as delayed bacterial growth after antibiotic removal. The same principle can apply to antiviral drugs. For example, significant delays in human immunodeficiency virus type 1 (HIV-1) replication can be observed after nucleoside/nucleotide reverse transcriptase inhibitor (N/NtRTI) removal from culture medium, because these prodrugs must be anabolized into active, phosphorylated forms once internalized into cells. A relatively new class of anti-HIV-1 drugs is the integrase strand transfer inhibitors (INSTIs), and the INSTIs raltegravir (RAL) and elvitegravir (EVG) were tested here alongside positive N/NtRTI controls tenofovir disoproxil fumarate (TDF) and azidothymidine (AZT), as well as the nonnucleoside reverse transcriptase inhibitor negative control nevirapine (NVP), to assess potential postantiviral effects. Transformed and primary CD4-positive cells pretreated with INSTIs significantly resisted subsequent challenge by HIV-1, revealing the following hierarchy of persistent intracellular drug strength: TDF > EVG ~ AZT > RAL > NVP. A modified time-of-addition assay was moreover developed to assess residual drug activity levels. Approximately 0.8% of RAL and 2% of initial EVG and TDF 1-h pulse drug levels persisted during the acute phase of HIV-1 infection. EVG furthermore displayed significant virucidal activity. Although there is no reason to suspect obligate intracellular modification, this study nevertheless defines significant intracellular persistence of prototype INSTIs. Ongoing second-generation formulations should therefore consider the potential for significant postantiviral effects among this drug class. Combined intracellular persistence and virucidal activities suggest potential pre-exposure prophylaxis applications for EVG. Article	2011	Kokolo, Madzouka B; Fergusson, Dean A; Cameron, D William	HIV pre-exposure prophylaxis (PrEP)--a quantitative ethics appraisal.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0022497	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3151244	BACKGROUND: There is now strong evidence that preventive oral antiretroviral therapy can moderately reduce likelihood of HIV infection. This concept is called HIV pre-exposure prophylaxis (PrEP). Premature closures of some previous PrEP clinical trials, secondary to ethical concerns, did not stop research. We aimed to appraise the extent of ethics considerations reporting in PrEP study documents. METHODS: We conducted a systematic quantitative ethics appraisal, grounded in PrEP literature and using eight principles proposed by Ezechiel Emanuel. We developed an a priori checklist of 101 evidence-based ethics items. We obtained protocols for eleven of nineteen clinical controlled studies identified. Two reviewers independently appraised study documents against the checklist. Ethics appraisal was synthesized using adjusted percentages of items reported. RESULTS: On average, 58% of the 101 ethics items were mentioned or addressed in documents, with variations noted both across studies and across principles. Considerations pertaining to social value were least reported (43% of checklist items, on average) whereas considerations related to informed consent and favorable risk-benefit ratio were most reported (75% of checklist items, on average). DISCUSSION: Some PrEP studies reportedly address more ethics considerations than others but, overall, ethics considerations reporting could be much improved. While this review does not allow us to comment on the actual execution of HIV PrEP trials, it is a reminder that optimism generated by potentially effective interventions should not overshadow the importance of ethics in research design and development. Improving ethics reporting might improve the perceived value of PrEP research and subsequent data. Article	2011	Krakower, Douglas; Mayer, Kenneth H.	Promising prevention approaches: tenofovir gel and prophylactic use of antiretroviral medications.	Current HIV/AIDS Reports	-	-	-	-	1548-3576 1548-3568	10.1007/s11904-011-0094-4	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3240840/	Thirty years into the global HIV epidemic, the need for effective prevention strategies remains critical. In July 2010, the CAPRISA-004 study demonstrated that topical administration of a gel containing the antiretroviral agent tenofovir decreased the risk of HIV acquisition among at-risk heterosexual women. Subsequently, the iPrEx study reported that prophylactic use of a daily oral tablet containing tenofovir and emtricitabine reduced the risk of HIV acquisition among high-risk men who have sex with men. These studies illustrate the promise of antiretroviral pre-exposure chemoprophylaxis (PrEP) as an innovative prevention approach. This review discusses the rationale for chemoprophylaxis, compares the advantages of topical and oral delivery, outlines recommended safety monitoring, offers principles to guide selection of antiretroviral agents, and highlights potential unintended consequences of PrEP use. If future studies confirm the safety and efficacy of tenofovir gel and oral PrEP, successful implementation of these strategies could significantly impact the HIV epidemic. Article	2011	Lampe, Margaret A; Smith, Dawn K; Anderson, Gillian J E; Edwards, Ashley E; Nesheim, Steven R	Achieving safe conception in HIV-discordant couples: the potential role of oral preexposure prophylaxis (PrEP) in the United States.	American Journal of Obstetrics and Gynecology	-	-	-	-	1097-6868	10.1016/j.ajog.2011.02.026	https://dx.doi.org/10.1016/j.ajog.2011.02.026	Approximately half of HIV-discordant heterosexual couples in the United States want children. Oral antiretroviral preexposure prophylaxis, if effective in reducing heterosexual HIV transmission, might be an option for discordant couples wanting to conceive. Couples should receive services to ensure they enter pregnancy in optimal health and receive education about all conception methods that reduce the risk of HIV transmission. In considering whether preexposure prophylaxis is indicated, the question is whether it contributes to lowering risk in couples who have decided to conceive despite known risks. If preexposure prophylaxis is used, precautions similar to those in the current heterosexual preexposure prophylaxis trials would be recommended, and the unknown risks of preexposure prophylaxis used during conception and early fetal development should be considered. Anecdotal reports suggest that oral preexposure prophylaxis use is already occurring. It is time to have open discussions of when and how preexposure prophylaxis might be indicated for HIV-discordant couples attempting conception.	conception; discordanr couples; hiv; preexposure prophylaxis; pregnancy	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2011	Leibowitz, AA; Parker, KB; Rotheram-Borus, MJ	A US Policy Perspective on Oral Preexposure Prophylaxis for HIV	American Journal of Public Health	-	-	-	-	0090-0036	10.2105/AJPH.2010.300066	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3093264/	Orally administered preexposure prophylaxis is an innovative and controversial HIV prevention strategy involving the regular use of antiretroviral medications by uninfected individuals. Antiretroviral medications protect against potential HIV infection by reducing susceptibility to the virus. Recent clinical trial results indicate that preexposure prophylaxis can be safe and efficacious for men who have sexual intercourse with men, yet there remain policy considerations surrounding costs, opportunity costs, and ethical issues that must be addressed before broad implementation in the United States. Resources for HIV prevention are limited, thus cost-effectiveness analyses of PrEP implementation in nonexperimental situations are needed to allocate prevention funding most productively. Findings from the randomized clinical trials that PrEP is efficacious should mark the beginning of the policy discussion, not its end. Article	2011	Leonardi, M.; Lee, E.; Tan, D. H. S.	Awareness of, usage of and willingness to use HIV pre-exposure prophylaxis among men in downtown Toronto, Canada.	International journal of STD & AIDS	-	-	-	-	1758-1052 0956-4624	10.1258/ijsa.2011.011057	https://pubmed.ncbi.nlm.nih.gov/22174057/	Pre-exposure prophylaxis (PrEP) is a promising strategy whereby HIV-uninfected people could take antiretroviral (ARV) medications to reduce their risk of HIV acquisition. Reports suggest that unsupervised PrEP use has been occurring in gay communities of USA cities before human safety and efficacy data became available. We administered a 20-item questionnaire to men undergoing HIV testing at Hassle Free Clinic, a sexual health clinic in the gay village of Toronto. Questionnaire items enquired about demographics, sexual partners, substance use and awareness of, usage of and willingness to use PrEP. Logistic regression was used to identify characteristics associated with PrEP-related outcomes. Of 256 participants, 11.7% were aware of PrEP, with more men who have sex with men (MSM) aware (14.1%) than non-MSM (4.9%). No participants reported PrEP usage. Willingness to consider PrEP use was high and associated with high-risk activities, suggesting opportunities for PrEP use in the future. Article	2011	Liu, AY; Vittinghoff, E; Sellmeyer, DE; Irvin, R; Mulligan, K; Mayer, K; Thompson, M; Grant, R; Pathak, S; O'Hara, B; Gvetadze, R; Chillag, K; Grohskopf, L; Buchbinder, SP	Bone mineral density in HIV-negative men participating in a tenofovir pre-exposure prophylaxis randomized clinical trial in San Francisco	PLOS One	-	-	-	-	NA	10.1371/journal.pone.0023688	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-00806021/full	BACKGROUND: Pre-exposure prophylaxis (PrEP) trials are evaluating regimens containing tenofovir-disoproxil fumarate (TDF) for HIV prevention. We determined the baseline prevalence of low bone mineral density (BMD) and the effect of TDF on BMD in men who have sex with men (MSM) in a PrEP trial in San Francisco. METHODS/FINDINGS: We evaluated 1) the prevalence of low BMD using Dual Energy X-ray Absorptiometry (DEXA) in a baseline cohort of 210 HIV-uninfected MSM who screened for a randomized clinical trial of daily TDF vs. placebo, and 2) the effects of TDF on BMD in a longitudinal cohort of 184 enrolled men. Half began study drug after a 9-month delay to evaluate changes in risk behavior associated with pill-use. At baseline, 20 participants (10%) had low BMD (Z score≤-2.0 at the L2-L4 spine, total hip, or femoral neck). Low BMD was associated with amphetamine (OR=5.86, 95% CI 1.70-20.20) and inhalant (OR=4.57, 95% CI 1.32-15.81) use; men taking multivitamins, calcium, or vitamin D were less likely to have low BMD at baseline (OR=0.26, 95% CI 0.10-0.71). In the longitudinal analysis, there was a 1.1% net decrease in mean BMD in the TDF vs. the pre-treatment/placebo group at the femoral neck (95% CI 0.4-1.9%), 0.8% net decline at the total hip (95% CI 0.3-1.3%), and 0.7% at the L2-L4 spine (95% CI -0.1-1.5%). At 24 months, 13% vs. 6% of participants experienced >5% BMD loss at the femoral neck in the TDF vs. placebo groups (p=0.13). CONCLUSIONS: Ten percent of HIV-negative MSM had low BMD at baseline. TDF use resulted in a small but statistically significant decline in BMD at the total hip and femoral neck. Larger studies with longer follow-up are needed to determine the trajectory of BMD changes and any association with clinical fractures. TRIAL REGISTRATION: ClinicalTrials.gov: NCT00131677. Article	2011	Martin, Michael; Vanichseni, Suphak; Suntharasamai, Pravan; Sangkum, Udomsak; Chuachoowong, Rutt; Mock, Philip A; Leethochawalit, Manoj; Chiamwongpaet, Sithisat; Kittimunkong, Somyot; van Griensven, Frits; McNicholl, Janet M; Paxton, Lynn; Choopanya, Kachit	Enrollment characteristics and risk behaviors of injection drug users participating in the Bangkok Tenofovir Study, Thailand.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0025127	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3182181	BACKGROUND: The Bangkok Tenofovir Study was launched in 2005 to determine if pre-exposure prophylaxis with tenofovir will reduce the risk of HIV infection among injecting drug users (IDUs). We describe recruitment, screening, enrollment, and baseline characteristics of study participants and contrast risk behavior of Tenofovir Study participants with participants in the 1999-2003 AIDSVAX B/E Vaccine Trial. METHODS: The Bangkok Tenofovir Study is an ongoing, phase-3, randomized, double-blind, placebo-controlled, HIV pre-exposure prophylaxis trial of daily oral tenofovir. The Tenofovir Study and the Vaccine Trial were conducted among IDUs at 17 drug-treatment clinics in Bangkok. Tenofovir Study sample size was based on HIV incidence in the Vaccine Trial. Standardized questionnaires were used to collect demographic, risk behavior, and incarceration data. The Tenofovir Study is registered with ClinicalTrials.gov, number--NCT00119106. RESULTS: From June 2005 through July 2010, 4094 IDUs were screened and 2413 enrolled in the Bangkok Tenofovir Study. The median age of enrolled participants was 31 years (range, 20-59), 80% were male, and 63% reported they injected drugs during the 3 months before enrollment. Among those who injected, 53% injected methamphetamine, 37% midazolam, and 35% heroin. Tenofovir Study participants were less likely to inject drugs, inject daily, or share needles (all, p<0.001) than Vaccine Trial participants. DISCUSSION: The Bangkok Tenofovir Study has been successfully launched and is fully enrolled. Study participants are significantly less likely to report injecting drugs and sharing needles than participants in the 1999-2003 AIDSVAX B/E Vaccine Trial suggesting HIV incidence will be lower than expected. In response, the Bangkok Tenofovir Study enrollment was increased from 1600 to 2400 and the study design was changed from a defined 1-year follow-up period to an endpoint-driven design. Trial results demonstrating whether or not daily oral tenofovir reduces the risk of HIV infection among IDUs are expected in 2012. Article	2011	Mehta, Sapna A.; Silvera, Richard; Bernstein, Kyle; Holzman, Robert S.; Aberg, Judith A.; Daskalakis, Demetre C.	Awareness of post-exposure HIV prophylaxis in high-risk men who have sex with men in New York City.	Sexually Transmitted Infections	-	-	-	-	1472-3263 1368-4973	10.1136/sti.2010.046284	https://pubmed.ncbi.nlm.nih.gov/21357600/	OBJECTIVES: To understand the factors associated with knowledge of non-occupational post-exposure prophylaxis (nPEP) and pre-exposure prophylaxis (PrEP), bathhouse patrons in New York City (NYC) were surveyed. METHODS: 554 men who have sex with men (MSM) at two NYC bathhouses were given a standardised survey focused on nPEP and PrEP at the time of HIV testing. RESULTS: In the previous 90 days, 63% of respondents reported unprotected sex with a male partner and 7% reported any sex with a known HIV-positive male partner. Less than half reported having a primary provider (primary care practitioner) who was aware of their MSM behaviour. 201 men (36%) were aware of nPEP or PrEP. In univariate analyses, race/ethnicity, previous HIV testing, gay self-identification, higher education level, having a primary provider aware of MSM behaviour, reported interaction with the healthcare system, use of the internet for meeting sex partners, reporting unprotected sex in the previous 90 days, reporting any sex with an HIV-positive male partner in the previous 90 days and having a higher number of sex partners were each significantly associated with being aware of nPEP or PrEP. In multivariate analysis, having a higher number of sex partners was significantly associated (OR 5.10, p=0.02) with post-exposure prophylaxis (PEP)/PrEP knowledge and disclosure to a primary care provider was also associated, although less robustly (OR 2.10, p=0.06). CONCLUSIONS: Knowledge of nPEP or PrEP among sexually active MSM in NYC is low and is associated with having a primary provider aware of their patient's same-sex behaviours. These findings show the need for improving education about nPEP among high-risk MSM in NYC and the role of providers in these efforts. The Partners PrEP Study is a randomized, double-blind, placebo-controlled trial of tenofovir and emtricitabine-tenofovir pre-exposure prophylaxis to decrease HIV-1 acquisition within heterosexual HIV-1 serodiscordant couples. We describe the trial design and characteristics of the study cohort.MethodsHIV-1 serodiscordant couples, in which the HIV-1 infected partner did not meet national guidelines for initiation of antiretroviral therapy, were enrolled at 9 research sites in Kenya and Uganda. The HIV-1 susceptible partner was randomized to daily oral tenofovir, emtricitabine-tenofovir, or matching placebo with monthly follow-up for 24-36 months.ResultsFrom July 2008 to November 2010, 7920 HIV-1 serodiscordant couples were screened and 4758 enrolled. For 62% (2966/4758) of enrolled couples, the HIV-1 susceptible partner was male. Median age was 33 years for HIV-1 susceptible and HIV-1 infected partners IQR (28-40) and (26-39) respectively. Most couples (98%) were married, with a median duration of partnership of 7.0 years (IQR 3.0-14.0) and recent knowledge of their serodiscordant status median 0.4 years (IQR 0.1-2.0). During the month prior to enrollment, couples reported a median of 4 sex acts (IQR 2-8); 27% reported unprotected sex and 14% of male and 1% of female HIV-1 susceptible partners reported sex with outside partners. Among HIV-1 infected partners, the median plasma HIV-1 level was 3.94 log(10) copies/mL (IQR 3.31-4.53) and median CD4 count was 496 cells/μL (IQR 375-662); the majority (64%) had WHO stage 1 HIV-1 disease.ConclusionsCouples at high risk of HIV-1 transmission were rapidly recruited into the Partners PrEP Study, the largest efficacy trial of oral PrEP. Article	2011	Myers, Gavin M; Mayer, Kenneth H	Oral preexposure anti-HIV prophylaxis for high-risk U.S. populations: current considerations in light of new findings.	AIDS Patient Care and STDs	-	-	-	-	1557-7449	10.1089/apc.2010.0222	https://dx.doi.org/10.1089/apc.2010.0222	This article reviews the status of current research evaluating oral preexposure prophylaxis (PrEP) for prevention of HIV infection in high-risk populations. In animal model studies, the use of antiretrovirals has been shown to be effective in preventing HIV acquisition. Early-phase PrEP studies have established safety in humans. Currently, more than 20,000 men and women will soon be enrolled in studies of oral or topical chemoprophylaxis, testing a variety of drug delivery methods including tenofovir disoproxil fumarate (TDF) gel applied vaginally or rectally, as well as oral PrEP using TDF by itself or coformulated with emtricitabine (FTC). The largest global PrEP trial in men who have sex with men (MSM), known as iPrEx has demonstrated that oral chemoprophylaxis can decrease HIV incidence in this population. Although TDF/FTC PrEP was generally well tolerated, side effects such as nausea, as well as mild and reversible renal abnormalities were increased among the men who received active medication, suggesting that PrEP users will need ongoing PrEP clinical monitoring. The prophylactic benefits of TDF/FTC were substantially attenuated by nonadherence, indicating that effective PrEP implementation programs will need to focus on this behavioral variable, in addition to safer sex counseling. This article considers biological, policy, and practical implications of large-scale oral PrEP implementation. Editorial	2011	Naswa, Smriti; Marfatia, Y	Pre-exposure prophylaxis of HIV	Indian Journal of Sexually Transmitted Diseases and AIDS	-	-	-	-	25890557	10.4103/0253-7184.81246	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-hiv/docview/870329683/se-2?accountid=8113	Pre-exposure prophylaxis (PrEP) is an experimental approach to HIV prevention and consists of antiretroviral drugs to be taken before potential HIV exposure in order to reduce the risk of HIV infection and continued during periods of risk. An effective PrEP could provide an additional safety net to sexually active persons at risk, when combined with other prevention strategies. Women represent nearly 60% of adults infected with HIV and PrEP can be a female-controlled prevention method for women who are unable to negotiate condom use. Two antiretroviral nucleoside analog HIV-1 reverse transcriptase inhibitor drugs are currently under trial as PrEP drugs, namely tenofovirdisoproxilfumarate (TDF) alone and TDF in combination with emtricitabine (FTC), to be taken as daily single dose oral drugs. There are 11 ongoing trials of ARV-based prevention in different at risk populations across the world. The iPrex trial showed that daily use of oral TDF/FTC by MSM resulted in 44% reduction in the incidence of HIV. This led to publication of interim guidance by CDC to use of PrEP by health providers for MSM. Few other trials are Bangkok Tenofovir Study, Partners PrEP Study, FEM-PrEP study, and VOICE (MTN-003) study. Future trials are being formulated for intermittent PrEP (iPrEP) where drugs are taken before and after sex, "stand-in dose" PrEP, vaginal or rectal PrEP, etc. There are various issues/concerns with PrEP such as ADRs and resistance to TDF/FTC, adherence to drugs, acceptability, sexual disinhibition, use of PrEP as first line of defense for HIV without other prevention strategies, and cost. The PrEP has a potential to address unmet need in public health if delivered as a part of comprehensive toolkit of prevention services, including risk-reduction, correct and consistent use of condoms, and diagnosis and treatment of sexually transmitted infections. Article	2011	Olesen, Rikke; Wahl, Angela; Denton, Paul W.; Garcia, J. Victor	Immune reconstitution of the female reproductive tract of humanized BLT mice and their susceptibility to human immunodeficiency virus infection.	Journal of Reproductive Immunology	-	-	-	-	1872-7603 0165-0378	10.1016/j.jri.2010.11.005	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6831040/	An HIV vaccine capable of providing sterilizing immunity from vaginal infection would reduce the spread of HIV to women. Unfortunately, only one of the four HIV-1 vaccine clinical trials has demonstrated any level of protection (31%) against HIV-1 transmission. Additionally, only one topical microbicide clinical trial has reported an overall reduction in HIV transmission (39%). Developing even more effective vaccines and microbicides will require a better understanding of the key events involved in HIV infection and dissemination at the site of exposure. Novel immunodeficient mice capable of being systemically reconstituted with human hematopoietic stem cells have provided new systems where HIV transmission studies can be performed. Specifically, a humanized mouse model of vaginal HIV transmission has been developed that utilizes the humanized bone marrow-liver-thymus (BLT) mouse. The female reproductive tract (FRT) of humanized BLT mice is reconstituted with functional human immune cells rendering them susceptible to vaginal HIV-1 infection. In this review we focus on four aspects of BLT mice for the study of vaginal HIV-1 transmission: (1) we discuss methods for creating humanized BLT mice and their reconstitution with human hematopoietic cells, (2) we describe reconstitution of the BLT mouse FRT with human immune cells, (3) we highlight the work done regarding vaginal HIV-1 transmission and (4) we summarize the efficacy of systemic pre-exposure prophylaxis (PrEP) to prevent vaginal HIV-1 transmission in BLT mice. BLT mice are a highly relevant small animal model for studying vaginal HIV-1 transmission, prevention and therapy. Article	2011	Patterson, Kristine B; Prince, Heather A; Kraft, Eric; Jenkins, Amanda J; Shaheen, Nicholas J; Rooney, James F; Cohen, Myron S; Kashuba, Angela D M	Penetration of tenofovir and emtricitabine in mucosal tissues: implications for prevention of HIV-1 transmission.	Science Translational Medicine	-	-	-	-	1946-6242	10.1126/scitranslmed.3003174	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3483088	A mainstay of strategies to prevent HIV-1 transmission is to use antiretroviral therapy (ART) for pre-exposure prophylaxis (PrEP). Critical to the design and interpretation of PrEP prevention trials is the ability to make accurate pharmacological measurements of ART drugs in human genital and colorectal mucosal tissues, the principal route of HIV transmission. Here, we evaluated two drugs that are preferentially used for PrEP: tenofovir (TFV) disoproxil fumarate (TDF) and emtricitabine (FTC). A single oral dose of TDF/FTC (Truvada) was administered to 15 healthy individuals. Over the next 14 days, TFV and FTC were measured in blood plasma and genital secretions using a sensitive assay (lower level of quantification, 0.1 ng/ml). The active intracellular phosphorylated metabolites of these drugs TFV diphospate (TFV-DP) and FTC triphosphate (FTC-TP) were measured in homogenates prepared from rectal, vaginal, and cervical tissues. TFV and FTC were detected in blood plasma 14 days after administration of a single dose. The area under the concentration-time curve from 24 hours to 14 days (AUC(1-14d)) for FTC in genital secretions was 27-fold greater than in blood plasma, whereas the AUC(1-14d) for TFV was only 2.5-fold greater in genital secretions than in blood plasma. In rectal tissue, TFV and TFV-DP concentrations were detectable for 14 days and were 100-fold higher than the concentrations in vaginal and cervical tissues. Vaginal and cervical tissue concentrations of FTC were 10- to 15-fold higher than in rectal tissue. Despite high concentrations of FTC in vaginal and cervical tissue, FTC-TP concentrations in all tissue types were detected for only 2 days after dose. The exposure to TFV, TFV-DP, FTC, and FTC-TP was wide ranging depending on the type of mucosal tissue. These results demonstrate the need for detailed pharmacological studies to improve the application of ART for PrEP to prevent transmission of HIV. Article	2011	Ramjee, G	Antiretroviral-based microbicides and oral pre-exposure prophylaxis for HIV prevention	Future Virology	-	-	-	-	1746-0794	10.2217/FVL.11.64	https://www.tandfonline.com/doi/pdf/10.2217/fvl.11.64	Numerous HIV prevention options have been tested, with limited success. Microbicides have been the focus of research specifically targeted to prevent new infections among women. After decades of research using non-HIV-specific microbicides, we now have proof of concept for antiretroviral-based microbicides. Issues of drug resistance, frequency of HIV testing and adherence to treatment remain to be explored. Drugs used for HIV treatment and with good safety profiles have been shown to provide protection to men who have sex with men. Ethical issues surrounding cost, access, future design of HIV prevention trials and composition of the prevention package offered to trial participants remain. The role of advocacy and market research will be crucial to ensure effective interventions are accessed and supported. There is renewed hope in the HIV prevention field with collective efforts needed to ensure we get the new prevention tools and options into the hands of men and women at risk of HIV infection. The purpose of this paper is to provide a review of existing research and identify issues for future enquiry.	tenofovir; emtricitabine; HIV prevention; microbicide; pre-exposure prophylaxis; UNITED-STATES; DOUBLE-BLIND; RISK BEHAVIOR; SEXUALLY-TRANSMITTED INFECTIONS; POSTEXPOSURE PROPHYLAXIS; MALE CIRCUMCISION; VAGINAL GEL; SIV INFECTION; IMMUNODEFICIENCY-VIRUS TYPE-1; RURAL SOUTH-AFRICA; topical gel	English	United Kingdom	Western and Central Europe and North America	South Africa	Eastern and Southern Africa	South Africa	Eastern and Southern Africa	Review
Article	2011	Ratcliffe, Libuse; Beadsworth, Michael B J; Pennell, Ashley; Phillips, Matthew; Vilar, Francisco J	Managing hepatitis B/HIV co-infected: adding entecavir to truvada (tenofovir disoproxil/emtricitabine) experienced patients.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0b013e328345ef5e	https://dx.doi.org/10.1097/QAD.0b013e328345ef5e	BACKGROUND: Combination emtricitabine (FTC) or lamivudine (LAM) with tenofovir disoproxil (TDF) is the recommended first-line regime for treatment in chronic hepatitis B virus (HBV)/HIV co-infection. However, in those failing to suppress, few data exist regarding further management. In HBV/HIV co-infection, there are no published data describing outcomes when entecavir (ETV) is then added to TDF-based regimes in patients no longer suppressing their HBV. We report the first series of patients using ETV with truvada-based HAART in HBV/HIV co-infected patients with previous HBV therapy failure, including inadequate suppression. METHODS: A prospective observational study. RESULTS: Thirteen HIV/HBV co-infected patients (all male, hepatitis B e antigen positive and hepatitis B e antibody negative) were commenced on ETV in addition to background truvada. All patients were previously exposed to LAM or FTC and TDF (median 53 months, range 6−123). Seven patients had LAM monotherapy prior to TDF/LAM or FTC combination; the remaining six patients were exposed to FTC or LAM and TDF combination. Median time of follow-up was 74 weeks (range 16−159) and median HBV decline was 2.53 log(10) IU/ml (range 1.28−7.36). Thirty-eight percent of patients achieved undetectable HBV DNA level by the end of the study and eight of 13 (62%) achieved normal alanine aminotransferase (ALT) levels with median reduction −28 U/l (range −152 to 37). TDF was stopped in one patient because of renal toxicity. ETV was well tolerated with no change of estimated glomerular filtration rate during the study. CONCLUSION: Entecavir can be considered in addition to TDF/FTC in HBV/HIV co-infected treatment-experienced patients failing to fully suppress their HBV viral load. Article	2011	Ribera, Esteban; Tuset, Montse; Martín, Maite; del Cacho, Elena	Characteristics of antiretroviral drugs.	Enfermedades Infecciosas y Microbiologia Clinica	-	-	-	-	1578-1852 0213-005X	10.1016/j.eimc.2011.02.004	https://pubmed.ncbi.nlm.nih.gov/21531048/	As of November 2010, a total of 22 antiretroviral agents are marketed in Spain. These agents are divided into 6 classes according to their mechanism of action: 1) nucleos(t)ide reverse transcriptase inhibitors (NRTI) (abacavir, didanosine, emtricitabine, stavudine, lamivudine, zidovudine, and tenofovir), 2) non-nucleoside reverse transcriptase inhibitors (NNRTI) (efavirenz, etravirine, and nevirapine), 3) protease inhibitors (PI) (atazanavir, darunavir, fosamprenavir, indinavir, lopinavir, nelfinavir, ritonavir, saquinavir, tipranavir), 4) entry inhibitors (enfuvirtide), 5) coreceptor CCR5 inhibitors (maraviroc), and 6) integrase inhibitors (raltegravir). All 22 agents are indicated for the treatment of HIV-1 infection in combination with other antiretroviral drugs. Most have also proven to be active against HIV-2 (except the NNRTIs, enfuvirtide, and maraviroc) and some are active against hepatitis B virus (lamivudine, emtricitabine, and tenofovir). The present article reviews the main characteristics of the different antiretroviral agents and classes, namely, commercial presentations, paediatric and adult dosages, dose adjustments in renal and hepatic insufficiency, pharmacokinetics and interactions, mechanism of action, treatment indications, resistance, adverse effects, and safety during pregnancy and breastfeeding. Some of the characteristics of antiretrovirals are class-specific and common to other agents of the same class, and others are individual and different from those of other drugs in the same class. Knowledge of these characteristics enables us to prepare efficacious therapeutic regimens according to the specific requirements of the patient (tolerability, simplicity, adaptability to lifestyle) and clinical setting (naive, simplification, rescue, resistance). Article	2011	Shiri, Tinevimbo; Welte, Alex	Modelling the impact of acute infection dynamics on the accumulation of HIV-1 mutations.	Journal of Theoretical Biology	-	-	-	-	1095-8541	10.1016/j.jtbi.2011.03.011	https://dx.doi.org/10.1016/j.jtbi.2011.03.011	Events over the past year have brought hope and have re-energized the interest in targeting pre-infection or early infection period with preventative or therapeutic interventions such as vaccines and pre-exposure prophylaxis (PrEP). In breakthrough infections, the incidence, long term prognosis and clinical significance of early infection events is not well understood but it is possible that these early events may be crucial in determining the subsequent course of disease. We use a branching process model in a deterministically varying environment to explore how the dynamics of early infection affects the accumulation of mutations which lay the seeds for long term evolution of drug resistance and immune system evasion. We relate this exploration to regimes of impact, on diversity, of tropical interventions strategies such as PrEP and vaccines. As a metric of diversity we compute the probability of existence of particular genomes which potentially arise. Using several model scenarios, we demonstrate various regimes of 'response' of evolution to 'intervention'. Transient effects of therapeutic interventions early in infection that impose a fitness cost on early viruses can significantly reduce the probability of diversity later during the chronic state of infection. This stands in contrast to the concern that early selective pressure may increase the probability of later existence of drug resistance mutations, for example. The branching process paradigm offers the ability to efficiently compute important indicators of viral diversity, in a framework with a modest number of simplifying assumptions, without simulating the full range of individual level scenarios. These models may be useful to illustrate the impact of vaccines and PrEP on viral evolution in the case of breakthrough infection. They also suggest that new measures of viral diversity which correlate to prognosis should be sought in trials for PrEP and vaccines. Article	2011	Sista, Nirupama Deshmane; Abdool Karim, Quarraisha; Hinson, Kathy; Donnell, Deborah; Eshleman, Susan H.; Vermund, Sten H.	Experience in international clinical research: the HIV Prevention Trials Network.	Clinical Investigation	-	-	-	-	2041-6792 2041-6806	10.4155/cli.11.156	https://www.researchgate.net/publication/221845581_Experience_in_international_clinical_research_The_HIV_Prevention_Trials_Network	The HIV Prevention Trials Network (HPTN) is supported by the NIH to conduct randomized clinical trials to assess the efficacy of HIV prevention strategies and technologies to reduce HIV transmission between adults. A special focus of attention is on the use of antiretroviral drugs to prevent HIV transmission, both by reducing infectiousness among HIV-infected persons taking combination antiretroviral therapy (cART) and also by reducing susceptibility among HIV-uninfected persons taking antiretrovirals for pre-exposure prophylaxis. Studies may be developmental in nature to assess novel ideas for interventions or for assessing trial feasibility. However, pivotal efficacy trials to test HIV-specific prevention strategies and technologies are the main HPTN priority. Examples include a major protocol investigating the impact of expanded testing and linkage to care on HIV surveillance indicators in the USA (HPTN 065). Another protocol is addressing similar issues while also investigating how combinations of prevention approaches are best deployed to make a community-level impact in southern Africa (HPTN 071). HPTN 068 is evaluating a novel conditional cash transfer structural intervention to increase school completion rates in young girls and thereby reduce their HIV risk. Studies outside the US address the epidemic in most at-risk populations and include an assessment of opiate agonist therapy to reduce risk of HIV seroconversion among injection drug users (HTPN 058), methods to increase HIV testing rates (HPTN 043), as well as methods for reducing high-risk behaviors, and increasing adherence to cART in HIV-infected individuals (HPTN 062 and HPTN 063, respectively). The recent HPTN 052 study demonstrated that a 96% reduction in HIV transmission could be achieved between serodiscordant sexual partners by providing the infected partners with cART at a CD4(+) cell count (350-550/μl) above the level that would usually qualify them for therapy in low- and middle-income countries. The immediate relevance to public health policy showcased in these trials is a paradigm for the HPTN: design and conduct of clinical trials using available licensed tools that can be rapidly translated for implementation ('Prevention NOW!').	developing country, HIV/AIDS, prevention, randomized clinical trial, research collaboration, research infrastructure	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2011	Stover, John	HIV models to inform health policy.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318 1746-630X	10.1097/COH.0b013e328343ac05	https://pubmed.ncbi.nlm.nih.gov/21505384/	PURPOSE OF REVIEW: To review the recent use of mathematical modeling to inform decision making in HIV policy and programs. RECENT FINDINGS: New mathematical modeling studies have provided information for policy and program development regarding male circumcision, the role of antiretroviral therapy in the prevention of new HIV infection, and the potential contribution of new prevention technologies such as pre-exposure prophylaxis and HIV vaccines. SUMMARY: Several modeling studies published recently intend to provide information to decision makers to support the development of policies and strategies. These models include a study on male circumcision that provides a consensus among modeling groups on key issues relating to impact and targeting, a study proposing a new approach to treatment and prevention and explorations of the potential impacts of two new technologies (pre-exposure prophylaxis and HIV vaccines) and the conditions under which they will be most beneficial. Article	2011	Supervie, V; Barrett, M; Musuka, G; Moeti, TL; Busang, L; Blower, S.	HIVFemale sex workersPre-exposure prophylaxisWillingness to acceptHuman immunodeficiency virusFemale sex workersPre-exposure prophylaxisAcceptability	Scientific Reports	-	-	-	-	1359-6535	10.1038/srep00185	https://pubmed.ncbi.nlm.nih.gov/22355700/	Clinical trials have recently demonstrated the effectiveness of Pre-Exposure Prophylaxis (PrEP) in preventing HIV infection. Consequently, PrEP may soon be used for epidemic control. We model the dynamic interactions that will occur between treatment programs and potential PrEP interventions in resource-constrained countries. We determine the consequences for HIV transmission and drug resistance. We use response hypersurface modeling to predict the effect of PrEP on decreasing transmission as a function of effectiveness, adherence and coverage. We predict PrEP will increase need for second-line therapies (SLT) for treatment-naïve individuals, but could significantly decrease need for SLT for treatment-experienced individuals. If the rollout of PrEP is carefully planned it could increase the sustainability of treatment programs. If not, need for SLT could increase and the sustainability of treatment programs could be compromised. Our results show the optimal strategy for rolling out PrEP in resource-constrained countries is to begin around the "worst" treatment programs. Essay	2011	Verma, Natasha A.; Lee, Anna C.; Herold, Betsy C.; Keller, Marla J.	Topical prophylaxis for HIV prevention in women: becoming a reality.	Current HIV/AIDS Reports	-	-	-	-	1548-3576 1548-3568	10.1007/s11904-011-0075-7	https://pubmed.ncbi.nlm.nih.gov/21424725/	Strategies to protect against sexual transmission of HIV include the development of products formulated for topical application, which limit the toxicities associated with systemic oral pre-exposure prophylaxis. Following several clinical trial failures, attention is now focused on antiretroviral (ARV) agents. Highly potent ARV topical formulations provide a female-controlled, targeted, and feasible option for HIV prevention. A recently completed tenofovir gel trial was the first to demonstrate significant protection against HIV acquisition. Topical ARVs have the advantage of delivering high concentration of drug at the site of transmission of HIV, with low systemic absorption. Sustained-release formulations, such as intravaginal rings, will likely improve adherence and can be designed to provide controlled and continuous delivery of ARV combinations. Further studies to test alternative dosing strategies and pharmacokinetic/pharmacodynamic relationships in the genital tract will provide valuable information as the field strives to improve upon the promising tenofovir gel trial results. Essay	2011	Veronese, Fulvia; Anton, Peter; Fletcher, Courtney V; DeGruttola, Victor; McGowan, Ian; Becker, Stephen; Zwerski, Sheryl; Burns, David	Implications of HIV PrEP trials results.	AIDS Research and Human Retroviruses	-	-	-	1931-8405	10.1089/AID.2010.0226	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3014767	Abstract Six randomized clinical trials have been implemented to examine the efficacy of tenofovir disoproxil fumarate (TDF) and/or TDF/emtricitabine (TDF/FTC) as preexposure prophylaxis for HIV-1 infection (PrEP). Although largely complementary, the six trials have many similar features. As the earliest results become available, an urgent question may arise regarding whether changes should be made in the conduct of the other trials. To consider this in advance, a Consultation on the Implications of HIV Pre-Exposure Prophylaxis (PrEP) Trials Results sponsored by the Division of AIDS (DAIDS) of the National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), and the Bill and Melinda Gates Foundation (BMGF) was held on January 29, 2010, at the Natcher Conference Center, NIH, Bethesda, MD. Participants included basic scientists, clinical researchers (including investigators performing the current PrEP trials), and representatives from the U.S. Food and Drug Administration (FDA) and the agencies sponsoring the trials: the U.S. Centers for Disease Control and Prevention (CDC), the U.S. Agency for International Development (USAID), the BMGF, and the U.S. NIH. We report here a summary of the presentations and highlights of salient discussion topics from the workshop. Article	2011	Wei, Suo-su; Zou, Yun-feng; Xu, Yong-fang; Liu, Jin-ji; Nong, Quan-xing; Bai, Yu; Shi, Yi; Zhong, Xiao-ni; Huang, Wen-xiang; Liang, Hao; Huang, Ai-long	Acceptability and influencing factors of pre-exposure prophylaxis among men who have sex with men in Guangxi.	Zhonghua Liu Xing Bing Xue Za Zhi (Chinese Journal of Epidemiology)	-	-	-	0254-6450	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-22336541	OBJECTIVE: To study the acceptability of pre-exposure prophylaxis (PrEP) to prevent the transmission of HIV among men who have sex with men (MSM) in Guangxi, China. METHODS: Snow-balling methods were used to recruit 650 MSM in Guangxi. Questionnaires and interview were administrated to these 650 men, using a self-designed questionnaire and face to face interviews to collect information on HIV-related risk behaviors, knowledge and acceptability of PrEP. RESULTS: After an introduction on PrEP by interviewers, followed by as the statement-'If PrEP was effective, safe and free of charge', 597 (91.9%) of the 650 MSM claimed that they would accept it, with the main reason as the recognition of 'PrEP can decrease the risk of HIV infection'. For those who refused to use it, most of them said that were afraid of the side-effect and doubted on the effectiveness of PrEP. Data from logistic regression analysis showed that those who had found partners through friends (OR = 6.21, P = 0.020) and those who would advise his friend to use PrEP (OR = 39.32, P = 0.000) were more likely to accept PrEP. Those who thought they could protect themselves from HIV infection (OR = 0.32, P = 0.010) or not having sex with the ones who refused to use a condom (OR = 0.34, P = 0.010) were less likely to accept PrEP. CONCLUSION: Effectiveness, safety and cost seemed to be the main influential factors related to the acceptability of PrEP. Peer education might improve the acceptability of PrEP. Article	2011	Whiteside, Y Omar; Harris, Tammy; Scanlon, Christopher; Clarkson, Stephen; Duffus, Wayne	Self-perceived risk of HIV infection and attitudes about preexposure prophylaxis among sexually transmitted disease clinic attendees in South Carolina.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2010.0224	https://dx.doi.org/10.1089/apc.2010.0224	Several domestic and international trials of the use of preexposure prophylaxis (PrEP) for HIV prevention are ongoing among groups at high risk for HIV infection. The objective of this cross-sectional study was to assess self-perceived risk of HIV infection and attitudes about PrEP among 405 sexually transmitted disease (STD) clinic attendees in South Carolina. Self-percieved risk of HIV infection and attitudes about PrEP were assessed using three questions from a self-administered survey. Ordinal logistic regression and logistic regression were used to evaluate differences in risk perception for HIV infection and attitudes about the use of PrEP among risk groups. Compared to heterosexual participants, homosexual participants were significantly more likely to have knowledge of PrEP (odds ratio OR=6.7, 95% confidence interval CI: 1.70-26.1). Compared to those participants who had 1 sexual partner in the past 3 months, individuals who had 2 to 4 sexual partners in the past 3 months were approximately 2.35 times as likely to have a lower level of agreement with the statement "I believe I am at risk of getting HIV" (p=0.0003). Compared to female participants, respondents who were male were approximately 2.8 times as likely to have a lower level of agreement with the statement "If I had to it would be very difficult for me (or my partner) to both use condoms and take daily pills to prevent HIV infection" (p<0.0001). These results suggest the need for the creation of PrEP implementation programs that are tailored to self-perceived risk perception, age, and gender. Article	2011	Xue, Q Y; Gao, J J; Song, P P; Qu, X J; Xu, L Z	Prospects for using pre-exposure prophylaxis to control the prevalence of HIV/AIDS in China.	Drug Discovery and Therapy (Drug Discov Ther)	-	-	-	1881-7831	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-22466295	Although important progress has been achieved in combating HIV/AIDs over the past 30 years, HIV/AIDs is still a serious threat to today's world. In China, figures on the incidence of this disease have painted a less than optimistic outlook. As the prevailing methods of preventing HIV/AIDS are all partially effective, novel and effective preventive interventions are needed in order to control the spread of the disease. Pre-exposure prophylaxis (PrEP) is one of the most promising prevention strategies and has garnered great attention worldwide. Current clinical trials on the efficacy and safety of this strategy have had some favorable results though major challenges around the world remain. Thus, China has taken an active part in the PrEP study to limit the prevalence of HIV/AIDS. This article describes the status of the PrEP study and discusses the opportunities and challenges encountered when implementing this strategy in China. Article	2011	Zablotska, Iryna B.; Prestage, Garrett; Holt, Martin; Poynten, Mary; de Wit, John; Guy, Rebecca; Mao, Limin; McAllister, John; Grulich, Andrew E.	Australian gay men who have taken nonoccupational postexposure prophylaxis for HIV are in need of effective HIV prevention methods.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0b013e318230e885	https://pubmed.ncbi.nlm.nih.gov/21857349/	BACKGROUND: Gay men who request nonoccupational postexposure prophylaxis (PEP) may seek preexposure prophylaxis (PrEP) should this become available. We explored trends and predictors of PEP use among Australian gay men to inform future biomedical prevention programs. METHODS: We used 2001-2010 data from Gay Community Periodic Surveys in 3 Eastern Australian states and assessed PEP awareness and use in the 6 months before each survey, and among HIV-uninfected men in all surveys predictors of PEP use. Analytical methods included chi-square test for trend and multivariate log-binomial estimation of associations. RESULTS: The awareness of PEP significantly increased from 23% in 2001 to 64% in 2010. PEP use also increased from 2.3% to 3.9%, respectively. PEP use was significantly associated with being in a regular relationship with an HIV-serodiscordant partner, higher number of sex partners, engaging in anal intercourse with casual partners, and regularly testing for HIV/sexually transmitted infections. However, fewer than 8% of men who engaged in these practices reported PEP use. CONCLUSIONS: Our findings highlight the profiles of current PEP users: men in HIV-serodiscordant relationships, and men having high numbers of casual partners and unprotected anal intercourse with them. These men are in need of effective HIV prevention strategies and may be receptive to preexposure prophylaxis in the future. Presently, targeted HIV education to improve risk assessment skills may prevent some seroconversions through the appropriate use of PEP. Article	2011	Zhang, Tao; Sturgis, Timothy F.; Youan, Bi-Botti C.	pH-responsive nanoparticles releasing tenofovir intended for the prevention of HIV transmission.	European Journal of Pharmaceutics and Biopharmaceutics	-	-	-	1873-3441 0939-6411	10.1016/j.ejpb.2011.06.007	https://www.sciencedirect.com/science/article/abs/pii/S0939641111001810	This study is designed to test the hypothesis that tenofovir (TNF) or tenofovir disoproxil fumarate (TDF) loaded nanoparticles (NPs) prepared with a blend of poly(lactic-co-glycolic acid) (PLGA) and methacrylic acid copolymer (Eudragit® S-100, or S-100) are noncytotoxic and exhibit significant pH-responsive release of anti-HIV microbicides in the presence of human semen fluid simulant (SFS). After NPs preparation by emulsification diffusion, their size, encapsulation efficiency (EE%), drug release profile, morphology, and cytotoxicity are characterized by dynamic light scattering, spectrophotometry, transmission electron microscopy, and cellular viability assay/transepithelial electrical resistance measurement, respectively. Cellular uptake was elucidated by fluorescence spectroscopy and confocal microscopy. The NPs have an average size of 250 nm, maximal EE% of 16.1% and 37.2% for TNF and TDF, respectively. There is a 4-fold increase in the drug release rate from the 75% S-100 blend in the presence of SFS over 72 h. At a concentration up to 10mg/ml, the PLGA/S-100 NPs are noncytotoxic for 48 h to vaginal endocervical/epithelial cells and Lactobacillus crispatus. The particle uptake (~ 50% in 24h) by these vaginal cell lines mostly occurred through caveolin-mediated pathway. These data suggest the promise of using PLGA/S-100 NPs as an alternative controlled drug delivery system in intravaginal delivery of an anti-HIV/AIDS microbicide. Article	2011	Zhen ZHAO; Yong SUN; Qian XUE; Fan-liang MENG; Ting ZHAO; Yinuer ZAI; Hong-fang ZHOU; Ying-hua ZHANG; Jiang-hong DAI; Ai-long HUANG	Acceptability of pre-exposure prophylaxis among female sex workers in Xinjiang	Journal of Zhejiang University. Medical Sciences	-	-	-	1008-9292	10.3785/j.issn.1008-9292.2011.03.009	https://pubmed.ncbi.nlm.nih.gov/21671488/#:~:text=Conclusion%3A%20The%20acceptability%20to%20use,Pr%2DEP%20in%20the%20future.	To assess the acceptability of pre-exposure prophylaxis (Pr-EP) among the female sex workers in Xinjiang.</p><p>METHODSA volunteer-based, anonymous and one-to-one questionnaire survey was conducted in 762 female sex workers (FSW) in Urumqi and Kelamayi of Xinjiang Uyghur Autonomous Region.</p><p>RESULTAmong 762 FSW surveyed, 673 (88.32%) was not aware of pre-exposure prophylaxis with an awareness rate of 11.55%. The awareness rate of FSWs working in high-end entertainment venues was higher than that of FSWs working in medium-low end entertainment venues(P<0.001). Five hundred and twenty eight FSWs (69.29%) were willing to take Pr-EP, 145 (19.03%) were unwilling to take the medicine and 89 (11.68%) were possible to use the Pr-EP. There was no significant difference in willingness of using Pr-EP among FSWs working in high and medium-low end entertainment venuew (P=0.285). The subjects who were willing to take Pr-EP mainly concerned of the drug security, effectiveness and cost. The main reasons for not willing to take Pr-EP were: not having risk of infecting HIV, suspecting effectiveness of Pr-EP and worrying about side effects.</p><p>CONCLUSIONThe acceptability to use Pr-EP in female sex workers of Xinjiang is relatively high and the drug security, effectiveness and cost will influence the promotion and application of Pr-EP in the future.</p>	Acquired immunodeficiency syndrome/preve; Questionnaires; Femalesexworkers; Occupationale exposure; Interventionstudies; Xinjiang	Chinese	China	Asia and the Pacific	China	Asia and the Pacific	China	Asia and the Pacific	Quantitative
Article	2012	Abraham, Bisrat K; Gulick, Roy	Next-generation oral preexposure prophylaxis: beyond tenofovir.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0b013e328358b9ce	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3732461	PURPOSE OF REVIEW: Clinical trials of oral preexposure prophylaxis (PrEP) have focused on regimens of tenofovir (TDF) with or without emtricitabine (FTC). However, TDF may be associated with toxicities (renal, bone), and FTC may select for drug resistance. Both are also first-line drugs for HIV treatment. In this review, we discuss agents that might serve as alternatives to TDF/FTC for HIV PrEP. RECENT FINDINGS: Several drug characteristics are important to consider when selecting agents for PrEP with the most critical being safety, tolerability, adequate penetration into target tissues for prevention of HIV infection, and long-lasting activity with convenient dosing. With these factors in mind, we review five potentially useful agents for PrEP. The first group includes drugs that are already Food and Drug Administration approved (maraviroc, raltegravir) with attributes that make them attractive for PrEP. The second group includes investigational agents with long-lasting activity that are being developed in parenteral form (rilpivirine-long acting, S/GSK1265744, ibalizumab). SUMMARY: Future PrEP drugs may give clinicians the flexibility to select agents on the basis of individual patient needs and preferences. Theses and Dissertations	2012	Afassinou, Komi.	Mathematical analysis of pre-exposure prophylaxis on HIV infection	-	-	South African National ETD Portal	-	-	NA	http://hdl.handle.net/10413/10602	We develop a mathematical model which seeks to assess the impact of HIV Pre-Exposure Prophylaxis (PrEP) on the prevalence and incidence of HIV infection. Mathematical analysis of the model is carried out to establish the threshold conditions that determine the stability of the steady states. Numerical simulations are performed to gain insight into the use and e cacy of PrEP. Results from our model reveal that the basic reproduction number is a function of the rate at which individuals use PrEP and the rate at which PrEP protects individuals from HIV infection. Furthermore, strategies where either PrEP awareness or PrEP e cacy was low show potential loop-holes that can lead to more complications than bene ts. The best strategies revealed by our results is that a high level of awareness and high PrEP e cacy are needed	Mathematical analysis., Theses -- Mathematics. Article	2012	Amico, K Rivet	Adherence to preexposure chemoprophylaxis: the behavioral bridge from efficacy to effectiveness.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0b013e3283582d4a	https://dx.doi.org/10.1097/COH.0b013e3283582d4a	PURPOSE OF REVIEW: Remarkable advances in the use of antiretroviral medication in the prevention of HIV acquisition are receiving well deserved widespread attention. The behavioral and social-cultural factors that contextualize use of study product or preexposure prophylaxis (PrEP) are comparatively poorly understood. Given that PrEP is a bio-behavioral intervention, optimizing the potential impact of PrEP on individual and public health requires a better understanding of the behavioral aspects of PrEP adherence. This review culls across available clinical trial findings to suggest a behavioral agenda for research and practice. RECENT FINDINGS: Product use differs dramatically both within and between recent PrEP trials; however, numerous issues with measuring use have emerged. Factors influencing use or adherence are not well identified and continue to focus on the individual and discrete correlates. Presently, execution and cyclical use of open-label PrEP is unknown but is under investigation in a number of demonstration and open-label projects. SUMMARY: Research to identify methods for assessing product and PrEP use, factors influencing individual and community-level PrEP uptake and use, development of comprehensive models of protection of sexual health via multiple strategies now available, and strategies to best support adherence to dosing and HIV-testing requirements are identified as critical in a behavioral research agenda. Article	2012	Anderson, PL; Glidden, DV; Liu, A; Buchbinder, S; Lama, JR; Guanira, JV; McMahan, V; Bushman, LR; Casapía, M; Montoya-Herrera, O; Veloso, VG; Mayer, KH; Chariyalertsak, S; Schechter, M; Bekker, LG; Kallás, EG; Grant, RM	Emtricitabine-tenofovir concentrations and pre-exposure prophylaxis efficacy in men who have sex with men	Science Translational Medicine	-	-	-	NA	10.1126/scitranslmed.3004006	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-00859544/full	Drug concentrations associated with protection from HIV-1 acquisition have not been determined. We evaluated drug concentrations among men who have sex with men in a substudy of the iPrEx trial (1). In this randomized placebo-controlled trial, daily oral doses of emtricitabine/tenofovir disoproxil fumarate were used as pre-exposure prophylaxis (PrEP) in men who have sex with men. Drug was detected less frequently in blood plasma and in viable cryopreserved peripheral blood mononuclear cells (PBMCs) in HIV-infected cases at the visit when HIV was first discovered compared with controls at the matched time point of the study (8% versus 44%; P < 0.001) and in the 90 days before that visit (11% versus 51%; P < 0.001). An intracellular concentration of the active form of tenofovir, tenofovir-diphosphate (TFV-DP), of 16 fmol per million PBMCs was associated with a 90% reduction in HIV acquisition relative to the placebo arm. Directly observed dosing in a separate study, the STRAND trial, yielded TFV-DP concentrations that, when analyzed according to the iPrEx model, corresponded to an HIV-1 risk reduction of 76% for two doses per week, 96% for four doses per week, and 99% for seven doses per week. Prophylactic benefits were observed over a range of doses and drug concentrations, suggesting ways to optimize PrEP regimens for this population. Article	2012	Arnold, Emily A; Hazelton, Patrick; Lane, Tim; Christopoulos, Katerina A; Galindo, Gabriel R; Steward, Wayne T; Morin, Stephen F	A qualitative study of provider thoughts on implementing pre-exposure prophylaxis (PrEP) in clinical settings to prevent HIV infection.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0040603	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3394704	BACKGROUND: A recent clinical trial demonstrated that a daily dose tenofovir disoproxil fumarate and emtricitabine (TDF-FTC) can reduce HIV acquisition among men who have sex with men (MSM) and transgender (TG) women by 44%, and up to 90% if taken daily. We explored how medical and service providers understand research results and plan to develop clinical protocols to prescribe, support and monitor adherence for patients on PrEP in the United States. METHODS: Using referrals from our community collaborators and snowball sampling, we recruited 22 healthcare providers in San Francisco, Oakland, and Los Angeles for in-depth interviews from May-December 2011. The providers included primary care physicians seeing high numbers of MSM and TG women, HIV specialists, community health clinic providers, and public health officials. We analyzed interviews thematically to produce recommendations for setting policy around implementing PrEP. Interview topics included: assessing clinician impressions of PrEP and CDC guidance, considerations of cost, office capacity, dosing schedules, and following patients over time. RESULTS: Little or no demand for PrEP from patients was reported at the time of the interviews. Providers did not agree on the most appropriate patients for PrEP and believed that current models of care, which do not involve routine frequent office visits, were not well suited for prescribing PrEP. Providers detailed the need to build capacity and were concerned about monitoring side effects and adherence. PrEP was seen as potentially having impact on the epidemic but providers also noted that community education campaigns needed to be tailored to effectively reach specific vulnerable populations. CONCLUSIONS: While PrEP may be a novel and clinically compelling prevention intervention for MSM and TG women, it raises a number of important implementation challenges that would need to be addressed. Nonetheless, most providers expressed optimism that they eventually could prescribe and monitor PrEP in their practice. Article	2012	Baeten, Jared M; Donnell, Deborah; Ndase, Patrick; Mugo, Nelly R; Campbell, James D; Wangisi, Jonathan; Tappero, Jordan W; Bukusi, Elizabeth A; Cohen, Craig R; Katabira, Elly; Ronald, Allan; Tumwesigye, Elioda; Were, Edwin; Fife, Kenneth H; Kiarie, James; Farquhar, Carey; John-Stewart, Grace; Kakia, Aloysious; Odoyo, Josephine; Mucunguzi, Akasiima; Nakku-Joloba, Edith; Twesigye, Rogers; Ngure, Kenneth; Apaka, Cosmas; Tamooh, Harrison; Gabona, Fridah; Mujugira, Andrew; Panteleeff, Dana; Thomas, Katherine K; Kidoguchi, Lara; Krows, Meighan; Revall, Jennifer; Morrison, Susan; Haugen, Harald; Emmanuel-Ogier, Mira; Ondrejcek, Lisa; Coombs, Robert W; Frenkel, Lisa; Hendrix, Craig; Bumpus, Namandjé N; Bangsberg, David; Haberer, Jessica E; Stevens, Wendy S; Lingappa, Jairam R; Celum, Connie	Antiretroviral prophylaxis for HIV prevention in heterosexual men and women.	New England Journal of Medicine	-	-	-	1533-4406	10.1056/NEJMoa1108524	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3770474	BACKGROUND: Antiretroviral preexposure prophylaxis is a promising approach for preventing human immunodeficiency virus type 1 (HIV-1) infection in heterosexual populations. METHODS: We conducted a randomized trial of oral antiretroviral therapy for use as preexposure prophylaxis among HIV-1-serodiscordant heterosexual couples from Kenya and Uganda. The HIV-1-seronegative partner in each couple was randomly assigned to one of three study regimens--once-daily tenofovir (TDF), combination tenofovir-emtricitabine (TDF-FTC), or matching placebo--and followed monthly for up to 36 months. At enrollment, the HIV-1-seropositive partners were not eligible for antiretroviral therapy, according to national guidelines. All couples received standard HIV-1 treatment and prevention services. RESULTS: We enrolled 4758 couples, of whom 4747 were followed: 1584 randomly assigned to TDF, 1579 to TDF-FTC, and 1584 to placebo. For 62% of the couples followed, the HIV-1-seronegative partner was male. Among HIV-1-seropositive participants, the median CD4 count was 495 cells per cubic millimeter (interquartile range, 375 to 662). A total of 82 HIV-1 infections occurred in seronegative participants during the study, 17 in the TDF group (incidence, 0.65 per 100 person-years), 13 in the TDF-FTC group (incidence, 0.50 per 100 person-years), and 52 in the placebo group (incidence, 1.99 per 100 person-years), indicating a relative reduction of 67% in the incidence of HIV-1 with TDF (95% confidence interval CI, 44 to 81; P<0.001) and of 75% with TDF-FTC (95% CI, 55 to 87; P<0.001). Protective effects of TDF-FTC and TDF alone against HIV-1 were not significantly different (P=0.23), and both study medications significantly reduced the HIV-1 incidence among both men and women. The rate of serious adverse events was similar across the study groups. Eight participants receiving active treatment were found to have been infected with HIV-1 at baseline, and among these eight, antiretroviral resistance developed in two during the study. CONCLUSIONS: Oral TDF and TDF-FTC both protect against HIV-1 infection in heterosexual men and women. Article	2012	Baeten, Jared; Celum, Connie	Oral antiretroviral chemoprophylaxis: current status	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0b013e3283582d30	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3501411	PURPOSE OF REVIEW: Preexposure prophylaxis (PrEP), in which HIV uninfected persons with ongoing HIV risk use oral antiretroviral medications as chemoprophylaxis against sexual HIV acquisition, is a promising new HIV prevention strategy. RECENT FINDINGS: During the past 2 years, proof-of-concept that PrEP protects against sexual HIV acquisition has been demonstrated in three clinical trials, conducted among MSM and heterosexual men and women. These trials used daily oral tenofovir disoproxil fumarate, alone or coformulated with emtricitabine. The degree of HIV protection in these trials was strongly related to the level of adherence to PrEP. Two additional clinical trials, both among heterosexual women, did not demonstrate HIV protection with PrEP, with low adherence to daily use of PrEP the leading hypothesis for lack of efficacy; adherence and biologic mechanisms for lack of efficacy in these trial populations are being evaluated. SUMMARY: Oral chemoprophylaxis, using tenofovir and combination emtricitabine-tenofovir, is effective for prevention of sexual HIV transmission. Next steps in the field include rigorous evaluation of uptake and adherence to PrEP in implementation settings. Article	2012	Baral, Stefan D; Strömdahl, Susanne; Beyrer, Chris	The potential uses of preexposure prophylaxis for HIV prevention among people who inject drugs.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0b013e328358e49e	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3819201	PURPOSE OF REVIEW: Oral preexposure prophylaxis (PrEP) has shown HIV preventive efficacy for several key populations at risk for HIV infection including MSM and heterosexual men and women in HIV serodiscordant relationships. An efficacy trial of daily oral tenofovir among people who inject drugs (IDU) is underway in Thailand. RECENT FINDINGS: Although efficacy data is pending, there is emerging biological and public health plausibility data suggesting the utility of PrEP as an effective component of combination HIV prevention for IDU. Drawing from studies characterizing adherence to antiretroviral therapy for IDU, there are a range of scientific and operational considerations for the potential use of PrEP for IDU. We review here the available literature on the potential use of PrEP for IDU, barriers to uptake and adherence, and potential implementation science questions, which could address, and potently increase, the effectiveness of this intervention. SUMMARY: IDU remain the most underserved population in the HIV response worldwide, and have a marked gap in prevention services, making PrEP a potentially promising addition to the prevention toolkit for people who use drugs and, for those already living with HIV infection, for their spouses and other sexual partners.	HIV, injecting drug user, preexposure prophylaxis, prevention	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Theses and Dissertations	2012	Bhan, Ashika Devi	Willingness to Use Alternative HIV Prevention Methods among Internet-Using Men Who Have Sex with Men in Brazil: Implications for Pre-Exposure Prophylaxis and Home HIV Testing	-	-	Emory University	-	-	NA	https://etd.library.emory.edu/concern/etds/sj1392524?locale=zh	Background: The HIV/AIDS epidemic in Brazil remains concentrated in populations with high vulnerability to infection, including men who have sex with men (MSM). This indicates an urgent need to develop alternative HIV prevention strategies. Pre-exposure prophylaxis (PrEP) and home HIV test kits are two promising approaches that can be utilized in an optimal comprehensive HIV prevention package targeted toward MSM. Objective: The purpose of this study was to assess willingness to use PrEP and home HIV testing and their associated factors among MSM in Brazil, and to evaluate knowledge of and attitudes toward these alternative HIV prevention methods. Methods: Data were collected through an online men's health survey conducted in April 2011 and targeted toward MSM in Brazil. The primary outcomes measured were likelihood of using PrEP and likelihood of using home HIV test kits. Logistic regression was used to model participant characteristics with each outcome in bivariate and multivariate analyses. Results: Overall willingness to use PrEP and home HIV test kits among MSM was high: 67% were extremely or very likely to take PrEP, and 90% agreed that they would be likely to use home HIV tests. Only 22% had previously heard of PrEP. MSM who were aware of PrEP were more willing to use it compared with men who were unaware (OR = 1.7, 95% CI: 1.04-2.6), and these odds increased with age. Men who had anal sex recently also had increased odds of being willing to use PrEP (OR = 3.1, 95% CI: 1.1-8.3). The only significant predictor of probable home HIV test use was age (P = 0.04). MSM reported overall high willingness to use at-home testing under various hypothetical situations (P < 0.05). Conclusions: MSM in Brazil are likely to use PrEP and home HIV testing as alternative methods of HIV prevention. Additional research is needed to determine the optimal components of a tailored HIV prevention package utilizing a combination of interventions for MSM and other high-risk populations. Article	2012	Brooks, Ronald A; Landovitz, Raphael J; Kaplan, Rachel L; Lieber, Eli; Lee, Sung-Jae	Sexual Risk Behaviors and Acceptability of HIV Pre-Exposure Prophylaxis Among HIV-Negative Gay and Bisexual Men in Serodiscordant Relationships: A Mixed Methods Study	AIDS Patient Care and STDs	-	-	-	1087-2914	https://doi.org/10.1089/apc.2011.0283	https://escholarship.org/uc/item/2p85f8c1	The objective of this mixed methods study was to examine current sexual risk behaviors, acceptability and potential adoption of pre-exposure prophylaxis (PrEP) for HIV prevention, and sexual behavior intentions with PrEP adoption among HIV-negative gay and bisexual men (GBM) in HIV serodiscordant relationships. A multiracial/ethnic sample of 25 HIV-negative GBM in serodiscordant relationships completed a qualitative interview and a brief interviewer-administered survey. A modified grounded theory approach was used to identify key themes relating to acceptability and future adoption of PrEP. Participants reported engaging in sexual risk behaviors that place them at risk for HIV infection. Participants also reported a high level of acceptability for PrEP and willingness to adopt PrEP for HIV prevention. Qualitative themes explaining future PrEP adoption included: (1) the opportunity to engage in sex using a noncondom HIV prevention method, (2) protection from HIV infection, and (3) less anxiety when engaging in sex with an HIV-positive partner. Associated with the future adoption of PrEP, a majority (64%) of participants indicated the likelihood for an increase in sexual risk behaviors and a majority (60%) of participants also indicated the likelihood for a decrease or abandonment of condom use, both of which are in contrast to the findings from the large iPrEx study. These findings suggest that the use of PrEP by HIV-negative GBM in serodiscordant relationships carries with it the potential for risk compensation. The findings suggest that PrEP only be offered as part of a comprehensive HIV prevention strategy that includes ongoing risk reduction counseling in the delivery of PrEP to help moderate risk compensation. Theses and Dissertations	2012	Bruno, Christine	Pharmacists as providers of HIV pre-exposure prophylaxis	-	-	University of California	-	2210-7703	https://doi.org/10.1007/s11096-012-9709-0	https://escholarship.org/uc/item/05r4j0gb	The efficacy of HIV pre-exposure prophylaxis (PrEP) has been demonstrated in four clinical trials to date; however, the success of PrEP is largely dependent on high levels of medication adherence. Due to their extensive experience and expertise in medication adherence counseling, as well as their ability to monitor and manage medication adverse effects and drug-drug interactions, clinical pharmacists are well-equipped to play a key role in effective PrEP utilization. Here we discuss reasons favoring the establishment of a protocol-based, pharmacist-run PrEP clinic. Article	2012	Calderon, Y; Leider, J; Cowan, E; Brusalis, C; Mantell, J; Sandfort, T	HIV pre-exposure prophylaxis (PrEP)- knowledge and attitudes among a New York City emergency department patient population	Retrovirology	-	-	-	1742-4690	10.1186/1742-4690-9-S1-P94	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3360228/	HIV Pre-exposure Prophylaxis (PrEP), in which HIV-negative individuals receive antiretroviral medications to prevent HIV acquisition, has shown potential as a means to reduce HIV incidence among high-risk persons. The acceptability of PrEP among at-risk persons will strongly impact the effectiveness of PrEP. This study aimed to assess knowledge and attitudes towards PrEP within a demographically-mixed community with high HIV prevalence. Materials and methods: A cross-sectional study was conducted with a convenience sample of Emergency Department (ED) patients at two New York City municipal hospitals. Eligible participants completed an anonymous written survey about knowledge and acceptability of PrEP. Means and standard deviations were calculated for continuous variables and proportions for categorical variables. Standard bivariate methods were used to compare acceptability and knowledge by race, ethnicity and gender. Results: 474 ED patients agreed to participate. The study population was 40.9% male, 40.7% Latino and 38.2% non-Hispanic Black. 7 participants (1.5%) self-identified as MSM. Mean age was 35.3, SD +/- 13.1 years. 66.4% reported inconsistent condom use and 78.4% had previously had an HIV test. 13.3% reported knowledge of either the term "PrEP" or the use of antiretroviral medications to prevent HIV acquisition. More people indicated they were unlikely or extremely unlikely to use PrEP (40.1%) than indicated they would likely take PrEP if available (32.2%). Many (27.7%) were unsure if they would or would not take PrEP. 44.4% thought that individuals would stop using condoms if on PrEP, while 27.0% thought that individuals would continue using them. Some participants (28.4%) incorrectly thought that PrEP needed to be taken only prior to sex. There were no differences in knowledge or acceptability of PrEP by gender. Latinos were more likely (17.6%) than blacks (8.8%) and others (12.4%) to report knowledge of PrEP. Conclusions Potential providers of PrEP must consider limitations in acceptability to this HIV prevention strategy. Future administration of PrEP must incorporate patient education to ensure user understanding of the technology and its potential limitations. Article	2012	Celum, Connie; Baeten, Jared M	Antiretroviral-based HIV-1 prevention: antiretroviral treatment and pre-exposure prophylaxis	Antiviral Therapy	-	-	-	2040-2058	10.3851/IMP2492	https://journals.sagepub.com/doi/epdf/10.3851/IMP2492	Antiretroviral-based HIV-1 prevention strategies - including antiretroviral treatment (ART) to reduce the infectiousness of individuals with HIV-1 and oral and topical pre-exposure prophylaxis (PrEP) for uninfected individuals to prevent HIV-1 acquisition - are the most promising new approaches for decreasing HIV-1 spread. Observational studies among HIV-1 serodiscordant couples have associated ART initiation with a reduction in HIV-1 transmission risk of 80-92%, and a recent randomized trial demonstrated that earlier initiation of ART (that is, at CD4(+) T-cell counts between 350 and 550 cells/mm(3)), in the context of virological monitoring and adherence support, resulted in a 96% reduction in HIV-1 transmission. A number of ongoing and recently-completed clinical trials have assessed the efficacy of PrEP for HIV-1 prevention as pericoitally administered or daily-administered 1% tenofovir gel and daily oral tenofovir disoproxil fumarate (TDF) and combination emtricitabine (FTC)/TDF. Completed studies have demonstrated HIV-1 protection efficacies ranging from 39% to 75%. However, two trials in African women have shown no HIV-1 protection with TDF and FTC/TDF PrEP; the reasons for lack of efficacy in those trials are being investigated. Adherence is likely the key to efficacy of antiretrovirals for HIV-1 prevention, both as ART and PrEP. Critical unanswered questions for successful delivery of antiretroviral-based HIV-1 prevention include how to target ART and PrEP to realize maximum population benefits, whether HIV-1-infected individuals at earlier stages of infection would accept ART to reduce their risk for transmitting HIV-1 and whether highest-risk HIV-1-negative persons would use PrEP, and whether high adherence could be sustained to achieve high effectiveness. Article	2012	Celum, Connie; Baeten, Jared M	Tenofovir-based pre-exposure prophylaxis for HIV prevention: evolving evidence	Current Opinion in Infectious Diseases	-	-	-	1473-6527	10.1097/QCO.0b013e32834ef5ef	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3266126	PURPOSE OF REVIEW: Topical tenofovir gel and oral tenofovir and emtricitabine-tenofovir FTC/tenofovir disoproxyl fumarate (TDF) have been demonstrated to have efficacy in preventing HIV-1 in some populations. Preexposure prophylaxis (PrEP) trials and future directions are summarized. RECENT FINDINGS: Pericoital use of 1% tenofovir gel in the CAPRISA 004 study reduced HIV-1 acquisition by 39% and herpes simplex virus-2 acquisition by 51%. Daily oral FTC/TDF demonstrated 44% reduction in HIV-1 acquisition among MSM in the iPrEx study (Pre-Exposure Prophylaxis Initiative). Both studies showed higher efficacy among those with higher adherence. Efficacy of daily oral TDF and FTC/TDF was 66 and 73%, respectively, among HIV-1-uninfected partners in an HIV-1 serodiscordant partnership in the Partners PrEP Study. Efficacy of daily oral FTC/TDF was 66% in young heterosexuals in Botswana in the TDF2 trial. The FEM-PrEP and VOICE (Vaginal and Oral Interventions to Control the Epidemic) studies in African women found no efficacy with oral FTC/TDF and TDF, respectively. Safety and tolerability were excellent and limited resistance was observed in seroconverters. SUMMARY: Topical tenofovir gel showed efficacy in African women and daily oral TDF and FTC/TDF were efficacious in MSM, and African HIV-1 serodiscordant couples and young heterosexuals. The reasons for lack of efficacy of oral FTC/TDF and TDF in two studies in African women are being investigated. Longer-acting formulations, intravaginal rings, and new candidate antiretrovirals are being evaluated for pre-exposure prophylaxis (PrEP). Article	2012	Chan, Philip A; Huang, Austin; Kantor, Rami	Low prevalence of transmitted K65R and other tenofovir resistance mutations across different HIV-1 subtypes: implications for pre-exposure prophylaxis.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.15.2.17701	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3494163	INTRODUCTION: Tenofovir-containing regimens have demonstrated potential efficacy as pre-exposure prophylaxis (PrEP) in preventing HIV-1 infection. Transmitted drug resistance mutations associated with tenofovir, specifically the reverse transcriptase (RT) mutation K65R, may impact the effectiveness of PrEP. The worldwide prevalence of transmitted tenofovir resistance in different HIV-1 subtypes is unknown. METHODS: Sequences from treatment-naïve studies and databases were aggregated and analyzed by Stanford Database tools and as per the International AIDS Society (IAS-USA) resistance criteria. RT sequences were collected from GenBank, the Stanford HIV Sequence Database and the Los Alamos HIV Sequence Database. Sequences underwent rigorous quality control measures. Tenofovir-associated resistance mutations included K65R, K70E, T69-insertion and ≥3 thymidine analogue mutations (TAMs), inclusive of M41L or L210W. RESULTS: A total of 19,823 sequences were evaluated across diverse HIV-1 subtypes (Subtype A: 1549 sequences, B: 9783, C: 3198, D: 483, F: 372, G: 594, H: 41, J: 69, K: 239, CRF01_AE: 1797 and CRF02_AG: 1698). Overall, tenofovir resistance prevalence was 0.4% (n=77/19,823, 95% confidence interval or CI: 0.3 to 0.5). K65R was found in 20 sequences (0.1%, 95% CI: 0.06 to 0.15). Differences in the prevalence of K65R between HIV-1 subtypes were not statistically significant. K70E and ≥3 TAMs were found in 0.015% (95% CI: 0.004 to 0.04) and 0.27% (95% CI: 0.2 to 0.4) of sequences, respectively. CONCLUSIONS: Prevalence of transmitted K65R and other tenofovir resistance mutations across diverse HIV-1 subtypes and recombinants is low, suggesting minimal effect on tenofovir-containing PrEP regimens. Article	2012	Chan, Roy	Biomedical strategies for human immunodeficiency virus (HIV) prevention? A new paradigm.	Annals of the Academy of Medicine Singapore	-	-	-	2972-4066 0304-4602	NA	https://www.annals.edu.sg/pdf/41VolNo12Dec2012/V41N12p595.pdf	INTRODUCTION: This article presents recent developments in biomedical interventions for prevention of sexual transmission of the human immunodeficiency virus (HIV) infection. MATERIALS AND METHODS: A review of results from randomised clinical trials on the use of antiretroviral (ARV) medications and other biomedical methods to prevent the transmission and acquisition of HIV infection. RESULTS: Pre-exposure prophylaxis (PrEP) refers to the provision of ARV medications to uninfected persons at high risk of HIV infection either in the form of topical agents, e.g. vaginal microbicide gels, or orally administered tablets. The Caprissa study demonstrated the efficacy of vaginal microbicides, the Vaginal and Oral Interventions to Control the Epidemic (VOICE) study however was not able to confirm these results. Oral PrEP was found to be efficacious in the iPrEx study on men who have sex with men (MSM), and among heterosexual couples in the Partners-PrEP and the TDF2 studies in Africa. The HPTN 052 trial demonstrated that the provision of early ARV treatment was able to prevent transmission of HIV by 92% compared with delayed treatment. This has led to enthusiasm to roll out treatment as prevention (TasP) programmes. Encouraging results from studies on male circumcision to prevent HIV acquisition have resulted in several implementation projects in Africa. Another encouraging result has been the success, albeit modest, of the prime-boost combination RV144 vaccine trial in Thailand. CONCLUSION: New advances in prevention strategies are urgently needed to slow down the HIV pandemic. Recent developments particularly in the form of PrEP and TasP have given new hope that we will be able to achieve this goal. Article	2012	Clercq, Erik De	Pre-exposure chemoprophylaxis of HIV infection: quo vadis?	Biochem Pharmacol	-	-	-	1873-2968	10.1016/j.bcp.2011.10.016	https://dx.doi.org/10.1016/j.bcp.2011.10.016	The pre-exposure chemoprophylaxis (now commonly referred to as PrEP) of HIV infection has gained increased momentum, concomitantly with the successful use of combination drug regimens for the treatment of AIDS. A pivotal component in the current drug combination regimens for the treatment of AIDS as well as the ongoing PrEP trials is tenofovir disoproxil fumarate (TDF, Viread®) and its combination with emtricitabine (FTC). The combination of TDF with FTC has been marketed as Truvada®. TDF and TDF/FTC has proven effective, if orally administered daily or intermittently, in the prevention of rectal simian human immunodeficiency virus (SHIV) infection in macaques. Topical tenofovir gel has proven effective in the prevention of HIV infection in women in South Africa. Oral TDF/FTC has proven effective in the prevention of HIV infection in men having sex with men, and recent press releases divulged that oral TDF/FTC is also effective in preventing HIV infection in serodiscordant couples in Botswana, Kenya and Uganda. Other PrEP studies are still ongoing. Available data point to the efficacy and safety of TDF with or without FTC in the prophylaxis of HIV infection (AIDS). Editorial	2012	Cohen, Myron S; Baden, Lindsey R	Preexposure Prophylaxis for HIV — Where Do We Go from Here?	The New England Journal of Medicine	-	-	-	00284793	10.1056/NEJMe1207438	https://www.proquest.com/scholarly-journals/preexposure-prophylaxis-hiv-where-do-we-go-here/docview/1030946076/se-2?accountid=8113	Transmission of the human immunodeficiency virus (HIV) continues at a staggering rate in many areas of the world. The rate of HIV acquisition in young, healthy adults (mostly women) was 3 to 5 per 100 person-years in two trials studying heterosexual transmission of HIV in sub-Saharan Africa, now reported in the Journal (the Preexposure Prophylaxis Trial for HIV Prevention among African Women FEM-PrEP1 and the TDF2 study2). This rate of HIV transmission demands the urgent development of new prevention strategies as well as the deployment of all existing strategies, including the use of condoms, male circumcision, and the treatment . . . Article	2012	Cohen, Myron S; Muessig, Kathryn E; Smith, M Kumi; Powers, Kimberly A; Kashuba, Angela D M	Antiviral agents and HIV prevention: controversies, conflicts, and consensus.	AIDS	-	-	-	1473-5571	10.1097/QAD.0b013e3283543e83	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3651739	Antiviral agents can be used to prevent HIV transmission before exposure as preexposure prophylaxis (PrEP), after exposure as postexposure prophylaxis, and as treatment of infected people for secondary prevention. Considerable research has shed new light on antiviral agents for PrEP and for prevention of secondary HIV transmission. While promising results have emerged from several PrEP trials, the challenges of poor adherence among HIV-negative clients and possible increase in sexual risk behaviors remain a concern. In addition, a broader pipeline of antiviral agents for PrEP that focuses on genital tract pharmacology and safety and resistance issues must be developed. Antiretroviral drugs have also been used to prevent HIV transmission from HIV-infected patients to their HIV-discordant sexual partners. The HIV Prevention Trials Network 052 trial demonstrated nearly complete prevention of HIV transmission by early treatment of infection, but the generalizability of the results to other risk groups - including intravenous drug users and MSM - has not been determined. Most importantly, the best strategy for use of antiretroviral agents to reduce the spread of HIV at either the individual level or the population level has not been developed, and remains the ultimate goal of this area of investigation.	antiretroviral agents; HIV prevention; preexposure prophylaxis; treatment as prevention	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2012	Cost, Marilyn; Dezzutti, Charlene S.; Clark, Meredith R.; Friend, David R.; Akil, Ayman; Rohan, Lisa Cencia	Characterization of UC781-tenofovir combination gel products for HIV-1 infection prevention in an ex vivo ectocervical model.	Antimicrobial Agents and Chemotherapy	-	-	-	1098-6596 0066-4804	10.1128/AAC.06284-11	https://pubmed.ncbi.nlm.nih.gov/22430977/	HIV continues to be a problem worldwide. Topical vaginal microbicides represent one option being evaluated to stop the spread of HIV. With drug candidates that have a specific action against HIV now being studied, it is important that, when appropriate and based on the mechanism of action, the drug permeates the tissue so that it can be delivered to specific targets which reside there. Novel formulations of the nucleotide reverse transcriptase inhibitor tenofovir (TFV) and the nonnucleoside reverse transcriptase inhibitor UC781 have been developed and evaluated here. Gels with three distinct rheological properties were prepared. The three gels released both UC781 and TFV under in vitro conditions at concentrations equal to or above the reported 50% effective concentrations (EC(50)s). The drug concentrations in ectocervical tissues were well in excess of the reported EC(50)s. The gels maintain ectocervical viability and prevent infection of ectocervical explants after a HIV-1 challenge. This study successfully demonstrates the feasibility of using this novel combination of antiretrovirals in an aqueous gel as an HIV infection preventative. Article	2012	Date, Abhijit A.; Shibata, Annemarie; Goede, Michael; Sanford, Bridget; La Bruzzo, Krista; Belshan, Michel; Destache, Christopher J.	Development and evaluation of a thermosensitive vaginal gel containing raltegravir+efavirenz loaded nanoparticles for HIV prophylaxis.	Antiviral Research	-	-	-	1872-9096 0166-3542	10.1016/j.antiviral.2012.09.015	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3513487/	The objective of this investigation was to develop a thermosensitive vaginal gel containing raltegravir+efavirenz loaded PLGA nanoparticles (RAL+EFV-NPs) for pre-exposure prophylaxis of HIV. RAL+EFV-NPs were fabricated using a modified emulsion-solvent evaporation method and characterized for size and zeta potential. The average size and surface charge of RAL+EFV-NP were 81.8±6.4 nm and -23.18±7.18 mV respectively. The average encapsulation efficiency of raltegravir and efavirenz was 55.5% and 98.2% respectively. Thermosensitive vaginal gel containing RAL+EFV-NPs was successfully prepared using a combination of Pluronic F127 (20% w/v) and Pluronic F68 (1% w/v). Incorporation RAL+EFV-NPs in the gel did not result in nanoparticle aggregation and RAL+EFV-NPs containing gel showed thermogelation at 32.5°C. The RAL+EFV-NPs were evaluated for inhibition of HIV-1(NL4-3) using TZM-bl indicator cells. The EC(90) of RAL+EFV-NPs was lower than raltegravir+efavirenz (RAL+EFV) solution but did not reach significance. Compared to control HeLa cells without any treatment, RAL+EFV-NPs or blank gel were not cytotoxic for 14 days in vitro. The intracellular levels of efavirenz in RAL+EFV-NPs treated HeLa cells were above the EC(90) for 14 days whereas raltegravir intracellular concentrations were eliminated within 4 days. Transwell experiments of NPs-in-gel demonstrated rapid transfer of fluorescent nanoparticles from the gel and uptake in HeLa cells within 30 min. These data demonstrate the potential of antiretroviral NP-embedded vagina gels for long-term vaginal pre-exposure prophylaxis of heterosexual HIV-1 transmission. Article	2012	De Clercq, Erik	Tenofovir: quo vadis anno 2012 (where is it going in the year 2012)?	Medicinal Research Reviews	-	-	-	1098-1128 0198-6325	10.1002/med.21267	https://pubmed.ncbi.nlm.nih.gov/22581627/	Twenty years after its original discovery, tenofovir has acquired a crucial position in the fight against human immunodeficiency virus (HIV). First, tenofovir disoproxil fumarate (TDF) is not only efficacious against, and has been licensed for the treatment of HIV (AIDS), but also HBV (hepatitis B). Second, for the treatment of HIV infections, TDF can be used in combination with other anti-HIV drugs, such as emtricitabine (combination termed Truvada(®)) and Truvada can be further combined with efavirenz, rilpivirine, elvitegravir, atazanavir, or darunavir, as a single once-daily oral pill. Third, Truvada can be used prophylactically to prevent transmission of HIV infection. And fourth, to prevent sexual HIV transmission, tenofovir could also be used topically (i.e., as a vaginal gel). It updates numerous preventive approaches including behavioral interventions, male circumcision (MC), pre- and post-exposure prophylaxis (PREP and PEP), vaccines, and microbicides. The manuscript summarizes current anti-retroviral treatment options, their impact in the western world, and difficulties faced by emerging and resource-limited nations in providing and maintaining appropriate treatment regimens. Current clinical and pre-clinical approaches toward a cure for HIV are described, including new drug compounds that target viral reservoirs and gene therapy approaches aimed at altering susceptibility to HIV infection. Recent progress in vaccine development is summarized, including novel approaches and new discoveries.	animal model; ART treatment; global strategies; HIV pandemic; prevention; vaccine development; RHESUS MACAQUES; ANTIRETROVIRAL THERAPY; PREEXPOSURE PROPHYLAXIS; DOUBLE-BLIND; HUMANIZED BLT MICE; INJECTION-DRUG USERS; NEUTRALIZING ANTIBODIES; EFFECTIVE HIV VACCINE; HISTONE DEACETYLASE INHIBITORS; STRUCTURE-BASED DESIGN	English	Switzerland	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2012	Dimitrov, Dobromir; Boily, Marie-Claude; Mâsse, Benoît R; Brown, Elizabeth R	Impact of Pill Sharing on Drug Resistance Due to a Wide-Scale Oral Prep Intervention in Generalized Epidemics.	Journal of AIDS & Clinical Research	-	-	-	2155-6113	10.4172/2155-6113.s5-004	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3870903	BACKGROUND: The first antiretroviral drug (Truvada) to be used as a pre-exposure prophylaxis (PrEP) in preventing HIV transmission is about to be approved. Behavioral studies suggest that a portion of users may share anti-retroviral drugs with sex partners, family, or friends. Pill sharing will decrease PrEP efficacy and adherence level, and potentially create an environment favorable for the development of drug resistance. We aim to evaluate the potential impact of pill sharing on the PrEP effectiveness and on the rates of drug-resistance development in heterosexual populations. METHODS: A transmission dynamic model was used to assess the population-level impact of oral PrEP. The fractions of new HIV infections prevented (CPF), drug resistance prevalence and the proportion of new infections in which drug-resistant HIV is transmitted (TDR) are evaluated over fixed time periods. The influence of different factors on CPF and TDR is studied through simulations, using epidemic parameters representative of the countries in Sub-Saharan Africa. RESULTS: Without pill sharing, a 70% efficacious PrEP used consistently by 60% of uninfected individuals prevents 52.8% (95% CI 49.4%-56.4%) of all new HIV infections over ten years with drug-resistant HIV transmitted in 2.2% of the new infections. Absolute CPF may vary by 9% if up to 20% of the users share PrEP while the level of TDR and total resistance prevalence may increase by up to 6-fold due to pill sharing in some intervention scenarios. CONCLUSION: Pill sharing may increase the PrEP coverage level achieved in the population but it also affects the PrEP efficacy for the users who do not follow the prescribed schedule. More importantly, it creates a pool of untracked users who remain unreached by the effort to avoid sub-optimal PrEP usage by infected people. This increases substantially the potential risk of drug resistance in the population. Article	2012	Dolling, D; Phillips, A N; Delpech, V; Pillay, D; Cane, P A; Crook, A M; Shepherd, J; Fearnhill, E; Hill, T; Dunn, D	Evaluating the extent of potential resistance to pre-exposure prophylaxis within the UK HIV-1-infectious population of men who have sex with men.	HIV Medicine	-	-	-	1468-1293	10.1111/j.1468-1293.2011.00968.x	https://dx.doi.org/10.1111/j.1468-1293.2011.00968.x	OBJECTIVES: Recent studies have shown that pre-exposure prophylaxis (PrEP) can substantially reduce the chance of acquiring HIV infection. However, PrEP efficacy has been found to be compromised in macaque studies if the challenge virus is antiretroviral therapy (ART)-resistant. Our objective was to evaluate the likelihood that a UK man who has sex with men (MSM) would be exposed to PrEP-resistant HIV in a homosexual encounter with an HIV-infectious partner. METHODS: Data from the UK Collaborative HIV Cohort (UK CHIC) study were linked to the UK HIV Drug Resistance Database for HIV-1-positive MSM patients seen between 2005 and 2008. Patients were categorized as undiagnosed; diagnosed but ART-naïve; ART-experienced and on treatment; and ART-experienced and on a treatment interruption. Considering current PrEP regimens, resistance to (a) tenofovir (TDF) alone, (b) TDF and emtricitabine (FTC), and (c) TDF or FTC was estimated. Patients without resistance tests had PrEP resistance imputed using bootstrapping and logistic regression models. RESULTS: The population-level prevalence of PrEP resistance in HIV-infectious individuals in 2008 was estimated to be 1.6, 0.9 and 4.1% for PrEP resistance definitions a, b and c, respectively. Prevalence in ART-experienced patients was highest, with negligible circulating resistance amongst ART-naïve individuals. The levels of resistance declined over the period of study. CONCLUSIONS: Our analysis indicates low levels of resistance to proposed PrEP drugs. The estimated PrEP resistance prevalence in UK HIV-infected MSM is towards the lower range of values used in simulation studies which have suggested that circulating PrEP drug resistance will have a negligible impact on PrEP efficacy at the population level. Article	2012	Duwal, Sulav; Schütte, Christof; von Kleist, Max	Pharmacokinetics and pharmacodynamics of the reverse transcriptase inhibitor tenofovir and prophylactic efficacy against HIV-1 infection.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0040382	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3394807	Antiviral pre-exposure prophylaxis (PrEP) through daily drug administration can protect healthy individuals from HIV-1 infection. While PrEP was recently approved by the FDA, the potential long-term consequences of PrEP implementation remain entirely unclear. The aim of this study is to predict the efficacy of different prophylactic strategies with the pro-drug tenofovir-disoproxil-fumarate (TDF) and to assess the sensitivity towards timing- and mode of TDF administration (daily- vs. single dose), adherence and the number of transmitted viruses. We developed a pharmacokinetic model for TDF and its active anabolite tenofovir-diphosphate (TFV-DP) and validated it with data from 4 different trials, including 4 distinct dosing regimes. Pharmacokinetics were coupled to an HIV model and viral decay following TDF mono-therapy was predicted, consistent with available data. Subsequently, a stochastic approach was used to estimate the % infections prevented by (i) daily TDF-based PrEP, (ii) one week TDF started either shortly before, or -after viral exposure and (iii) a single dose oral TDF before viral challenge (sd-PrEP). Analytical solutions were derived to assess the relation between intracellular TFV-DP concentrations and prophylactic efficacy. The predicted efficacy of TDF was limited by a slow accumulation of active compound (TFV-DP) and variable TFV-DP half-life and decreased with increasing numbers of transmitted viruses. Once daily TDF-based PrEP yielded Formula: see text80% protection, if at least 40% of pills were taken. Sd-PrEP with 300 mg or 600 mg TDF could prevent Formula: see text50% infections, when given at least before virus exposure. The efficacy dropped to Formula: see text10%, when given 1 h before 24 h exposure. Efficacy could not be increased with increasing dosage or prolonged administration. Post-exposure prophylaxis poorly prevented infection. The use of drugs that accumulate more rapidly, or local application of tenofovir gel may overcome the need for drug administration long before virus exposure. Article	2012	Eisingerich, Andreas B; Wheelock, Ana; Gomez, Gabriela B; Garnett, Geoffrey P; Dybul, Mark R; Piot, Peter K	Attitudes and acceptance of oral and parenteral HIV preexposure prophylaxis among potential user groups: a multinational study.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0028238	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3256136	BACKGROUND: The use of antiviral medications by HIV negative people to prevent acquisition of HIV or pre-exposure prophylaxis (PrEP) has shown promising results in recent trials. To understand the potential impact of PrEP for HIV prevention, in addition to efficacy data, we need to understand both the acceptability of PrEP among members of potential user groups and the factors likely to determine uptake. METHODS AND FINDINGS: Surveys of willingness to use PrEP products were conducted with 1,790 members of potential user groups (FSWs, MSM, IDUs, SDCs and young women) in seven countries: Peru, Ukraine, India, Kenya, Botswana, Uganda and South Africa. Analyses of variance were used to assess levels of acceptance across different user groups and countries. Conjoint analysis was used to examine the attitudes and preferences towards hypothetical and known attributes of PrEP programs and medications. Overall, members of potential user groups were willing to consider taking PrEP (61% reported that they would definitely use PrEP). Current results demonstrate that key user groups in different countries perceived PrEP as giving them new possibilities in their lives and would consider using it as soon as it becomes available. These results were maintained when subjects were reminded of potential side effects, the need to combine condom use with PrEP, and for regular HIV testing. Across populations, route of administration was considered the most important attribute of the presented alternatives. CONCLUSIONS: Despite multiple conceivable barriers, there was a general willingness to adopt PrEP in key populations, which suggests that if efficacious and affordable, it could be a useful tool in HIV prevention. There would be a willingness to experience inconvenience and expense at the levels included in the survey. The results suggest that delivery in a long lasting injection would be a good target in drug development. Theses and Dissertations	2012	Evans, Emerson	Assessing the Knowledge and Attitudes of Black/African American Men who have Sex with Men on HIV Pre-Exposure Prophylaxis	-	-	University of Pittsburgh	-	na	NA	http://d-scholarship.pitt.edu/12021/	Background: African American men who have sex with men (MSM) represent 37% of the HIV incidence among all MSM and young Black MSM observed a significant increase of 48% in new infections during 2006-2009. There were 6,500 infections in Black MSM aged 13-29 exceeding the number of infections of White MSM aged 13-29 and 30-39 combined. In 2010, results from the Global iPrEX clinical trial showed 44% efficacy of oral pre-exposure prophylaxis among MSM. The implementation of PrEP as a HIV prevention tool may have positive implications in reducing the disparity of HIV infection among Black MSM. Methods: Participants were recruited and sampled for an online survey using the social networking sites Facebook and Twitter. Eligibility for participation was contingent upon self-reported response as Black/African American, an MSM, HIV negative or unaware of HIV status, and over 18 years of age. Informed consent was obtained. Behavioral data was collected from participants on sexual behaviors, HIV testing, and self-perceived susceptibility to HIV infection. Participants were asked specifically their knowledge of PrEP and likeliness of using PrEP to reduce risk of HIV infection. Results: The sample pre-eligibility included 178 respondents. 20.5% (32) respondents reported being HIV positive. After eligibility was determined 99 respondents were included in the analysis. 56.4% of the sample reported having little or no knowledge of PrEP yet would use PrEP to reduce their risk of HIV infection. Age was the strongest indicator of all the independent variables on PrEP acceptance being statistically significant in all models of the regression analysis. Conclusions: Contrary to the original hypothesis, an inverse relationship between PrEP knowledge and acceptance was ascertained in the current study. Some possible explanations for this interesting finding are that respondents were unaware of the risks and benefits of pre-exposure prophylaxis and were concerned about preventing themselves from contracting HIV. Also if respondents were to use PrEP, it would likely have to be at little or no individual out of pocket costs. There are a number of factors influencing such high acceptance of PrEP among Black MSM and the current study was able to ascertain some of these factors. These findings have public health significance to the current epidemiology of HIV infection in the United States and further prevention efforts. Article	2012	Fei-Fei GAO	Pre-exposure prophylaxis for HIV high-risk groups: An analysis of clinical compliance	Academic Journal of Second Military Medical University	-	-	-	0258-879X	NA	https://pesquisa.bvsalud.org/portal/resource/pt/wpr-839866	Objective: To investigate the factors influencing the compliance of pre-exposure prophylaxis (PrEP) among high-risk groups of human immunodeficiency virus (HIV). Methods: A total of 352 subjects were selected into the cohort by non-probability sampling, including 153 men who have sex with men (MSM), 36 female sex workers (FSMs), and 163 fixed sex partners(PARs) of HIV carriers. Each subject was randomly given a medication regimen of either once daily or twice a week. The pre-exposure prophylaxis compliance was evaluated by observing the maintenance of the cohort and medication omission every 4 weeks from week 0 to week 28. Cochran-Mantel-Haenszel (CMH) test was employed to conduct univariate analysis and logistic regression was adopted for multiple variable analysis. Results: It was found that 76. 70% (270/352) of the subjects finished the 28-week-observation in this PrEP clinical trial among high-risk groups of HIV. The medication omission rate fluctuated around 35% during the follow-up, with the total compliance score being 82. 12 ± 27. 48 and the median score being 95. 24. Logistic regression suggested that the monthly income, presence of worries or difficulties during the trials, need for medical service, and the way of follow-up were the factors influencing the maintenance of cohort. The marital status, medication method, presence of worries or difficulties during the trial, and presence of adverse effect were the influencing factors of medication omission. The population typ e, number of sex partners, taking of other drugs at the same time, need of medical service during the trial, and way of follow-up were the factors impacting the overall compliance score. Conclusion: The compliance of the present PrEP clinical trials among high-risk groups of HIV is high, and it has multiple influencing factors. Compliance management should be reinforced among MSM and FSW populations with greater motility. The cohort management model of follow-up by fixed specialists should be continued with more frequent follow-up; meanwhile, classified management should be implemented for individuals with different characters, so as to ensure a good compliance during the clinical trials. Article	2012	Fernández-Montero, José Vicente; Barreiro, Pablo; Del Romero, Jorge; Soriano, Vincent	Antiretroviral drugs for pre-exposure prophylaxis of HIV infection.	AIDS Reviews	-	-	-	1698-6997	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-22297504	Though a large number of antiretrovirals have been developed for the treatment of HIV infection, new HIV infections continue to occur, especially among certain high-risk groups, such as men who have sex with men. Overall, the current estimated incidence of HIV infection is 2.5-fold higher than the number of individuals that begin antiretroviral therapy every year worldwide. Along with the personal drama caused by the diagnosis of HIV infection, other considerations in society, including economics and interpersonal relationships, make the need for HIV prevention strategies a priority. Though vaccines have shown great efficacy in the combat of other epidemics, currently there is no effective vaccine against HIV, and it is unlikely that any will become available in the near future. Thus, new approaches such as pre-exposure prophylaxis are viewed with increasing interest. The results from recent clinical trials have provided support in favor of distinct pre-exposure prophylaxis modalities. However, concerns exist about increasing risky behaviors and selection and spread of antiretroviral drug resistance with a broader use of pre-exposure prophylaxis. The aim of this review is to examine the evidence available on the effectiveness of pre-exposure prophylaxis and its potential influence on the HIV epidemics. Article	2012	Flash, Charlene; Krakower, Douglas; Mayer, Kenneth H	The Promise of Antiretrovirals for HIV Prevention.	Current Infectious Disease Reports	-	-	-	1534-3146	10.1007/s11908-012-0242-z	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3901012	With an estimated 2.6 million new HIV infections diagnosed annually, the world needs new prevention strategies to partner with condom use, harm reduction approaches for injection drug users, and male circumcision. Antiretrovirals can reduce the risk of mother-to-child HIV transmission and limit HIV acquisition after occupational exposure. Macaque models and clinical trials demonstrate efficacy of oral or topical antiretrovirals used prior to HIV exposure to prevent HIV transmission, ie pre-exposure prophylaxis (PrEP). Early initiation of effective HIV treatment in serodiscordant couples results in a 96% decrease in HIV transmission. HIV testing to determine serostatus and identify undiagnosed persons is foundational to these approaches. The relative efficacy of different approaches, adherence, cost and long-term safety will affect uptake and impact of these strategies. Ongoing research will help characterize the role for oral and topical formulations and help quantify potential benefits in sub-populations at risk for HIV acquisition. Article	2012	Galindo, Gabriel R; Garrett-Walker, J J; Hazelton, Patrick; Lane, Tim; Steward, Wayne T; Morin, Stephen F; Arnold, Emily A	Community member perspectives from transgender women and men who have sex with men on pre-exposure prophylaxis as an HIV prevention strategy: implications for implementation.	Implementation Science	-	-	-	1748-5908	10.1186/1748-5908-7-116	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3527231	BACKGROUND: An international randomized clinical trial (RCT) on pre-exposure prophylaxis (PrEP) as an human immunodeficiency virus (HIV)-prevention intervention found that taken on a daily basis, PrEP was safe and effective among men who have sex with men (MSM) and male-to-female transgender women. Within the context of the HIV epidemic in the United States (US), MSM and transgender women are the most appropriate groups to target for PrEP implementation at the population level; however, their perspectives on evidenced-based biomedical research and the results of this large trial remain virtually unknown. In this study, we examined the acceptability of individual daily use of PrEP and assessed potential barriers to community uptake. METHODS: We conducted semi-structured interviews with an ethnoracially diverse sample of thirty HIV-negative and unknown status MSM (n = 24) and transgender women (n = 6) in three California metropolitan areas. Given the burden of disease among ethnoracial minorities in the US, we purposefully oversampled for these groups. Thematic coding and analysis of data was conducted utilizing an approach rooted in grounded theory. RESULTS: While participants expressed general interest in PrEP availability, results demonstrate: a lack of community awareness and confusion about PrEP; reservations about PrEP utilization, even when informed of efficacious RCT results; and concerns regarding equity and the manner in which a PrEP intervention could be packaged and marketed in their communities. CONCLUSIONS: In order to effectively reduce HIV health disparities at the population level, PrEP implementation must take into account the uptake concerns of those groups who would actually access and use this biomedical intervention as a prevention strategy. Recommendations addressing these concerns are provided. Article	2012	García-Lerma, J Gerardo; Heneine, Walid	Animal models of antiretroviral prophylaxis for HIV prevention.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0b013e328358e484	https://dx.doi.org/10.1097/COH.0b013e328358e484	PURPOSE OF REVIEW: Oral and topical pre-exposure prophylaxis (PrEP) with antiretroviral drugs are novel biomedical interventions recently found to prevent HIV transmission among high-risk populations. In this review, we outline lessons learned from animal studies and discuss next steps in preclinical PrEP research including the study of new PrEP modalities, pharmacologic correlates of protection, and biological factors that may modulate PrEP efficacy. RECENT FINDINGS: Studies using macaque or humanized mice models of mucosal simian immunodeficiency virus (SIV), HIV, or simian/human immunodeficiency virus (SHIV) transmission have provided efficacy data against rectal and vaginal infection. A multitude of oral and topical PrEP regimens including drugs such as tenofovir (TFV), tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) were found protective against either wild-type or drug-resistant viruses. These models have also helped define prophylactic windows of protection of nondaily dosing and are being used increasingly to study pharmacokinetic and pharmacodynamic relationships. SUMMARY: As human data from PrEP trials validate animal models or help fine tune them, it is expected that these models will play increasingly important roles in PrEP development as the field extends into new drug classes and combinations, episodic dosing, and novel long-acting drug formulations. By providing both efficacy and pharmacologic information these models can define correlates and mechanisms of protection, inform dose selection, and advance the most promising PrEP candidates and dosing modalities. Article	2012	Gengiah, Tanuja N; Baxter, Cheryl; Mansoor, Leila E; Kharsany, Ayesha Bm; Abdool Karim, Salim S	A drug evaluation of 1% tenofovir gel and tenofovir disoproxil fumarate tablets for the prevention of HIV infection.	Expert Opinion on Investigational Drugs	-	-	-	1744-7658	10.1517/13543784.2012.667072	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3460694	INTRODUCTION: More than a million people acquire HIV infection annually. Pre-exposure prophylaxis (PrEP) using antiretrovirals is currently being investigated for HIV prevention. Oral and topical formulations of tenofovir have undergone preclinical and clinical testing to assess acceptability, safety and effectiveness in preventing HIV infection. AREAS COVERED: The tenofovir drug development pathway from compound discovery, preclinical animal model testing and human testing were reviewed for safety, tolerability and efficacy. Tenofovir is well tolerated and safe when used both systemically or applied topically for HIV prevention. High drug concentrations at the site of HIV transmission and concomitant low systemic drug concentrations are achieved with vaginal application. Coitally applied gel may be the favored prevention option for women compared with the tablets, which may be more suitable for prevention in men and sero-discordant couples. However, recent contradictory effectiveness outcomes in women need to be better understood. EXPERT OPINION: Emerging evidence has brought new hope that antiretrovirals can potentially change the course of the HIV epidemic when used as early treatment for prevention, as topical or oral PrEP. Although some trial results appear conflicting, behavioral factors, adherence to dosing and pharmacokinetic properties of the different tenofovir formulations and dosing approaches offer plausible explanations for most of the variations in effectiveness observed in different trials. Article	2012	Gibb, Diana M.; Kizito, Hilda; Russell, Elizabeth C.; Chidziva, Ennie; Zalwango, Eva; Nalumenya, Ruth; Spyer, Moira; Tumukunde, Dinah; Nathoo, Kusum; Munderi, Paula; Kyomugisha, Hope; Hakim, James; Grosskurth, Heiner; Gilks, Charles F.; Walker, A. Sarah; Musoke, Phillipa	Pregnancy and infant outcomes among HIV-infected women taking long-term ART with and without tenofovir in the DART trial.	PLOS Medicine	-	-	-	1549-1676 1549-1277	10.1371/journal.pmed.1001217	https://journals.plos.org/plosmedicine/article?id=10.1371/journal.pmed.1001217	BACKGROUND: Few data have described long-term outcomes for infants born to HIV-infected African women taking antiretroviral therapy (ART) in pregnancy. This is particularly true for World Health Organization (WHO)-recommended tenofovir-containing first-line regimens, which are increasingly used and known to cause renal and bone toxicities; concerns have been raised about potential toxicity in babies due to in utero tenofovir exposure. METHODS AND FINDINGS: Pregnancy outcome and maternal/infant ART were collected in Ugandan/Zimbabwean HIV-infected women initiating ART during The Development of AntiRetroviral Therapy in Africa (DART) trial, which compared routine laboratory monitoring (CD4; toxicity) versus clinically driven monitoring. Women were followed 15 January 2003 to 28 September 2009. Infant feeding, clinical status, and biochemistry/haematology results were collected in a separate infant study. Effect of in utero ART exposure on infant growth was analysed using random effects models. 382 pregnancies occurred in 302/1,867 (16%) women (4.4/100 woman-years 95% CI 4.0-4.9). 226/390 (58%) outcomes were live-births, 27 (7%) stillbirths (≥22 wk), and 137 (35%) terminations/miscarriages (<22 wk). Of 226 live-births, seven (3%) infants died <2 wk from perinatal causes and there were seven (3%) congenital abnormalities, with no effect of in utero tenofovir exposure (p>0.4). Of 219 surviving infants, 182 (83%) enrolled in the follow-up study; median (interquartile range IQR) age at last visit was 25 (12-38) months. From mothers' ART, 62/9/111 infants had no/20%-89%/≥90% in utero tenofovir exposure; most were also zidovudine/lamivudine exposed. All 172 infants tested were HIV-negative (ten untested). Only 73/182(40%) infants were breast-fed for median 94 (IQR 75-212) days. Overall, 14 infants died at median (IQR) age 9 (3-23) months, giving 5% 12-month mortality; six of 14 were HIV-uninfected; eight untested infants died of respiratory infection (three), sepsis (two), burns (one), measles (one), unknown (one). During follow-up, no bone fractures were reported to have occurred; 12/368 creatinines and seven out of 305 phosphates were grade one (16) or two (three) in 14 children with no effect of in utero tenofovir (p>0.1). There was no evidence that in utero tenofovir affected growth after 2 years (p=0.38). Attained height- and weight for age were similar to general (HIV-uninfected) Ugandan populations. Study limitations included relatively small size and lack of randomisation to maternal ART regimens. CONCLUSIONS: Overall 1-year 5% infant mortality was similar to the 2%-4% post-neonatal mortality observed in this region. No increase in congenital, renal, or growth abnormalities was observed with in utero tenofovir exposure. Although some infants died untested, absence of recorded HIV infection with combination ART in pregnancy is encouraging. Detailed safety of tenofovir for pre-exposure prophylaxis will need confirmation from longer term follow-up of larger numbers of exposed children. Article	2012	Gilliam, Bruce L.; Patel, Devang; Talwani, Rohit; Temesgen, Zelalem	HIV in Africa: Challenges and Directions for the Next Decade.	Current Infectious Disease Reports	-	-	-	1534-3146 1523-3847	10.1007/s11908-011-0230-8	https://pubmed.ncbi.nlm.nih.gov/22143960/	Africa carries a disproportionate burden of the global HIV endemic, accounting for two thirds of the global 33.3 million people living with HIV. While tremendous advances have been made in addressing the HIV epidemic in Africa, considerable challenges remain. Testing for HIV increased by 86% from 2007 to 2009 but more than 75% of people 15-49 years remain unaware of their HIV status. CD4 count at diagnosis tends to be low and linkage to care and treatment is suboptimal. The scale-up of antiretroviral therapy is ongoing but is hampered by the lack of diagnostic capability to monitor response to therapy and a substantial healthcare workforce shortage. Prevention strategies such as male circumcision, pre-exposure prophylaxis, and antiretroviral therapy for prevention have generated great excitement but cost and healthcare infrastructure deficiencies may limit their widespread applicability. Operational research to validate and inform treatment decisions, health care policies, and prevention strategies is sorely needed.	HIV. Africa. Antiretroviral treatment. Monitoring. Article	2012	Gomez, Gabriela B; Borquez, Annick; Caceres, Carlos F; Segura, Eddy R; Grant, Robert M; Garnett, Geoff P; Hallett, Timothy B	The potential impact of pre-exposure prophylaxis for HIV prevention among men who have sex with men and transwomen in Lima, Peru: a mathematical modelling study.	PLOS Medicine	-	-	-	1549-1676	10.1371/journal.pmed.1001323	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3467261	BACKGROUND: HIV pre-exposure prophylaxis (PrEP), the use of antiretroviral drugs by uninfected individuals to prevent HIV infection, has demonstrated effectiveness in preventing acquisition in a high-risk population of men who have sex with men (MSM). Consequently, there is a need to understand if and how PrEP can be used cost-effectively to prevent HIV infection in such populations. METHODS AND FINDINGS: We developed a mathematical model representing the HIV epidemic among MSM and transwomen (male-to-female transgender individuals) in Lima, Peru, as a test case. PrEP effectiveness in the model is assumed to result from the combination of a "conditional efficacy" parameter and an adherence parameter. Annual operating costs from a health provider perspective were based on the US Centers for Disease Control and Prevention interim guidelines for PrEP use. The model was used to investigate the population-level impact, cost, and cost-effectiveness of PrEP under a range of implementation scenarios. The epidemiological impact of PrEP is largely driven by programme characteristics. For a modest PrEP coverage of 5%, over 8% of infections could be averted in a programme prioritising those at higher risk and attaining the adherence levels of the Pre-Exposure Prophylaxis Initiative study. Across all scenarios, the highest estimated cost per disability-adjusted life year averted (uniform strategy for a coverage level of 20%, US$1,036-US$4,254) is below the World Health Organization recommended threshold for cost-effective interventions, while only certain optimistic scenarios (low coverage of 5% and some or high prioritisation) are likely to be cost-effective using the World Bank threshold. The impact of PrEP is reduced if those on PrEP decrease condom use, but only extreme behaviour changes among non-adherers (over 80% reduction in condom use) and a low PrEP conditional efficacy (40%) would adversely impact the epidemic. However, PrEP will not arrest HIV transmission in isolation because of its incomplete effectiveness and dependence on adherence, and because the high cost of programmes limits the coverage levels that could potentially be attained. CONCLUSIONS: A strategic PrEP intervention could be a cost-effective addition to existing HIV prevention strategies for MSM populations. However, despite being cost-effective, a substantial expenditure would be required to generate significant reductions in incidence. Please see later in the article for the Editors' Summary. Article	2012	Grobler, Anneke C.; Abdool Karim, Salim S.	Design challenges facing clinical trials of the effectiveness of new HIV-prevention technologies.	AIDS	-	-	-	1473-5571 0269-9370	10.1097/QAD.0b013e3283509a29	https://journals.lww.com/aidsonline/citation/2012/03130/design_challenges_facing_clinical_trials_of_the.1.aspx	Recent successes of antiretroviral pre-exposure prophylaxis (PrEP) in preventing HIV infection have raised questions whether further placebo controlled trials of new HIV-prevention technologies are ethically justifiable. A trial with active agent(s) in the comparator group can be designed either as a superiority or non-inferiority trial. In a non-inferiority trial the hypothesis tested is that the intervention is not inferior to, by a predefined clinically relevant amount, or at least as effective as, the comparator. Non-inferiority trials pose challenges in data interpretation. Firstly it is possible to show equivalence of two non-effective interventions. If the active comparator intervention is ineffective, the new intervention would be shown to be non-inferior to this inactive intervention, while neither intervention is superior to placebo or no intervention. The second challenge is that any effect that dilutes the true efficacy of an intervention in a trial, such as non-adherence, loss to follow-up or protocol violations, makes it easier for the two interventions to be declared equivalent. Non-differential low adherence is unlikely to lead to the conclusion that an inferior intervention is non-inferior. However, differential adherence between study arms, which is more likely in non-blinded trials, is likely to bias the results and lead to incorrect conclusions. Investigators conducting non-inferiority trials will have to pay special attention to supporting, measuring and maintaining high adherence. The goal in future non-inferiority trials should be to maintain similar levels of high adherence in all study arms, but at a minimum to reduce the likelihood of differential adherence across study arms. Article	2012	Heffron, Renee; Ngure, Kenneth; Mugo, Nelly; Celum, Connie; Kurth, Ann; Curran, Kathryn; Baeten, Jared M	Willingness of Kenyan HIV-1 serodiscordant couples to use antiretroviral-based HIV-1 prevention strategies.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0b013e31825da73f	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3427394	INTRODUCTION: Antiretroviral treatment (ART) and pre-exposure prophylaxis (PrEP) have demonstrated efficacy as new human immunodeficiency virus-1 (HIV-1) prevention approaches for HIV-1 serodiscordant couples. METHODS: Among Kenyan HIV-1 serodiscordant heterosexual couples participating in a clinical trial of PrEP, we conducted a cross-sectional study and used descriptive statistical methods to explore couples' willingness to use antiretrovirals for HIV-1 prevention. The study was conducted before July 2011, when studies among heterosexual populations reported that ART and PrEP reduced HIV-1 risk. RESULTS: For 181 couples in which the HIV-1-infected partner had a CD4 count ≥350 cells per microliter and had not yet initiated ART (and thus did not qualify for ART under Kenyan guidelines), 60.2% of HIV-1 infected partners (69.4% of men and 57.9% of women) were willing to use early ART (at CD4 ≥350 cells per microliter) for HIV-1 prevention. Among HIV-1 uninfected partners, 92.7% (93.8% of men and 86.1% of women) reported willingness to use PrEP. When given a hypothetical choice of early ART or PrEP for HIV-1 prevention, 52.5% of HIV-1-infected participants would prefer to initiate ART early and 56.9% of HIV-1-uninfected participants would prefer to use PrEP. CONCLUSIONS: Nearly 40% of Kenyan HIV-1-infected individuals in known HIV-1 serodiscordant partnerships reported reservations about early ART initiation for HIV-1 prevention. PrEP interest in this PrEP-experienced population was high. Strategies to achieve high uptake and sustained adherence to ART and PrEP for HIV-1 prevention in HIV-1 serodiscordant couples will require responding to couples' preferences for prevention strategies. Article	2012	Hendrix, Craig W	The clinical pharmacology of antiretrovirals for HIV prevention.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0b013e32835847ae	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6986781	PURPOSE OF REVIEW: Pre-exposure prophylaxis (PrEP) clinical trial results using antiretrovirals can seem confusing, if not conflicting. We review recent antiretroviral pharmacokinetic studies to help explain PrEP trial results. RECENT FINDINGS: Pharmacokinetic studies indicate that topical dosing, compared with oral dosing, achieves far higher colon and vaginal tissue drug concentrations, and far lower drug concentrations in blood. After oral dosing, higher tenofovir diphosphate concentrations are found in colon tissue than cervico-vaginal tissue, but the reverse is the case for emtricitabine triphosphate, although it does not persist as long. Vaginal dosing achieves measurable tenofovir concentrations in the rectum and vice versa. Within and among oral PrEP trials, increased drug concentration is associated with increased HIV protection, with drug concentration differences best explained by adherence, rather than pharmacokinetics. The poor level of protection in topical studies is not consistent with concentration-response in oral studies indicating unknown variables in need of further investigation. SUMMARY: Sparse pharmacokinetic sampling in large trials combined with more intensive sampling in smaller pharmacokinetic-focused studies help explain trial outcome differences due largely to differences in adherence, tissue pharmacokinetics, and type of HIV exposure. Pharmacokinetic analysis can identify protective drug concentration targets, guide dose optimization, and inform future trials. Article	2012	Heneine, Walid; Kashuba, Angela	HIV prevention by oral preexposure prophylaxis.	Cold Spring Harbor Perspectives in Medicine	-	-	-	2157-1422	10.1101/cshperspect.a007419	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3282498	The impressive advances in antiretroviral (ARV) therapy of chronic human immunodeficiency virus (HIV) infections during the last decade and the availability of potent ARV drugs have fueled interest in using chemoprophylaxis as a novel HIV prevention strategy. Preexposure prophylaxis (PrEP) refers to the use of ARV drugs in HIV-negative persons to prevent HIV infection. The rationale for PrEP builds on the success of ARV prophylaxis in preventing mother-to-child transmission of HIV and on a large body of animal studies that show the efficacy of PrEP against mucosal and parenteral infection. We focus on oral administration of ARV drugs for prevention of HIV infection. Identifying an effective prophylactic pill that individuals can take outside the setting of sexual intercourse precludes the necessity to disclose such use to their partners, thereby empowering those who might not be in a position to negotiate with their partners. Several human clinical trials evaluating the efficacy of daily regimens of the HIV reverse-transcriptase (RT) inhibitors tenofovir disoproxil fumarate (TDF) or Truvada (TDF and emtricitabine FTC) are under way among high-risk populations. The results of one trial among men who have sex with men showed that daily Truvada was safe and effective, providing the first support for oral PrEP as a prevention strategy. Here we outline the preclinical and clinical research on oral PrEP, pharmacologic considerations, and future directions and challenges. Article	2012	Henry, Keith	Antiretroviral medications as prevention: will the new paradigm reverse the HIV epidemic?	Minnesota Medicine	-	-	-	0026-556X	NA	https://www.mnmed.org/application/files/2616/6967/7204/August_2012.pdf	Fifteen years after recognition of the AIDS epidemic, the development of potent antiretroviral therapy (ART) resulted in a significant reduction in HIV-related morbidity and mortality for persons in resource-rich regions of the world. Now 30 years after the HIV/AIDS epidemic began, we have learned that potent ART also decreases transmission of HIV and that judicious use of antiretroviral medications in people who do not have the virus but are at high risk for contracting it (pre-exposure prophylaxis or PREP) can protect against HIV infection. We now have the necessary tools to significantly decrease the scope of the epidemic in the decades ahead. Whether we use them-that is, provide antiretrovirals prophylactically or conduct widespread testing for HIV and treat all people who are found to have the virus-will depend on the concerted actions of societies, governments, public health authorities, clinicians and individuals. Article	2012	Holt, Martin; Murphy, Dean A; Callander, Denton; Ellard, Jeanne; Rosengarten, Marsha; Kippax, Susan C; de Wit, John B F	Willingness to use HIV pre-exposure prophylaxis and the likelihood of decreased condom use are both associated with unprotected anal intercourse and the perceived likelihood of becoming HIV positive among Australian gay and bisexual men.	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2011-050312	https://dx.doi.org/10.1136/sextrans-2011-050312	OBJECTIVES: To investigate willingness to use HIV pre-exposure prophylaxis (PrEP) and the likelihood of decreased condom use among Australian gay and bisexual men. METHODS: A national, online cross-sectional survey was conducted in April to May 2011. Bivariate relationships were assessed with χ2 or Fisher's exact test. Multivariate logistic regression analysis was performed to assess independent relationships with primary outcome variables. RESULTS: Responses from 1161 HIV-negative and untested men were analysed. Prior use of antiretroviral drugs as PrEP was rare (n=6). Just over a quarter of the sample (n=327; 28.2%) was classified as willing to use PrEP. Willingness to use PrEP was independently associated with younger age, having anal intercourse with casual partners (protected or unprotected), having fewer concerns about PrEP and perceiving oneself to be at risk of HIV. Among men who were willing to use PrEP (n=327), only 26 men (8.0%) indicated that they would be less likely to use condoms if using PrEP. The likelihood of decreased condom use was independently associated with older age, unprotected anal intercourse with casual partners (UAIC) and perceiving oneself to be at increased risk of HIV. CONCLUSIONS: The Australian gay and bisexual men the authors surveyed were cautiously optimistic about PrEP. The minority of men who expressed willingness to use PrEP appear to be appropriate candidates, given that they are likely to report UAIC and to perceive themselves to be at risk of HIV. Article	2012	Jackson, Todd; Huang, Ailong; Chen, Hong; Gao, Xiao; Zhong, Xiaoni; Zhang, Yan	Cognitive, psychosocial, and sociodemographic predictors of willingness to use HIV pre-exposure prophylaxis among Chinese men who have sex with men.	AIDS and Behavior	-	-	-	1573-3254 1090-7165	10.1007/s10461-012-0188-z	https://link.springer.com/article/10.1007/s10461-012-0188-z	This study was designed to identify predictors of lower versus higher willingness to use pre-exposure prophylaxis (PrEP) to reduce HIV among men who have sex with men (MSM) in China. Participants were 570 MSM who completed self-report measures of willingness to use HIV PrEP, beliefs about HIV, psychosocial factors, sexual experiences and sociodemographic characteristics. Results of a hierarchical binary logistic regression analysis indicated that membership in a higher willingness group was predicted by previous consultation about HIV, more reported barriers to using condoms, and elevations in depressive symptoms. Independent of these factors, higher willingness to use HIV PrEP was predicted by beliefs that the intervention was low in stigma and high in potential benefits. In sum, the study highlighted the utility of broad-based assessment of demographic, behavioral, personality, and cognitive factors in identifying Chinese MSM who express willingness to use a promising biologically-based intervention to lower HIV risk. Article	2012	Juusola, Jessie L; Brandeau, Margaret L; Owens, Douglas K; Bendavid, Eran	The cost-effectiveness of preexposure prophylaxis for HIV prevention in the United States in men who have sex with men.	Annals of Internal Medicine	-	-	-	1539-3704	10.7326/0003-4819-156-8-201204170-00001	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3690921	BACKGROUND: A recent randomized, controlled trial showed that daily oral preexposure chemoprophylaxis (PrEP) was effective for HIV prevention in men who have sex with men (MSM). The Centers for Disease Control and Prevention recently provided interim guidance for PrEP in MSM at high risk for HIV. Previous studies did not reach a consistent estimate of its cost-effectiveness. OBJECTIVE: To estimate the effectiveness and cost-effectiveness of PrEP in MSM in the United States. DESIGN: Dynamic model of HIV transmission and progression combined with a detailed economic analysis. DATA SOURCES: Published literature. TARGET POPULATION: MSM aged 13 to 64 years in the United States. TIME HORIZON: Lifetime. PERSPECTIVE: Societal. INTERVENTION: PrEP was evaluated in both the general MSM population and in high-risk MSM and was assumed to reduce infection risk by 44% on the basis of clinical trial results. OUTCOME MEASURES: New HIV infections, discounted quality-adjusted life-years (QALYs) and costs, and incremental cost-effectiveness ratios. RESULTS OF BASE-CASE ANALYSIS: Initiating PrEP in 20% of MSM in the United States would reduce new HIV infections by an estimated 13% and result in a gain of 550,166 QALYs over 20 years at a cost of $172,091 per QALY gained. Initiating PrEP in a larger proportion of MSM would prevent more infections but at an increasing cost per QALY gained (up to $216,480 if all MSM receive PrEP). Preexposure chemoprophylaxis in only high-risk MSM can improve cost-effectiveness. For MSM with an average of 5 partners per year, PrEP costs approximately $50,000 per QALY gained. Providing PrEP to all high-risk MSM for 20 years would cost $75 billion more in health care-related costs than the status quo and $600,000 per HIV infection prevented, compared with incremental costs of $95 billion and $2 million per infection prevented for 20% coverage of all MSM. RESULTS OF SENSITIVITY ANALYSIS: PrEP in the general MSM population would cost less than $100,000 per QALY gained if the daily cost of antiretroviral drugs for PrEP was less than $15 or if PrEP efficacy was greater than 75%. LIMITATION: When examining PrEP in high-risk MSM, the investigators did not model a mix of low- and high-risk MSM because of lack of data on mixing patterns. CONCLUSION: PrEP in the general MSM population could prevent a substantial number of HIV infections, but it is expensive. Use in high-risk MSM compares favorably with other interventions that are considered cost-effective but could result in annual PrEP expenditures of more than $4 billion. PRIMARY FUNDING SOURCE: National Institute on Drug Abuse, Department of Veterans Affairs, and National Institute of Allergy and Infectious Diseases. Article	2012	Keller, M. J.; Malone, A. M.; Carpenter, C. A.; Lo, Y.; Huang, M.; Corey, L.; Willis, R.; Nguyen, C.; Kennedy, S.; Gunawardana, M.; Guerrero, D.; Moss, J. A.; Baum, M. M.; Smith, T. J.; Herold, B. C.	Safety and pharmacokinetics of aciclovir in women following release from a silicone elastomer vaginal ring.	The Journal of Antimicrobial Chemotherapy	-	-	-	1460-2091 0305-7453	10.1093/jac/dks151	https://pubmed.ncbi.nlm.nih.gov/22556381/	OBJECTIVES: Systemic aciclovir and its prodrug valaciclovir are effective in treating and reducing recurrences of genital herpes simplex virus (HSV) and reducing transmission. Local aciclovir delivery, if it can achieve and maintain comparable intracellular genital tract levels, may be equally effective in the treatment and suppression of genital HSV. Intravaginal ring (IVR) delivery of aciclovir may provide pre-exposure prophylaxis against HSV acquisition. METHODS: Tolerability and pharmacokinetics were evaluated in six HIV-negative women with recurrent genital HSV who switched from their daily oral valaciclovir suppression to an aciclovir IVR for 7 days (n=3) or 14 days (n=3). Blood and cervicovaginal lavage (CVL) were collected after oral and IVR dosing to measure aciclovir concentrations and genital swabs were obtained to quantify HSV shedding by PCR. RESULTS: The rings were well tolerated. Median plasma aciclovir concentrations were 110.2 ng/mL (IQR, 85.9-233.5) 12-18 h after oral valaciclovir. Little or no drug was detected in plasma following IVR dosing. Median (IQR) CVL aciclovir levels were 127.3 ng/mL (21-660.8) 2 h after oral valaciclovir, 154.4 ng/mL (60.7-327.5) 12-18 h after oral valaciclovir and 438 ng/mL (178.5-618.5) after 7 days and 393 ng/mL (31.6-1615) after 14 days of aciclovir ring use. Median CVL aciclovir levels 2 h after oral dosing were similar to levels observed 7 (P=0.99) and 14 (P=0.75) days after ring use. HSV DNA was not detected in genital swabs and there was no significant change in inflammatory mediators. CONCLUSIONS: This first-in-human study demonstrated that an IVR could safely deliver mucosal levels of aciclovir similar to oral valaciclovir without systemic absorption. More intensive site-specific pharmacokinetic studies are needed to determine whether higher local concentrations are needed to achieve optimal drug distribution within the genital tract. Article	2012	Kersh, Ellen N; Luo, Wei; Zheng, Qi; Adams, Debra R; Hanson, Debra; Youngpairoj, Ae S; Cong, Mian-er; Butler, Katherine; Hendry, R Michael; McNicholl, Janet M; Heneine, Walid; Garcia-Lerma, J Gerardo	Reduced inflammation and CD4 loss in acute SHIV infection during oral pre-exposure prophylaxis.	Journal of Infectious Diseases	-	-	-	1537-6613	10.1093/infdis/jis422	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3491742	BACKGROUND: The impact of pre-exposure prophylaxis (PrEP) with antiretrovirals on breakthrough HIV or SHIV infection is not fully documented. We addressed the hypothesis that SHIV(SF162P3) infection despite active PrEP results in altered early immune parameters, compared with untreated infection. METHODS: Eleven rhesus macaques were infected during repeated, rectal, low-dose SHIV(SF162P3) exposures while receiving concurrent oral PrEP (Truvada n = 2 or GS7340 n = 4) or as untreated controls (n = 5). We measured SHIV RNA, inflammatory cytokines, CD4 cells, and SHIV-specific memory T cells until 20 weeks after peak viremia. RESULTS: SHIV infection during PrEP resulted in 100-fold lower peak viremia and lower IL-15, IL-18, and IL-1Ra levels, compared with controls (P < .05; Wilcoxon rank-sum test). Unlike controls, PrEP-treated macaques showed no significant CD4 cell count reduction during acute infection and developed more SHIV-specific central memory T cells, relative to controls. After in vivo CD8 cell depletion, viral load increased to similar levels, indicating that CD8 cells were critical for viral control in both groups. CONCLUSIONS: PrEP with antiretrovirals has beneficial effects on early SHIV infection even when infection is not prevented. Although long-term immune control could not be examined in this SHIV infection model, our results suggest that PrEP results in improved early disease parameters in breakthrough infections. Article	2012	Khawcharoenporn, Thana; Kendrick, Sabrina; Smith, Kimberly	HIV risk perception and preexposure prophylaxis interest among a heterosexual population visiting a sexually transmitted infection clinic.	AIDS Patient Care and STDs	-	-	-	-	1557-7449	10.1089/apc.2011.0202	https://dx.doi.org/10.1089/apc.2011.0202	Low perception of HIV risk despite behaviors associated with increased risk is thought to be a contributing factor for a higher prevalence of HIV in blacks than other groups in the United States. We sought to determine HIV risk perception and its impact on safer sex practices and interest in preexposure prophylaxis (PrEP). From August 1 to October 31, 2010, an anonymous survey was conducted at a sexually transmitted infection clinic asking questions about demographics, risk behaviors, and PrEP interest. Participants were categorized into high-risk, moderate-risk, and low-risk groups according to predefined HIV risk characteristics. Only heterosexual high-risk participants were further assessed for their risk perception, condom use and PrEP interest. There were 494 participants; 63% male, 70% blacks, 88% heterosexual; 83% were categorized into the high-risk group. Of the 359 heterosexual high-risk participants, 301 (84%) perceived themselves at no or low-risk. Rates of consistent condom use with vaginal, oral, and anal sex were low (<20%) in this group despite high levels of knowledge about HIV transmission risks. Rates of condom use were not affected by risk perception. No interest in PrEP was associated with low education level (adjusted odds ratio 4.97; p=0.02) and low risk perception. These findings suggest that despite having knowledge about HIV transmission risks, the majority of high-risk participants did not recognize their risks and used condoms with low frequency. Low risk perception and low education level may impact PrEP interest. Enhanced interventions are needed to improve HIV risk perception, safer sex practices, and knowledge about PrEP. Article	2012	Kibengo, FM; Ruzagira, E; Bahemuka, UM; Katende, D; Abaasa, A; Barin, B; Priddy, F; Haberer, J; Kampala, A	Performance of self-reported adherence to oral pre-exposure prophylaxis (PrEP) among HIV heterosexual serodiscordant couples in rural Uganda	Retrovirology	-	-	-	-	1742-4690	10.1186/1742-4690-9-S2-P213	https://www.proquest.com/scholarly-journals/performance-self-reported-adherence-oral-pre/docview/1039270425/se-2?accountid=8113	Background Adherence is one of the main determinants of PrEP efficacy. Most PrEP studies applied subjective adherence measures, which often produce overestimates and problematic efficacy data interpretation; creating a need for more objective measures. This study examines selfreported adherence to oral PrEP compared to Medical Events Monitoring System (MEMS). Methods Seventy-two HIV-uninfected partners (50% women) in Uganda were randomized to daily or intermittent (Monday, Friday and within 2 hours after sex, not exceeding 1 dose/day) oral emtricitabine/tenofovir or placebo in a 2:1:2:1 ratio for four months. Adherence was assessed monthly by MEMS and self-reported taken or missed doses by timeline follow-back calendar. MEMS data was adjusted for extra openings without pill removal and removal of multiple pills. Non-fixed days within intermittent regimen were classified as adherent/non-adherent based on self-reported sex by SMS. Adherence rates by taken/missed doses were compared to raw MEMS data using Spearman correlation. Results Treatment and placebo groups were combined since adherence rates were similar. Daily raw MEMS adherence rate was significantly higher than fixed Intermittent rate (p=0.04) and post-coital dosing rate (p<0.0001). Raw MEMS data for daily and fixed intermittent dosing, poorly correlated with self-reported taken doses (r=0.14, p=0.42 and r=0.01, p=0.94, respectively) and missed doses (r=0.30, p=0.08 and r=0.07, p=0.69, respectively). Self-reported daily adherence had high sensitivity but only fair positive predictive value (PPV) and very poor specificity. Self-reported adherence to intermittent fixed dosing had fair sensitivity, PPV and negative predictive value (NPV), but poor specificity. Self-reported adherence to post-coital dosing had very good sensitivity and NPV but poor specificity. Conclusion Median adherence for daily and intermittent fixed PrEP was high by objective and subjective measures, but poorly correlated. Adherence to post-coital dosing was poor and likely overestimated by self-report (possibly reflecting technical challenges of SMS). Self-reported adherence measures were highly sensitive but poorly specific. Theses and Dissertations	2012	Kinoti, F	Contraceptive use and reproductive desire among HIV-1 discordant couples in Nairobi, Kenya	-	-	University of Nairobi	University of Nairobi	-	NA	NA	http://erepository.uonbi.ac.ke:8080/xmlui/handle/123456789/9342	Most HIV transmission worldwide occur among HIV discordant couples {where one partner is HIV infected and the other is not}, either sexually or in association with pregnancy. childbirth or breastfeeding. This makes discordant couples an important cohort for HIV transmission prevention strategies. Use of contraceptives reduces vertical transmission by preventing unwanted pregnancies while use of condoms reduces transmission from the positive to the negative partner. Contraception uptake in sub Saharan Africa is low. Discordant couples face unique challenges relating to their reproductive health. They have difficult choices to make concerning sexuality, fertility, parenthood desires and family life. Counseling and health provider knowledge on how to balance the reproductive desire of the couples and yet reduce transmission is crucial. Objectives The main objective of the study was to describe the contraceptive practice, experience and attitude and the determinants of reproductive desire among HIV sero-discordant couples enrolled in the Pre-exposure Prophylaxis Study (PrEP) and in addition describe the role of the healthcare providers in discordant couple reproductive health. Methodology This was a cross-sectional study done at the PrEP Study Clinic in Kenyatta National Hospital,Nairobi between March and July 2011. Women of reproductive age (18-46 years) and their partners in a heterosexual sero-discordant relationship and health care providers who work amongst discordant couples were enrolled in this study. Structured questionnaires were used to collect quantitative data and Focus group discussions (FGDs) were used to collect qualitative data . Results The study surveyed 350 participants (175 couples) of who 84 couples had a female HIV negative and 91 couples had a female HIV positive partner. Three FGDs were held, stratified by gender and sero-status. Overall, 190(54.3%) of the participants wanted to have more children. Majority 159(90.9%) of the women used some method of contraception. Only 49(28%) of these women used dual contraception. Of the women who did not use dual contraception, fear of side effects 56(44.4%), planning on conceiving 39(31.0%), condoms are sufficient as contraception 33(26.2%) and partner objecting to their use of contraception 25(19.8%) were identified as the commonest reasons for not using dual contraception. The HIV status, age and the number of children were associated with wanting more children. In the FGDs, the availability of PMTCT, ARVs, sperm washing were promoters to increasing desire for children. Relationship dynamics, domestic violence and discussing contraception with the partners were promoters to contraception use. Overall, 12(6.9%) of the women were pregnant, with an equal number of HIV positive and negative women. All pregnancies were unplanned. Of these 9(75%) were on condoms only at the time the pregnancy happened. Majority 19(70.4%) of the health care providers were adequately trained. The contraception they prescribed to the HIV…	NA	English	Kenya	Eastern and Southern Africa	Kenya	Eastern and Southern Africa	-	-	Mixed methods
Article	2012	Kiser, Patrick F.; Mesquita, Pedro M. M.; Herold, Betsy C.	A perspective on progress and gaps in HIV prevention science.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/aid.2012.0277	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3484765/	In the past few years, the transdisciplinary field of HIV prevention has reached several milestones. Topically applied tenofovir gel provided significant protection from sexual transmission of HIV in a large-scale clinical trial and oral Truvada (emtricitabine/tenofovir disoproxil fumarate) was recently approved for preexposure prophylaxis (PrEP) following two successful clinical trials in men and women. These achievements are tempered by the disappointing results of other clinical trials, which highlight the complexities of prevention research. In this perspective, we discuss scientific and developmental gaps for topical chemoprophylaxis of the sexual transmission of HIV, which depends on the complex interactions between the pharmacokinetics and pharmacodynamics of drugs, formulation and delivery systems, anatomic site of transmission, and host mucosal immune defenses. Despite the considerable time and resources devoted to unraveling the initial steps in sexual transmission of HIV, current knowledge is based on animal models and human explanted tissue, which may not fully recapitulate what happens clinically. Understanding these events, including the role that sex hormones, semen, and mucosal secretions play in transmission, and the interplay between innate immunity, the mucosal environment, and drug efficacy is paramount. This drives some of the most pressing questions in the field. Article	2012	Krakower, Douglas S; Mimiaga, Matthew J; Rosenberger, Joshua G; Novak, David S; Mitty, Jennifer A; White, Jaclyn M; Mayer, Kenneth H	Limited Awareness and Low Immediate Uptake of Pre-Exposure Prophylaxis among Men Who Have Sex with Men Using an Internet Social Networking Site.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0033119	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3314648	BACKGROUND: In 2010, the iPrEx trial demonstrated that oral antiretroviral pre-exposure prophylaxis (PrEP) reduced the risk of HIV acquisition among high-risk men who have sex with men (MSM). The impact of iPrEx on PrEP knowledge and actual use among at-risk MSM is unknown. Online surveys were conducted to assess PrEP awareness, interest and experience among at-risk MSM before and after iPrEx, and to determine demographic and behavioral factors associated with these measures. METHODS AND FINDINGS: Cross-sectional, national, internet-based surveys were administered to U.S. based members of the most popular American MSM social networking site 2 months before (nâ=â398) and 1 month after (nâ=â4 558) publication of iPrEx results. Comparisons were made between these samples with regards to PrEP knowledge, interest, and experience. Data were collected on demographics, sexual risk, and experience with post-exposure prophylaxis (PEP). Regression analyses were performed to identify factors associated with PrEP awareness, interest, and experience post-iPrEx. Most participants were white, educated, and indicated high-risk sexual behaviors. Awareness of PrEP was limited pre- and post-iPrEx (13% vs. 19%), whereas interest levels after being provided with a description of PrEP remained high (76% vs. 79%). PrEP use remained uncommon (0.7% vs. 0.9%). PrEP use was associated with PEP awareness (OR 7.46; CI 1.52-36.6) and PEP experience (OR 34.2; CI 13.3-88.4). PrEP interest was associated with older age (OR 1.01; CI 1.00-1.02), unprotected anal intercourse with ≥1 male partner in the prior 3 months (OR 1.40; CI 1.10-1.77), and perceiving oneself at increased risk for HIV acquisition (OR 1.20; CI 1.13-1.27). CONCLUSIONS: Among MSM engaged in online networking, awareness of PrEP was limited 1 month after the iPrEx data were released. Utilization was low, although some MSM who reported high-risk behaviors were interested in using PrEP. Studies are needed to understand barriers to PrEP utilization by at-risk MSM. Article	2012	Krakower, Douglas; Mayer, Kenneth H	Engaging healthcare providers to implement HIV pre-exposure prophylaxis.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0b013e3283590446	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3769645	PURPOSE OF REVIEW: Recent randomized controlled trials have demonstrated that HIV pre-exposure prophylaxis (PrEP) can decrease HIV incidence among several at-risk populations, including men who have sex with men, serodiscordant couples, and heterosexual men and women. As PrEP is a biomedical intervention that requires clinical monitoring and a high level of medication adherence, maximizing the public health effectiveness of PrEP in real-world settings will require the training of a cadre of healthcare providers to prescribe PrEP. Therefore it is critical to understand provider knowledge, practices, and attitudes towards PrEP prescribing, and to develop strategies for engaging and training providers to provide PrEP. RECENT FINDINGS: Limited numbers of studies have focused on PrEP implementation by healthcare providers. These studies suggest that some providers are knowledgeable about PrEP, but many are not, or express misgivings. Although many clinicians report willingness to provide PrEP, few have prescribed PrEP in clinical practice. Provider comfort and skills in HIV risk assessment are suboptimal, which could limit identification of individuals who are most likely to benefit from PrEP use. SUMMARY: Further studies to understand facilitators and barriers to HIV-risk assessment and PrEP prescribing by practicing clinicians are needed. Innovative training strategies and decision-support interventions for providers could optimize PrEP implementation and therefore merit additional research. Article	2012	Krakower, Douglas; Mayer, Kenneth H.	What primary care providers need to know about preexposure prophylaxis for HIV prevention: a narrative review.	Annals of Internal Medicine	-	-	-	-	1539-3704 0003-4819	10.7326/0003-4819-157-7-201210020-00510	https://pubmed.ncbi.nlm.nih.gov/22821365/	As HIV prevalence climbs globally, including more than 50 000 new infections per year in the United States, we need more effective HIV prevention strategies. The use of antiretrovirals for preexposure prophylaxis (PrEP) among high-risk persons without HIV is emerging as one such strategy. Randomized, controlled trials have demonstrated that once-daily oral PrEP decreased HIV incidence among at-risk men who have sex with men and African heterosexuals, including serodiscordant couples. An additional randomized, controlled trial of a topical pericoital antiretroviral microbicide gel decreased HIV incidence among at-risk heterosexual South African women. Two other studies in African women did not demonstrate the efficacy of oral or topical PrEP, raising concerns about adherence patterns and efficacy in this population. The U.S. Food and Drug Administration (FDA) Antiviral Drugs Advisory Committee reviewed these studies and additional data in May 2012 and voted to advise the approval of oral tenofovir-emtricitabine for PrEP in high-risk populations. On 16 July 2012, the FDA recommended that this combination medication be approved for use as PrEP in high-risk persons without HIV. Patients may seek PrEP from their primary care providers, and those receiving PrEP require monitoring. Thus, primary care providers should become familiar with PrEP. This review outlines current knowledge about PrEP as it pertains to primary care, including identifying persons likely to benefit from PrEP; counseling to maximize adherence and reduce potential increases in risky behavior; and monitoring for potential drug toxicities, HIV acquisition, and antiretroviral drug resistance. Issues related to cost and insurance coverage are also discussed. Recent data suggest that PrEP, combined with other prevention strategies, holds promise in helping to curtail the HIV epidemic. Article	2012	Lacor, P	Preparing for PrEP	European Journal of Contraception and Reproductive Health Care	-	-	-	-	1362-5187	10.3109/13625187.2012.723225	https://pubmed.ncbi.nlm.nih.gov/23113873/	Recent studies have shown that in selected conditions antiretroviral drugs can be used to protect HIV seronegative persons from becoming infected, when exposed to the risk of sexual HIV transmission. This concept of pre-exposure prophylaxis' or 'PrEP' has raised many questions that concern cost, safety and ethical issues. In this article, different aspects of PrEP are analysed with a view to trying to answer the question whether today's society is already prepared to accept PrEP as one of the tools to prevent transmission of HIV by high-risk sexual contacts. Article	2012	Li, Xuefeng; Lu, Hongyan; Raymond, H. F.; Sun, Yanming; Jia, Yujiang; He, Xiong; Fan, Song; Shao, Yiming; McFarland, Willi; Xiao, Yan; Ruan, Yuhua	Untested and undiagnosed: barriers to HIV testing among men who have sex with men, Beijing, China.	Sexually Transmitted Infections	-	-	-	-	1472-3263 1368-4973	10.1136/sextrans-2011-050248	https://sti.bmj.com/content/88/3/187	OBJECTIVES: Undiagnosed HIV presents great potential for the spread of infection. The authors identify the prevalence and correlates of never testing and being unaware of HIV infection in Beijing men who have sex with men (MSM). METHODS: Cross-sectional biological and behavioural survey using respondent-driven sampling; 500 MSM were included. RESULTS: HIV prevalence was 7.2% with 86.1% unaware of their infection; 33.2% had never tested. Never testing was associated with lower educational (adjusted odds ratio (AOR) 1.6, 95% CI (CI) 1.1 to 2.5), living in Beijing for ≤3 years (AOR 1.5, 95% CI 1.0 to 2.3), unprotected anal intercourse with most recent male partner (AOR 1.6, 95% CI 1.0 to 2.4), being unaware of the most recent male partner's HIV status (AOR 3.6, 95% CI 2.1 to 6.1) and holding stigmatised attitudes towards persons with HIV (AOR 1.1 per scale point, 95% CI 1.0 to 1.1). Predictors of having undiagnosed HIV infection were being married (AOR 2.4, 95% CI 1.0 to 5.4), living in Beijing for ≤3 years (AOR 3.6, 95% CI 1.5 to 8.4), being unaware of the most recent male partner's HIV status (AOR 6.8, 95% CI 0.9 to 51.6) and holding negative attitudes towards safe sex (AOR 1.1 per scale point, 95% CI 1.0 to 1.1). CONCLUSIONS: Recent attention has focused on HIV prevention interventions that depend upon knowing one's serostatus, including viral load suppression, prevention with positives, pre-exposure prophylaxis and seroadaptation. Until the low level of testing and resulting high level of undiagnosed HIV infection are addressed, these tools are not likely to be effective for MSM in China.	*Homosexuality, Male; Adolescent; Adult; Humans; Male; Middle Aged; Young Adult; Aged; Cross-Sectional Studies; China; Prevalence; HIV Infections/*diagnosis/*epidemiology/prevention & control/transmission	English	United Kingdom	Western and Central Europe and North America	China	Asia and the Pacific	China	Asia and the Pacific	Quantitative
Article	2012	Liegler, T; Abdel-Mohsen, M; Defechereux, P; Atchison, R; Bentley, LG; Taylor, D; Kashuba, A; Ahmed, K; Agot, K; Rammutla, E; Lombaard, J; Crucitti, T; Fransen, K; De Baetselier, I; Van Damme, L; Grant, RM	Drug resistance among HIV-1 seroconverters in the FEM-PrEP Study	Antiviral Therapy	-	-	-	-	NA	NA	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01031722/full	BACKGROUND: Results from HIV chemoprophylaxis trials show differing efficacies for preventing infection. The FEM-PrEP trial of daily oral administration of the combination pill emtricitabine and tenofovir disoproxyl fumarate (FTC/TDF) versus placebo was unable to determine effectiveness for HIV infection prevention in African women. Selection of drug resistant HIV is a concern, especially in settings of reduced efficacy due to low or intermittent product adherence. METHODS: Clinical drug resistance to FTC/TDF at study visits at or near first evidence of seroconversion was determined by genotype (TRUGENE, Siemens) and phenotype (Phenosense, Monogram Biosciences). Minor variant drug resistance was measured using an allele-specific PCR assay that maintains specificity with divergent viruses. Plasma tenofovir (TFV) and FTC concentrations and cellular tenofovir diphosphate (TDP) concentrations were used to measure adherence levels among resistant cases. RESULTS: Specimens from 68 women infected during regular study follow-up (33 FTC/TDF, 35 placebo) and from 2 women with pre-study infection (RNA-positive, antibody-negative) who had access to study drug until documented seroconversion, were tested for drug resistance. Viral loads at seroconversion visits ranged from 117 to >1×107 copies/ml (mean, 1.6×105), with no difference between arms. No infections showed clinical resistance to TFV, while five (one placebo, four FTC/TDF) showed genotypic resistance to FTC (M184V/I). Mutations waned over time in the active arm participants following drug termination. Phenotypic resistance to FTC was seen in 4/4 tested, accompanied by increased susceptibility to TFV, stavudine and zidovudine. Other mutations not associated with exposure to FTC/TDF (K103N, E138A) were coexistent in two subjects randomized to the active arm. Three subjects showed low-level (0.50-1%) minor variant drug resistance, each at a single mutation, K70E, M184V or M184I. TFV, FTC and TDP concentrations were undetectable in the one active arm participant with minor variant resistance and in two with clinical FTC resistance. Moderate to high concentrations of TFV, FTC and TDF were detected in the additional two active arm participants with clinical FTC resistance. CONCLUSIONS: FTC-associated drug resistance was observed in FEM-PrEP, but infrequently in the presence of measurable plasma and cellular drug concentrations, consistent with the overall level of adherence to study drug.	*Human immunodeficiency virus; *drug resistance; *hepatitis virus; *workshop; Allele; Arm; Assay; Chemoprophylaxis; Drug concentration; Exposure; Female; Follow up; Genotype; Human; Human immunodeficiency virus infection; Infection; Infection prevention; Mutation; Oral drug administration; Phenotype; Pill; Plasma; Seroconversion; Virus; Virus load	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2012	Lorente, Nicolas; Fugon, Lionel; Carrieri, Maria Patrizia; Andreo, Christian; Le Gall, Jean-Marie; Cook, Emmanuel; Aboulker, Jean-Pierre; Capitant, Catherine; Molina, Jean-Michel; Spire, Bruno	Acceptability of an "on-demand" pre-exposure HIV prophylaxis trial among men who have sex with men living in France.	AIDS Care	-	-	-	-	1360-0451	10.1080/09540121.2011.626394	https://dx.doi.org/10.1080/09540121.2011.626394	Although predictors of willingness to take daily, self-administered pre-exposure HIV prophylaxis (PrEP) for men who have sex with men (MSM) have been studied in the context of several PrEP trials internationally, little is known about MSM interested in participating in a trial on the use of PrEP on an "on -demand" basis, i.e., taking a first dose of combined tenofovir/emtricitabine a few hours before possible HIV sexual exposure and a second dose a few hours afterwards. A double-blind placebo randomized PrEP trial will soon begin in France to evaluate the effectiveness of PrEP in terms of reducing HIV infection rates, among MSM self-administering "on-demand" PrEP. To assess potential participants' characteristics associated with willingness to participate in the trial and identify barriers and facilitators to implementation, MSM completed a self-administered questionnaire, distributed via gay venues and community websites. Among the 443 respondents who reported being HIV-negative, 40% reported being interested in participating. Factors independently associated with interest included: reporting lower educational level, more than 20 male sexual partners in the previous year, reporting unprotected anal sex with casual partners and preferring PrEP follow-up visits in a devoted area within a hospital. There is great interest in participating in a future "on-demand" PrEP trial among HIV-negative MSM and particularly in those at potentially high risk of HIV exposure. Providing confidentiality and tailored counseling during PrEP follow-up are important issues.	men who have sex with menpre-exposure prophylaxisHIV preventionsexual behaviorrisk reduction	English	United Kingdom	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Clinical
Article	2012	Mansergh, Gordon; Koblin, Beryl A; Sullivan, Patrick S	Challenges for HIV Pre-Exposure Prophylaxis among Men Who Have Sex with Men in the United States	PLOS Medicine	-	-	-	-	15491277	10.1371/journal.pmed.1001286	https://www.proquest.com/scholarly-journals/challenges-hiv-pre-exposure-prophylaxis-among-men/docview/1288095750/se-2?accountid=8113	Abbreviations: ARV, anti-retroviral; MSM, men who have sex with men; CDC, Centers for Disease Control and Prevention; PEP, HIV post-exposure prophylaxis; PrEP, HIV pre-exposure prophylaxis Summary Points * Pre-exposure prophylaxis (PrEP) with anti-retroviral (ARV) medications is partially efficacious for preventing HIV infection among men who have sex with men (MSM) and heterosexuals. * As PrEP becomes available and prescribed for use among MSM a better understanding of willingness to use PrEP and avoidance of condom use are needed so that behavioral programs and counseling may be enhanced for maximum benefit. * Targeted messaging will be needed about ARV prophylaxis for various at risk populations, but the general message should be that condoms continue to be the most effective way to prevent HIV transmission through sex and that PrEP is an additional biomedical intervention. * As new effective biomedical intervention methods, such as PrEP, become available language about "protected" and "unprotected" sex, which used to exclusively mean condom use, will need to adapt. Given the emergence of this prophylaxis option, public health officials and providers are challenged to address community-level monitoring of prescribed and non-prescribed PrEP use in addition to condom use; develop effective multiple messages about condom use and PrEP for MSM and for their health care providers; disseminate information about the hazards of sharing ARV medications; and develop language about HIV prevention and risk reduction that has historically focused almost exclusively on condom use for sexually active MSM. Article	2012	Mark, D; Amico, KR; Wallace, M; Roux, S; Grant, R; Wood, R; Bekker, LG	Acceptability of oral intermittent pre-exposure prophylaxis as a biomedical HIV prevention strategyresults from the South African ADAPT (HPTN 067) Preparatory Study	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.1016/S2352-4642(20)30248-0	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC9832157/	Background: HIV incidence among adolescents in southern Africa remains unacceptably high. Pre-exposure prophylaxis (PrEP) is an effective HIV prevention intervention but there are few data on its implementation among adolescents. We aimed to investigate the safety, feasibility, and acceptability of PrEP with oral tenofovir disoproxil fumarate and emtricitabine as part of a comprehensive HIV prevention package in an adolescent population in South Africa.Methods: This open-label single-arm phase 2 study (PlusPills) was done in two research clinics in Cape Town and Johannesburg, South Africa. Adolescents aged 15-19 years were recruited into the study through recruitment events and outreach in the community. Potential participants were eligible for enrolment if they reported being sexually active. Exclusion criteria were a positive test for HIV or pregnancy at enrolment, breastfeeding, or any relevant co-morbidities. Participants were given oral tenofovir disoproxil fumarate and emtricitabine for PrEP to take daily for the first 12 weeks and were then given the choice to opt in or out of PrEP use at three monthly intervals during scheduled clinic visits. Participants were invited to monthly visits for adherence counselling and HIV testing during the study period. The primary outcomes were acceptability, use, and safety of PrEP. Acceptability was measured by the proportion of participants who reported willingness to take up PrEP and remain on PrEP at each study timepoint. Use was defined as the number of participants who continued to use PrEP after the initial 12-week period until the end of the study (week 48). Safety was measured by grade 2, 3, and 4 laboratory and clinical adverse events using the Division of AIDS table for grading the severity of adult and paediatric adverse events, version 1.0. Dried blood spot samples were collected at each study time-point to measure tenofovir diphosphate concentrations. This trial is registered with ClinicalTrials.gov, NCT02213328.Findings: Between April 28, 2015, and Nov 11, 2016, 244 participants were screened, and 148 participants were enrolled (median age was 18 years; 99 participants [67%] were female) and initiated PrEP. PrEP was stopped by 26 of the 148 (18%) participants at 12 weeks. Cumulative PrEP opt-out, from the total cohort, was 41% (60 of 148 participants) at week 24 and 43% (63 of 148 participants) at week 36. PrEP was well tolerated with only minor adverse events (grade 2) thought to be related to study drug, which included headache (n=4, 3%), gastrointestinal upset (n=8, 5%), and skin rash (n=2, 1%). Two participants (1%) experienced grade 3 weight loss, which was deemed related to the study drug and resolved fully when PrEP was discontinued. Tenofovir diphosphate concentrations were detectable (>16 fmol/punch) in dried blood spot samples in 108 (92%) of 118 participants who reported PrEP use at week 12, in 74 (74%) of 100 participants at week 24, and in 22 (59%) of 37 participants by the study end at week 48.Interpretation: In this cohort of self-selected South African adolescents at risk of HIV acquisition, PrEP appears safe and tolerable in those who continued use. PrEP use decreased throughout the course of the study as the number of planned study visits declined. Adolescents in southern Africa needs access to PrEP with tailored adherence support and possibly the option for more frequent and flexible visit schedules.Funding: National Institute of Allergy and Infectious Diseases of the US National Institutes of Health. Article	2012	Matthews, Lynn T; Smit, Jennifer A; Cu-Uvin, Susan; Cohan, Deborah	Antiretrovirals and safer conception for HIV-serodiscordant couples.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0b013e328358bac9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3695736	PURPOSE OF REVIEW: Many men and women living with HIV and their uninfected partners attempt to conceive children. HIV-prevention science can be applied to reduce sexual transmission risk while respecting couples' reproductive goals. Here we discuss antiretrovirals as prevention in the context of safer conception for HIV-serodiscordant couples. RECENT FINDINGS: Antiretroviral therapy (ART) for the infected partner and pre-exposure prophylaxis (PrEP) for the uninfected partner reduce the risk of heterosexual HIV transmission. Several demonstration projects suggest the feasibility and acceptability of antiretroviral (ARV)s as periconception HIV-prevention for HIV-serodiscordant couples. The application of ARVs to periconception risk reduction may be limited by adherence. SUMMARY: For male-infected (M+F-) couples who cannot access sperm processing and female-infected (F+M-) couples unwilling to carry out insemination without intercourse, ART for the infected partner, PrEP for the uninfected partner, combined with treatment for sexually transmitted infections, sex limited to peak fertility, and medical male circumcision (for F+M couples) provide excellent, well tolerated options for reducing the risk of periconception HIV sexual transmission.	antiretrovirals as prevention, conception, fertility, HIV prevention, HIV-serodiscordance, perinatal HIV transmission, sexual HIV transmission	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2012	Mehta, Mandana; Semitala, Fred; Lynen, Lutgarde; Colebunders, Robert	Antiretroviral treatment in low-resource settings: what has changed in the last 10 years and what needs to change in the coming years?	Expert Review of Anti-Infective Therapy	-	-	-	-	1744-8336 1478-7210	10.1586/eri.12.129	https://pubmed.ncbi.nlm.nih.gov/23241186/	In the past decade, access to antiretroviral therapy (ART) has witnessed a rapid scale-up. This has been made possible by significant donor funding, price reductions facilitated by flexible trade agreements and the standardization of antiretroviral prescription. Currently the global HIV community stands on the cusp of a new chapter in HIV care, that of initiating ART even earlier in the course of the infection, possibly as pre-exposure prophylaxis, or as part of a 'test-and-treat' approach. In this article, the authors provide an overview of the significant advances made in improving access to antiretrovirals in low-resource settings, as well as the challenges facing new approaches to ART in the next decade. Article	2012	Mensch, Barbara S; van der Straten, Ariane; Katzen, Lauren L	Acceptability in microbicide and PrEP trials: current status and a reconceptualization.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0b013e3283590632	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4026162	PURPOSE OF REVIEW: Assessment of acceptability is a central component of most oral PrEP and microbicide trials. In this paper we review current definitions and frameworks employed in acceptability research, discuss findings from recent studies of product acceptability and summarize trends in acceptability research. We conclude by offering a new framework for investigating product acceptability within clinical trials, one which considers product acceptability to be conceptually distinct from adherence. RECENT FINDINGS: Although numerous studies have investigated product acceptability, a consensus is lacking regarding the definition and operationalization of the concept. In addition fewer than half of the studies reviewed investigated actual candidate products. To the extent that an overall measure of acceptability is considered, the consensus is that most participants find the products acceptable. However, it is the rare study that investigates whether product adherence is associated with acceptability. SUMMARY: Given that adherence is critical to the success of clinical trials, it is important to identify the extent to which acceptability is a factor in product usage and to ascertain which dimensions of acceptability - product attributes, dosing regimen, delivery mechanism, use attributes, partner's attitudes, effect of product on the sexual encounter, product-related norms - if any, affect adherence. Article	2012	Michael, M; Rosengarten, M	HIV, Globalization and Topology: Of Prepositions and Propositions	Theory, Culture & Society	-	-	-	-	0263-2764	10.1177/0263276412443567	https://journals.sagepub.com/doi/10.1177/0263276412443567?icid=int.sj-abstract.citing-articles.51	In this article we explore how two enactments of HIV - the UN's AIDS Clock and clinical trials for an HIV biomedical prevention technology or pre-exposure prophylaxis (PrEP) - entail particular globalizing and localizing dynamics. Drawing on Latour's and Whitehead's concept of proposition, and Serres' call for a philosophy of prepositions, we use the composite notion of pre/pro-positions to trace the shifting topological status of HIV. For example, we show how PrEP emerges through topological entwinements of globalizing biomedical standardization, localizing protests against PrEP trials and globalizing ethical principles. We go on to examine how our own analysis manifests a parallel topological pattern in which we deploy a globalizing argument about the localizing of the globalizing found in the AIDS Clock and the PrEP trails. Finally, we consider how the movement of 'topology' into the social sciences might itself benefit from a topological treatment. Article	2012	Muchomba, Felix M; Gearing, Robin E; Simoni, Jane M; El-Bassel, Nabila	State of the science of adherence in pre-exposure prophylaxis and microbicide trials.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0b013e31826f9962	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4068619	For pre-exposure prophylaxis (PrEP) and microbicides to effectively prevent HIV, optimal treatment adherence is required. Adherence to these strategies, however, has not been sufficiently studied. This investigation systematically reviews oral PrEP and microbicide trials across 4 domains of adherence: (1) definition and measures used, (2) risks for nonadherence, (3) promotion strategies, and (4) effects on outcomes. Nineteen (n = 19) trials, with 47,157 participants, published between 1987 and 2012 were identified. Reported mean adherence to microbicides was 79% and to oral PrEP 87%. Common risks for microbicide nonadherence were decreased motivation over time, sex with primary (noncommercial/casual) partners, and insufficient supply. Oral PrEP nonadherence risks were older age and medication side effects. Psychoeducation and outreach to participants and communities were frequently used promotion strategies. Most trials failed to systematically identify barriers and monitor and promote adherence, although adherence moderated outcomes. Recommendations for attending to adherence in future trials are provided. Article	2012	Mutua, Gaudensia; Sanders, Eduard; Mugo, Peter; Anzala, Omu; Haberer, Jessica E; Bangsberg, David; Barin, Burc; Rooney, James F; Mark, David; Chetty, Paramesh; Fast, Patricia; Priddy, Frances H	Safety and adherence to intermittent pre-exposure prophylaxis (PrEP) for HIV-1 in African men who have sex with men and female sex workers.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0033103	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3325227	BACKGROUND: Little is known about safety of and adherence to intermittent HIV PrEP regimens, which may be more feasible than daily dosing in some settings. We present safety and adherence data from the first trial of an intermittent PrEP regimen among Kenyan men who have sex with men (MSM) and female sex workers (FSW). METHODS/PRINCIPAL FINDINGS: MSM and FSW were randomized to daily oral FTC/TDF or placebo, or intermittent (Monday, Friday and within 2 hours after sex, not to exceed one dose per day) oral FTC/TDF or placebo in a 2:1:2:1 ratio; volunteers were followed monthly for 4 months. Adherence was assessed with the medication event monitoring system (MEMS). Sexual activity data were collected via daily text message (SMS) queries and timeline followback interviews with a one-month recall period. Sixty-seven men and 5 women were randomized into the study. Safety was similar among all groups. Median MEMS adherence rates were 83% IQR: 63-92 for daily dosing and 55% IQR:28-78 for fixed intermittent dosing (p = 0.003), while adherence to any post-coital doses was 26% IQR:14-50. SMS response rates were low, which may have impaired measurement of post-coital dosing adherence. Acceptability of PrEP was high, regardless of dosing regimen. CONCLUSIONS/SIGNIFICANCE: Adherence to intermittent dosing regimens, fixed doses, and in particular coitally-dependent doses, may be more difficult than adherence to daily dosing. However, intermittent dosing may still be appropriate for PrEP if intracellular drug levels, which correlate with prevention of HIV acquisition, can be attained with less than daily dosing and if barriers to adherence can be addressed. Additional drug level data, qualitative data on adherence barriers, and better methods to measure sexual activity are necessary to determine whether adherence to post-coital PrEP could be comparable to more standard regimens. Article	2012	Nakasone, T; Murakami, T; Yamamoto, N	Double Oral Administration of Emtricitabine/Tenofovir Prior to Virus Exposure Protects against Highly Pathogenic Simian/Human Immunodeficiency Virus Infection in Macaques	Japanese Journal of Infectious Diseases	-	-	-	-	1344-6304	10.7883/yoken.65.345	https://pubmed.ncbi.nlm.nih.gov/22814162/	In the absence of any effective vaccine against human immunodeficiency virus (HIV), current anti-retroviral drugs may be suitable for pre-exposure prophylaxis (PrEP). Previous large clinical trials showed that PrEP reduced HIV infection in high-risk populations. Emtricitabine/tenofovir (FTC/TDF) may be a suitable agent for PrEP. FTC/TDF PrEP efficacy was evaluated using a highly pathogenic simian/human immunodeficiency virus (SHIV) in a non-human primate model of AIDS, the SHIV-KS661c/cynomolgus monkey model. Double oral administration of FTC/TDF (20/30 mg/kg), at 24 h and a few minutes prior to exposure, completely protected 2/3 monkeys from infection. Interestingly, a single oral administration 2 weeks before viral exposure moderately rescued CD4 cells, although the data did not reach statistical significance. These results are consistent with previous primate studies and with recent clinical data. Article	2012	Okwundu, Charles I; Uthman, Olalekan A; Okoromah, Christy An	Antiretroviral pre-exposure prophylaxis (PrEP) for preventing HIV in high-risk individuals.	Cochrane Database Syst Rev	-	-	-	-	1469-493X	10.1002/14651858.CD007189.pub3	https://dx.doi.org/10.1002/14651858.CD007189.pub3	BACKGROUND: More than 30 years into the global HIV/AIDS epidemic, infection rates remain alarmingly high, with over 2.7 million people becoming infected every year. There is a need for HIV prevention strategies that are more effective. Oral antiretroviral pre-exposure prophylaxis (PrEP) in high-risk individuals may be a reliable tool in preventing the transmission of HIV. OBJECTIVES: To evaluate the effects of oral antiretroviral chemoprophylaxis in preventing HIV infection in HIV-uninfected high-risk individuals. SEARCH METHODS: We revised the search strategy from the previous version of the review and conducted an updated search of MEDLINE, the Cochrane Central Register of Controlled Trials and EMBASE in April 2012. We also searched the WHO International Clinical Trials Registry Platform and ClinicalTrials.gov for ongoing trials. SELECTION CRITERIA: Randomised controlled trials that evaluated the effects of any antiretroviral agent or combination of antiretroviral agents in preventing HIV infection in high-risk individuals DATA COLLECTION AND ANALYSIS: Data concerning outcomes, details of the interventions, and other study characteristics were extracted by two independent authors using a standardized data extraction form. Relative risk with a 95% confidence interval (CI) was used as the measure of effect. MAIN RESULTS: We identified 12 randomised controlled trials that meet the criteria for the review. Six were ongoing trials, four had been completed and two had been terminated early. Six studies with a total of 9849 participants provided data for this review. The trials evaluated the following: daily oral tenofovir disoproxil fumarate (TDF) plus emtricitabine (FTC) versus placebo; TDF versus placebo and daily TDF-FTC versus intermittent TDF-FTC. One of the trials had three study arms: TDF, TDF-FTC and placebo arm. The studies were carried out amongst different risk groups, including HIV-uninfected men who have sex with men, serodiscordant couples and other high risk men and women.Overall results from the four trials that compared TDF-FTC versus placebo showed a reduction in the risk of acquiring HIV infection (RR 0.51; 95% CI 0.30 to 0.86; 8918 participants). Similarly, the overall results of the studies that compared TDF only versus placebo showed a significant reduction in the risk of acquiring HIV infection (RR 0.38; 95% CI 0.23 to 0.63, 4027 participants). There were no significant differences in the risk of adverse events across all the studies that reported on adverse events. Also, adherence and sexual behaviours were similar in both the intervention and control groups. AUTHORS' CONCLUSIONS: Finding from this review suggests that pre-exposure prophylaxis with TDF alone or TDF-FTC reduces the risk of acquiring HIV in high-risk individuals including people in serodiscordant relationships, men who have sex with men and other high risk men and women. Article	2012	Omeje, Innocent; Okwundu, Charles I.	WITHDRAWN: Effectiveness and safety of first-line tenofovir + emtricitabine + efavirenz for patients with HIV.	The Cochrane Database of Systematic Reviews	-	-	-	-	1469-493X 1361-6137	10.1002/14651858.CD007276.pub3	https://www.cochranelibrary.com/cdsr/doi/10.1002/14651858.CD007276.pub2/full	BACKGROUND: The current recommended antiretroviral treatment is a highly active antiretroviral therapy (HAART). Although HAART has been associated with improved clinical response to treatment, issues of adherence and viral resistance are major challenges limiting its success. There is a need for an effective and safe first-line regimen, to cope with the ever-increasing incidence of non-adherence and primary resistance. A more recent first-line treatment regimen consists of Tenofovir (TDF, 300 mg) + Emtricitabine (FTC, 200 mg) + Efavirenz (EFV, 600 mg). OBJECTIVES: To evaluate the effects and safety of TDF + FTC + EFV as first-line treatment for patients with HIV. SEARCH METHODS: We searched the Cochrane Central Register of Controlled Trials, EMBASE, GATEWAY, LILACS, PubMed, AEGIS, and the WHO prospective clinical trials registry in November 2011. SELECTION CRITERIA: Randomized controlled trials evaluating the effects of TDF + FTC + EFV compared with other HAART regimens. DATA COLLECTION AND ANALYSIS: Two reviewers independently assessed trial eligibility and risk of bias, and extracted data from the included study. MAIN RESULTS: Only one study involving 517 antiretroviral-naive HIV infected adults was included in this review. Participants were randomly assigned to receive either a regimen of TDF (300 mg), FTC (200mg), and EFV (600mg) once daily; or a regimen of fixed-dose zidovudine (AZT) (300 mg) and lamivudine (3TC) (150 mg) twice daily plus EFV (600mg) once daily. Significantly more patients in the TDF-FTC group reached and maintained HIV RNA levels of less than 50 copies per milliliter compared to the AZT- 3TC group (RR 1.13; 95% CI 1.02 to 1.25). Also, more participants in the TDF-FTC group had greater increase from baseline CD4 cell counts compared to the AZT-3TC group (190 vs. 158 cells per mm(3)). More patients in the AZT-3TC group than in the TDF-FTC group had adverse events resulting in discontinuation of the study drugs (9% vs. 4%, respectively; P = 0.02). There was no statistically significant difference in all cause mortality (RR 0.50; 95% CI 0.05 to 5.46). AUTHORS' CONCLUSIONS: Only one trial has shown beneficial effects and safety of TDF+ FTC + EFV as first-line treatment for patients with HIV. The effects and safety of TDF + FTC + EFV as first-line treatment for patients with HIV cannot be assessed on the basis of only one trial. Further studies evaluating the effects and safety of TDF + FTC + EFV as first-line treatment for patients with HIV are needed. Article	2012	Patton, Cindy; Kim, Hye Jin	The cost of science : knowledge and ethics in the HIV pre-exposure prophylaxis trials.	Journal of Bioethical Inquiry	-	-	-	-	1872-4353	10.1007/s11673-012-9383-x	https://dx.doi.org/10.1007/s11673-012-9383-x	Over the past decade AIDS research has turned toward the use of pharmacology in HIV prevention, including pre-exposure prophylaxis (PrEP): the use of HIV medication as a means of preventing HIV acquisition in those who do not have it. This paper explores the contradictory reasons offered in support of PrEP-to empower women, to provide another risk-reduction option for gay men-as the context for understanding the social meaning of the experimental trials that appear to show that PrEP works in gay men and heterosexual couples but not single women. The PrEP debates reveal the different ideas about "demedicalization" in the earlier gay health and women's health movements and highlight the relationship between health activism and critique of research ethics in the context of a global pharmaceutical market. Article	2012	Paxton, Lynn A.	Considerations regarding antiretroviral chemoprophylaxis and heterosexuals in generalized epidemic settings.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318 1746-630X	10.1097/COH.0b013e328359064a	https://pubmed.ncbi.nlm.nih.gov/23032738/	PURPOSE OF REVIEW: To discuss the factors pertinent to the use of pre-exposure prophylaxis (PrEP) by at-risk heterosexuals in countries with generalized HIV epidemics. RECENT FINDINGS: PrEP will have the greatest prevention effect if targeted to those at highest risk, but identifying and engaging such persons is challenging. Serodiscordant couples account for a high proportion of new infections and are an appropriate target for PrEP, but the proportion of people in such relationships is small and outside partnerships are common. Differences in adherence coupled to pharmacology of the drugs may account for differences in efficacy seen in the trials. Mathematical modeling indicates that the benefits of PrEP in highly endemic settings outweigh the risk of induced viral resistance. Behavioral risk compensation was not observed in the trials, but current open-label studies will better determine if disinhibition will be an important problem. CONCLUSIONS: PrEP is a potentially useful HIV-prevention strategy for generalized heterosexual epidemics. Optimal implementation will require learning more about ways to improve acceptability and adherence and how best to deliver PrEP within the context of limited resource availability. Article	2012	Peng, Bin; Yang, Xiaowei; Zhang, Yan; Dai, Jianghong; Liang, Hao; Zou, Yunfeng; Luo, Jinkun; Peng, Hongbin; Zhong, Xiaoni; Huang, Ailong	Willingness to use pre-exposure prophylaxis for HIV prevention among female sex workers: a cross-sectional study in China.	HIV AIDS (Auckland)	-	-	-	-	1179-1373	10.2147/HIV.S33445	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3463398	BACKGROUND: Pre-exposure prophylaxis (PrEP) is a strategy developed to prevent individuals who are human immunodeficiency virus (HIV)-negative from developing HIV infection. In China, while conducting a clinical trial to investigate the effectiveness and safety of PrEP, we performed this survey to assess the willingness of female sex workers to use PrEP, and identify predictors of this willingness. METHODS: From July 2009 to April 2010, a cross-sectional study was carried out in four provinces of China. We recruited 1611 female sex workers who completed a self-administered survey to assess their awareness of and intention to use PrEP. The survey also canvassed demographic, behavioral, and psychosocial variables. Bivariate and multivariable logistic regression models were fitted to identify predictors of intent to use PrEP. RESULTS: In total, 69% of the women (95% confidence interval CI 66.7-71.3) reported intent to use PrEP, and 12% (95% CI 10.5-13.7) had used drugs in the past to prevent a sexually transmitted infection. Further, 16.5% (95% CI 14.7-18.4) had previously heard of PrEP, and 1.4% (95% CI 0.9-2.1) had used PrEP previously to prevent HIV infection. Multivariate analysis indicated the following significant predictors of intent to use PrEP: Han ethnicity (adjusted odds ratio AOR 1.446; P = 0.011), urban residence (AOR 1.302; P = 0.027), knowledge about transmission of HIV/acquired immune deficiency virus syndrome (AIDS, AOR 1.817; P = 0.0007), a history of sexually transmitted infection (AOR 1.830; P < 0.0001), a history of using medication to prevent a sexually transmitted disease (AOR 2.547; P < 0.0001), and willingness to access knowledge about HIV/AIDS (AOR 2.153; P < 0.0001). CONCLUSION: The majority of female sex workers reported intent to use PrEP if it is safe and effective. Given that most of the participants had never heard of PrEP before, we strongly recommend that educational materials be developed with detailed introduction of PrEP. The risks and benefits of PrEP use should be fully explained to potential users when promoting PrEP in the future.	human immunodeficiency virus, infection, pre-exposure prophylaxis, PrEP, willingness, female sex workers	English	New Zealand	Asia and the Pacific	China	Asia and the Pacific	China	Asia and the Pacific	Quantitative

Article	2012	Person, Anna K.; Hicks, Charles B.	Pre-exposure prophylaxis--one more tool for HIV prevention.	Current HIV Research	-	-	-	-	1873-4251 1570-162X	10.2174/157016212799937254	https://pubmed.ncbi.nlm.nih.gov/22329517/	The 30 years of the human immunodeficiency virus (HIV) epidemic have been marked by many triumphs. Today, thanks to life-saving anti-retroviral medications, patients are living longer than ever. However, despite scientific advances in the field of HIV treatment, HIV prevention has had less success. Despite efforts on several fronts, the number of new HIV diagnoses each year in the United States is unchanged. In this review, we will give a brief overview of the ups and downs of the field of HIV prevention, focusing on pre-exposure prophylaxis (PrEP). CAPRISA 004, iPrEx, FEMPREP, the VOICE trial and HPTN 052, among other prevention trials, are discussed. The CAPRISA 004 and iPrEx studies suggest optimism regarding the use of PrEP for those at risk for HIV infection, but the recent early termination of FEM-PREP and of one arm of VOICE has led to tempered enthusiasm. Many questions remain: Who should get PrEP? How long is it safe to take PrEP? What role will adherence play, and will there be problems with acquired resistance to the drugs with larger numbers using it daily? What is the best method of administering PrEP? Pre-exposure prophylaxis alone is unlikely to be the magic bullet- instead, this strategy will likely need to be part of a broader test-and-treat effort, ongoing education, treatment of sexually transmitted infections, and condom use. Article	2012	Pialoux, G; Chas, J; Bonnard, P	Pre-exposure prophylaxis, a new tool for prevention against HIV	Journal des Anti-Infectieux	-	-	-	-	2210-6545	10.1016/j.antinf.2012.10.003	https://pubmed.ncbi.nlm.nih.gov/37312073/	The HIV epidemic in France is characterized by a very low prevalence in the general population, a higher, heterogeneous and poorly documented prevalence in Sub-Saharan African immigrants, and a high prevalence in homosexual men. The aim of preventive measures in this setting is to reduce the incidence of HIV infection in the population in general and among MSM in particular, and to reduce the risk that a given individual will contract or spread the virus. Eradication of HIV from the entire population is not currently a realistic objective. Male and female condoms, post-exposure prophylaxis, and circumcision are preventive methods currently recognized and promoted worldwide. Other methods are being evaluated, such as vaginal and rectal microbicides, pre-exposure prophylaxis (PreP), and, of course, vaccination with poor results. We discuss, here, the recent results of prevention trials, especially those focusing on PreP, and those focusing on treatment as prevention (TasP) and more recently on circumcision. Article	2012	Poynten, I. Mary; Zablotska, Iryna; Grulich, Andrew E.	Considerations regarding antiretroviral chemoprophylaxis in MSM.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318 1746-630X	10.1097/COH.0b013e3283582c71	https://pubmed.ncbi.nlm.nih.gov/22918448/	PURPOSE OF REVIEW: HIV infection among MSM remains a significant issue. Data relevant to MSM populations from animal models, pharmacokinetic studies and clinical trials are summarized and challenges and potential consequences of use of preexposure prophylaxis (PrEP) by MSM are discussed. RECENT FINDINGS: Rectal simian-human immunodeficiency virus transmission in macaque models can be prevented by intermittent PrEP dosing. The Preexposure Prophylaxis Initiative (iPrEx) study found that daily oral emtricitabine-tenofovir disoproxyl fumarate (TDF/FTC) decreased HIV infection by 44% among 2499 high-risk MSM. Men with detectable levels of TDF or FTC in plasma and peripheral blood mononuclear cells experienced more than 90% protective effect, emphasizing the importance of adherence. In iPrEX and other studies, PrEP was generally safe and well tolerated. However, it appears that TDF use is associated with a small but significant decrease in mean bone mineral density. No risk compensation has been demonstrated, but this remains an area of potential concern when PrEP is used outside the setting of a placebo-controlled trial. Numerous PrEP trials in MSM are currently underway. SUMMARY: Oral FTC/TDF is effective in preventing HIV infection among MSM. Optimal PrEP agents and dosing regimens now need to be identified. Understanding the patterns of and impediments to PrEP use among MSM is vital and these should be monitored in ongoing demonstration projects and open-label studies.	*Homosexuality, Male; Administration, Oral; Emtricitabine; Humans; Male; Tenofovir; Treatment Outcome; Animals; Clinical Trials as Topic; Disease Models, Animal; HIV Infections/*prevention & control; Chemoprevention/*methods; Medication Adherence; Plasma/chemistry; Leukocytes, Mononuclear/chemistry; Drug-Related Side Effects and Adverse Reactions/epidemiology; Adenine/administration & dosage/adverse effects/analogs & derivatives/pharmacokinetics/pharmacology; Anti-HIV Agents/*administration & dosage/adverse effects/pharmacokinetics/pharmacology; Deoxycytidine/administration & dosage/adverse effects/analogs & derivatives/pharmacokinetics/pharmacology; Organophosphonates/administration & dosage/adverse effects/pharmacokinetics/pharmacology	English	United Kingdom	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review
Article	2012	R Amico, K; McMahan, Vanessa; Goicochea, Pedro; Vargas, Lorena; Marcus, Julia L; Grant, Robert M; Liu, Albert	Supporting study product use and accuracy in self-report in the iPrEx study: next step counseling and neutral assessment.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-012-0182-5	https://dx.doi.org/10.1007/s10461-012-0182-5	The recent successes of biomedical HIV prevention approaches have sparked considerable debate over the scalability, feasibility, and acceptability of pre-exposure prophylaxis (PrEP) as a widespread prevention strategy for men who have sex with men and trans-gender. Anticipated difficulties with PrEP adherence and concerns about resources required to best support it have tempered enthusiasm of PrEP demonstration projects and roll-out. While no evidence-based approach for supporting PrEP use is presently available, a number of approaches have been developed in the context of double-blind, randomized, placebo-controlled trials of PrEP that can provide guidance in moving forward with real world support of open label PrEP use. We present the development, implementation and evaluation of feasibility and acceptability of next-step counseling (NSC) and neutral assessment (NA), the adherence support and promotion of accurate reporting approaches used in the late phases of the iPrEx study. Evaluation of the approach from the perspective of implementers of over 15,000 NSC sessions in seven different countries with almost 2,000 iPrEx participants provided support for NSC, its brevity (averaging ~14 min per follow-up session) and overall acceptability and feasibility. NA also was generally well supported, with a majority of study staff believing this approach was feasible and acceptable; however, lower acceptability for certain aspects of NA was noted amongst staff reporting NA was different from their previous interview approach. Quantitative and qualitative data gathered from implementers were used to make modifications for supporting PrEP use in the open-label extension of iPrEx. Article	2012	Radzio, Jessica; Aung, Wutyi; Holder, Angela; Martin, Amy; Sweeney, Elizabeth; Mitchell, James; Bachman, Shanon; Pau, Chou-Pong; Heneine, Walid; Garcia-Lerma, J Gerardo	Prevention of vaginal SHIV transmission in macaques by a coitally-dependent Truvada regimen.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0050632	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3514231	BACKGROUND: Daily pre-exposure prophylaxis (PrEP) with Truvada (a combination of emtricitabine (FTC) and tenofovir (TFV) disoproxil fumarate (TDF)) is a novel HIV prevention strategy recently found to prevent HIV transmission in men who have sex with men and heterosexual couples. We previously showed that a coitally-dependent Truvada regimen protected macaques against rectal SHIV transmission. Here we examined FTC and tenofovir TFV exposure in vaginal tissues after oral dosing and assessed if peri-coital Truvada also protects macaques against vaginal SHIV infection. METHODS: The pharmacokinetic profile of emtricitabine (FTC) and tenofovir (TFV) was evaluated at first dose. FTC and TFV levels were measured in blood plasma, rectal, and vaginal secretions. Intracellular concentrations of FTC-triphosphate (FTC-TP) and TFV-diphosphate (TFV-DP) were measured in PBMCs, rectal tissues, and vaginal tissues. Efficacy of Truvada in preventing vaginal SHIV infection was assessed using a repeat-exposure vaginal SHIV transmission model consisting of weekly exposures to low doses of SHIV162p3. Six pigtail macaques with normal menstrual cycles received Truvada 24 h before and 2 h after each weekly virus exposure and six received placebo. Infection was monitored by serology and PCR amplification of SHIV RNA and DNA. RESULTS: As in humans, the concentration of FTC was higher than the concentration of TFV in vaginal secretions. Also as in humans, TFV levels in vaginal secretions were lower than in rectal secretions. Intracellular TFV-DP concentrations were also lower in vaginal tissues than in rectal tissues. Despite the low vaginal TFV exposure, all six treated macaques were protected from infection after 18 exposures or 4 full menstrual cycles. In contrast, all 6 control animals were infected. CONCLUSIONS: We modeled a peri-coital regimen with two doses of Truvada and showed that it fully protected macaques from repeated SHIV exposures. Our results open the possibility for simplified PrEP regimens to prevent vaginal HIV transmission in women. Article	2012	Ruffin, Nicolas; Borggren, Marie; Euler, Zelda; Fiorino, Fabio; Grupping, Katrijn; Hallengärd, David; Javed, Aneele; Mendonca, Kevin; Pollard, Charlotte; Reinhart, David; Saba, Elisa; Sheik-Khalil, Enas; Sköld, Annette; Ziglio, Serena; Scarlatti, Gabriella; Gotch, Frances; Wahren, Britta; Shattock, Robin J.	Rational design of HIV vaccines and microbicides: report of the EUROPRISE annual conference 2011.	Journal of Translational Medicine	-	-	-	-	1479-5876	10.1186/1479-5876-10-144	https://translational-medicine.biomedcentral.com/articles/10.1186/1479-5876-10-144	Europrise is a Network of Excellence supported by the European Commission within the 6th Framework programme from 2007 to 2012. The Network has involved over 50 institutions from 13 European countries together with 3 industrial partners and 6 African countries. The Network encompasses an integrated program of research, training, dissemination and advocacy within the field of HIV vaccines and microbicides. A central and timely theme of the Network is the development of the unique concept of co-usage of vaccines and microbicides. Training of PhD students has been a major task, and some of these post-graduate students have here summarized novel ideas emanating from presentations at the last annual Europrise meeting in Prague. The latest data and ideas concerning HIV vaccine and microbicide studies are included in this review; these studies are so recent that the majority have yet to be published. Data were presented and discussed concerning novel immunisation strategies; microbicides and PrEP (alone and in combination with vaccines); mucosal transmission of HIV/SIV; mucosal vaccination; novel adjuvants; neutralizing antibodies; innate immune responses; HIV/SIV pathogenesis and disease progression; new methods and reagents. These - necessarily overlapping topics - are comprehensively summarised by the Europrise students in the context of other recent exciting data. Article	2012	Saberi, Parya; Gamarel, Kristi E; Neilands, Torsten B; Comfort, Megan; Sheon, Nicolas; Darbes, Lynae A; Johnson, Mallory O	Ambiguity, ambivalence, and apprehensions of taking HIV-1 pre-exposure prophylaxis among male couples in San Francisco: a mixed methods study.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0050061	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3498189	OBJECTIVE: We conducted a mixed-methods study to examine serodiscordant and seroconcordant (HIV-positive/HIV-positive) male couples' PrEP awareness, concerns regarding health care providers offering PrEP to the community, and correlates of PrEP uptake by the HIV-negative member of the couple. DESIGN: Qualitative sub-study included one-on-one interviews to gain a deeper understanding of participants' awareness of and experiences with PrEP and concerns regarding health care providers offering PrEP to men who have sex with men (MSM). Quantitative analyses consisted of a cross-sectional study in which participants were asked about the likelihood of PrEP uptake by the HIV-negative member of the couple and level of agreement with health care providers offering PrEP to anyone requesting it. METHODS: We used multivariable regression to examine associations between PrEP questions and covariates of interest and employed an inductive approach to identify key qualitative themes. RESULTS: Among 328 men (164 couples), 62% had heard about PrEP, but approximately one-quarter were mistaking it with post-exposure prophylaxis. The majority of participants had low endorsement of PrEP uptake and 40% were uncertain if health care providers should offer PrEP to anyone requesting it. Qualitative interviews with 32 men suggest that this uncertainty likely stems from concerns regarding increased risk compensation. Likelihood of future PrEP uptake by the HIV-negative member of the couple was positively associated with unprotected insertive anal intercourse but negatively correlated with unprotected receptive anal intercourse. CONCLUSIONS: Findings suggest that those at greatest risk may not be receptive of PrEP. Those who engage in moderate risk express more interest in PrEP; however, many voice concerns of increased risk behavior in tandem with PrEP use. Results indicate a need for further education of MSM communities and the need to determine appropriate populations in which PrEP can have the highest impact. Article	2012	Schackman, Bruce R; Eggman, Ashley A	Cost-effectiveness of pre-exposure prophylaxis for HIV: a review.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0b013e3283582c8b	https://dx.doi.org/10.1097/COH.0b013e3283582c8b	PURPOSE OF REVIEW: The US Food and Drug Administration (FDA) recently approved the use of tenofovir-emtricitabine for pre-exposure prophylaxis (PrEP) for HIV prevention. PrEP is also being investigated in clinical trials as a component of HIV prevention in resource-limited settings. Cost-effectiveness models are useful in identifying health programs with the greatest societal value and projecting long-term program impacts. This review examines six recent studies of the cost-effectiveness of PrEP for preventing HIV transmission in the USA and South Africa. RECENT FINDINGS: Studies used both individual-level and population-level transmission models. PrEP was found to be a cost-effective HIV-prevention intervention in high-risk MSM with HIV incidence at least 2% in the USA (<US$100â000 per quality-adjusted life year) and in young women in South Africa (cost per life year <GDP per capita). Results were sensitive to the cost and efficacy of PrEP and to assumptions about HIV testing and access to treatment in the absence of PrEP. SUMMARY: Future cost effectiveness studies should consider PrEP implementation issues (uptake in high-risk versus low-risk groups, duration on PrEP, adherence), budget impact, and the role of PrEP as part of combination HIV-prevention strategies including expanded testing and treatment access. Article	2012	Schneider, John; Kumar, Rupali; Dandona, Rakhi; Kumar, Prem; Kumar, Anil; Lakshmi, Vemu; Laumann, Edward; Mayer, Kenneth; Dandona, Lalit	Social network and risk-taking behavior most associated with rapid HIV testing, circumcision, and preexposure prophylaxis acceptability among high-risk Indian men.	AIDS Patient Care and STDs	-	-	-	-	1557-7449	10.1089/apc.2012.0188	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3462390	Indian truck drivers and their younger apprentice drivers are at increased risk of HIV infection. We determine network and risk practices associated with willingness to adopt HIV prevention interventions currently not being used in India: rapid HIV testing, circumcision, and preexposure prophylaxis (PrEP) in order to inform the National AIDS Control Program (NACP). Truck drivers and truck cleaners were systematically recruited to participate in a social network and risk survey in Hyderabad, Southern India. Three separate composite measures of acceptability of rapid HIV testing, circumcision, and PrEP acceptability were utilized to independently assess the relationship of these prevention interventions with risk-practices and social network characteristics. An 89% participation rate yielded 1602 truck drivers and truck cleaners with 54.2% younger than 30 years of age and 2.8% HIV infected. Twenty-five percent of respondents reported sex with female sex workers (FSW) and 5% with men (MSM). Rapid testing, circumcision, and PrEP acceptability were 97.4%, 9.1%, and 85.9%, respectively. Participants reporting prosocial network characteristics were more accepting of rapid testing (adjusted odds ratio AORs 3.07-6.71; p<0.05) and demonstrated variable PrEP acceptability (AORs 0.08-2.22; p<0.001). Sex with FSWs was associated with PrEP acceptability (AOR 4.27; p<0.001); sex with MSM was associated with circumcision acceptability only (AOR 2.66; p<0.01). Social network factors and risk-practices were associated with novel prevention acceptability, but not consistently across intervention type and with variable directionality. The NACP will need to consider that intervention uptake may likely be most successful when efforts are targeted to individuals with specific behavior and social network characteristics. Article	2012	Stoddart, CA; Nault, G; Galkina, SA; Bousquet-Gagnon, N; Bridon, D; Quraishi, O	Preexposure Prophylaxis with Albumin-Conjugated C34 Peptide HIV-1 Fusion Inhibitor in SCID-hu Thy/Liv Mice	Antimicrobial Agents and Chemotherapy	-	-	-	-	0066-4804	10.1128/AAC.05015-11	https://pubmed.ncbi.nlm.nih.gov/22252805/	PC-1505 is a C34 peptide derived from the heptad repeat 2 region of HIV-1 gp41 conjugated to human serum albumin for sustained in vivo activity. One single preexposure dose of PC-1505 reduced viral RNA in HIV-1-infected SCID-hu Thy/Liv mice by 3.3 log(10) and protected T cells from virus-mediated depletion. In contrast, a single preexposure dose of Truvada reduced viral RNA by only 0.8 log(10) and was substantially less effective in preventing T cell depletion. Article	2012	Storim, J; Jochum, C; Timm, J; Schadendorf, D; Esser, S	HIV-infection during treatment of a chronic hepatitis B virus infection: implications for PrEP?	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.15.6.18169	https://www.proquest.com/scholarly-journals/hiv-infection-during-treatment-chronic-hepatitis/docview/2290137613/se-2?accountid=8113	The protective effect of oral tenofovir disoproxil fumarate (TDF) with or without emtricitabine (FTC) as pre-exposure prophylaxis (PrEP) against HIV differed significantly among clinical studies and poor PrEP-adherence was closely associated with PrEP-failure. Despite HIV-infections during PrEP-exposure the development of resistance mutations against PrEP was rarely observed so far. As PrEP is an emerging tool against HIV transmission, it is important to identify risk-factors for PrEP-failure and the induction of PrEP-associated resistance mutations against antiretroviral drugs. We here present the case of a 25-year old MSM who was successfully treated with TDF due to a chronic hepatitis B virus (HBV) infection (HBV-DNA always <357 IU/ml after ten months of treatment). As HIV tests were negative when the treatment was initiated and six months later, no routine HIV tests were performed although the patient repetitively acquired sexually transmitted infections (STI). After 30 months, an HIV infection (subtype B) was diagnosed during a syphilis re-infection. At this point, HIV was TDF-resistant (K65R and A62V mutations within the reverse transcriptase gene). Retrospective analysis of frozen serum samples revealed HIV-seroconversion 12 months prior to diagnosis and low HIV-RNA levels from seroconversion to diagnosis (always <400 copies/ml). The TDF-based therapy of the chronic HBV-infection resembles a TDF-HIV-PrEP. But here poor therapy adherence is an unlikely cause for the 'PrEP-failure' as the constantly suppressed HBV-DNA indicates therapeutic TDF-levels over years. Combining TDF with FTC might have augmented the prophylactic effect. However, TDF-levels in the rectal mucosa are high and should therefore protect MSM who practice receptive anal intercourse. On the other hand, the concomitant STI of our patient may have promoted HIV transmission (via compromising the mucosal barrier function and promoting inflammatory reactions) and therefore possibly counteracted TDF-effects. Finally, infection with a TDF-resistant virus strain might explain the lack of protection in this case. But K65R is a rarely transmitted drug resistance mutation and low level viremia for one year suggests considerable TDF effectiveness. In fact, we here rather present a K65R mutation induced by a PrEP-like TDF therapy. The development of the K65R mutation in a PrEP-like situation emphasizes the urgent need of regular HIV-tests during PrEP exposure. Article	2012	Strathdee, Steffanie A; Shoptaw, Steven; Dyer, Typhanye Penniman; Quan, Vu Minh; Aramrattana, Apinun	Towards combination HIV prevention for injection drug users: addressing addictophobia, apathy and inattention.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0b013e32835369ad	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3646543	PURPOSE OF REVIEW: Recent breakthroughs in HIV-prevention science led us to evaluate the current state of combination HIV prevention for injection drug users (IDUs). We review the recent literature focusing on possible reasons why coverage of prevention interventions for HIV, hepatitis C virus (HCV) and tuberculosis among IDUs remains dismal. We make recommendations for future HIV research and policy. RECENT FINDINGS: IDUs disproportionately under-utilize voluntary HIV counseling and testing (VCT), primary care and antiretroviral therapy (ART), especially in countries that have the largest burden of HIV among IDUs. IDUs present later in the course of HIV infection and experience greater morbidity and mortality. Why are IDUs under-represented in HIV-prevention research, access to treatment for both HIV and addiction, and access to HIV combination prevention? Possible explanations include addictophobia, apathy, and inattention, which we describe in the context of recent literature and events. SUMMARY: This commentary discusses the current state of HIV-prevention interventions for IDUs including VCT, needle and syringe program (NSP), opioid substitution therapy (OST), ART and pre-exposure chemoprophylaxis (PrEP), and discusses ways to work towards true combination HIV prevention for IDU populations. Communities need to overcome tacit assumptions that IDUs can navigate through systems that are maintained as separate silos, and begin to take a rights-based approach to HIV prevention to ensure that IDUs have equitable access to life-saving prevention and treatments. Article	2012	Supervie, V; Blower, S	Predicting effect of pre-exposure prophylaxis on HIV epidemics	The Lancet	-	-	-	-	0140-6736	10.1016/S0140-6736(12)61057-5	https://pubmed.ncbi.nlm.nih.gov/22748579/	"We agree with Angela Kashuba and colleagues (June 30, p 2409)1 that it is essential to develop new methods for measuring adherence to preexposure prophylaxis (PrEP) for HIV prevention in clinical trials. However, another important issue also needs to be addressed. Specifi cally, how can adherence data from clinical trials be interpreted and used to predict the success of PrEP in reducing transmission in the real world? We suggest that one approach is to use mathematical models to translate these data into population-level predictions. In each of the successful clinical trials of PrEP,2,3 several estimates of effi cacy have been calculated: an overall estimate of effi cacy calculated by use of data from all individuals irrespective of their level of adherence, and adherence-stratifi ed effi cacies for which each estimate was calculated for a specifi ed range of adherence. For example, in the IPrEx trial3,4 (in which adherence was defi ned on the basis of number of visits) the overall effi cacy was estimated to be 42% and adherence-stratifi ed effi cacies (based on an as-treated analysis4) were estimated to be 68% (adherence ≥90%), 34% (50–90% adherence), and 16% (<50% adherence). Such data are necessary, but—even if adherence is measured accurately—are not suffi cient for predicting the success of PrEP in the real world. To make predictions, it is also necessary to know how population-level patterns of adherence to PrEP will aff ect success, where such patterns are defi ned in terms of the proportion of the population in each adherence category. The fi gure shows predictions from a mathematical model that translates adherence data from clinical trials of PrEP into populationlevel predictions.5 Contours show the reduction in transmission as a function of the proportion of the population that is highly (>90%) adherent to PrEP (Y-axis) and the average adherence in the rest of the population (X-axis). To generate these predictions, adherencestratifi ed effi cacy estimates, based on clinical trial data, were used.5 The fi gure illustrates that populationlevel adherence patterns (which cannot be measured in clinical trials) will be as important as effi cacy in determining success. Therefore even when it becomes possible to measure adherence accurately in clinical trials, these trials will not be able to generate all of the necessary data for predicting the success of PrEP in reducing HIV transmission in the real world." Article	2012	Thigpen, MC; Kebaabetswe, PM; Paxton, LA; Smith, DK; Rose, CE; Segolodi, TM; Henderson, FL; Pathak, SR; Soud, FA; Chillag, KL; Mutanhaurwa, R; Chirwa, LI; Kasonde, M; Abebe, D; Buliva, E; Gvetadze, RJ; Johnson, S; Sukalac, T; Thomas, VT; Hart, C; Johnson, JA; Malotte, CK; Hendrix, CW; Brooks, JT	Antiretroviral preexposure prophylaxis for heterosexual HIV transmission in Botswana	New England Journal of Medicine	-	-	-	-	0028-4793	10.1056/NEJMoa1110711	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-00840265/full	BACKGROUND: Preexposure prophylaxis with antiretroviral agents has been shown to reduce the transmission of human immunodeficiency virus (HIV) among men who have sex with men; however, the efficacy among heterosexuals is uncertain. METHODS: We randomly assigned HIV-seronegative men and women to receive either tenofovir disoproxil fumarate and emtricitabine (TDF-FTC) or matching placebo once daily. Monthly study visits were scheduled, and participants received a comprehensive package of prevention services, including HIV testing, counseling on adherence to medication, management of sexually transmitted infections, monitoring for adverse events, and individualized counseling on risk reduction; bone mineral density testing was performed semiannually in a subgroup of participants. RESULTS: A total of 1219 men and women underwent randomization (45.7% women) and were followed for 1563 person-years (median, 1.1 years; maximum, 3.7 years). Because of low retention and logistic limitations, we concluded the study early and followed enrolled participants through an orderly study closure rather than expanding enrollment. The TDF-FTC group had higher rates of nausea (18.5% vs. 7.1%, P<0.001), vomiting (11.3% vs. 7.1%, P=0.008), and dizziness (15.1% vs. 11.0%, P=0.03) than the placebo group, but the rates of serious adverse events were similar (P=0.90). Participants who received TDF-FTC, as compared with those who received placebo, had a significant decline in bone mineral density. K65R, M184V, and A62V resistance mutations developed in 1 participant in the TDF-FTC group who had had an unrecognized acute HIV infection at enrollment. In a modified intention-to-treat analysis that included the 33 participants who became infected during the study (9 in the TDF-FTC group and 24 in the placebo group; 1.2 and 3.1 infections per 100 person-years, respectively), the efficacy of TDF-FTC was 62.2% (95% confidence interval, 21.5 to 83.4; P=0.03). CONCLUSIONS: Daily TDF-FTC prophylaxis prevented HIV infection in sexually active heterosexual adults. The long-term safety of daily TDF-FTC prophylaxis, including the effect on bone mineral density, remains unknown. (Funded by the Centers for Disease Control and Prevention and the National Institutes of Health; TDF2 ClinicalTrials.gov number, NCT00448669.). Article	2012	Thurman, A. R.; Doncel, G. F.	Herpes simplex virus and HIV: genital infection synergy and novel approaches to dual prevention.	International journal of STD & AIDS	-	-	-	-	1758-1052 0956-4624	10.1258/ijsa.2012.011356	https://pubmed.ncbi.nlm.nih.gov/23033511/	Sexual transmission of HIV-1, in the absence of co-factors, is poorly efficient. Data support that herpes simplex virus type-2 (HSV-2) may increase a woman's susceptibility to HIV-1. Potential mechanisms by which HSV-2 serves as an HIV-1 enhancing co-factor include (1) initiation of a clinical or subclinical mucosal inflammatory response, (2) alteration of innate mucosal immunity and (3) weakening or breaching the protective genital epithelia. No clinical trial has examined prevention of primary HSV-2 infection to eliminate the major morbidities of this recurrent disease and as a strategy to reduce HIV-1 transmission. Topical administration of potent antivirals can achieve local concentrations that are orders of magnitude higher than those obtained with oral administration. This paper reviews major advances in oral and topical pre-exposure prophylaxis of HIV-1 and HSV-2 and, based on these data, hypothesizes that simultaneous prevention of sexual acquisition of HSV-2 and HIV-1 via topical antiretroviral agents will have a synergistic impact on both epidemics. Article	2012	Tressler, Randall; Godfrey, Catherine	NRTI backbone in HIV treatment: will it remain relevant?	Drugs	-	-	-	-	1179-1950 0012-6667	10.2165/11640830-000000000-00000	https://link.springer.com/article/10.2165/11640830-000000000-00000	Nucleoside reverse transcriptase inhibitors (NRTIs) remain a critical component of therapy for HIV-infected patients. The drugs are effective, relatively inexpensive and an important component of antiretroviral therapy (ART), particularly in areas where the introduction of effective therapy has been delayed. They are an essential part of initial therapy for HIV and for prevention of mother-to-child transmission; however, toxicities and resistance may limit their use. The role for pre-exposure prophylaxis (PrEP) to reduce sexual transmission of HIV is still undefined, but this use may have a significant impact on NRTI resistance worldwide, most particularly in areas where subtype C predominates. With increasing prevalence of resistant HIV, the approval of new agents that are effective against resistant virus, and those that use novel cellular targets, are essential. Large studies are now in progress examining the safety and efficacy of NRTI-sparing regimens, but results are not currently available. NRTIs may lose relevance in the not distant future unless steps are put in place to reduce the development and spread of NRTI-resistant viruses, and new NRTIs with minimal toxicity are developed that have a novel resistance profile. This article describes the principal NRTIs, their mechanism of action, and resistance and selected toxicities of the class and of the individual drugs. Article	2012	Tripathi, A; Whiteside, O; Scanlon, C; Duffus, W	Perceptions and attitudes about PrEP among seronegative partners and the potential of sexual disinhibition associated with the use of PrEP	Journal of the International AIDS Society	-	-	-	-	1758-2652	NA	https://pubmed.ncbi.nlm.nih.gov/24096949/#:~:text=Conclusions%3A%20Overall%2C%20these%20results%20suggest,be%20reduced%20by%20ongoing%20education.	Objectives: Preexposure prophylaxis (PrEP) is a promising strategy to prevent human immunodeficiency virus (HIV) infection, especially among high-risk individuals such as seronegative partners; however, many caveats such as the potential risk of sexual disinhibition and noncompliance need to be considered. We explored the sociodemographic and behavioral factors associated with the adoption of PrEP among HIV seronegative men who have sex with men and heterosexual partners. Methods: A prepiloted self-administered survey was conducted among seronegative partners in a Ryan White HIV/AIDS Clinic in South Carolina from 2010 to 2011. Bivariate and multivariable analyses were used to explore the data. Results: The survey was completed by 89 seronegative partners. The median age was 42 years (interquartile range 32-50) and a majority were men (56%), black (70%), and heterosexual (74%). A majority (94%) was willing to use PrEP if available; however, 26% of subjects suggested that they would be likely to have unprotected sex with an HIV-positive partner while using PrEP, and 27% suggested that it would be difficult to take a daily dose of PrEP and consistently use condoms. The multivariable results suggest that the belief that a condom is no longer needed while taking PrEP was more likely among those who did not use a condom during their last sexual intercourse (adjusted odds ratio 7.45; 95% confidence interval 1.57-35.45) and among those with a higher HIV knowledge score (adjusted odds ratio 0.43; 95% confidence interval 0.23-0.78). Conclusions: Overall, these results suggest high acceptability of PrEP among seronegative partners to lower the risk of HIV transmission; however, there is a substantial risk of sexual disinhibition and noncompliance while using PrEP that may be reduced by ongoing education. Article	2012	Tripathi, Avnish; Ogbuanu, Chinelo; Monger, Mauda; Gibson, James J; Duffus, Wayne A	Preexposure prophylaxis for HIV infection: healthcare providers' knowledge, perception, and willingness to adopt future implementation in the southern US.	Southern Medical Journal	-	-	-	-	1541-8243	10.1097/SMJ.0b013e31824f1a1b	https://dx.doi.org/10.1097/SMJ.0b013e31824f1a1b	BACKGROUND: Understanding providers' perspective on preexposure prophylaxis (PrEP) would facilitate planning for future implementation. METHODS: A survey of care providers from sexually transmitted disease and family planning clinics in South Carolina and Mississippi was conducted to assess their knowledge, perception, and willingness to adopt PrEP. Multivariable logistic and general linear regression with inverse propensity score treatment weights were used for analyses. RESULTS: Survey response rate was 360/480 (75%). Median age was 46.9 years and a majority were women (279 78%), non-Hispanic white (277 78%), nonphysicians (254 71%), and public health care providers (223 62%). Knowledge about PrEP was higher among physicians compared with nonphysicians (P = 0.001); nonpublic health care providers compared with public health care providers (P = 0.023), and non-Hispanic whites compared with non-Hispanic blacks (P = 0.034). The majority of the providers were concerned about the safety, efficacy, and cost of PrEP. Providers' perceptions about PrEP were significantly associated with their sociodemographic and occupational characteristics. The willingness to prescribe PrEP was more likely with higher PrEP knowledge scores (adjusted odds ratio aOR 14.94; 95% confidence interval CI 3.21-69.61), older age (aOR 1.14; 95% CI 1.01-1.29), and in those who agreed that "PrEP would empower women" (aOR 2.90; 95% CI 1.28-6.61); and was less likely for "other" race/ethnicity versus white (aOR 0.23; 95% CI 0.07-0.76) and in those who agreed that "PrEP, if not effective, could lead to higher HIV transmission" (aOR 0.45; 95% CI 0.27-0.75). CONCLUSIONS: To improve the acceptance of PrEP among providers, there is a need to develop tailored education/training programs to alleviate their concerns about the safety and efficacy of PrEP. Article	2012	Uckun, Fatih M; Cahn, Pedro; Qazi, Sanjive; D'Cruz, Osmond	Stampidine as a promising antiretroviral drug candidate for pre-exposure prophylaxis against sexually transmitted HIV/AIDS.	Expert Opinion on Investigational Drugs	-	-	-	-	1744-7658	10.1517/13543784.2012.664635	https://dx.doi.org/10.1517/13543784.2012.664635	INTRODUCTION: Pre-exposure prophylaxis (PrEP) is an evolving new approach to prevention of sexually transmitted HIV-1 that employs antiretroviral (ARV) agents prior to potential HIV-1 exposure in an attempt to reduce the likelihood of HIV-1 infection postexposure. The identification of new ARV agents with potent activity against multidrug-resistant HIV remains an unmet and urgent challenge in the field of PrEP. AREAS COVERED: This article reviews the preclinical and early clinical activity and safety profile of stampidine, a novel antiretroviral (ARV) drug candidate that exhibits remarkable subnanomolar to low nanomolar in vitro antiretroviral potency against genotypically and phenotypically nucleoside reverse transcriptase inhibitor (NRTI)-resistant primary clinical HIV isolates, non-nucleoside RT-resistant HIV-1 isolates. Stampidine has a favorable pharmacokinetic profile in mice, rats, dogs and cats with 25 or 50 mg/kg tolerable dose levels yielding micromolar plasma concentrations that are 1000-fold higher than its in vitro IC(50) value against HIV. Stampidine has a favorable, safety profile in mice, rats, dogs and cats and it showed significant in vivo ARV activity in HIV-infected Hu-PBL-SCID mice as well as FIV-infected domestic cats. Furthermore, it did not cause any maternal toxicity, developmental toxicity or teratogenicity in rabbits treated at 10 - 40 mg/kg/day dose levels. In a recently completed first-in-human Phase I clinical trial, stampidine did not cause dose-limiting toxicity at single dose levels ranging from 5 to 25 mg/kg. EXPERT OPINION: The favorable safety and activity profile of stampidine warrants its further development as a promising next-generation PrEP candidate to prevent the sexual transmission of HIV-1. The discovery of stampidine as a potent antiretroviral agent represents a significant step forward in the development of effective therapeutic as well as preventive strategies against HIV/AIDS. The primary objective was to assess the effectiveness of TDF–FTC in preventing HIV acquisition and to evaluate safety.ResultsHIV infections occurred in 33 women in the TDF–FTC group (incidence rate, 4.7 per 100 person-years) and in 35 in the placebo group (incidence rate, 5.0 per 100 person-years), for an estimated hazard ratio in the TDF–FTC group of 0.94 (95% confidence interval, 0.59 to 1.52; P=0.81). The proportions of women with nausea, vomiting, or elevated alanine aminotransferase levels were significantly higher in the TDF–FTC group (P=0.04, P<0.001, and P=0.03, respectively). Rates of drug discontinuation because of hepatic or renal abnormalities were higher in the TDF–FTC group (4.7%) than in the placebo group (3.0%, P=0.051). Less than 40% of the HIV-uninfected women in the TDF–FTC group had evidence of recent pill use at visits that were matched to the HIV-infection window for women with seroconversion. The study was stopped early, on April 18, 2011, because of lack of efficacy.ConclusionsProphylaxis with TDF–FTC did not significantly reduce the rate of HIV infection and was associated with increased rates of side effects, as compared with placebo. Despite substantial counseling efforts, drug adherence appeared to be low. (Supported by the U.S. Agency for International Development and others; FEM-PrEP ClinicalTrials.gov number, NCT00625404.) Article	2012	van der Straten, Ariane; Van Damme, Lut; Haberer, Jessica E; Bangsberg, David R	Unraveling the divergent results of pre-exposure prophylaxis trials for HIV prevention.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0b013e3283522272	https://dx.doi.org/10.1097/QAD.0b013e3283522272	Although the balance of recent evidence supports the efficacy of antiretroviral (ARV)-based pre-exposure prophylaxis (PrEP) against HIV-1 infection, recent negative trial results are perplexing. Of seven trials with available HIV endpoints, three different products have been tested: tenofovir 1% vaginal gel, oral tenofovir disoproxil fumarate (TDF) tablets, and TDF/emtricitabine tablets. Six of these trials were conducted exclusively in sub-Saharan Africa; all found the products to be well tolerated, and four demonstrated effectiveness. Furthermore, the HIV Prevention Trial Network (HPTN) 052 trial recently confirmed that antiretroviral treatment leads to 96% reduction in transmission to HIV-negative partners in HIV-serodiscordant couples. These results, along with human and animal data, provide substantial evidence for the efficacy of antiretroviral-based HIV prevention. Yet assessment of oral TDF/emtricitabine in the FEM-PrEP study and of oral and vaginal tenofovir in the Microbicide Trial Network (MTN)-003 trial (VOICE) was stopped for futility. How do we make sense of these discrepant results? We believe that adherence is a key factor, although it cannot be the only factor. Expanding upon a recent editorial in the Lancet, we discuss the impact of suboptimal product adherence on PrEP efficacy in the context of variable drug concentration at the exposure site, integrity of the vaginal epithelium, and the role of acute infection. Article	2012	van Lunzen, Jan; Maggiolo, Franco; Arribas, José R.; Rakhmanova, Aza; Yeni, Patrick; Young, Benjamin; Rockstroh, Jürgen K.; Almond, Steve; Song, Ivy; Brothers, Cindy; Min, Sherene	Once daily dolutegravir (S/GSK1349572) in combination therapy in antiretroviral-naive adults with HIV: planned interim 48 week results from SPRING-1, a dose-ranging, randomised, phase 2b trial.	The Lancet Infectious Diseases	-	-	-	-	1474-4457 1473-3099	10.1016/S1473-3099(11)70290-0	https://pubmed.ncbi.nlm.nih.gov/22018760/	BACKGROUND: Dolutegravir (S/GSK1349572) is a new HIV-1 integrase inhibitor that has antiviral activity with once daily, unboosted dosing. SPRING-1 is an ongoing study designed to select a dose for phase 3 assessment. We present data from preplanned primary and interim analyses. METHODS: In a phase 2b, multicentre, dose-ranging study, treatment-naive adults were randomly assigned (1:1:1:1) to receive 10 mg, 25 mg, or 50 mg dolutegravir or 600 mg efavirenz. Dose but not drug allocation was masked. Randomisation was by a central integrated voice-response system according to a computer-generated code. Study drugs were given with either tenofovir plus emtricitabine or abacavir plus lamivudine. Our study was done at 34 sites in France, Germany, Italy, Russia, Spain, and the USA beginning on July 9, 2009. Eligible participants were seropositive for HIV-1, aged 18 years or older, and had plasma HIV RNA viral loads of at least 1000 copies per mL and CD4 counts of at least 200 cells per μL. Our primary endpoint was the proportion of participants with viral load of less than 50 copies per mL at week 16 and we present data to week 48. Analyses were done on the basis of allocation group and included all participants who received at least one dose of study drug. This study is registered with ClinicalTrials.gov, number NCT00951015. FINDINGS: 205 patients were randomly allocated and received at least one dose of study drug: 53, 51, and 51 to receive 10 mg, 25 mg, and 50 mg dolutegravir, respectively, and 50 to receive efavirenz. Week 16 response rates to viral loads of at most 50 copies per mL were 93% (144 of 155 participants) for all doses of dolutegravir (with little difference between dose groups) and 60% (30 of 50) for efavirenz; week 48 response rates were 87% (139 of 155) for all doses of dolutegravir and 82% (41 of 50) for efavirenz. Response rates between nucleoside reverse transcriptase inhibitor subgroups were similar. We identified three virological failures in the dolutegravir groups and one in the efavirenz group-we did not identify any integrase inhibitor mutations. We did not identify any dose-related clinical or laboratory toxic effects, with more drug-related adverse events of moderate-or-higher intensity in the efavirenz group (20%) than the dolutegravir group (8%). We did not judge that any serious adverse events were related to dolutegravir. INTERPRETATION: Dolutegravir was effective when given once daily without a pharmacokinetic booster and was well tolerated at all assessed doses. Our findings support the assessment of once daily 50 mg dolutegravir in phase 3 trials. Article	2012	Volk, Jonathan E; Liu, Albert; Vittinghoff, Eric; Irvin, Risha; Kroboth, Elizabeth; Krakower, Douglas; Mimiaga, Matthew J; Mayer, Kenneth H; Sullivan, Patrick S; Buchbinder, Susan P	Sexual frequency and planning among at-risk men who have sex with men in the United States: implications for event-based intermittent pre-exposure prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3427423	Intermittent dosing of pre-exposure prophylaxis (iPrEP) has potential to decrease costs, improve adherence, and minimize toxicity. Practical event-based dosing of iPrEP requires men who have sex with men (MSM) to be sexually active on fewer than 3 days each week and plan for sexual activity. MSM who may be most suitable for event-based dosing were older, more educated, more frequently used sexual networking websites, and more often reported that their last sexual encounter was not with a committed partner. A substantial proportion of these MSM endorse high-risk sexual activity, and event-based iPrEP may best target this population.	intermittent pre-exposure prophylaxis (iPrEP), pre-exposure prophylaxis (PrEP), event-based dosing, men-who-have-sex-with-men (MSM), HIV, sexual frequency, sexual planning	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2012	Walensky, Rochelle P; Park, Ji-Eun; Wood, Robin; Freedberg, Kenneth A; Scott, Callie A; Bekker, Linda-Gail; Losina, Elena; Mayer, Kenneth H; Seage, George R; Paltiel, A David	The cost-effectiveness of pre-exposure prophylaxis for HIV infection in South African women.	Clinical Infectious Diseases	-	-	-	-	1537-6591	10.1093/cid/cis225	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3334365	BACKGROUND: Recent trials report the short-term efficacy of tenofovir-based pre-exposure prophylaxis (PrEP) for prevention of human immunodeficiency virus (HIV) infection. PrEP's long-term impact on patient outcomes, population-level transmission, and cost-effectiveness remains unknown. METHODS: We linked data from recent trials to a computer model of HIV acquisition, screening, and care to project lifetime HIV risk, life expectancy (LE), costs, and cost-effectiveness, using 2 PrEP-related strategies among heterosexual South African women: (1) women receiving no PrEP and (2) women not receiving PrEP (a tenofovir-based vaginal microbicide). We used a South African cohort and published data to estimate population demographic characteristics, age-adjusted incidence of HIV infection, and HIV natural history and treatment parameters. Baseline PrEP efficacy (percentage reduction in HIV transmission) was 39% at a monthly cost of $5 per woman. Alternative parameter values were examined in sensitivity analyses. RESULTS: Among South African women, PrEP reduced mean lifetime HIV risk from 40% to 27% and increased population discounted (undiscounted) LE from 22.51 (41.66) to 23.48 (44.48) years. Lifetime costs of care increased from $7280 to $9890 per woman, resulting in an incremental cost-effectiveness ratio of $2700/year of life saved, and may, under optimistic assumptions, achieve cost savings. Under baseline HIV infection incidence assumptions, PrEP was not cost saving, even assuming an efficacy >60% and a cost <$1. At an HIV infection incidence of 9.1%/year, PrEP achieved cost savings at efficacies ≥50%. CONCLUSIONS: PrEP in South African women is very cost-effective by South African standards, conferring excellent value under virtually all plausible data scenarios. Although optimistic assumptions would be required to achieve cost savings, these represent important benchmarks for future PrEP study design. Article	2012	Ware, NC; Wyatt, MA; Haberer, JE; Baeten, JM; Kintu, A; Psaros, C; Safren, S; Tumwesigye, E; Celum, CL; Bangsberg, DR	What's love got to do with it? Explaining adherence to oral antiretroviral pre-exposure prophylaxis for HIV-serodiscordant couples	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	NA	10.1097/QAI.0b013e31824a060b	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-00842821/full	OBJECTIVE: Adherence may be the "Achilles heel" of pre-exposure prophylaxis (PrEP), a promising biomedical approach to HIV prevention. This article presents an explanation of PrEP adherence for African serodiscordant couples derived from qualitative data. DESIGN: Explaining quantitative findings is one way qualitative investigation contributes to research in medicine and public health. This qualitative interview study was nested in the Partners PrEP Study, a phase III randomized trial evaluating oral tenofovir and emtricitabine/tenofovir PrEP to prevent HIV acquisition by HIV-uninfected partners in serodiscordant heterosexual couples. METHODS: In-depth qualitative interviews were provided by 60 Partners PrEP Study participants in Uganda. Interviews used open-ended questions eliciting information on adherence experiences, barriers, and facilitators. An inductive approach informed by grounded theory methodology was used to analyze study data. RESULTS: The proposed explanation may be summarized as follows. Serodiscordance destabilizes couples, as the HIV-negative partner reacts with anger, fear, and sadness to the implication of infidelity represented by HIV infection. A "discordance dilemma" ensues, as the desire to avoid acquiring HIV and the advantages of preserving the relationship become competing priorities. PrEP is seen as a solution-a means of safeguarding health without ending the relationship. PrEP users benefit from the support of partners, who reinforce adherence. Where discord in the relationship persists, adherence suffers. CONCLUSIONS: PrEP adherence in serodiscordant couples may be understood as a function of the desire to reduce risk although preserving a partnered relationship. PrEP use in stable couples may be associated with improved adherence and thus, greater effectiveness. Article	2012	Wheelock, Ana; Eisingerich, Andreas B; Gomez, Gabriela B; Gray, Emily; Dybul, Mark R; Piot, Peter	Views of policymakers, healthcare workers and NGOs on HIV pre-exposure prophylaxis (PrEP): a multinational qualitative study.	BMJ Open	-	-	-	-	2044-6055	10.1136/bmjopen-2012-001234	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3391366	OBJECTIVES: To examine policymakers and providers' views on pre-exposure prophylaxis (PrEP) and their willingness to support its introduction, to inform policy and practice in this emerging field. DESIGN: Semistructured qualitative interview study. SETTING: Peru, Ukraine, India, Kenya, Uganda, Botswana and South Africa. PARTICIPANTS: 35 policymakers, 35 healthcare workers and 21 non-governmental organisation representatives involved in HIV prevention. RESULTS: Six themes emerged from the data: (1) perceived HIV prevention landscape: prevention initiatives needed to be improved and expanded; (2) PrEP awareness: 50 of 91 participants had heard of PrEP; (3) benefits of PrEP: one component of the combination prevention arsenal that could help prioritise HIV prevention, empower key populations and result in economic gains; (4) challenges of PrEP: regimen complexity, cost and cost-effectiveness, risk compensation, efficacy and effectiveness, stigmatisation and criminalisation, information and training and healthcare system capacity; (5) programmatic considerations: user eligibility, communication strategy, cost, distribution, medication and HIV testing compliance and (6) early versus late implementation: participants were divided as to whether they would support an early introduction of PrEP in their country or would prefer to wait until it has been successfully implemented in other countries, with around half of those we spoke to supporting each option. Very few said they would not support PrEP at all. CONCLUSIONS: Despite the multiple challenges identified, there was general willingness to support the introduction of PrEP. Yet, strengthening existing HIV prevention efforts was also deemed necessary. Our results suggest that an effective PrEP programme would be delivered in healthcare facilities and involve non-governmental organisations and the community and consider the needs of mobile populations. Comprehensive information packages and training for users and providers would be critical. The cost of PrEP would be affordable and possibly segmented. Extensive counselling and innovative monitoring measures ought to be considered. Article	2012	White, Jaclyn M; Mimiaga, Matthew J; Krakower, Douglas S; Mayer, Kenneth H	Evolution of Massachusetts physician attitudes, knowledge, and experience regarding the use of antiretrovirals for HIV prevention.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2012.0030	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3432573	The Center for the AIDS Programme of Research in South Africa (CAPRISA) 004 and Pre-exposure Prophylaxis Initiative (iPrEx) studies demonstrated that topical or oral chemoprophylaxis could decrease HIV transmission. Yet to have an appreciable public health impact, physicians will need to be educated about these new HIV prevention modalities. Massachusetts physicians were recruited via e-mail to complete an online survey of their knowledge and use of HIV prevention interventions. Data were collected before (July-December, 2010) (n=178) and after (December, 2010-April, 2011) (n=115) the release of iPrEx data. Over the two time intervals, knowledge of oral PrEP significantly increased (79% to 92%, p<0.01), whereas knowledge about topical microbicides was already high (89% pre-iPrEx). Post-iPrEx, specialists were more knowledgeable about oral PrEP (p<0.01) and topical microbicides (p<0.001) than generalists. The majority of the respondents would prefer to prescribe topical microbicides (75%) than oral PrEP (25%; p<0.001), primarily because they perceived fewer side effects (95%). Respondents indicated that PrEP should be available if it were a highly effective, daily pill; however, ongoing concerns included: potential drug resistance (93%), decreased funds for other forms of HIV prevention (88%), medication side effects (83%), and limited data regarding PrEP's clinical efficacy (75%). Participants indicated that formal CDC guidelines would have the greatest impact on their willingness to prescribe PrEP (96%). Among Massachusetts physicians sampled, chemoprophylaxis knowledge was high, but current experience was limited. Although topical gel was preferred, responses suggest a willingness to adapt practices pending additional efficacy data and further guidance from normative bodies. Educational programs aimed at incorporating antiretroviral chemoprophylaxis into physicians' HIV prevention practices are warranted. Article	2012	Xun ZHONG	Attitude on pre-exposure prophylaxis (PrEP) among drug users from high-risk population of aids in western China	Academic Journal of Second Military Medical University	-	-	-	0258-879X	NA	https://pesquisa.bvsalud.org/portal/resource/pt/wpr-839685	Objective To investigate the attitude on pre-exposure prophylaxis (PrEP) among drug users from high-risk population of AIDS in western China and its influencing factors. Methods A total of 190 drug users were recruited by snowball sampling from high-risk population of AIDS including those involved in mem having sex with men (MSM), female sex workers(FSW) and the spouse or sex partner (PAR) of HIV carrier in Chongqing, Sichuan, Guangxi and Xinjiang. Self-ad ministered questionnaire survey was conducted with the assistance of investigators. Univariate and multivariate logistic regression was employed for statistical analysis. Results MSM, FSW and PAR accounted for 34. 74% (66/190), 48. 42% (92/190) and 16. 84% (32/190) among the 190 drug users, respectively. The positive attitude rate for PrEP among drug users reached 70% in the premise of drug safety and effectiveness, which increased with favorable condition provided. The results of multivariate logistic regression analysis indicated that the factors significantly associated with the positive attitude for PrEP included awareness of AIDS seriousness (OR-. 2.66, 95% CI: 1.14-6.25, P = 0.024 2), attitudes towards HIV patients (OR. 4.41, 95% CI: 1.68-11.58, P = 0.002 6, OR-. 2.99, 95% CI: 1.05-8.54, P = 0. 040 3) and virus detection of AIDS (OR-. 1.94, 95% CI: 0. 98-3. 87, P = 0. 058 1). Conclusion The attitude for PrEP among drug users from AIDS high-risk population is mainly related to the attitude for AIDS, AIDS- related knowledge and behavior, and preventive measures for AIDS, indicating that PrEP should be implemented and promoted with a sound social background, and education on HIV/AIDS prevention should be reinforced. Positive attitude towards AIDS prevention need to be developed among drug users by various behavioral therapies, so as to improve the attitude for PrEP among drug users with high HIV risks. Article	2012	Yang, D; Chariyalertsak, C; Wongthanee, A; Kawichai, S; Yotruean, K; Guadamuz, T; Suwanvanichkij, V; Beyrer, C; Chariyalertsak, S	Acceptability of HIV pre-exposure prophylaxis (PrEP) with Truvada among men who have sex with men (MSM) and male-to-female transgender persons (TG) in northern Thailand	Journal of the International AIDS Society	-	-	-	1758-2652	10.1371/journal.pone.0076650	https://pubmed.ncbi.nlm.nih.gov/24116132/	Background: Northern Thailand has a high burden HIV epidemic among MSM and TG. Oral pre-exposure prophylaxis (PrEP) with tenofovir-emtricitabine has demonstrated efficacy in preventing HIV among MSM and TG in Chiang Mai, Thailand. Determinants of PrEP acceptability are needed to gauge the potential uptake of this prevention strategy.Methods: From January to February 2012, 238 MSM and TG participants, who self-reported as HIV-uninfected or of unknown status, completed a self-administered survey on hand-held computers. Participants were recruited by venue-day-time sampling and asked to rate their likelihood of using oral PrEP for HIV prevention with an efficacy of 50%. PrEP acceptability was defined as being "very likely" to use PrEP. Odds ratios and 95% CIs were calculated to identify correlates of acceptability.Results: 131 MSM and 107 TG responded, with mean ages of 23.7 and 21.8, respectively. 24% of MSM engaged primarily in receptive anal sex vs. 74% of TG. 21% of MSM and 44% of TG reported regular medication use. Prior awareness of PrEP was high at 66% among both MSM and TG respondents. 41% of MSM and 37% of TG were "very likely" to use PrEP. Among MSM, factors associated with PrEP acceptability included a prior history of STIs (AOR 4.6; 95%CIs 1.1-12.6), previous HIV testing (AOR 2.4 95%CIs 1.1-5.3), regularly planned sex (AOR 2.8 95%CIs 1.1-7.2), and infrequent sex (AOR 2.9 95%CIs 1.3-6.3). Among TG, factors associated with acceptability included prior awareness of PrEP (AOR 3.3; 95%CIs 1.2-9.0) and having private insurance (AOR 5.0; 95%CIs 1.3-19.0).Conclusion: MSM and TG in Northern Thailand are distinct groups in terms of sexual behaviors, patterns of medication use, and correlates of PrEP acceptability. Efforts to maximize PrEP uptake should include expanded HIV testing services and the provision of financial subsidies to reduce the cost of PrEP. Article	2012	Zheng, Qi; Ruone, Susan; Switzer, William M; Heneine, Walid; García-Lerma, J Gerardo	Limited SHIV env diversification in macaques failing oral antiretroviral pre-exposure prophylaxis.	Retrovirology	-	-	-	1742-4690	10.1186/1742-4690-9-40	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3464968	BACKGROUND: Pre-exposure prophylaxis (PrEP) with daily Truvada a combination of emtricitabine (FTC) and tenofovir disoproxil fumarate (TDF) is a novel HIV prevention strategy recently found to prevent HIV transmission among men who have sex with men and heterosexual couples. Acute infection in adherent persons who fail PrEP will inevitably occur under concurrent antiretroviral therapy, thus raising questions regarding the potential impact of PrEP on early viral dynamics. We investigated viral evolution dynamics in a macaque model of PrEP consisting of repeated rectal exposures to SHIV162P3 in the presence of PrEP. RESULTS: Four macaques were infected during daily or intermittent PrEP with FTC or FTC/TDF, and five were untreated controls. SHIV env sequence evolution was monitored by single genome amplification with phylogenetic and sequence analysis. Mean nucleotide divergence from transmitted founder viruses calculated 17 weeks (range = 12-20) post peak viremia was significantly lower in PrEP failures than in control animals (7.2 × 10-3 compared to 1.6 × 10-2 nucleotide substitutions per site per year, respectively, p < 0.0001). Mean virus diversity was also lower in PrEP failures after 17 weeks (0.13% vs. 0.53% in controls, p < 0.0001). CONCLUSIONS: Our results in a macaque model of acute HIV infection suggest that infection during PrEP limits early virus evolution likely because of a direct antiviral effect of PrEP and/or reduced target cell availability. Reduced virus diversification during early infection might enhance immune control by slowing the selection of escape mutants. Article	2012	Zhou, Feng; Gao, Lei; Li, Shuming; Li, Dongliang; Zhang, Lifen; Fan, Wensheng; Yang, Xueying; Yu, Mingrun; Xiao, Dong; Yan, Li; Zhang, Zheng; Shi, Wei; Luo, Fengji; Ruan, Yuhua; Jin, Qi	Willingness to accept HIV pre-exposure prophylaxis among Chinese men who have sex with men.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0032329	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3316531	OBJECTIVE: We investigated the awareness and acceptability of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) and potential predicting factors. METHODS: This study was conducted among MSM in Beijing, China. Study participants, randomly selected from an MSM cohort, completed a structured questionnaire, and provided their blood samples to test for HIV infection and syphilis. Univariate logistic regression analyses were performed to evaluate the factors associated with willingness to accept (WTA) PrEP. Factors independently associated with willingness to accept were identified by entering variables into stepwise logistic regression analysis. RESULTS: A total of 152 MSM completed the survey; 11.2% had ever heard of PrEP and 67.8% were willing to accept it. Univariate analysis showed that age, years of education, consistent condom use in the past 6 months, heterosexual behavior in the past 6 months, having ever heard of PrEP and the side effects of antiretroviral drugs, and worry about antiretroviral drugs cost were significantly associated with willingness to accept PrEP. In the multivariate logistic regression model, only consistent condom use in the past 6 months (odds ratio OR: 0.31; 95% confidence interval CI: 0.13-0.70) and having ever heard of the side effects of antiretroviral drugs (OR: 0.30; 95% CI: 0.14-0.67) were independently associated with willingness to accept PrEP. CONCLUSIONS: The awareness of PrEP in the MSM population was low. Sexual behavioral characteristics and knowledge about ART drugs may have effects on willingness to accept PrEP. Comprehensive prevention strategies should be recommended in the MSM community. Article	2012	Zorrilla, CD; Rabionet, SE; Mosquera, AM; de Arellano, ABR	Biomedical HIV Prevention Strategies: State of the Art and Implications for Public Health Policy in the Caribbean	Puerto Rico Health Sciences Journal	-	-	-	0738-0658	NA	https://pubmed.ncbi.nlm.nih.gov/23038893/	Recent advances in the field of biomedical prevention have induced optimism among both the scientific community and the public in general. The discussion of the research evidence is complemented with a discussion of the implications of this evidence for the Caribbean, highlighting the issues and controversies that should be considered in order to encourage and advance the responsible consideration of biomedical strategies. Traditionally, HIV prevention strategies have been characterized as predominantly behavior, social or biomedical. In practice, however, some strategies defy classification: even when they rely on technological or pharmaceutical elements, they have to be adopted by a society and the individuals within it. Moreover, whatever the strategy used, it will have to be distributed, implemented and made available through health care systems or other means. And its cost will be absorbed by specific funders or by society in general. Given the current historical context of the HIV/AIDS epidemic and the array of strategies required to control it, these distinctions (biomedical vs. behavior) can hinder the collaborations required to provide the needed combinations of strategies. The efficacy of the diverse strategies range from: 99% for programs to prevent MTCT, 63% for pre-exposure prophylaxis (PrEP), 96% for treatment as prevention, 39% for vaginal microbicides (54% with good adherence), post exposure prophylaxis (PEP), 31% for a vaccine and 53-60% for medical voluntary adult circumcision. To curtail and eliminate the HIV/AIDS epidemic in the future, expansion and scaled-up implementation of combinations of such strategies will be needed. Theses and Dissertations	2012	Αφαντενού Σεβαστή; Afantenou Sevasti	Pre exposure HIV prophylaxis: a review	-	-	National and Kapodistrian University of Athens	-	NA	NA	https://pergamos.lib.uoa.gr/uoa/dl/object/uoadl:1315071	Εισαγωγή: Η λοίμωξη από τον ιό του HIV αποτελεί μια παγκόσμια επιδημία με κρούσματα να αναφέρονται σε όλο τον κόσμο. Η χρήση των αντιρετροϊκών φαρμάκων κατάφερε να αυξήσει το προσδόκιμο επιβίωσης και να εξασφαλίσει στους νοσούντες μια αξιοπρεπή ποιότητα ζωής. Επιπρόσθετα, κατόρθωσε, χρησιμοποιούμενη ως προφύλαξη σε άτομα που έχουν εκτεθεί στον ιό, να μειώσει το ποσοστό εκείνων που τελικά θα μολυνθούν. Η χρήση των ουσιών αυτών ως χημειοπροφυλακτικών παραγόντων, για την προ της έκθεσης μείωση του κινδύνου μετάδοσης του HIV, αποτελεί τη νέα πρόκληση που έχουν να αντιμετωπίσουν οι ερευνητές. Σκοπός της μελέτης: Η ανασκόπηση της ελληνικής και διεθνούς βιβλιογραφίας με στόχο την καταγραφή όλων των διαθέσιμων φαρμάκων που χρησιμοποιούνται σε κλινικές δοκιμές για την προ της έκθεσης στον ιό του HIV αντιρετροϊκή θεραπεία ,καθώς και η ανασκόπηση των μέχρι τώρα δεδομένων που αφορούν την ασφάλεια, την αποτελεσματικότητα και την ανάπτυξη ανθεκτικών στη θεραπεία στελεχών του ιού του HIV. Υλικό και Μέθοδος: Έγινε αναζήτηση της ελληνικής και ξένης βιβλιογραφίας στη βάση δεδομένων του pubmed, του scopus, της Cochrane library , του the Database of Abstracts of Reviews of Effects (DARE), του google και του scholar google , με λέξεις κλειδιά "hiv pre exposure prophylaxis", "hiv prevention", "hiv prophylaxis", "truvada hiv prevention", "microbicides for hiv prevention", "gel tenofovir", "dapivirine vaginal ring", "viread hiv prevention","rectal microbicides" , FEM-PrEP, CAPRISA 004, iPrEX, TDF2. Αποκλείστηκαν άρθρα τα οποία αναφέρονταν σε κλινικές δοκιμές σε ζώα, άρθρα που αφορούσαν εγκύους, άρθρα που είχαν εκδοθεί πριν από το 2007 και άρθρα που αναφέρονταν σε οικονομικές μελέτες και κοινωνικές μελέτες της HIV pre exposure prophylaxis. Στην παρούσα μελέτη συμπεριλήφθηκαν 45 άρθρα. Αποτελέσματα - Συζήτηση: Διάφορες ουσίες έχουν μελετηθεί όπως tenofovir, emtricitabine, dapivirine, maviroc κ.α σε τοπικά gel, δακτυλίους , films και ταμπλέτες και σε συστηματική χορήγηση. Από αυτά, ευρέως χρησιμοποιούμενο στις μελέτες είναι το τοπικό gel tenofovir 1%, το από του στόματος χορηγούμενο tenofovir και ο από του στόματος συνδυασμός tenofovir/emtricitabine. Το gel tenofovir παρουσίασε στη μελέτη CAPRISA 004 μια μείωση του κινδύνου μετάδοσης του HIV, σε ποσοστό 39% γενικά και σε άτομα με καλή συμμόρφωση στη χορηγούμενη θεραπεία το ποσοστό ανήλθε στο 54%. Τα αποτελέσματα αυτά δεν επιβεβαιώθηκαν από την επόμενη μελέτη VOICE, ενώ αναμένονται τα συμπεράσματα της μελέτης FACTS 001. Σε ετεροφυλόφιλους άνδρες και γυναίκες, η μελέτη TDF 2 ανέδειξε ότι η χορήγηση tenofovir/emtricitabine (TDF/FTC) μειώνει τον κίνδυνο μετάδοσης του HIV κατά 62% και η μελέτη Partners PrEP κατά 75% σε εκείνους που λάμβαναν TDF/FTC και κατά 62% σε εκείνους που είχε χορηγηθεί TDF. Σε άνδρες που κάνουν σεξ με άνδρες η μελέτη iPrEX ανέδειξε μια μείωση του κινδύνου λοίμωξης από HIV σε ένα ποσοστό 44 % στην ομάδα που λάμβανε συνδυασμό TDF/FTC. Σε όλες τις μελέτες η αποτελεσματικότητα της χορηγούμενης αγωγής παρουσίαζε άμεση…	hiv προφυλαξη, Πριν από την εκθεση προφύλαξη, χημειοπροφύλαξη , αντιρετροικηπροφύλξη	Greek	Greece	Western and Central Europe and North America	Greece	Western and Central Europe and North America	-	-	Review
Article	2013	Aaron, Erika; Cohan, Deborah	Preexposure prophylaxis for the prevention of HIV transmission to women	AIDS	-	-	-	1473-5571	10.1097/QAD.0b013e32835917b4	https://dx.doi.org/10.1097/QAD.0b013e32835917b4	The Food and Drug Administration (FDA) recently approved a new preexposure prophylaxis (PrEP) indication for emtricitabine/tenofovir for men and women, allowing a new effective HIV prevention intervention. Recent clinical trials have demonstrated the efficacy of PrEP in reducing the risk of HIV acquisition among women. Its efficacy depends largely on adherence. Perception of HIV risk appears to drive adherence to PrEP. What motivates PrEP use is specific to the population and its unique vulnerabilities. Future interventions exploring the efficacy of PrEP must include a behavioral arm that is specific to the unique vulnerabilities of the population being studied.There are an estimated 140 000 heterosexual serodiscordant couples in the United States; approximately, half of these couples desire conception. HIV-uninfected women in serodiscordant couples seeking conception may prove to be an ideal population for PrEP. Periconceptional PrEP in highly motivated couples could be not only effective but also affordable and feasible. In order to make PrEP accessible to those populations most vulnerable to HIV infection, the following steps need to occur: PrEP needs to be affordable, particularly for those uninsured; HIV providers, primary care practitioners, and reproductive healthcare providers need to welcome PrEP as a component of their scope of practice; clinicians need to take adequate sexual histories of all their patients in order to identify those at risk and best candidates for PrEP; and identifying ways to promote adherence must include population-specific PrEP adherence interventions.	discordant heterosexual couples; hiv prevention; hiv-positive women; preexpousure prophylaxis	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2013	Abbas, Ume L; Glaubius, Robert; Mubayi, Anuj; Hood, Gregory; Mellors, John W	Antiretroviral therapy and pre-exposure prophylaxis: combined impact on HIV transmission and drug resistance in South Africa.	Journal of Infectious Diseases	-	-	-	1537-6613	10.1093/infdis/jit150	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3895950	BACKGROUND: The potential impact of antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) with overlapping and nonoverlapping antiretrovirals (ARVs) on human immunodeficiency virus (HIV) transmission and drug resistance is unknown. METHODS: A detailed mathematical model was used to simulate the epidemiological impact of ART alone, PrEP alone, and combined ART + PrEP in South Africa. RESULTS: ART alone initiated at a CD4 lymphocyte cell count <200 cells/µL (80% coverage and 96% effectiveness) prevents 20% of HIV infections over 10 years but increases drug resistance prevalence to 6.6%. PrEP alone (30% coverage and 75% effectiveness) also prevents 21% of infections but with lower resistance prevalence of 0.5%. The ratio of cumulative infections prevented to prevalent drug-resistant cases after 10 years is 7-fold higher for PrEP than for ART. Combined ART + PrEP with overlapping ARVs prevents 35% of infections but increases resistance prevalence to 8.2%, whereas ART + PrEP with nonoverlapping ARVs prevents slightly more infections (37%) and reduces resistance prevalence to 7.2%. CONCLUSIONS: Combined ART + PrEP is likely to prevent more HIV infections than either strategy alone, but with higher prevalence of drug resistance. ART is predicted to contribute more to resistance than is PrEP. Optimizing both ART and PrEP effectiveness and delivery are the keys to preventing HIV transmission and drug resistance.	The potential impact of pre-exposure chemoprophylaxis (PrEP) on heterosexual transmission of HIV-1 infection in resource-limited settings is uncertain. Article	2013	Aghaizu, Adamma; Mercey, Danielle; Copas, Andrew; Johnson, Anne M; Hart, Graham; Nardone, Anthony	Who would use PrEP? Factors associated with intention to use among MSM in London: a community survey	Sexually Transmitted Infections	-	-	-	13684973	10.1136/sextrans-2012-050648	https://www.proquest.com/scholarly-journals/who-would-use-prep-factors-associated-with/docview/1781726460/se-2?accountid=8113	Objective To assess current and intended future use of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) and characterise those attending sexual health clinics, the anticipated PrEP delivery setting. Design Cross-sectional study. Methods Self-administered survey of 842 HIV negative MSM recruited from social venues in London in 2011. Results One in 10 (10.2%, 83/814, 95% CI 8.2% to 12.5%) and one in 50 (2.1%, 17/809, 95% CI 1.2% to 3.3%) reported having ever used post-exposure prophylaxis (PEP) and PrEP respectively. Half reported they would be likely to use PrEP if it became available as a daily pill (50.3%, 386/786, 95% CI 46.7% to 53.9%). MSM were more likely to consider future PrEP use if they were <35 years (adjusted OR (AOR) 1.57, 95% CI 1.16 to 2.14), had unprotected anal intercourse with casual partners (AOR 1.70, 95% CI 1.13 to 2.56), and had previously used PEP (AOR 1.94, 95% CI 1.17 to 3.24). Over half of MSM (54.8% 457/834 95% CI 51.3 to 58.2) attended a sexual health clinic the previous year. Independent factors associated with attendance were age <35 (AOR 2.29, 95% CI 1.68 to 3.13), and âper thousand¥10 anal sex partners in the last year (AOR 2.49, 95% CI 1.77 to 3.52). Conclusions The concept of PrEP for HIV prevention in the form of a daily pill is acceptable to half of sexually active MSM in London. MSM reporting higher risk behaviours attend sexual health clinics suggesting this is a suitable setting for PrEP delivery. Theses and Dissertations	2013	Akil, Ayman	VAGINAL POLYMERIC FILM CONTAINING ANTIRETROVIRAL COMBINATION FOR PREVENTION OF HIV SEXUAL TRANSMISSION	-	-	University of Pittsburgh	-	-	NA	http://d-scholarship.pitt.edu/20099/	The HIV epidemic is an ongoing global health challenge. Prevention strategies are one means to combat HIV. Part of prevention incudes behavior modifications, circumcision, vaccine product development and oral and topical pre-exposure prophylaxis (PrEP). Topical PrEP products, also referred to as topical microbicides, are designed for vaginal or rectal application for the purpose of prevention of HIV-1 sexual transmission. Products being designed are coitally or pericoitally dependent or provide sustained release of the active agent for long term protection. The potency of antiretrovirals (ARVs) in HIV therapy promoted the exploration of their use as topical microbicides. Dapivirine (DPV) and Tenofovir (TFV) are replication inhibitors which have been explored as topical microbicides most widely in clinical trials. A 1% TFV vaginal gel applied in a coitally dependent fashion was shown to reduce HIV acquisition by 39%. However, other trials have not been able to show similar successful results with use of the same TFV gel. Therefore, to improve efficacy, combinations of ARVs are being pursued as topical microbicides. The development and characterization of a polymeric vaginal film containing DPV and TFV is presented in this dissertation. Drug – drug compatibility and a solid state solubility for polymer selection process are described. Physical and chemical characterization of the film demonstrated acceptable film properties. Efficacy testing in vitro showed the film to be effective at preventing HIV infection. Finally, stability testing proved the film to be stable at different environmental conditions for 6 months. Moreover, as ARVs drug tissue level is important for their bioactivity, the impact of the co-delivery of TFV and DPV on their tissue accumulation and distribution was assessed in an excised human ecto-cervical model. Results showed that the film was able to release both agents from the film for subsequent delivery into the target tissue. Interestingly, the data showed that the combination film product resulted in achieving higher DPV tissue amounts in the stroma whereas no impact on TFV tissue accumulation was observed. Collectively, these results provide evidence of the ability of polymeric films to accommodate ARVs combinations and illustrate the impact of co-delivery on drug tissue accumulation and distribution. Article	2013	Amico, K Rivet; Mansoor, Leila E; Corneli, Amy; Torjesen, Kristine; van der Straten, Ariane	Adherence support approaches in biomedical HIV prevention trials: experiences, insights and future directions from four multisite prevention trials.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-013-0429-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3672509	Adherence is a critical component of the success of antiretroviral-based pre-exposure prophylaxis (PrEP) in averting new HIV-infections. Ensuring drug availability at the time of potential HIV exposure relies on self-directed product use. A deeper understanding of how to best support sustained PrEP adherence remains critical to current and future PrEP efforts. This paper provides a succinct synthesis of the adherence support experiences from four pivotal PrEP trials--Centre for the AIDS Programme of Research in South Africa (CAPRISA) 004, FEM-PrEP, Iniciativa Profilaxis (iPrEx), and Vaginal and Oral Interventions to Control the Epidemic (VOICE). Notwithstanding variability in the design, population/cohort, formulation, drug, dosing strategy, and operationalization of adherence approaches utilized in each trial, the theoretical basis and experiences in implementation and monitoring of the approaches used by these trials provide key lessons for optimizing adherence in future research and programmatic scale-up of PrEP. Recommendations from across these trials include participant-centered approaches, separating measurement of adherence from adherence counseling, incorporating tailored strategies that go beyond education, fostering motivation, and addressing the specific context in which an individual incorporates and negotiates PrEP use. Article	2013	Ariën, Kevin K; Venkatraj, Muthusamy; Michiels, Johan; Joossens, Jurgen; Vereecken, Katleen; Van der Veken, Pieter; Abdellati, Saïd; Cuylaerts, Vicky; Crucitti, Tania; Heyndrickx, Leo; Heeres, Jan; Augustyns, Koen; Lewi, Paul J; Vanham, Guido	Diaryltriazine non-nucleoside reverse transcriptase inhibitors are potent candidates for pre-exposure prophylaxis in the prevention of sexual HIV transmission.	Journal of Antimicrobial Chemotherapy	-	-	-	1460-2091	10.1093/jac/dkt166	https://dx.doi.org/10.1093/jac/dkt166	OBJECTIVES: Pre-exposure prophylaxis and topical microbicides are important strategies in the prevention of sexual HIV transmission, especially since partial protection has been shown in proof-of-concept studies. In search of new candidate drugs with an improved toxicity profile and with activity against common non-nucleoside reverse transcriptase inhibitor (NNRTI)-resistant HIV, we have synthesized and investigated a library of 60 new diaryltriazine analogues. METHODS: From this library, 15 compounds were evaluated in depth using a broad armamentarium of in vitro assays that are part of a preclinical testing algorithm for microbicide development. Antiviral activity was assessed in a cell line, and in primary human cells, against both subtype B and subtype C HIV-1 and against viruses resistant to therapeutic NNRTIs and the candidate NNRTI microbicide dapivirine. Toxicity towards primary blood-derived cells, cell lines originating from the female reproductive tract and female genital microflora was also studied. RESULTS AND CONCLUSIONS: We identified several compounds with highly potent antiviral activity and toxicity profiles that are superior to that of dapivirine. In particular, compound UAMC01398 is an interesting new candidate that warrants further investigation because of its superior toxicity profile and potent activity against dapivirine-resistant viruses. Article	2013	Ayala, George; Makofane, Keletso; Santos, Glenn-Milo; Beck, Jack; Do, Tri D; Hebert, Pato; Wilson, Patrick A; Pyun, Thomas; Arreola, Sonya	Access to Basic HIV-Related Services and PrEP Acceptability among Men Who Have sex with Men Worldwide: Barriers, Facilitators, and Implications for Combination Prevention.	Journal of Sexually Transmitted Diseases	-	-	-	2090-7893	10.1155/2013/953123	https://pubmed.ncbi.nlm.nih.gov/26316968/	Introduction. Men who have sex with men (MSM) are disproportionately impacted by HIV globally. Easily accessible combination HIV prevention strategies, tailored to the needs of MSM, are needed to effectively address the AIDS pandemic. Methods and Materials. We conducted a cross-sectional study among MSM (n = 3748) from 145 countries from April to August 2012. Using multivariable random effects models, we examined factors associated with acceptability of preexposure prophylaxis (PrEP) and access to condoms, lubricants, HIV testing, and HIV treatment. Results. Condoms and lubricants were accessible to 35% and 22% of all respondents, respectively. HIV testing was accessible to 35% of HIV-negative respondents. Forty-three percent of all HIV-positive respondents reported that antiretroviral therapy was easily accessible. Homophobia, outness, and service provider stigma were significantly associated with reduced access to services. Conversely, community engagement, connection to gay community, and comfort with service providers were associated with increased access. PrEP acceptability was associated with lower PrEP-related stigma, less knowledge about PrEP, less outness, higher service provider stigma, and having experienced violence for being MSM. Conclusions. Ensuring HIV service access among MSM will be critical in maximizing the potential effectiveness of combination approaches, especially given the interdependence of both basic and newer interventions like PrEP. Barriers and facilitators of HIV service access for MSM should be better understood and addressed. Article	2013	Baeten, Jared M; Grant, Robert	Use of antiretrovirals for HIV prevention: what do we know and what don't we know?	Current HIV/AIDS Reports	-	-	-	1548-3576	10.1007/s11904-013-0157-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3644362	Pre-exposure prophylaxis (PrEP), in which HIV uninfected persons with ongoing HIV risk use antiretroviral medications as chemoprophylaxis against sexual HIV acquisition, is a promising new HIV prevention strategy. Proof-of-concept that PrEP, as oral or vaginal topical tenofovir-based products, protects against sexual HIV acquisition has been demonstrated in clinical trials conducted among men who have sex with men and heterosexual men and women. The degree of HIV protection in these trials was strongly related to the level of adherence to PrEP. Many questions are yet unanswered--including how to motivate uptake of and sustain adherence to PrEP for HIV prevention, how much PrEP use is enough to achieve HIV protection, and the potential of "next-generation" PrEP agents to improve on this effective technology.	antiretroviral medications, chemoprophylaxis, global epidemic, HIV/AIDS, HIV prevention, pre-exposure prophylaxis (PrEP), sexual HIV transmission	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2013	Baeten, Jared; Celum, Connie	Systemic and topical drugs for the prevention of HIV infection: antiretroviral pre-exposure prophylaxis.	Annual Review of Medicine	-	-	-	1545-326X	10.1146/annurev-med-050911-163701	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3730272	Pre-exposure prophylaxis (PrEP), in which HIV-uninfected persons use oral or topical antiretroviral medications to protect against HIV acquisition, is a promising new HIV prevention strategy. The biologic rationale for evaluation of PrEP for sexual HIV prevention included nonhuman primate models and the efficacy of antiretroviral prophylaxis for HIV-exposed infants. Proof-of-concept that PrEP protects against sexual HIV acquisition has been demonstrated in four clinical trials, which used the antiretroviral medication tenofovir, either as a vaginal gel or as daily oral tenofovir disoproxil fumarate, alone or coformulated with emtricitabine. Importantly, however, two trials failed to demonstrate HIV protection with PrEP; low adherence to daily use of PrEP is the leading hypothesis to account for the lack of efficacy. Next steps in the field include rigorous evaluation of uptake and adherence to PrEP in implementation settings and research into next-generation PrEP agents with longer half-life and less user dependence. Article	2013	Bailey, Theodore C; Sugarman, Jeremy	Social justice and HIV vaccine research in the age of pre-exposure prophylaxis and treatment as prevention.	Current HIV Research	-	-	-	1873-4251	10.2174/1570162x113116660054	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4084567	The advent of pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP) as means of HIV prevention raises issues of justice concerning how most fairly and equitably to apportion resources in support of the burgeoning variety of established HIV treatment and prevention measures and further HIV research, including HIV vaccine research. We apply contemporary approaches to social justice to assess the ethical justification for allocating resources in support of HIV vaccine research given competing priorities to support broad implementation of HIV treatment and prevention measures, including TasP and PrEP. We argue that there is prima facie reason to believe that a safe and effective preventive HIV vaccine would offer a distinct set of ethically significant benefits not provided by current HIV treatment or prevention methods. It is thereby possible to justify continued support for HIV vaccine research despite tension with priorities for treatment, prevention, and other research. We then consider a counter-argument to such a justification based on the uncertainty of successfully developing a safe and effective preventive HIV vaccine. Finally, we discuss how HIV vaccine research might now be ethically designed and conducted given the new preventive options of TasP and PrEP, focusing on the ethically appropriate standard of prevention for HIV vaccine trials. Article	2013	Baral, Stefan; Scheibe, Andrew; Sullivan, Patrick; Trapence, Gift; Lambert, Andrew; Bekker, Linda-Gail; Beyrer, Chris	Assessing priorities for combination HIV prevention research for men who have sex with men (MSM) in Africa.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-012-0202-5	https://dx.doi.org/10.1007/s10461-012-0202-5	A consultation was hosted in South Africa (March 2011) to assess the combination HIV prevention research priorities of academics, implementers and MSM community leaders. Sixty-nine participants, representing 17 African countries, participated. Interactive strategies were used to present current data on HIV interventions and discussions on research possibilities were facilitated with research priorities identified using the nominal group technique. Data were analysed using directed content analysis. Health worker training, social mobilisation, and community engagement were prioritised as structural interventions. Comprehensive counselling was identified as the most important behavioural intervention, with adherence, mental health, and risk reduction counselling identified as key counselling topics. Rectal microbicides, oral pre-exposure prophylaxis and condom and lubricant distribution were the most important biomedical interventions. This consultation resulted in the first combination HIV prevention research agenda for MSM in Africa. Outcomes will inform future research and be used to advocate for combination approaches to HIV prevention for MSM. Article	2013	Bauermeister, Jose A; Meanley, Steven; Pingel, Emily; Soler, Jorge H; Harper, Gary W	PrEP awareness and perceived barriers among single young men who have sex with men.	Current HIV Research	-	-	-	1873-4251	10.2174/1570162x12666140129100411	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4152728	Pre-exposure prophylaxis (PrEP) has the potential to help reduce new HIV infections among young men who have sex with men (YMSM). Using a cross-sectional survey of YMSM (N=1,507; ages 18-24), we gauged YMSM's PrEP awareness and PrEP-related beliefs regarding side effects, accessibility, and affordability. Overall, 27% of the sample had heard about PrEP; 1% reported ever using PrEP prior to sex. In a multivariate logistic regression, we found that YMSM were more likely to have heard about PrEP if they were older, more educated, were residentially unstable in the prior 30 days, had insurance, or reported having at least one sexually transmitted infection in their lifetime. We found no differences by race/ethnicity, history of incarceration, or recent sexual risk behavior. In multivariate linear regression models, Black and Latino YMSM were more likely than Whites to state they would not use PrEP because of side effect concerns. YMSM were more likely to indicate that they would not be able to afford PrEP if they did not have insurance or if they had a prior sexually transmitted infection, PrEP rollout may be hindered due to lack of awareness, as well as perceived barriers regarding its use. We propose strategies to maximize equity in PrEP awareness and access if it is to be scaled up among YMSM.	quality assurance, mystery shopping, testing resources, systems, community	English	Netherlands	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2013	Biswas, Nabanita; Rodriguez-Garcia, Marta; Crist, Sarah G.; Shen, Zheng; Bodwell, Jack E.; Fahey, John V.; Wira, Charles R.	Effect of tenofovir on nucleotidases and cytokines in HIV-1 target cells.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0078814	https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0078814	Tenofovir (TFV) has been widely used for pre-exposure prophylaxis of HIV-1 infection with mixed results. While the use of TFV in uninfected individuals for prevention of HIV-1 acquisition is actively being investigated, the possible consequences of TFV exposure for the HIV-target cells and the mucosal microenvironment are unknown. In the current study, we evaluated the effects of TFV treatment on blood-derived $CD4^+$ T cells, monocyte-derived macrophages and dendritic cells (DC). Purified HIV-target cells were treated with different concentrations of TFV (0.001-1.0 mg/ml) for 2 to 24 hr. RNA was isolated and RT-PCR was performed to compare the levels of mRNA expression of nucleotidases and pro-inflammatory cytokine genes (MIP3α, IL-8 and TNFα) in the presence or absence of TFV. We found that TFV increases 5'-ecto-nucleotidase (NT5E) and inhibits mitochondrial nucleotidase (NT5M) gene expression and increases 5' nucleotidase activity in macrophages. We also observed that TFV stimulates the expression and secretion of IL-8 by macrophages, DC, and activated $CD4^+$ T cells and increases the expression and secretion of MIP3α by macrophages. In contrast, TFV had no effect on TNFα secretion from macrophages, DC and $CD4^+$ T cells. Our results demonstrate that TFV alters innate immune responses in HIV-target cells with potential implications for increased inflammation at mucosal surfaces. As new preventive trials are designed, these findings should provide a foundation for understanding the effects of TFV on HIV-target cells in microbicide trials. Article	2013	Blumenthal, Jill; Haubrich, Richard	Pre-exposure prophylaxis for HIV infection: how antiretroviral pharmacology helps to monitor and improve adherence.	Expert Opinion on Pharmacotherapy	-	-	-	1744-7666	10.1517/14656566.2013.812072	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3954121	INTRODUCTION: Pre-exposure prophylaxis (PrEP) with antiretroviral drugs is a novel biomedical intervention that can prevent HIV transmission among high-risk populations. As findings from multiple PrEP studies have suggested that adherence is vital to achieve the full prevention benefits of PrEP, it is important to understand the clinical pharmacology and pharmacokinetic (PK) properties of PrEP antiretrovirals, the association of PK and PrEP efficacy, and the potential for drug concentration measurement to be used as a tool to monitor PrEP adherence. AREAS COVERED: This review examines studies related to PrEP adherence with attention to the clinical pharmacology and PK of current and novel PrEP agents. Studies of animal models, PK, and clinical trials related to PrEP and adherence were reviewed. EXPERT OPINION: In summary, when combined as part of a comprehensive prevention strategy that includes use of condoms and risk-reduction counseling, PrEP has tremendous promise as an adjunctive biomedical HIV prevention intervention, providing that adherence is maintained. Article	2013	Boot, Jenneke; Rump, Babette O.; Boucher, Charles A. B.; Op de Coul, Eline L. M.; van Agtmael, Michiel A.; van de Vijver, David A. M. C.; Burger, David M.; Fanoy, Ewout B.	Pre-exposure prophylaxis for the prevention of sexual HIV transmission; new preventative strategy using tenofovir/emtricitabine.	Nederlands Tijdschrift voor Geneeskunde	-	-	-	1876-8784 0028-2162	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-23838402	The Netherlands has approximately 20,000 registered HIV-infected patients. The current HIV prevention policy consisting of condom use and active HIV testing does not effectively mitigate the HIV epidemic in all risk groups. In July of 2012, tenofovir/emtricitabine (TDF/FTC) was approved by the American Food and Drug Administration (FDA) for pre-exposure prophylaxis (PrEP) for long-term use in persons who exhibit frequent risky and unsafe sexual behaviour. With once-daily use and good therapy compliance, TDF/FTC has proved to be effective as PrEP, and few side effects are reported. Drawbacks in the use of TDF/FTC as PrEP are the potential risk of viral resistance and reduced condom use, the relatively high cost and the intensive counselling required. In special cases, long-term PrEP could enhance the current Dutch preventive policy. Further research is needed into the practical feasibility and protective efficacy of the ad hoc use of TDF/FTC as PrEP before a high-risk contact occurs. Theses and Dissertations	2013	Bórquez, Annick	Exploring the HIV epidemic among key populations in Latin America	-	-	Imperial College London/Ethos UK	-	-	NA	https://spiral.imperial.ac.uk/handle/10044/1/11051	The work is focussed on the HIV epidemic among key populations in Latin America, a region that has received limited international attention due to the concentrated nature of its epidemic. It faces important challenges in prevention and risks missing the opportunity to control the epidemic. Despite the evidence available showing the disproportionate burden of infection among key populations, principally men who have sex with men (MSM) and to a lesser extent injecting drug users (IDU) and female sex workers (FSW), a small percentage of countries' HIV prevention spending is allocated towards prevention interventions among these groups. In this thesis, we first estimate the distribution of new infections by type of exposure in the Dominican Republic, Mexico and Peru and find that MSM account for a large share of new infections in the three countries (over 50% in Mexico and Peru and 30% in Dominican Republic). This highlights that this population should be prioritised in prevention programmes. We then turn to interventions for MSM, and investigate whether pre-exposure prophylaxis (PrEP) to prevent HIV acquisition among MSM in Lima, Peru represents a cost-effective intervention at the population level. We find PrEP to be a potentially cost-effective intervention although unaffordable at a large scale. We conclude it should be considered as an additional tool within a combination prevention approach among this population. Following these, we seek to understand the dynamics, causes and consequences of risk behaviours and HIV infection in another key population that has rarely been prioritised by public health programmes: prison inmates. We use data from the largest prison in Peru and find that HIV prevalence is 4 times higher than national prevalence and inmates engage in riskier sexual behaviours than in the general population. Nevertheless, there are indications of risk behaviours and HIV prevalence reducing in recent years. To help direct prevention efforts in this setting, we characterise the risk profile of inmates who engaged in sex with FSW, other men and in unprotected sex with casual partners and identify inmates who have sex with men as being at heightened risk of infection (due to higher levels of drug use and unprotected sex). We use those data to develop a mathematical model that represents the HIV epidemic in the prison. Contrary to expectations, we find that incidence is likely to be less than 1% per year within the prison and that the dynamics of HIV in prisons are principally driven by inmates infected before their incarceration. We further estimate that since the beginning of the epidemic, at least 5% of HIV cases identified in Lima have passed through the prison, suggesting that the routine screening system in place at prisons could make a substantial contribution to controlling the HIV epidemic across the city. Finally, we formulate a conceptual framework of HIV risk among prison inmates in Latin America focussing on the social and underlying determinants of risk and develop a structured questionnaire to test the hypotheses proposed through the framework and obtain information relevant to the design of interventions within prisons and at the community level. Together this work draws on social and quantitative science to provide new insights into key populations in Latin America that should contribute to stronger and responsive HIV prevention programmes, to the benefit of all those that remain at risk of HIV in the region. Article	2013	Campbell, James D; Herbst, Jeffrey H; Koppenhaver, Robert T; Smith, Dawn K	Antiretroviral prophylaxis for sexual and injection drug use acquisition of HIV.	American Journal of Preventive Medicine	-	-	-	1873-2607	10.1016/j.amepre.2012.09.045	https://dx.doi.org/10.1016/j.amepre.2012.09.045	During the past few years, much has been learned about pre-exposure prophylaxis (PrEP) of HIV from studies conducted in the U.S. and elsewhere. A review and summary was conducted of articles and reports published through August 2012 on the safety and efficacy of PrEP in humans; U.S.-based studies assessing PrEP knowledge, attitudes, and use among at-risk populations and healthcare providers; and models of the cost effectiveness of PrEP. PrEP is generally safe and effective and may be cost effective in a targeted population. Awareness and interest in PrEP are increasing. PrEP is an important new addition to HIV prevention services, but continued study is warranted. Theses and Dissertations	2013	Canhões, Raquel Salazar Albuquerque Rodrigues; Taveira, Nuno	Profilaxia de pré-exposição da infeção por HIV	-	-	INSTITUTO SUPERIOR DE CIÊNCIAS DA SAÚDE EGAS MONIZ	-	NA	NA	http://hdl.handle.net/10400.26/14170	A redução consistente do número de infeções pelo Vírus da Imunodeficiência Humana (HIV) requer a implementação de novas estratégias preventivas. A profilaxia de pré-exposição (PrEP) da infeção por HIV consiste em intervenções que previnem a infeção num indivíduo antes de uma exposição de elevado risco. Entre as intervenções mais estudadas estão a circuncisão masculina, a administração oral preventiva de antirretrovirais e a utilização de microbicidas.De uma forma geral, as diferentes modalidades de PrEP são eficazes, reduzindo o risco de infeção e proporcionando benefícios clínicos. Os resultados menos favoráveis dos microbicidas e da toma preventiva de antirretrovirais explicam-se pela baixa adesão, pelo que, desta forma, a implementação de estratégias que promovam uma maior adesão é crucial para o sucesso da PrEP.A profilaxia antes da exposição a um comportamento de risco é uma estratégia promissora na prevenção da infeção por HIV e consequente combate da epidemia por este retrovirus.Resumo alternativo:Consistent reduction in the number of infections by human immunodeficiency virus (HIV) requires the implementation of new preventive strategies. The HIV infection pre-exposure prophylaxis (PrEP) consists of interventions that prevent infection in an individual before a high risk exposure. Among these interventions, the better studied are male circumcision, oral administration of antiretroviral drugs and preventive use of microbicides.In general, the different methods of PrEP are effective, reducing the risk of infection and providing clinical benefits. The less favorable results of microbicides and administration of preventive antiretroviral drugs are explained by poor adherence, which makes the implementation of strategies to promote greater adherence crucial to the success of PrEP.Prophylaxis before exposure to a high risk behavior is a promising strategy in the prevention of HIV infection and against HIV incidence. Article	2013	Chaowanachan, Thanyanan; Krogstad, Emily; Ball, Cameron; Woodrow, Kim A.	Drug synergy of tenofovir and nanoparticle-based antiretrovirals for HIV prophylaxis.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0061416	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3632578/	BACKGROUND: The use of drug combinations has revolutionized the treatment of HIV but there is no equivalent combination product that exists for prevention, particularly for topical HIV prevention. Strategies to combine chemically incompatible agents may facilitate the discovery of unique drug-drug activities, particularly unexplored combination drug synergy. We fabricated two types of nanoparticles, each loaded with a single antiretroviral (ARV) that acts on a specific step of the viral replication cycle. Here we show unique combination drug activities mediated by our polymeric delivery systems when combined with free tenofovir (TFV). METHODOLOGY/PRINCIPAL FINDINGS: Biodegradable poly(lactide-co-glycolide) nanoparticles loaded with efavirenz (NP-EFV) or saquinavir (NP-SQV) were individually prepared by emulsion or nanoprecipitation techniques. Nanoparticles had reproducible size (d ~200 nm) and zeta potential (-25 mV). The drug loading of the nanoparticles was approximately 7% (w/w). NP-EFV and NP-SQV were nontoxic to TZM-bl cells and ectocervical explants. Both NP-EFV and NP-SQV exhibited potent protection against HIV-1 BaL infection in vitro. The HIV inhibitory effect of nanoparticle formulated ARVs showed up to a 50-fold reduction in the 50% inhibitory concentration (IC50) compared to free drug. To quantify the activity arising from delivery of drug combinations, we calculated combination indices (CI) according to the median-effect principle. NP-EFV combined with free TFV demonstrated strong synergistic effects (CI50=0.07) at a 1:50 ratio of IC50 values and additive effects (CI50=1.05) at a 1:1 ratio of IC50 values. TFV combined with NP-SQV at a 1:1 ratio of IC50 values also showed strong synergy (CI50=0.07). CONCLUSIONS: ARVs with different physicochemical properties can be encapsulated individually into nanoparticles to potently inhibit HIV. Our findings demonstrate for the first time that combining TFV with either NP-EFV or NP-SQV results in pronounced combination drug effects, and emphasize the potential of nanoparticles for the realization of unique drug-drug activities. Article	2013	Chateau, Morgan; Swanson, Michael D; Garcia, J Victor	Inefficient vaginal transmission of tenofovir-resistant HIV-1.	Journal of Virology	-	-	-	1098-5514	10.1128/JVI.01777-12	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3554084	Transmission of drug-resistant HIV has been postulated to be a threat to current first-line antiretroviral therapy (ART) regimens and the efficacy of several antiretroviral-based preexposure prophylaxis (PrEP) strategies being tested. Here we evaluated the effect of the common tenofovir (TFV) resistance mutation K65R on vaginal HIV transmission. Our results demonstrate that despite no overt loss of overall replication competence in vivo, this mutation results in significantly reduced mucosal transmission. When transmitted, the mutant virus eventually reverted to the wild type in 2 of 3 animals examined.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Article	2013	Chen, Yea-Hung; Raymond, H. Fisher; Grasso, Michael; Nguyen, Binh; Robertson, Tyler; McFarland, Willi	Prevalence and predictors of conscious risk behavior among San Franciscan men who have sex with men.	AIDS and Behavior	-	-	-	1573-3254 1090-7165	10.1007/s10461-012-0169-2	https://pubmed.ncbi.nlm.nih.gov/22392158/	We estimated the prevalence of conscious risk, specifically defined as unprotected anal intercourse with an HIV-serodiscordant partner, and identified individual-level and partnership-level predictors of this behavior. Conscious risk was estimated to be practiced by 4.8% of HIV-negative MSM and 15.7% of HIV-positive MSM over a six-month period (p < 0.01). Among HIV-negative MSM, episodes of conscious risk were estimated to be more frequent among individuals between the ages of 18 and 24 (compared to those 55 years of age or older), among African Americans and Whites (compared to Latinos and Asians), individuals earning less than 10,000 dollars per year (compared to those earning 50,000 and 70,000 dollars per year), and among users of methamphetamine, downers, pain killers, and amyl nitrate (poppers). Among HIV-positive MSM, episodes of conscious risk were more frequent among Whites and Asians (compared to those of "other" races, i.e., those of mixed race, or those who did not exclusively self-report as White, Black, Latino, or Asian), those with full-time employment (as opposed to those with part-time employment), those earning between 30,000 and 50,000 dollars per year or 70,000 dollars per year or greater (compared to those earning under 10,000 dollars per year), and recent users of poppers. Conscious risk was more frequently reported in partnerships with large age gaps and in main partnerships (as opposed to casual or exchange partnerships). Individuals at high risk for conscious risk may be ideal candidates for pre-exposure prophylaxis (PrEP). Theses and Dissertations	2013	Chilukwa, Mwimba Martin	An ethical assessment of the adoption of pre-exposure prophylaxis as a potential HIV prevention method in Zambia	-	-	University of Zimbabwe	-	na	NA	https://dspace.unza.zm/items/25875144-4887-4639-b98e-3233f19ed3e7	The aim of this dissertation is to evaluate, from an ethical point of view, whether Pre-exposure Prophylaxis a method used to prevent HIV infection by administering anti-retroviral drugs to HIV negative people should be implemented in Zambia. The current HIV prevention methods include condoms and Post-exposure Prophylaxis. The specific objectives of the study are to explain methods aimed at preventing HIV infections, to investigate the current situation in Zambia on Pre-exposure Prophylaxis, and to assess, from an ethical point of view, whether Pre-exposure Prophylaxis should be adopted in Zambia. Clinical trials have shown that the drug Truvada given to HIV negative people can reduce HIV infection by 73 percent. The study used empirical and ethical methods. The empirical methods, face to face interviews were conducted with a purposive sample of health workers and NGO representatives using a semi-structured interview schedule. The ethical method consisted in an application of the Precautionary Principle and Utilitarianism. The main empirical findings of this study are that a majority of 80 percent of the respondents have already heard of Pre-exposure Prophylaxis. The benefits of Pre-exposure Prophylaxis include reduction in the risk of HIV transmission. A majority of 85 percent mentioned kidney failure and 31 percent liver toxicity as side effects. The study has shown that 50 percent cited high cost of implementation as a concern. The study also shows that 60 percent preferred early adoption of Pre-exposure Prophylaxis. On the other hand 31 percent cited resistance, monitoring and high cost as the general harms. Compared to other options, most participants preferred Pre-exposure Prophylaxis for high risk groups with more emphasis on monitoring and adherence services so as to reduce new HIV infections. The result of the ethical evaluation is that according to both, the Precautionary Principle and Utilitarianism, implementing Pre-exposure Prophylaxis for high risk groups is morally better than the current policy of not adopting Pre-exposure Prophylaxis. This study shows therefore that implementing Pre-exposure Prophylaxis for high risk groups is ethically preferable to the current Zambian policy of not adopting Pre-exposure Prophylaxis. Article	2013	Choopanya, Kachit; Martin, Michael; Suntharasamai, Pravan; Sangkum, Udomsak; Mock, Philip A; Leethochawalit, Manoj; Chiamwongpaet, Sithisat; Kitisin, Praphan; Natrujirote, Pitinan; Kittimunkong, Somyot; Chuachoowong, Rutt; Gvetadze, Roman J; McNicholl, Janet M; Paxton, Lynn A; Curlin, Marcel E; Hendrix, Craig W; Vanichseni, Suphak	Antiretroviral prophylaxis for HIV infection in injecting drug users in Bangkok, Thailand (the Bangkok Tenofovir Study): a randomised, double-blind, placebo-controlled phase 3 trial.	The Lancet	-	-	-	1474-547X	10.1016/S0140-6736(13)61127-7	https://dx.doi.org/10.1016/S0140-6736(13)61127-7	BACKGROUND: Antiretroviral pre-exposure prophylaxis reduces sexual transmission of HIV. We assessed whether daily oral use of tenofovir disoproxil fumarate (tenofovir), an antiretroviral, can reduce HIV transmission in injecting drug users. METHODS: In this randomised, double-blind, placebo-controlled trial, we enrolled volunteers from 17 drug-treatment clinics in Bangkok, Thailand. Participants were eligible if they were aged 20-60 years, were HIV-negative, and reported injecting drugs during the previous year. We randomly assigned participants (1:1; blocks of four) to either tenofovir or placebo using a computer-generated randomisation sequence. Participants chose either daily directly observed treatment or monthly visits and could switch at monthly visits. Participants received monthly HIV testing and individualised risk-reduction and adherence counselling, blood safety assessments every 3 months, and were offered condoms and methadone treatment. The primary efficacy endpoint was HIV infection, analysed by modified intention-to-treat analysis. This trial is registered with ClinicalTrials.gov, number NCT00119106. FINDINGS: Between June 9, 2005, and July 22, 2010, we enrolled 2413 participants, assigning 1204 to tenofovir and 1209 to placebo. Two participants had HIV at enrolment and 50 became infected during follow-up: 17 in the tenofovir group (an incidence of 0·35 per 100 person-years) and 33 in the placebo group (0·68 per 100 person-years), indicating a 48·9% reduction in HIV incidence (95% CI 9·6-72·2; p=0·01). The occurrence of serious adverse events was much the same between the two groups (p=0·35). Nausea was more common in participants in the tenofovir group than in the placebo group (p=0·002). INTERPRETATION: In this study, daily oral tenofovir reduced the risk of HIV infection in people who inject drugs. Pre-exposure prophylaxis with tenofovir can now be considered for use as part of an HIV prevention package for people who inject drugs. Article	2013	Cong, Mian-er; Mitchell, James; Sweeney, Elizabeth; Bachman, Shanon; Hanson, Debra L; Heneine, Walid; García-Lerma, J Gerardo	Prophylactic efficacy of oral emtricitabine and tenofovir disoproxil fumarate combination therapy against a tenofovir-resistant simian/human immunodeficiency virus containing the K65R mutation in macaques.	Journal of Infectious Diseases	-	-	-	1537-6613	10.1093/infdis/jit189	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3699008	Daily preexposure prophylaxis (PrEP) with emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) is a novel strategy for preventing human immunodeficiency virus infection. We investigated in macaques whether FTC/TDF prevents transmission of a tenofovir-resistant simian/human immunodeficiency virus (SHIV) containing the K65R mutation. Six macaques received weekly a dose of FTC/TDF 3 days before rectal SHIV exposures and a second dose 2 hours after. Six untreated animals were controls. Animals were exposed rectally to escalating virus doses weekly for up to 28 weeks. PrEP significantly delayed infection with SHIVK65R (P = .028), although 4 of 6 FTC/TDF-treated macaques were infected at the end of the challenges. These findings highlight the need to closely monitor PrEP efficacy in areas with prevalent K65R.	Preexposure prophylaxis; HIV-1 drug resistance; tenofovir disoproxil fumarate; emtricitabine. Article	2013	Conway, JM; Konrad, BP; Coombs, D	STOCHASTIC ANALYSIS OF PRE- AND POSTEXPOSURE PROPHYLAXIS AGAINST HIV INFECTION	SIAM Journal on Applied Mathematics	-	-	-	0036-1399	10.1137/120876800	https://www.jstor.org/stable/23479955	The events that occur following HIV exposure, preceding any detectable infection, are difficult to study experimentally. However, there is considerable evidence that these events can be influenced by the action of antiretroviral drugs, taken either as pre-or postexposure prophylaxis (PrEP and PEP, respectively). We present simple theoretical models of HIV dynamics immediately following exposure, and apply these models to understanding how drug prophylaxis can act to reduce the risk of infection. Because HIV infection following exposure is a relatively rare event, we work with stochastic models which we base on continuous-time branching processes, allowing us to compute the risk of infection under different scenarios. We obtain analytical solutions for viral extinction probabilities, allowing us to avoid extensive computer simulations. We predict in the case of PrEP that reverse transcriptase inhibitors should be somewhat more effective than protease inhibitors and also that single drugs should be nearly as effective as a combination approach. We then model viral dynamics under PEP and find that fast initiation of therapy is essential for risk reduction. However, we predict that a two-week PEP regimen would be nearly as effective as the current recommendation of four weeks of therapy. Our work provides a coherent platform for studying the early dynamics of HIV and indicates possible directions for experimental and theoretical work. Article	2013	Cotter, Aoife G; Vrouenraets, Saskia M E; Brady, Jennifer J; Wit, Ferdinand W; Fux, Christoph A; Furrer, Hansjakob; Brinkman, Kees; Sabin, Caroline A; Reiss, Peter; Mallon, Patrick W G	Impact of switching from zidovudine to tenofovir disoproxil fumarate on bone mineral density and markers of bone metabolism in virologically suppressed HIV-1 infected patients; a substudy of the PREPARE study.	Journal of Clinical Endocrinology and Metabolism	-	-	-	1945-7197	10.1210/jc.2012-3686	https://dx.doi.org/10.1210/jc.2012-3686	CONTEXT: In virologically suppressed, antiretroviral-treated patients, the effect of switching to tenofovir (TDF) on bone biomarkers compared to patients remaining on stable antiretroviral therapy is unknown. METHODS: We examined bone biomarkers (osteocalcin OC, procollagen type 1 amino-terminal propeptide, and C-terminal cross-linking telopeptide of type 1 collagen) and bone mineral density (BMD) over 48 weeks in virologically suppressed patients (HIV RNA < 50 copies/ml) randomized to switch to TDF/emtricitabine (FTC) or remain on first-line zidovudine (AZT)/lamivudine (3TC). PTH was also measured. Between-group differences in bone biomarkers and associations between change in bone biomarkers and BMD measures were assessed by Student's t tests, Pearson correlation, and multivariable linear regression, respectively. All data are expressed as mean (SD), unless otherwise specified. RESULTS: Of 53 subjects (aged 46.0 y; 84.9% male; 75.5% Caucasian), 29 switched to TDF/FTC. There were reductions in total hip and lumbar spine BMD in those switching to TDF/FTC (total hip, TDF/FTC, -1.73 (2.76)% vs AZT/3TC, -0.39 (2.41)%; between-group P = .07; lumbar spine, TDF/FTC, -1.50 (3.49)% vs AZT/3TC, +0.25 (2.82)%; between-group P = .06), but they did not reach statistical significance. Greater declines in lumbar spine BMD correlated with greater increases in OC (r = -0.28; P = .05). The effect of TDF/FTC on bone biomarkers remained significant when adjusted for baseline biomarker levels, gender, and ethnicity. There was no difference in change in PTH levels over 48 weeks between treatment groups (between-group P = .23). All biomarkers increased significantly from weeks 0 to 48 in the switch group, with no significant change in those remaining on AZT/3TC (between-group, all biomarkers, P < .0001). CONCLUSION: A switch to TDF/FTC compared to remaining on a stable regimen is associated with increases in bone turnover that correlate with reductions in BMD, suggesting that TDF exposure directly affects bone metabolism in vivo. Article	2013	Craig, Sineath R; Finneran, Catherine; Sullivan, Patrick; Sanchez, Travis; Smith, Dawn K; Griensven Frits van; Wimonsate Wipas; Stephenson, Rob	Knowledge of and Interest in Using Preexposure Prophylaxis for HIV Prevention among Men Who Have Sex with Men in Thailand	Journal of the International Association of Physicians in AIDS Care	-	-	-	23259574	10.1177/2325957413488184	https://www.proquest.com/scholarly-journals/knowledge-interest-using-preexposure-prophylaxis/docview/2343473374/se-2?accountid=8113	Little is known about HIV preexposure prophylaxis (PrEP) acceptability among men who have sex with men (MSM) in Thailand. The authors recruited an online convenience sample of Thai MSM (n = 404) to assess the knowledge of and interest in PrEP. Less than 7% had heard of PrEP; however, 35% indicated interest in PrEP after an explanation of its possible efficacy. Regression modeling demonstrated that HIV knowledge and risk behavior, but not demographics, are significant predictors of PrEP interest. More information and education about PrEP is necessary and more research is needed to examine PrEP acceptability and to inform the message for PrEP uptake. Article	2013	Cremin, Ide; Alsallaq, Ramzi; Dybul, Mark; Piot, Peter; Garnett, Geoffrey; Hallett, Timothy B.	The new role of antiretrovirals in combination HIV prevention: a mathematical modelling analysis.	AIDS	-	-	-	1473-5571 0269-9370	10.1097/QAD.0b013e32835ca2dd	https://pubmed.ncbi.nlm.nih.gov/23296196/	BACKGROUND AND OBJECTIVES: Antiretroviral drugs can reduce HIV acquisition among uninfected individuals (as pre-exposure prophylaxis: PrEP) and reduce onward transmission among infected individuals (as antiretroviral treatment: ART). We estimate the potential impact and cost-effectiveness of antiretroviral-based HIV prevention strategies. DESIGN AND METHODS: We developed and analysed a mathematical model of a hyperendemic setting with relatively low levels of condom use. We estimated the prevention impact and cost of various PrEP interventions, assuming a fixed amount of spending on PrEP; investigated the optimal role of PrEP and earlier ART in terms of epidemiological impact and cost; and systematically explored the impact of earlier ART and PrEP, in combination with medical male circumcision services; on HIV transmission. RESULTS: A PrEP intervention is unlikely to generate a large reduction in HIV incidence, unless the cost is substantially reduced. In terms of infections averted and quality adjusted life years gained, at a population-level maximal cost-effectiveness is achieved by providing ART to more infected individuals earlier rather than providing PrEP to uninfected individuals. However, early ART alone cannot reduce HIV incidence to very low levels and PrEP can be used cost-effectively in addition to earlier ART to reduce incidence further. If implemented in combination and at ambitious coverage levels, medical male circumcision, earlier ART and PrEP could produce dramatic declines in HIV incidence, but not stop transmission completely. CONCLUSION: A combination prevention approach based on proven-efficacy interventions provides the best opportunity for achieving the much hoped for prevention advance and curbing the spread of HIV. Article	2013	Culp, Lindsay; Caucci, Lisa	State adolescent consent laws and implications for HIV pre-exposure prophylaxis.	American Journal of Preventive Medicine	-	-	-	1873-2607	10.1016/j.amepre.2012.09.044	https://dx.doi.org/10.1016/j.amepre.2012.09.044	BACKGROUND: Recent large clinical trials have found that pre-exposure prophylaxis (PrEP) reduced HIV infection among men who have sex with men (MSM), but efforts to provide clinical care to minors, including young MSM, may be complicated by a lack of clarity regarding parental consent requirements with respect to medical services. PURPOSE: The goal of this paper was to analyze law related to a minor's ability to consent to medical care, including HIV diagnostic testing and treatment, and its implications for PrEP. METHODS: Analysis was performed in 2012 on laws current as of December 31, 2011. Public Health Law Program staff collected all statutes and regulations pertaining to an adolescent's ability to consent to HIV diagnostic testing and treatment and sexually transmitted infection (STI) diagnostic testing, treatment, and prevention. RESULTS: No state expressly prohibits minors' access to PrEP or other HIV prevention methods. All jurisdictions expressly allow some minors to consent to medical care for the diagnosis or treatment of STIs, but only eight jurisdictions allow consent to preventive or prophylactic services. Thirty-four states either expressly allow minors to consent to HIV services or allow consent to STI or communicable disease services and classify HIV as an STI or communicable disease. Seventeen jurisdictions allow minors to consent to STI testing and treatment, but they do not have an express HIV provision nor classify HIV as an STI or communicable disease. CONCLUSIONS: Minors' access to PrEP without parental consent is unclear, and further analysis is needed to evaluate how state law may relate to the provision of clinical interventions for the prevention of HIV infection.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2013	Curran, K; Mugo, NR; Kurth, A; Ngure, K; Heffron, R; Donnell, D; Celum, C; Baeten, JM	Daily short message service surveys to measure sexual behavior and pre-exposure prophylaxis use among Kenyan men and women	AIDS and Behavior	-	-	-	na	10.1007/s10461-013-0510-4	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01015593/full	Pre-exposure prophylaxis (PrEP) is a novel HIV prevention strategy which requires high adherence. We tested the use of daily short message service (i.e., SMS/text message) surveys to measure sexual behavior and PrEP adherence in Kenya. Ninety-six HIV-uninfected adult individuals, taking daily oral PrEP in a clinical trial, received daily SMS surveys for 60 days. Most participants (96.9 %) reported taking PrEP on ≥80 % days, but 69.8 % missed at least one dose. Unprotected sex was reported on 4.9 % of days; however, 47.9 % of participants reported unprotected sex at least once. Unprotected sex was not correlated with PrEP use (OR = 0.95). Participants reporting more sex were less likely to report PrEP non-adherence and those reporting no sex were more likely to report missing a PrEP dose (adjusted OR = 1.87). PrEP adherence was high, missed doses were correlated with sexual abstinence, and unprotected sex was not associated with decreased PrEP adherence. Article	2013	Dai, James Y; Gilbert, Peter B; Hughes, James P; Brown, Elizabeth R	Estimating the Efficacy of Preexposure Prophylaxis for HIV Prevention Among Participants With a Threshold Level of Drug Concentration	American Journal of Epidemiology	-	-	-	00029262	10.1093/aje/kws324	https://www.proquest.com/scholarly-journals/estimating-efficacy-preexposure-prophylaxis-hiv/docview/1291186997/se-2?accountid=8113	Assays for detecting levels of antiretroviral drugs in study participants are increasingly popular in preexposure prophylaxis (PrEP) trials, since they provide an objective measure of adherence. Current correlation analyses of drug concentration data are prone to bias. In this article, we formulate the causal estimand of prevention efficacy among drug compliers, those who would have had a threshold level of drug concentration had they been assigned to the drug arm of the trial. The identifiability of the causal estimand is facilitated by exploiting the exclusion restriction; that is, drug noncompliers do not acquire any prevention benefit. In addition, we develop an approach to sensitivity analysis that relaxes the exclusion restriction. Applications to published data from 2 PrEP trials, namely the Preexposure Prophylaxis Initiative (iPrEx) trial and the Centre for the AIDS Programme of Research in South Africa (CAPRISA) 004 trial, suggest high efficacy estimates among drug compliers (in the iPrEx trial, odds ratio = 0.097 (95% confidence interval: 0.027, 0.352); in the CAPRISA 004 trial, odds ratio = 0.104 (95% confidence interval: 0.024, 0.447)). In summary, the proposed inferential method provides an unbiased assessment of PrEP efficacy among drug compliers, thus adding to the primary intention-to-treat analysis and correlation analyses of drug concentration data. Article	2013	De Man, Jeroen; Colebunders, Robert; Florence, Eric; Laga, Marie; Kenyon, Christopher	What is the place of pre-exposure prophylaxis in HIV prevention?	AIDS Reviews	-	-	-	1698-6997	10.1097/COH.0b013e3283582c8b.	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-23685443	New tools are needed to bring down ongoing high HIV incidence. This review aims to evaluate the place of one of these new tools (pre-exposure prophylaxis) in a comprehensive prevention strategy. Several trials have demonstrated the safety and the efficacy of pre-exposure prophylaxis in HIV prevention. Two large trials have, however, failed to show such efficacy. This was likely due to poor adherence in these trials. New forms of long-acting pre-exposure prophylaxis currently in trials may deal with these problems of low adherence. Pre-exposure prophylaxis has been demonstrated to be cost-effective within certain settings. The introduction of pre-exposure prophylaxis into prevention programs needs to be carefully thought through. For example, pre-exposure prophylaxis-induced risk compensation, at both an individual and population level, could undermine other aspects of a comprehensive HIV prevention program. In conclusion, pre-exposure prophylaxis could be a useful additional tool for the prevention of HIV in specific high-risk groups. It should be implemented in a way that deals with issues such as ensuring high adherence and ensuring that pre-exposure prophylaxis does not detract from, but complements, other more fundamental elements of HIV prevention programs. Article	2013	De Rosa, María Fabiana; Robillard, Kevin R.; Kim, Connie J.; Hoque, Md Tozammel; Kandel, Gabor; Kovacs, Colin; Kaul, Rupert; Bendayan, Reina	Expression of membrane drug efflux transporters in the sigmoid colon of HIV-infected and uninfected men.	Journal of Clinical Pharmacology	-	-	-	1552-4604 0091-2700	10.1002/jcph.132	https://pubmed.ncbi.nlm.nih.gov/23856938/	The use of antiretroviral therapy (ART) as pre-exposure prophylaxis (PrEP) has gained global attention as a promising HIV prevention strategy in men who have sex with men. Permeability of these agents in the rectal mucosa may be partially regulated by interactions with drug efflux transporters, P-glycoprotein (P-gp), multidrug resistance-associated proteins (MRPs) and/or breast cancer resistance protein (BCRP). The objective of this work was to investigate the expression of drug efflux transporters in recto-sigmoid colon tissues of HIV-infected and uninfected men, and evaluate the association of ART and/or HIV infection with drug transporter expression. MDR1/P-gp, MRPs (1-4) and BCRP mRNA and protein expression were detected in sigmoid colon biopsies of HIV-infected and uninfected men. Biopsies from HIV-infected, ART-naïve participants revealed a significant downregulation of P-gp and MRP2 protein levels compared to HIV-uninfected individuals. Biopsies from HIV-infected ART-treated patients showed 1.9-fold higher P-gp protein expression and 1.5-fold higher MRP2 protein expression compared to the ones obtained from the HIV-infected ART-naïve patients. This is a first report demonstrating that HIV infection or ART could alter expression of drug efflux transporters in gut mucosa which in turn could affect the permeability of PrEP antiretroviral agents across this barrier, a highly vulnerable site of HIV transmission. Article	2013	Dimitrov, Dobromir; Boily, Marie-Claude; Brown, Elizabeth R; Hallett, Timothy B	Analytic review of modeling studies of ARV Based PrEP interventions reveals strong influence of drug-resistance assumptions on the population-level effectiveness.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0080927	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3840039	BACKGROUND: Four clinical trials have shown that oral and topical pre-exposure prophylaxis (PrEP) based on tenofovir may be effective in preventing HIV transmission. The expected reduction in HIV transmission and the projected prevalence of drug resistance due to PrEP use vary significantly across modeling studies as a result of the broad spectrum of assumptions employed. Our goal is to quantify the influence of drug resistance assumptions on the predicted population-level impact of PrEP. METHODS: All modeling studies which evaluate the impact of oral or topical PrEP are reviewed and key assumptions regarding mechanisms of generation and spread of drug-resistant HIV are identified. A dynamic model of the HIV epidemic is developed to assess and compare the impact of oral PrEP using resistance assumptions extracted from published studies. The benefits and risks associated with ten years of PrEP use are evaluated under identical epidemic, behavioral and intervention conditions in terms of cumulative fractions of new HIV infections prevented, resistance prevalence among those infected with HIV, and fractions of infections in which resistance is transmitted. RESULTS: Published models demonstrate enormous variability in resistance-generating assumptions and uncertainty in parameter values. Depending on which resistance parameterization is used, a resistance prevalence between 2% and 44% may be expected if 50% efficacious oral PrEP is used consistently by 50% of the population over ten years. We estimated that resistance may be responsible for up to a 10% reduction or up to a 30% contribution to the fraction of prevented infections predicted in different studies. CONCLUSIONS: Resistance assumptions used in published studies have a strong influence on the projected impact of PrEP. Modelers and virologists should collaborate toward clarifying the set of resistance assumptions biologically relevant to the PrEP products which are already in use or soon to be added to the arsenal against HIV.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2013	Donnell, Deborah; Hughes, James P; Wang, Lei; Chen, Ying Q; Fleming, Thomas R	Study design considerations for evaluating efficacy of systemic preexposure prophylaxis interventions.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0b013e3182986fac	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3725298	BACKGROUND: The development of interventions for systemic pre-exposure prophylaxis (PrEP) faces several significant challenges following the US Food and Drug Administration's approval of emtricitabine/tenofovir (FTC/TDF) for HIV prevention. This development is particularly complex because of inconsistency of efficacy results of FTC/TDF PrEP trials for HIV prevention. METHODS: Possible designs for a PrEP phase 3 efficacy trial are obtained by considering scenarios for potential experimental PrEP and control regimens, including consideration of placebo and active controls, longer acting PrEP and alternate dosing schedules. RESULTS: Noninferiority (NI) trials with hazard ratio NI margins ranging from 1.10 to 1.25 can be justified in the contexts of the 3 PrEP trials demonstrating efficacy of FTC/TDF. However, these HIV endpoint trials may require extremely large number of participants, particularly in settings where FTC/TDF has been shown to reduce the risk of HIV acquisition. NI trials also are often difficult to interpret because they depend on previous placebo-controlled efficacy results. Superiority trials for PrEP are plausible in settings where FTC/TDF efficacy is not yet established, possibly due to low adherence (ie, women at risk as in FemPrEP and VOICE): a new product with potential for higher adherence and potency would be a promising candidate in this setting. CONCLUSIONS: Following Food and Drug Administration's approval of FTC/TDF for PrEP, trials to establish efficacy of new PrEP regimens require stringent design standards, together with rigorous debate about adherence within study populations and many important ethical issues. Article	2013	Friend, David R; Clark, Justin T; Kiser, Patrick F; Clark, Meredith R	Multipurpose prevention technologies: products in development.	Antiviral Research	-	-	-	1872-9096	10.1016/j.antiviral.2013.09.030	https://dx.doi.org/10.1016/j.antiviral.2013.09.030	Multipurpose prevention technologies (MPTs) are broadly defined as products capable of simultaneously addressing multiple sexual and reproductive health needs including unintended pregnancy, STIs including HIV-1, and other reproductive tract infections. MPTs have been discussed for a few decades but little product development has occurred. With the recent proof-of-concept that a topically applied antiretroviral (ARV) can effectively reduce sexual transmission of HIV-1 (tenofovir 1% gel) the impetus to develop MPTs is gaining momentum. Products currently in development are broadly categorized as either long-acting or on-demand. Long-acting MPTs include intravaginal rings (IVRs) and long-acting injectable products. Several IVR MPTs are under development including one designed to release tenofovir to prevent transmission of HIV-1 and levonorgestrel (LNG) to prevent unintended pregnancy over a 90-day period. Another MPT IVR under development is designed to release the ARV dapivirine and LNG for 2 months. Long-acting injectable pre-exposure prophylaxis (PrEP) formulations of rilpivirine (TMC278) and GSK1265744 have entered clinical evaluation and could form the basis of long-acting injectable products for HIV-1 prevention and prevention of unintended pregnancy. On-demand products include TFV 1% gel (HIV-1/HSV-2 prevention), a zinc/carrageenan zinc gel (HIV-1/HSV-2 prevention), and the SILCS diaphragm administered with TFV 1% gel. Significant technical, funding, and regulatory hurdles must be overcome to develop most MPTs; however, the significant reproductive health benefits to many women around the world should provide motivation to overcome these hurdles. This article is based on a presentation at the "Product Development Workshop 2013: HIV and Multipurpose Prevention Technologies", held in Arlington, Virginia on February 21-22, 2013. It forms part of a special supplement to Antiviral Research.	Contraception; HIV-1 prevention; Herpes simplex virus-2 prevention; Multipurpose prevention technologies. Article	2013	Friend, DR; Kiser, PF	Assessment of topical microbicides to prevent HIV-1 transmission: Concepts, testing, lessons learned	Antiviral Research	-	-	-	0166-3542	10.1016/j.antiviral.2013.06.021	https://pubmed.ncbi.nlm.nih.gov/23845918/	The development of topically applied products capable of preventing vaginal and rectal transmission of HIV-1 has been on-going for nearly 20 years. Despite this, only one clinical trial has demonstrated protection against sexual transmission of HIV-1 in women. This review covers the development of microbicides, also referred to as topical pre-exposure prophylaxis (PrEP), through three stages. The first stage focused on nonspecific agents, including surfactants such as nonoxynol-9 (N-9), to prevent HIV-1 transmission. Unfortunately, N-9 enhanced susceptibility to sexual transmission of HIV-1 when evaluated for efficacy. Soon thereafter, other nonspecific agents (polyanions) were quickly moved into large efficacy trials. Due to a lack of coordination among investigators and funders, a large investment was made in a class of compounds shown ultimately to be ineffective, although poor adherence may have contributed to these findings. The second stage involved the assessment of the antiretroviral drug tenofovir, formulated as a vaginal gel, which was found to be modestly effective in a Phase IIb trial (CAPRISA-004) when dosed in a coitally-dependent manner. In another Phase IIb trial, VOICE (MTN-003), tenofovir gel was found to be ineffective when dosed once-daily in a coitally-independent manner. Based on pharmacokinetic data, it was concluded the participants were poorly adherent to this dosing regimen, leading to a lack of efficacy. Tenofovir gel is currently in a Phase III safety and efficacy trial in South Africa (FACTS-001), using the coitally-dependent dosing regimen employed in CAPRISA-004. We are now in the third stage of microbicide research. The antiretroviral drug dapivirine is currently in two Phase III safety and efficacy studies formulated as a vaginal ring. It is hoped that the once-monthly dosing regimen will lead to higher adherence than found in the VOICE study. It is now clear that product adherence could be the greatest challenge to demonstrating topical (and to a similar extent oral) PrEP. Novel dosage forms should play a role in creating products that women will use correctly. (C) 2013 Elsevier B.V. All rights reserved. Article	2013	Fuchs, Jonathan D; Sobieszczyk, Magdalena E; Madenwald, Tamra; Grove, Doug; Karuna, Shelly T; Andrasik, Michele; Sherwat, Adam; Broder, Gail; Mayer, Kenneth; Koblin, Beryl; Hammer, Scott	Intentions to use preexposure prophylaxis among current phase 2B preventive HIV-1 vaccine efficacy trial participants.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0b013e318296df94	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3714219	In November 2010, the iPrEx study reported that preexposure prophylaxis (PrEP) with daily tenofovir disoproxil fumarate/emtricitabine reduced HIV infections by 44% among men who have sex with men and subsequent trials corroborated efficacy among heterosexual men and women. During regularly scheduled follow-up visits from January to March 2011, participants in an ongoing phase 2b vaccine efficacy trial completed an anonymous Web survey about PrEP. Among 376 respondents, 17% reported they were very likely to use PrEP in the next year. Nonwhite participants were more likely to use PrEP. Among those with some level of interest, intent to use PrEP was greatest if the drug were available through the clinical trial or health insurance. Most (91%) believed taking PrEP would not change their willingness to stay in the vaccine trial and few thought it would affect recruitment. As key stakeholders, currently enrolled trial participants can offer vital input about emerging prevention technologies that may affect the design of future HIV vaccine and nonvaccine prevention trials. Article	2013	Gao, Yajing; Katz, David F.	Multicompartmental pharmacokinetic model of tenofovir delivery by a vaginal gel.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0074404	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3770582/	BACKGROUND: Trials of a vaginal Tenofovir gel for pre-exposure prophylaxis (PrEP) for HIV have given conflicting results. Knowledge of concentrations of Tenofovir and its active form Tenofovir diphosphate, at putative sites of anti-HIV functioning, is central to understanding trial outcomes and design of products and dosage regimens. Topical Tenofovir delivery to the vaginal environment is complex, multivariate and non-linear; determinants relate to drug, vehicle, dosage regimen, and environment. Experimental PK methods cannot yield mechanistic understanding of this process, and have uncontrolled variability in drug sampling. Mechanistic modeling of the process could help delineate its determinants, and be a tool in design and interpretation of products and trials. METHODS AND FINDINGS: We created a four-compartment mass transport model for Tenofovir delivery by a gel gel, epithelium, stroma, blood. Transport was diffusion-driven in vaginal compartments; blood concentration was time-varying but homogeneous. Parameters for the model derived from in vitro and in vivo PK data, to which model predictions gave good agreement. Steep concentration gradients occurred in stroma ≤ 8 hours after gel release. Increasing epithelial thickness delayed initial TFV delivery to stroma and its decline: tmax increased but AUC at 24 hours was not significantly altered. At 24 and 48 hours, stromal concentrations were 6.3% and 0.2% of C(max). Concentrations in simulated biopsies overestimated stromal concentrations, as much as ~5X, depending upon time of sampling, biopsy thickness and epithelial thickness. CONCLUSIONS: There was reasonably good agreement of model predictions with clinical PK data. Conversion of TFV to TFV-DP was not included, but PK data suggest a linear relationship between them. Thus contrasts predicted by this model can inform design of gels and dosage regimens in clinical trials, and interpretation of PK data. This mass transport based approach can be extended to TFV conversion to TFV-DP, and to other drugs and dosage forms. Article	2013	Gilmore, Hailey J; Liu, Albert; Koester, Kimberly Ann; Amico, K Rivet; McMahan, Vanessa; Goicochea, Pedro; Vargas, Lorena; Lubensky, David; Buchbinder, Susan; Grant, Robert	Participant experiences and facilitators and barriers to pill use among men who have sex with men in the iPrEx pre-exposure prophylaxis trial in San Francisco.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2013.0116	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3791030	In 2010, the iPrEx study demonstrated efficacy of daily emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) pre-exposure prophylaxis (PrEP) in reducing HIV acquisition among men who have sex with men. Adherence to study product was critical for PrEP efficacy, and varied considerably, with FTC/TDF detection rates highest in the United States. We conducted a qualitative study to gain insights into the experiences of iPrEx participants in San Francisco (SF) where there was high confirmed adherence, to understand individual and contextual factors influencing study product use in this community. In 2009 and 2011, we conducted focus groups and in-depth interviews in 36 and 16 SF iPrEx participants, respectively. Qualitative analyses indicate that participants joined the study out of altruism. They had a clear understanding of study product use, and pill taking was facilitated by establishing or building on an existing routine. Participants valued healthcare provided by the study and relationships with staff, whom they perceived as nonjudgmental, and found client-centered counseling to be an important part of the PrEP package. This facilitated pill taking and accurate reporting of missed doses. Adherence barriers included changes in routine, side effects/intercurrent illnesses, and stress. Future PrEP adherence interventions should leverage existing routines and establish client-centered relationships/ environments to support pill taking and promote accurate reporting. Article	2013	Golub, Sarit A.; Gamarel, Kristi E.	The impact of anticipated HIV stigma on delays in HIV testing behaviors: findings from a community-based sample of men who have sex with men and transgender women in New York City.	AIDS Patient Care and STDs	-	-	-	1557-7449 1087-2914	10.1089/apc.2013.0245	https://pubmed.ncbi.nlm.nih.gov/24138486/	Treatment as prevention (TaSP) is a critical component of biomedical interventions to prevent HIV transmission. However, its success is predicated on testing and identifying undiagnosed individuals to ensure linkage and retention in HIV care. Research has examined the impact of HIV-associated stigma on HIV-positive individuals, but little work has explored how anticipated HIV stigma-the expectation of rejection or discrimination against by others in the event of seroconversion-may serve as a barrier to HIV testing behaviors. This study examined the association between anticipated stigma and HIV testing behaviors among a sample of 305 men who have sex with men (MSM) and transgender women living in New York City. Participants' mean age was 33.0; 65.5% were racial/ethnic minority; and 50.2% earned <$20,000 per year. Overall, 32% of participants had not had an HIV test in the past 6 months. Anticipated stigma was negatively associated with risk perception. In multivariate models, anticipated stigma, risk perception, and younger age were significant predictors of HIV testing behaviors. Anti-HIV stigma campaigns targeting HIV-negative individuals may have the potential to significantly impact social norms around HIV testing and other biomedical strategies, such pre-exposure prophylaxis, at a critical moment for the redefinition of HIV prevention. Article	2013	Golub, Sarit A; Gamarel, Kristi E; Rendina, H Jonathon; Surace, Anthony; Lelutiu-Weinberger, Corina L	From efficacy to effectiveness: facilitators and barriers to PrEP acceptability and motivations for adherence among MSM and transgender women in New York City.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2012.0419	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3624632	This study examined potential facilitators and barriers to pre-exposure prophylaxis (PrEP) use and their association with PrEP acceptability and motivations for adherence among 184 MSM and transgender women living in New York City. Participants were presented with educational information about PrEP and completed a computerized survey. Overall, 55.4% of participants reported willingness to take PrEP. The most highly endorsed barriers to PrEP use were health concerns, including both long-term impacts and short-term side effects, questions about PrEP's impact on future drug resistance, and concerns that PrEP does not provide complete protection against HIV. The most highly endorsed facilitator was free access to PrEP, followed by access to support services such as regular HIV testing, sexual health care/monitoring, and access to one-on-one counseling. Participants of color rated both barriers and facilitators as more important than their White counterparts. In multivariate models, barrier and facilitator scores significantly predicted not only PrEP acceptability, but also motivation for PrEP adherence among those who were likely to use PrEP. PrEP implementation programs should consider addressing these barriers and facilitators in protocol and policy development. Findings underscore the importance of support services, such as sexual health counseling, to the success of PrEP as a prevention strategy. Article	2013	Gomez, Gabriela B; Borquez, Annick; Case, Kelsey K; Wheelock, Ana; Vassall, Anna; Hankins, Catherine	The cost and impact of scaling up pre-exposure prophylaxis for HIV prevention: a systematic review of cost-effectiveness modelling studies.	PLOS Medicine	-	-	-	1549-1676	10.1371/journal.pmed.1001401	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3595225	BACKGROUND: Cost-effectiveness studies inform resource allocation, strategy, and policy development. However, due to their complexity, dependence on assumptions made, and inherent uncertainty, synthesising, and generalising the results can be difficult. We assess cost-effectiveness models evaluating expected health gains and costs of HIV pre-exposure prophylaxis (PrEP) interventions. METHODS AND FINDINGS: We conducted a systematic review comparing epidemiological and economic assumptions of cost-effectiveness studies using various modelling approaches. The following databases were searched (until January 2013): PubMed/Medline, ISI Web of Knowledge, Centre for Reviews and Dissemination databases, EconLIT, and region-specific databases. We included modelling studies reporting both cost and expected impact of a PrEP roll-out. We explored five issues: prioritisation strategies, adherence, behaviour change, toxicity, and resistance. Of 961 studies retrieved, 13 were included. Studies modelled populations (heterosexual couples, men who have sex with men, people who inject drugs) in generalised and concentrated epidemics from Southern Africa (including South Africa), Ukraine, USA, and Peru. PrEP was found to have the potential to be a cost-effective addition to HIV prevention programmes in specific settings. The extent of the impact of PrEP depended upon assumptions made concerning cost, epidemic context, programme coverage, prioritisation strategies, and individual-level adherence. Delivery of PrEP to key populations at highest risk of HIV exposure appears the most cost-effective strategy. Limitations of this review include the partial geographical coverage, our inability to perform a meta-analysis, and the paucity of information available exploring trade-offs between early treatment and PrEP. CONCLUSIONS: Our review identifies the main considerations to address in assessing cost-effectiveness analyses of a PrEP intervention--cost, epidemic context, individual adherence level, PrEP programme coverage, and prioritisation strategy. Cost-effectiveness studies indicating where resources can be applied for greatest impact are essential to guide resource allocation decisions; however, the results of such analyses must be considered within the context of the underlying assumptions made. Article	2013	Gupta, Ravindra K.; Van de Vijver, David A. M. C.; Manicklal, Sheetal; Wainberg, Mark A.	Evolving uses of oral reverse transcriptase inhibitors in the HIV-1 epidemic: from treatment to prevention.	Retrovirology	-	-	-	1742-4690	10.1186/1742-4690-10-82	https://pubmed.ncbi.nlm.nih.gov/23902855/	The HIV epidemic continues unabated, with no highly effective vaccine and no cure. Each new infection has significant economic, social and human costs and prevention efforts are now as great a priority as global antiretroviral therapy (ART) scale up. Reverse transcriptase inhibitors, the first licensed class of ART, have been at the forefront of treatment and prevention of mother to child transmission over the past two decades. Now, their use in adult prevention is being extensively investigated. We describe two approaches: treatment as prevention (TasP) - the use of combination ART (2NRTI and 1NNRTI) following HIV diagnosis to limit transmission and pre-exposure prophylaxis (PrEP) -the use of single or dual oral agents prior to sexual exposure. Prevention of mother-to-child transmission using NRTI has been highly successful, though does not involve sustained use of NRTI to limit transmission. Despite theoretical and preliminary support for TasP and PrEP, data thus far indicate that adherence, retention in care and late diagnosis are the major barriers to their successful, sustained implementation. Future advances in drug technologies will be needed to overcome the issue of drug adherence, through development of drugs that involve both less frequent dosing as well as reduced toxicity, possibly through specific targeting of infected cells. Article	2013	Gupta, Ravindra K; Wainberg, Mark A; Brun-Vezinet, Francoise; Gatell, Jose M; Albert, Jan; Sönnerborg, Anders; Nachega, Jean B	Oral antiretroviral drugs as public health tools for HIV prevention: global implications for adherence, drug resistance, and the success of HIV treatment programs.	Journal of Infectious Diseases	-	-	-	1537-6613	10.1093/infdis/jit108	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3708737	Recent data from studies on treatment as prevention (TasP) and preexposure prophylaxis (PrEP) show that antiretroviral drugs can be used in prevention, as well as in treatment. The movement from first-generation antiretroviral therapy (ART) coformulations based on thymidine analogues to second-generation ART coformulations based on tenofovir may coincide with future prevention strategies that also use tenofovir/emtricitabine, raising concerns regarding drug resistance. In published studies, failure of prophylaxis was associated with poor adherence and low plasma drug levels. Although rates of drug resistance in cases of failed prevention was low, regular human immunodeficiency virus (HIV) testing was undertaken in these clinical trials. Although legitimate concerns exist about ART adherence and drug resistance associated with PrEP and TasP in real-world settings, efforts to curb the continuing HIV epidemic through use of these novel prevention strategies should move forward because the development and approval of newer drugs reserved for prevention might take many more years. Efforts must be made to monitor ART adherence and to intervene through counseling and other means in order to optimize adherence and retention in care, whenever necessary. Finally, further research involving the generalized epidemic is needed to determine when suboptimal drug use may occur and when regular testing and monitoring of the long-term consequences of ART use may not be routine.	antiretroviral drug resistance, adherence, PrEP, TasP	English	United States	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Clinical

Article	2013	Haberer, Jessica E; Baeten, Jared M; Campbell, James; Wangisi, Jonathan; Katabira, Elly; Ronald, Allan; Tumwesigye, Elioda; Psaros, Christina; Safren, Steven A; Ware, Norma C; Thomas, Katherine K; Donnell, Deborah; Krows, Meighan; Kidoguchi, Lara; Celum, Connie; Bangsberg, David R	Adherence to antiretroviral prophylaxis for HIV prevention: a substudy cohort within a clinical trial of serodiscordant couples in East Africa.	PLOS Medicine	-	-	-	1549-1676	10.1371/journal.pmed.1001511	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3769210	BACKGROUND: Randomized clinical trials of oral antiretroviral pre-exposure prophylaxis (PrEP) for HIV prevention have widely divergent efficacy estimates, ranging from 0% to 75%. These discrepancies are likely due to differences in adherence. To our knowledge, no studies to date have examined the impact of improving adherence through monitoring and/or intervention, which may increase PrEP efficacy, or reported on objective behavioral measures of adherence, which can inform PrEP effectiveness and implementation. METHODS AND FINDINGS: Within the Partners PrEP Study (a randomized placebo-controlled trial of oral tenofovir and emtricitabine/tenofovir among HIV-uninfected members of serodiscordant couples in Kenya and Uganda), we collected objective measures of PrEP adherence using unannounced home-based pill counts and electronic pill bottle monitoring. Participants received individual and couples-based adherence counseling at PrEP initiation and throughout the study; counseling was intensified if unannounced pill count adherence fell to <80%. Participants were followed monthly to provide study medication, adherence counseling, and HIV testing. A total of 1,147 HIV-uninfected participants were enrolled: 53% were male, median age was 34 years, and median partnership duration was 8.5 years. Fourteen HIV infections occurred among adherence study participants--all of whom were assigned to placebo (PrEP efficacy = 100%, 95% confidence interval 83.7%-100%, p<0.001). Median adherence was 99.1% (interquartile range IQR 96.9%-100%) by unannounced pill counts and 97.2% (90.6%-100%) by electronic monitoring over 807 person-years. Report of no sex or sex with another person besides the study partner, younger age, and heavy alcohol use were associated with <80% adherence; the first 6 months of PrEP use and polygamous marriage were associated with >80% adherence. Study limitations include potential shortcomings of the adherence measures and use of a convenience sample within the substudy cohort. CONCLUSIONS: The high PrEP adherence achieved in the setting of active adherence monitoring and counseling support was associated with a high degree of protection from HIV acquisition by the HIV-uninfected partner in heterosexual serodiscordant couples. Low PrEP adherence was associated with sexual behavior, alcohol use, younger age, and length of PrEP use. Please see later in the article for the Editors' Summary. Article	2013	Hadas, Eran; Chao, Wei; He, Hongxia; Saini, Manisha; Daley, Eleen; Saifuddin, Mohammed; Bentsman, Galina; Ganz, Eric; Volsky, David J; Potash, Mary Jane	Transmission of chimeric HIV by mating in conventional mice: prevention by pre-exposure antiretroviral therapy and reduced susceptibility during estrus.	Disease Models & Mechanisms (Dis Model Mech)	-	-	-	1754-8411	10.1242/dmm.012617	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3759349	Heterosexual transmission accounts for the majority of new human immunodeficiency virus (HIV) cases worldwide. The current approach to investigate HIV heterosexual transmission in animals involves application of virus stock to the vaginal surface, a method that does not reproduce the physiological conditions of vaginal intercourse that influence the rate of transmission. We have previously described efficient infection of conventional mice using EcoHIV/NL4-3 and EcoHIV/NDK, chimeric HIV molecular clones constructed to express all HIV structural and regulatory genes except envelope, which is replaced by a rodent-tropic envelope gene. Here we investigated whether EcoHIV/NDK-infected male mice transmit virus to females during coitus, and the sensitivity of this transmission to HIV pre-exposure prophylaxis and the estrus state. Our general approach was to allow mating between EcoHIV/NDK-infected male mice and uninfected females for 1-7 nights. At 1-6 weeks after mating, mice were euthanized and virus burdens were measured by quantitative PCR (qPCR) amplification of HIV RNA or DNA in peritoneal macrophages, inguinal lymph node cells, spleen cells or vas deferens, or by ELISA for antibodies to HIV Gag. We found that 70-100% of female mice mated to EcoHIV/NDK-infected males acquired infection. Pericoital treatment of females with either 2',3'-dideoxycytidine (ddC) or tenofovir largely prevented their EcoHIV/NDK infection by mating (P<0.05 and P<0.003, respectively). In males, T cells were dispensable for virus transmission. The rate of EcoHIV/NDK sexual transmission to females in estrus declined sharply (P=0.003) but their infection by injection was unaffected, indicating that the local environment in the female reproductive tract influences susceptibility to HIV. We conclude that this system of EcoHIV/NDK transmission during mouse mating reproduces key features of heterosexual transmission of HIV in humans and can be used to investigate its biology and control. Article	2013	Haire, Bridget; Folayan, Morenike Oluwatoyin; Hankins, Catherine; Sugarman, Jeremy; McCormack, Sheena; Ramjee, Gita; Warren, Mitchell	Ethical considerations in determining standard of prevention packages for HIV prevention trials: examining PrEP.	Developing World Bioethics	-	-	-	1471-8847	10.1111/dewb.12032	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3716830	The successful demonstration that antiretroviral (ARV) drugs can be used in diverse ways to reduce HIV acquisition or transmission risks--either taken as pre-exposure prophylaxis (PrEP) by those who are uninfected or as early treatment for prevention (T4P) by those living with HIV--expands the armamentarium of existing HIV prevention tools. These findings have implications for the design of future HIV prevention research trials. With the advent of multiple effective HIV prevention tools, discussions about the ethics and the feasibility of future HIV prevention trial designs have intensified. This article outlines arguments concerning the inclusion of newly established ARV-based HIV prevention interventions as standard of prevention in HIV prevention trials from multiple perspectives. Ultimately, there is a clear need to incorporate stakeholders in a robust discussion to determine the appropriate trial design for each study population.	antiretroviral therapy, HIV/AIDS, research ethics, developing world bioethics, guidelines, international justice	English	United Kingdom	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review
Article	2013	Haire, Bridget; Kaldor, John M	Ethics of ARV based prevention: treatment-as-prevention and PrEP.	Developing World Bioethics	-	-	-	1471-8847	10.1111/dewb.12026	https://dx.doi.org/10.1111/dewb.12026	Published data show that new HIV prevention strategies including treatment-as-prevention and pre-exposure prophylaxis (PrEP) using oral antiretroviral drugs (ARVs) are highly, but not completely, effective if regimens are taken as directed. Consequently, their implementation may challenge norms around HIV prevention. Specific concerns include the potential for ARV-based prevention to reframe responsibility, erode beneficial sexual norms and waste resources. This paper explores what rights claims uninfected people can make for access to ARVs for prevention, and whether moral claims justify the provision of ARV therapy to those who do not yet clinically require treatment as a way of reducing HIV transmission risk. An ethical analysis was conducted of the two strategies, PrEP and treatment-as-prevention, using a public health stewardship model developed by the Nuffield Bioethics Council to consider and compare the application of PrEP and treatment-as-prevention strategies. We found that treating the person with HIV rather than the uninfected person offers advantages in settings where there are limited opportunities to access care. A treatment-as-prevention strategy that places all the emphasis upon the positive person's adherence however carries a disproportionate burden of responsibility. PrEP remains an important option for receptive partners who face increased biological vulnerability. We conclude that the use of ARV for prevention is ethically justified, despite imperfect global to drugs for those in clinical need. The determination of which ARV-based HIV prevention strategy is ethically preferable is complex and must take into account both public health and interpersonal considerations. Essay	2013	Hankins, Catherine A; Dybul, Mark R	The promise of pre-exposure prophylaxis with antiretroviral drugs to prevent HIV transmission: a review.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0b013e32835b809d	https://dx.doi.org/10.1097/COH.0b013e32835b809d	PURPOSE OF REVIEW: Public health experts are wrestling with how to translate recent scientific findings from pre-exposure prophylaxis (PrEP) effectiveness trials into real-world programmes. This review summarizes clinical trial findings on oral and topical PrEP, discusses how decision-makers can evaluate the place of PrEP within combination prevention and highlights anticipated developments that could be important in future HIV-prevention strategies. RECENT FINDINGS: PrEP taken daily as oral tablets to create systemic protection has been found to be effective in the Pre-Exposure Prophylaxis Initiative (iPrEx), Partners' PrEP and TDF2 trials, but not in Fem-PrEP or the Vaginal and Oral Interventions to Control the Epidemic (VOICE) tenofovir arm. Tenofovir gel for topical protection was effective in CAPRISA 004 when used peri-coitally but not in VOICE with daily use. These findings underscore the importance of adherence to achieve adequate drug levels and the potential additive role of PrEP within combination prevention. Pivotal phase III trials are underway of the dapivirine ring, whereas phase I trials of injectable formulations show promise. SUMMARY: Antiretroviral-based HIV-prevention programmes should be tailored to those most likely to be adherent, providing them with state-of-the-art counselling and support to achieve high adherence during the time period of use. Long-acting products, if found well tolerated and effective, could be ideal for overcoming adherence challenges.	combination HIV prevention; pre-exposure prophylaxis; programme implementation; tenofovir	English	United Kingdom	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Other
Article	2013	Hellinger, Fred J	Assessing the cost effectiveness of pre-exposure prophylaxis for HIV prevention in the US.	PharmacoEconomics	-	-	-	1179-2027	10.1007/s40273-013-0111-0	https://dx.doi.org/10.1007/s40273-013-0111-0	About 50,000 people are infected with HIV in the US each year and this number has remained virtually the same for the past decade. Yet, in the last few years, evidence from several multinational randomized clinical trials has shown that the provision of antiretroviral drug to uninfected persons (i.e. pre-exposure prophylaxis) reduces the incidence of HIV by about 50 %. However, evidence from cost-effectiveness studies conducted in the US yield widely varying estimates of the cost per quality-adjusted life-year (QALY) gained, and this variation reflects the substantial uncertainty surrounding the determinants of HIV transmission (e.g. adherence rates to prophylactic medications, the average number of sexual partners, the number and types of sexual acts, the viral load of infected partners, and the proportion of contacts where condoms are used), as well as different approaches to translating a reduction in HIV cases into an estimate of the increase in the number of QALYs. Article	2013	Hendrix, Craig W; Chen, Beatrice A; Guddera, Vijayanand; Hoesley, Craig; Justman, Jessica; Nakabiito, Clemensia; Salata, Robert; Soto-Torres, Lydia; Patterson, Karen; Minnis, Alexandra M; Gandham, Sharavi; Gomez, Kailazarid; Richardson, Barbra A; Bumpus, Namandje N	MTN-001: randomized pharmacokinetic cross-over study comparing tenofovir vaginal gel and oral tablets in vaginal tissue and other compartments.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0055013	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3559346	BACKGROUND: Oral and vaginal preparations of tenofovir as pre-exposure prophylaxis (PrEP) for human immunodeficiency virus (HIV) infection have demonstrated variable efficacy in men and women prompting assessment of variation in drug concentration as an explanation. Knowledge of tenofovir concentration and its active form, tenofovir diphosphate, at the putative vaginal and rectal site of action and its relationship to concentrations at multiple other anatomic locations may provide key information for both interpreting PrEP study outcomes and planning future PrEP drug development. OBJECTIVE: MTN-001 was designed to directly compare oral to vaginal steady-state tenofovir pharmacokinetics in blood, vaginal tissue, and vaginal and rectal fluid in a paired cross-over design. METHODS AND FINDINGS: We enrolled 144 HIV-uninfected women at 4 US and 3 African clinical research sites in an open label, 3-period crossover study of three different daily tenofovir regimens, each for 6 weeks (oral 300 mg tenofovir disoproxil fumarate, vaginal 1% tenofovir gel 40 mg, or both). Serum concentrations after vaginal dosing were 56-fold lower than after oral dosing (p<0.001). Vaginal tissue tenofovir diphosphate was quantifiable in ≥90% of women with vaginal dosing and only 19% of women with oral dosing. Vaginal tissue tenofovir diphosphate was ≥130-fold higher with vaginal compared to oral dosing (p<0.001). Rectal fluid tenofovir concentrations in vaginal dosing periods were higher than concentrations measured in the oral only dosing period (p<0.03). CONCLUSIONS: Compared to oral dosing, vaginal dosing achieved much lower serum concentrations and much higher vaginal tissue concentrations. Even allowing for 100-fold concentration differences due to poor adherence or less frequent prescribed dosing, vaginal dosing of tenofovir should provide higher active site concentrations and theoretically greater PrEP efficacy than oral dosing; randomized topical dosing PrEP trials to the contrary indicates that factors beyond tenofovir's antiviral effect substantially influence PrEP efficacy. TRIAL REGISTRATION: ClinicalTrials.gov NCT00592124. Article	2013	Hosek, Sybil G; Green, Keith R; Siberry, George; Lally, Michelle; Balthazar, Christopher; Serrano, Pedro A; Kapogiannis, Bill	Integrating Behavioral HIV Interventions into Biomedical Prevention Trials with Youth: Lessons from Chicago's Project PrEPare.	Journal of HIV/AIDS & Social Services	-	-	-	1538-1501	10.1080/15381501.2013.773575	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3818104	On the heels of several trials demonstrating the efficacy of pre-exposure prophylaxis (PrEP) and the recent approval by the FDA of the supplemental indication for Truvada as PrEP, researchers, advocates, and community providers are calling for the investigation of implementation strategies that combine behavioral interventions with biomedical prevention. This paper describes the modification and integration of an evidence-based group-level intervention into a small PrEP pilot trial with young men who have sex with men (YMSM). The behavioral intervention as well as ongoing risk reduction counseling sessions were found to be highly acceptable among a sample of racially diverse YMSM. Article	2013	Hosek, Sybil G; Siberry, George; Bell, Margo; Lally, Michelle; Kapogiannis, Bill; Green, Keith; Fernandez, M Isabel; Rutledge, Brandy; Martinez, Jaime; Garofalo, Robert; Wilson, Craig M	The acceptability and feasibility of an HIV preexposure prophylaxis (PrEP) trial with young men who have sex with men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0b013e3182801081	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3656981	BACKGROUND: This study examined the feasibility of a combination prevention intervention for young men who have sex with men (YMSM), an anticipated target population for HIV preexposure prophylaxis (PrEP). METHODS: Project PrEPare, a pilot study using a randomized 3-arm design, compared an efficacious behavioral HIV prevention intervention (Many Men, Many Voices-3 MV) alone, 3 MV combined with PrEP (tenofovir/emtricitabine), and 3 MV combined with placebo. Eligible participants were 18- to 22-year-old HIV-uninfected men who reported unprotected anal intercourse in the past year. Participants were screened for preliminary eligibility at youth venues and community organizations and were also referred through social networks. Laboratory screening determined final eligibility. Behavioral and biomedical data were collected at baseline and every 4 weeks thereafter for 24 weeks. RESULTS: Sixty-eight youth (mean age = 19.97 years; 53% African American, 40% Latino) were enrolled; 58 were randomized. Self-reported medication adherence averaged 62% (range, 43%-83%), whereas rates of detectable tenofovir in plasma of participants in the emtricitabine/tenofovir disoproxil fumarate arm ranged from 63.2% (week 4) to 20% (week 24). There were 5 ≥ grade 2 adverse events possibly/probably related to the study medication. Sexual risk behavior declined from baseline to week 24 in all study arms. CONCLUSIONS: The feasibility of enrolling at-risk youth, particularly young men who have sex with men of color, into Project PrEPare has been demonstrated. The acceptability of the group intervention along with counseling and testing was high. Self-reported medication adherence and corresponding plasma drug concentrations were low indicating the need for enhanced adherence counseling. Exploration of PrEP use among youth in nonrandomized open label trials is warranted. Article	2013	Ippolito, G; Rezza, G	HIV treatment as prevention: population effect vs. individual protection?	Annali di Igiene	-	-	-	1120-9135	10.7416/ai.2013.1910	https://dx.doi.org/10.7416/ai.2013.1910	There are compelling data suggesting that antiretroviral (ARV) drugs can prevent the transmission of HIV: 1) ARV therapy reduces the intrinsic risk of transmission by cutting down the viral load in infected people; 2) ARVs may be used to prevent transmission in uninfected subjects who experienced high risk exposures. Despite these encouraging preliminary results, there are several questions that need to be answered before recommending the use of ARV among uninfected subjects: 1) the efficacy of these strategies amongst women is not yet established; 2) the cost-effectiveness of pre-exposure prophylaxis (PrEP) in the long term is undefined since PrEP efficacy may depend on adherence; 3) treating uninfected individuals may be counter-effective, as it may increase risky behaviour due to the belief that ARV drugs have unlimited protective power. In conclusion, the public-health use of ARV drugs represents a new paradigm in the field of HIV prevention. However, ARV treatment cannot be considered as a substitute for other measures for preventing transmission but a complement to individual protection. In particular, post-exposure prophylaxis may be used in selected cases, whereas PrEP appears to be a highly costly method with limited public-health potential and possible safety concerns. Article	2013	Jackson, Akil; Moyle, Graeme; Watson, Victoria; Tjia, John; Ammara, Alieu; Back, David; Mohabeer, Malika; Gazzard, Brian; Boffito, Marta	Tenofovir, emtricitabine intracellular and plasma, and efavirenz plasma concentration decay following drug intake cessation: implications for HIV treatment and prevention.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0b013e3182829bd0	https://dx.doi.org/10.1097/QAI.0b013e3182829bd0	BACKGROUND: In vivo data on tenofovir (TFV), emtricitabine (FTC), and efavirenz (EFV) concentration decay after intake cessation are limited; determinations of "true" elimination half-lives (t½) have often been based on suboptimal sampling windows. Understanding these parameters is important in managing missed doses and planning HIV pre-exposure prophylaxis (PrEP). This study investigated the pharmacokinetics (PK) of plasma TFV/FTC, their intracellular (IC) anabolites, TFV-diphosphate (DP) and FTC-triphosphate (TP), and plasma EFV over 10 days after intake cessation in HIV-negative volunteers. METHODS: Volunteers received an Atripla (TFV/FTV/EFV) tablet daily for 14 days. PK sampling occurred before final dose and up to 228 hours after stopping. Peripheral blood mononuclear cells for IC(drug) and plasma(drug) were isolated, with analysis by tandem mass spectrometry. RESULTS: Sixteen participants completed the study. Geometric mean plasma (t½)(228h) of TFV and FTC were 31 and 37 hours. These were longer than the previous reports (TFV 12-18 hours, FTC 10 hours).Geometric mean (t½)(228h) of IC TFV-DP and FTC-TP were 164 and 39 hours, whereas for EFV in plasma was 92 hours. EFV(plasma) in 5/16 participants were below the suggested MEC of 1000 ng/mL within 48 hours postdose; however, 50% of the participants maintained concentrations above this level after 84 hours. CONCLUSIONS: These data fully characterize the PK of TFV and TFV-DP, FTC and FTC-TP, and EFV after stopping the drug combination. Although decay in concentrations can be related to a target for EFV, this is more difficult for the IC phosphates. Consensus on 'target' triphosphate/diphosphate concentrations will further our understanding of missed/delayed doses in treatment and prevention strategies. Article	2013	Jackson, Todd; Huang, Ailong; Chen, Hong; Gao, Xiao; Zhang, Yan; Zhong, Xiaoni	Predictors of willingness to use HIV pre-exposure prophylaxis among female sex workers in Southwest China.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2012.726341	https://dx.doi.org/10.1080/09540121.2012.726341	This research examined predictors of willingness to use pre-exposure prophylaxis (PrEP) among female sex workers (FSW) in Southwest China. The final sample included 395 women (mean age=26.73 years, SD=6.74 years) who were predominantly of Han majority ethnicity (84.6%) and had completed middle-school education or lower (63.0%). Participants were recruited initially from commercial sex venues (e.g., saunas, massage parlors) in the cities of Nanchang, Luizhou, Nanning, Urumqi, and Karamay as well as two districts of Chongqing municipality and subsequently via snowball procedures. They completed a battery of self-report measures assessing beliefs about HIV and PrEP, psychosocial influences, demographics and willingness to use HIV PrEP. Willingness to use HIV PrEP was predicted by high levels of trust in physicians and more reported unmet interpersonal belongingness needs. Beyond these factors, willing and unwilling groups were differentiated on the basis of intervention-specific beliefs (perceived stigma and self-efficacy in use of PrEP). Together, findings suggested interpersonal factors should be considered in concert with perceptions of intervention characteristics in assessing motivations to enroll in PrEP within this particular at-risk group. Theses and Dissertations	2013	James, Amanda Marie	Intracellular Quantitation And Pharmacokinetic Modeling Of Nucleoside Analogs In The Female Genital Tract	-	-	University of Alabama at Birmingham	-	NA	NA	https://digitalcommons.library.uab.edu/etd-collection/2031/	Human Immunodeficiency Virus (HIV) is one of the leading infectious diseases in the world. In spite of substantial progress in the advancement of antiretroviral therapy for HIV treatment, new infections outpace the number of infected persons initiating ART. Therefore, the prevention of HIV remains a crucial health issue. Pre-Exposure Prophylaxis, (PrEP), which involves using one or more antiretroviral agents to reduce the risk of HIV infection prior to potential exposure, has shown effectiveness at reducing HIV transmission in study volunteers with different sexual orientation around the world. The clinical pharmacology of antiretroviral drugs, specifically tenofovir (TFV) and emtricitabine (FTC), in relation to their ability to prevent HIV transmission is still being evaluated. The objective of this dissertation was to develop pharmacokinetic models of TFV and FTC in the plasma and eventually peripheral blood mononuclear cells (PBMCs) and the female genital tract (FGT), which can be used to simulate the appropriate dosing interval needed to achieve optimal drug concentrations for PrEP in each compartment. The development of liquid chromatography/ mass spectrometry (LC/MS/MS) methods resulted in successful quantification of TFV and FTC in plasma, PBMCs, cervical fluid, and endothelial cells of the FGT from 30 HIV-seropositive (HIV+) women. Also, utilizing the LC/MS/MS methods developed, <italic>in vitro</italic> TFV and FTC uptake in non-monocytic genital tract cells was determined and compared in the presence and absence of hormonal contraceptives. The major results demonstrated 1) CD4+ and squamous epithelia cells exhibited significantly increased uptake relative to control for both antiretrovirals; 2) individually, synthetic estrogen and progesterone significantly altered uptake across all cell lines except squamous epithelium cells for TFV and CD4+ cells for FTC; and 3) CD8+ and dendritic cells demonstrated decreased uptake of TFV and FTC when dosed one hour prior to being dosed with combined hormonal contraceptives. Development of predictive pharmacokinetic models of TFV and FTC concentration-time profiles in the plasma was achieved using population pharmacokinetic analysis software. Collectively, the results expand upon current knowledge of antiretroviral penetration into the FGT for the use of evaluating PrEP agents and help guide PrEP research on ideal dosing for prevention and transmission of HIV. Article	2013	Kenworthy, Nora J.; Bulled, Nicola	From modeling to morals: Imagining the future of HIV PREP in Lesotho	Developing World Bioethics	-	-	-	14718731	10.1111/dewb.12029	https://onlinelibrary.wiley.com/doi/abs/10.1111/dewb.12029	Amidst growing global endorsements of new biomedical HIV prevention strategies, ARV-based pre-exposure prophylaxis (ARV PrEP) has garnered considerable attention as a potentially promising prevention strategy. Though it may offer more effective protection for certain at-risk groups than conventional prevention strategies (such as sexual partner reduction, condom use, and prevention of mother-to-child transmission), PrEP is more costly. PrEP requires more ongoing contact between individuals and providers, and a level of surveillance from the health system that is not necessary with other preventive measures. In this sense, it represents a new bio-technology for HIV prevention that poses particular challenges for worldwide implementation, given developing countries' struggling health systems and incomplete HIV treatment programs. Since the emergence of PrEP has stimulated ethical discussions premised on incomplete knowledge of efficacy and implementation, this paper explores the ethical parameters of a likely scenario for PrEP usage in a single, resource-poor country. We first develop a plausible model for PrEP deployment and utilization based on current PrEP research, while carefully considering the reigning institutional values of feasibility and effectiveness in global health approaches. Drawing on ethnographic research of HIV treatment and prevention approaches in Lesotho, we address ethical questions arising from this scenario of PrEP delivery. Lesotho presents a compelling and emblematic case study of PrEP's potential successes and pitfalls in a developing country, given the country's high HIV prevalence, struggles to achieve universal access to HIV treatment regimes, continued existence of stigma around the epidemic, and difficulties in addressing persistent social inequalities that fuel infections. Article	2013	Kibengo, Freddie M; Ruzagira, Eugene; Katende, David; Bwanika, Agnes N; Bahemuka, Ubaldo; Haberer, Jessica E; Bangsberg, David R; Barin, Burc; Rooney, James F; Mark, David; Chetty, Paramesh; Fast, Patricia; Kamali, Anatoli; Priddy, Frances H	Safety, adherence and acceptability of intermittent tenofovir/emtricitabine as HIV pre-exposure prophylaxis (PrEP) among HIV-uninfected Ugandan volunteers living in HIV-serodiscordant relationships: a randomized, clinical trial.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0074314	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3784443	BACKGROUND: Efficacy of oral pre-exposure prophylaxis (PrEP) in prevention of HIV acquisition has been evaluated using a daily regimen. However, adherence to long term daily medication is rarely perfect. Intermittent regimen may be a feasible alternative. Preclinical studies have demonstrated effectiveness of intermittent PrEP in SHIV prevention among animals. However, little is known about intermittent PrEP regimens. DESIGN: Seventy two HIV-uninfected volunteers in HIV serodiscordant couple relationships in Uganda were randomly assigned to receive daily oral Tenofovir/Emtricitabine (TDF/FTC-Truvada) or placebo, or intermittent (Monday, Friday and within 2 hours after sex, not to exceed one dose per day) oral TDF/FTC or placebo in a 2:1:2:1 ratio. Volunteers and study staff were blinded to drug assignment, but not to regimen assignment. METHODS: Volunteers were followed for 4 months after randomization, with monthly clinical and laboratory safety assessments and comprehensive HIV risk reduction services. Adherence was monitored using medication event monitoring system (MEMS) and self-report. Sexual activity data were collected via daily short text message (SMS) and self-report. HIV-specific immune responses were assessed by IFN-Î³ ELISPOT. RESULTS: Both daily and intermittent oral TDF/FTC regimens were well tolerated. Median MEMS adherence rates were 98% (IQR: 93-100) for daily PrEP regimen, 91% (IQR: 73-97) for fixed intermittent dosing and 45% (IQR: 20-63) for post-coital dosing. SMS response rate was 74%, but increased to 80% after excluding server outages; results may have been affected by the novelty of this measure. The majority of volunteers expressed willingness with no particular preference for either regimen. CONCLUSIONS: Both daily and intermittent oral PrEP dosing regimens were safe. Adherence was high for daily and fixed intermittent dosing; post-coital dosing was associated with poor adherence. Fixed intermittent PrEP regimens may be feasible especially if a minimum effective drug concentration correlating with HIV prevention can be achieved with this dosing. REGISTRATION: Clinicaltrials.gov number NCT00931346. Theses and Dissertations	2013	Kintu, Alexander	The Association between Sexual Behavior and Adherence to Hiv Pre-exposure Prophylaxis Medication in Hiv Serodiscordant Couples	-	-	U of Massachusetts : Masters	-	NA	https://doi.org/10.7275/4473682	http://scholarworks.umass.edu/theses/1131	High levels of adherence have been identified as a key factor for effective pre-exposure prophylaxis medication (PrEP). Because PrEP is a new concept in HIV prevention, there are limited data on predictors of adherence, though initial findings indicate that sexual behavior could be an influencing factor. This study examines different aspects of sexual behavior and their associations with monthly rates and patterns of adherence. We enrolled 1147 HIV-negative individuals living in long-term serodiscordant relationships at three sites in Uganda. Sexual behavior was assessed via monthly in-person interviews and adherence was measured through electronic monitoring of pill bottle openings. We used generalized estimation equations to adjust for risk factors of low adherence to PrEP medication. Fifty-three percent of participants were male, 51% were aged between 18 and 34 years, the median number of years they had lived with the HIV-positive partner was 8.5 years and 24.2% were in polygamous relationships. Participants who had sex with other partners and also had less than 100% use of condoms were more than twice as likely to have less than 80% adherence (OR=2.48, 95%CI=1.70-3.62). Per electronic monitoring, 54.7% of cohort participants had at least one 72-hour consecutive gap in adherence. Participants who had sex with other partners and were also had also reported less than 100% use of condoms had a 50% increase in odds of having a 72-hour gap in adherence (OR=1.50, 95%CI=1.19-31.91). Low overall adherence and extended gaps in adherence were more common in participants that abstained from sex and those that reported sex outside their primary partnership. Despite high monthly adherence rates, many study participants had long periods of non-adherence during which they engaged in risky sexual behavior with potential for HIV acquisition. Article	2013	Koenig, Linda J; Lyles, Cynthia; Smith, Dawn K	Adherence to antiretroviral medications for HIV pre-exposure prophylaxis: lessons learned from trials and treatment studies.	American Journal of Preventive Medicine	-	-	-	1873-2607	10.1016/j.amepre.2012.09.047	https://dx.doi.org/10.1016/j.amepre.2012.09.047	several recent clinical trials have shown that daily oral pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate and emtricitabine (TDF– FTC) can reduce the risk for sexually acquired HIV infection in men and women. However, the efficacy of PrEP has varied widely across trials,1 and it is affected heavily by adherence to daily doses of TDF–FTC. To better understand the importance of medication adherence to achieving the PrEP efficacy required for public health impact, and to provide the best guidance for supporting optimal adherence in real-world contexts when PrEP is implemented more broadly, the current paper reviews and summarizes findings from (1) adherence analyses from PrEP clinical trials and (2) the antiretroviral treatment adherence literature. Article	2013	Leyva, Francisco J.; Bakshi, Rahul P.; Fuchs, Edward J.; Li, Liye; Caffo, Brian S.; Goldsmith, Arthur J.; Ventuneac, Ana; Carballo-Diéguez, Alex; Du, Yong; Leal, Jeffrey P.; Lee, Linda A.; Torbenson, Michael S.; Hendrix, Craig W.	Isoosmolar enemas demonstrate preferential gastrointestinal distribution, safety, and acceptability compared with hyperosmolar and hypoosmolar enemas as a potential delivery vehicle for rectal microbicides.	AIDS Research and Human Retroviruses	-	-	-	1931-8405 0889-2229	10.1089/aid.2013.0189	https://pubmed.ncbi.nlm.nih.gov/23885722/	Rectally applied antiretroviral microbicides for preexposure prophylaxis (PrEP) of HIV infection are currently in development. Since enemas (rectal douches) are commonly used by men who have sex with men prior to receptive anal intercourse, a microbicide enema could enhance PrEP adherence by fitting seamlessly within the usual sexual practices. We assessed the distribution, safety, and acceptability of three enema types-hyperosmolar (Fleet), hypoosmolar (distilled water), and isoosmolar (Normosol-R)-in a crossover design. Nine men received each enema type in random order. Enemas were radiolabeled (99m)Tc-diethylene triamine pentaacetic acid (DTPA) to assess enema distribution in the colon using single photon emission computed tomography/computed tomography (SPECT/CT) imaging. Plasma (99m)Tc-DTPA indicated mucosal permeability. Sigmoidoscopic colon tissue biopsies were taken to assess injury as well as tissue penetration of the (99m)Tc-DTPA. Acceptability was assessed after each product use and at the end of the study. SPECT/CT imaging showed that the isoosmolar enema had greater proximal colonic distribution (up to the splenic flexure) and greater luminal and colon tissue concentrations of (99m)Tc-DTPA when compared to the other enemas (p<0.01). Colon biopsies also showed that only the hyperosmolar enema caused sloughing of the colonic epithelium (p<0.05). In permeability testing, the hypoosmolar enema had higher plasma (99m)Tc-DTPA 24-h area under the concentration-time curve and peak concentration compared to the hyperosmolar and isoosmolar enemas, respectively. Acceptability was generally good with no clear preferences among the three enema types. The isoosmolar enema was superior or similar to the other enemas in all categories and is a good candidate for further development as a rectal microbicide vehicle. Article	2013	Liu, AY; Vittinghoff, E; Chillag, K; Mayer, K; Thompson, M; Grohskopf, L; Colfax, G; Pathak, S; Gvetadze, R; O'Hara, B; Collins, B; Ackers, M; Paxton, L; Buchbinder, SP	Sexual Risk Behavior Among HIV-Uninfected Men Who Have Sex With Men Participating in a Tenofovir Preexposure Prophylaxis Randomized Trial in the United States	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	10.1097/QAI.0b013e31828f097a.	https://pubmed.ncbi.nlm.nih.gov/23481668/	Objective: To evaluate for changes in sexual behaviors associated with daily pill use among men who have sex with men (MSM) participating in a preexposure prophylaxis trial. Design: Randomized, double-blind, placebo-controlled trial. Participants were randomized 1: 1: 1: 1 to receive tenofovir disoproxil fumarate or placebo at enrollment or after a 9-month delay and followed for 24 months. Methods: Four hundred HIV-negative MSM reporting anal sex with a man in the past 12 months and meeting other eligibility criteria enrolled in San Francisco, Atlanta, and Boston. Sexual risk was assessed at baseline and quarterly visits using Audio Computer-Assisted Self-Interview. The association of pill taking with sexual behavior was evaluated using logistic and negative-binomial regressions for repeated measures. Results: Overall indices of behavioral risk declined or remained stable during follow-up. Mean number of partners and proportion reporting unprotected anal sex declined during follow-up (P < 0.05), and mean unprotected anal sex episodes remained stable. During the initial 9 months, changes in risk practices were similar in the group that began pills immediately vs. those in the delayed arm. These indices of risk did not differ significantly after initiation of pill use in the delayed arm or continuation of study medication in the immediate arm. Use of poppers, amphetamines, and sexual performance-enhancing drugs were independently associated with one or more indices of sexual risk. Conclusions: There was no evidence of risk compensation among HIV-uninfected MSM in this clinical trial. Monitoring for risk compensation should continue now that preexposure prophylaxis has been shown to be efficacious in MSM and other populations and will be provided in open-label trials and other contexts. Article	2013	Long, Elisa F.; Stavert, Robert R.	Portfolios of biomedical HIV interventions in South Africa: a cost-effectiveness analysis.	Journal of General Internal Medicine	-	-	-	1525-1497 0884-8734	10.1007/s11606-013-2417-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3785647/	BACKGROUND: Recent clinical trials of male circumcision, oral pre-exposure prophylaxis (PrEP), and a vaginal microbicide gel have shown partial effectiveness at reducing HIV transmission, stimulating interest in implementing portfolios of biomedical prevention programs. OBJECTIVE: To evaluate the effectiveness and cost-effectiveness of combination biomedical HIV prevention and treatment scale-up in South Africa, given uncertainty in program effectiveness. DESIGN: Dynamic HIV transmission and disease progression model with Monte Carlo simulation and cost-effectiveness analysis. PARTICIPANTS: Men and women aged 15 to 49 years in South Africa. INTERVENTIONS: HIV screening and counseling, antiretroviral therapy (ART), male circumcision, PrEP, microbicide, and select combinations. MAIN MEASURES: HIV incidence, prevalence, discounted costs, discounted quality-adjusted life years (QALYs), and incremental cost-effectiveness ratios. KEY RESULTS: Providing half of all uninfected persons with PrEP averts 28 % of future HIV infections for $9,000/QALY gained, but the affordability of such a program is questionable. Given limited resources, annual HIV screening and ART utilization by 75 % of eligible infected persons could avert one-third of new HIV infections, for approximately $1,000/QALY gained. Male circumcision is more cost-effective, but disproportionately benefits men. A comprehensive portfolio of expanded screening, ART, male circumcision, microbicides, and PrEP could avert 62 % of new HIV infections, reducing HIV prevalence from a projected 14 % to 10 % after 10 years. This strategy doubles treatment initiation and adds 31 million QALYs to the population. Despite uncertainty in program effectiveness, a comprehensive portfolio costs less than $10,000/QALY gained in 33 % of simulation iterations and less than $30,000/QALY gained in 90 % of iterations, assuming an annual microbicide cost of $100. CONCLUSIONS: A portfolio of modestly-effective biomedical HIV prevention programs, including male circumcision, vaginal microbicides, and oral PrEP, could substantially reduce HIV incidence and prevalence in South Africa and be likely cost-effective. Given limited resources, PrEP is the least cost-effective intervention of those considered. Article	2013	Louissaint, Nicolette A; Cao, Ying-Jun; Skipper, Paul L; Liberman, Rosa G; Tannenbaum, Steven R; Nimmagadda, Sridhar; Anderson, Jean R; Everts, Stephanie; Bakshi, Rahul; Fuchs, Edward J; Hendrix, Craig W	Single dose pharmacokinetics of oral tenofovir in plasma, peripheral blood mononuclear cells, colonic tissue, and vaginal tissue.	AIDS Research and Human Retroviruses	-	-	-	1931-8405	10.1089/AID.2013.0044	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3809387	HIV seroconversion outcomes in preexposure prophylaxis (PrEP) trials of oral tenofovir (TFV)-containing regimens are highly sensitive to drug concentration, yet less-than-daily dosing regimens are under study. Description of TFV and its active moiety, TFV diphosphate (TFV-DP), in blood, vaginal tissue, and colon tissue may guide the design and interpretation of PrEP clinical trials. Six healthy women were administered a single oral dose of 300 mg tenofovir disoproxil fumarate (TDF) and 4.3 mg (12.31 MBq, 333 μCi) (14)C-TDF slurry. Blood was collected every 4 h for the first 24 h, then at 4, 8, 11, and 15 days postdosing. Colonic and vaginal samples (tissue, total and CD4(+) cells, luminal fluid and cells) were collected 1, 8 and 15 days postdose. Samples were analyzed for TFV and TFV-DP. Plasma TFV demonstrated triphasic decay with terminal elimination half-life median interquartile range (IQR) 69 h (58-77). Peripheral blood mononuclear cell (PBMC) TFV-DP demonstrated biphasic peaks (median 12 h and 96 h) followed by a terminal 48 h (38-76) half-life; Cmax was 20 fmol/million cells (2-63). One day postdose, the TFV-DP paired colon:vaginal tissue concentration ratio was 1 or greater in all subjects' tissue homogenates, median 124 (range 1-281), but was not sustained. The ratio was lower and more variable in cells extracted from tissue. Among all sample types, TFV and TFV-DP half-life ranged from 23 to 139 h. PBMC TFV-DP rose slowly in the hours after dosing indicating that success with exposure-driven dosing regimens may be sensitive to timing of the dose prior to exposure. Colonic tissue homogenate TFV-DP concentrations were greater than in vaginal homogenate at 24 h, but not in cells extracted from tissue. These and the other pharmacokinetic findings will guide the interpretation and design of future PrEP trials. Article	2013	Marcus, Julia L; Glidden, David V; Mayer, Kenneth H; Liu, Albert Y; Buchbinder, Susan P; Amico, K Rivet; McMahan, Vanessa; Kallas, Esper Georges; Montoya-Herrera, Orlando; Pilotto, Jose; Grant, Robert M	No evidence of sexual risk compensation in the iPrEx trial of daily oral HIV preexposure prophylaxis.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0081997	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3867330	OBJECTIVE: Preexposure prophylaxis (PrEP) with emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) reduced HIV acquisition in the iPrEx trial among men who have sex with men and transgender women. Self-reported sexual risk behavior decreased overall, but may be affected by reporting bias. We evaluated potential risk compensation using biomarkers of sexual risk behavior. DESIGN AND METHODS: Sexual practices were assessed at baseline and quarterly thereafter; perceived treatment assignment and PrEP efficacy beliefs were assessed at 12 weeks. Among participants with ≥1 follow-up behavioral assessment, sexual behavior, syphilis, and HIV infection were compared by perceived treatment assignment, actual treatment assignment, and perceived PrEP efficacy. RESULTS: Overall, acute HIV infection and syphilis decreased during follow-up. Compared with participants believing they were receiving placebo, participants believing they were receiving FTC/TDF reported more receptive anal intercourse partners prior to initiating drug (12.8 vs. 7.7, P = 0.04). Belief in receiving FTC/TDF was not associated with an increase in receptive anal intercourse with no condom (ncRAI) from baseline through follow-up (risk ratio RR 0.9, 95% confidence interval CI: 0.6-1.4; P = 0.75), nor with a decrease after stopping study drug (RR 0.8, 95% CI: 0.5-1.3; P = 0.46). In the placebo arm, there were trends toward lower HIV incidence among participants believing they were receiving FTC/TDF (incidence rate ratio IRR 0.8, 95% CI: 0.4-1.8; P = 0.26) and also believing it was highly effective (IRR 0.5, 95% CI: 0.1-1.7; P = 0.12). CONCLUSIONS: There was no evidence of sexual risk compensation in iPrEx. Participants believing they were receiving FTC/TDF had more partners prior to initiating drug, suggesting that risk behavior was not a consequence of PrEP use. Theses and Dissertations	2013	Marcus, Julia Lenore	Maximizing Effectiveness of HIV Preexposure Prophylaxis Among Men Who Have Sex with Men	-	-	-	-	NA	https://escholarship.org/content/qt71w4b6v8/qt71w4b6v8_noSplash_e5fe8a9a0925102344f1fb1b0b67f84e.pdf?t=mfyqw7	Despite decades of prevention and treatment efforts, human immunodeficiency virus (HIV) infection is a global pandemic, with HIV-acquired immunodeficiency syndrome (AIDS) among the leading causes of death for children and adults in developing countries. HIV/AIDS disproportionately affects men who have sex with men (MSM), including in the United States, where MSM account for over half of all new HIV infections. Existing HIV prevention tools have not been sufficient to curb the pandemic, and biomedical prevention strategies, such as circumcision and microbicides, had not been shown to be effective in preventing HIV infection in MSM until 2010, when the multi-national iPrEx study found that daily oral preexposure prophylaxis (PrEP) using antiretroviral therapy (emtricitabine/tenofovir, or FTC/TDF) prevented HIV infection among MSM and transgender women. Although the success of FTC/TDF PrEP in such trials has given new hope to the HIV prevention field, excitement has been tempered by concerns about low adherence to daily pill use among trial participants. Adherence, as measured by self-reported pill use, was high among participants in the iPrEx trial, but testing for evidence of the drug in participants' blood revealed much lower adherence than suggested by self-report. Low adherence to PrEP in the iPrEx trial and other studies of oral PrEP in development for MSM was detected in blood experienced a substantially greater reduction in HIV risk than was seen overall. The iPrEx results suggest that low adherence may be a barrier to successful implementation of PrEP as an HIV prevention strategy among MSM. Identification of effective strategies for supporting the consistent use of prophylactic medications could provide much-needed guidance in the development of interventions to support adherence to PrEP.In addition to concerns about adherence, there is a widespread concern that PrEP could result in an increase in sexual risk behaviors by lowering users' perception of their risk of acquiring HIV infection; such risk compensation could reduce or even negate the benefits of PrEP. Foundational to most models of health behavior is the hypothesis that perceived risk is a primary motivation for self-protective behavior. Risk compensation is based on this theory, when a new prevention strategy, such as PrEP, is introduced, risk compensation could be prevented by increasing individuals' perceptions of their risk. The act of taking PrEP on a daily basis could result in risk compensation, it could also provide a daily opportunity to contemplate and manage HIV risk, thus motivating condom use and other self-protective behaviors. Risk compensation could also occur in the form of increased sexual risk behaviors, such as unprotected sex with more partners, in response to perceived protection.In addition to preventing HIV infection, there is evidence that FTC/TDF PrEP may also be protective against infection with herpes simplex virus type 2 (HSV-2). HSV-2 is the primary cause of genital ulcer disease worldwide, and HSV-2 infection is known to increase the risk of sexual transmission and acquisition of HIV infection. In the CAPRISA 004 study, a topical 1% tenofovir gel used as PrEP against HIV infection also reduced the risk of HSV-2 acquisition by 51% in women. In the Partners PrEP study, oral FTC/TDF reduced HSV-2 acquisition by 15% among heterosexual couples. Protection against HSV-2 acquisition or expression could enhance the public health impact of PrEP, but it is unknown whether FTC/TDF has anti-herpetic properties in men who have sex with men. The effectiveness of FTC/TDF PrEP in protecting against HIV infection depends on individual-level behaviors, including adherence and sustained risk reduction, as well as its effect on other sexually transmitted infections (STI) that increase the risk of HIV acquisition. Chapter 1 of this dissertation describes a systematic review that aimed to identify interventions that have been used to support adherence to daily oral medications prescribed to healthy or asymptomatic individuals. This review found evidence of interventions that demonstrated short-term improvements in medication adherence across a variety of prevention settings, thus identifying potential strategies for adherence support among PrEP users. Chapter 2 describes an analysis of data from the randomized phase of the iPrEx study to determine whether sexual risk compensation occurred among trial participants who received active study drug. The analysis found that participants who received active drug were more likely to report condomless anal sex with male partners than those who received placebo, and that the drug was highly effective. Finally, Chapter 3 describes an analysis that used data from the randomized phase of iPrEx to measure the effect of FTC/TDF on HIV-2 acquisition and expression among men who have sex with men. Although there was no effect of FTC/TDF on HSV-2 acquisition, participants receiving the active drug had a lower prevalence of herpetic ulcers than participants receiving the placebo. Taken together, these papers contribute to the HIV prevention field by providing guidance on behavioral support strategies for daily oral PrEP and identifying anti-herpetic properties of FTC/TDF that could increase its effectiveness as a novel prevention tool.	men who have sex with men (MSM); human immunodeficiency virus (HIV); Epidemiologic; preexposure prophylaxis (PrEP)	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	Review
Article	2013	McDaid, LM; Aghaizu, A; Young, I; Mercey, D; Copas, A; Johnson, AM; Hart, G; Nardone, A	OPPORTUNITIES FOR HIV PREVENTION AMONG MEN WHO HAVE SEX WITH MEN IN THE UK: HIV TESTING AND WILLINGNESS TO USE PRE-EXPOSURE PROPHYLAXIS	-	-	-	-	-	https://www.researchgate.net/publication/273653890_3422_Opportunities_For_HIV_Prevention_Among_Men_Who_Have_Sex_with_Men_in_the_UK_HIV_Testing_and_Willingness_to_Use_Pre-Exposure_Prophylaxis	Background Men who have sex with men (MSM) remain most at risk of acquiring HIV in the UK. While biomedical prevention methods, such as Pre-Exposure Prophylaxis (PrEP), present new prevention opportunities, questions remain over their acceptability and fit with existing prevention strategies and HIV risk management, including regular HIV testing. Here, we investigate the HIV testing behaviours and willingness to use PrEP among MSM in the UK. Methods Data were collected from 1,117 participants recruited in sexual health clinics in London, Brighton and Manchester. Results 1,117/2216 of participants had an HIV test in the previous 12 months and 29.4% (642/2167) reported 4+ unused HIV tests in the last two years. 48.2% (437/907) reported that their most recent HIV test was a regular test or sexual health check. Among men at higher risk of HIV infection (reporting unprotected anal intercourse [UAI] with multiple, casual or unknown/discordant partners), 40.2% (343/854) reported regular testing. Half of all participants would be willing to take PrEP on a daily basis (52.3%, 1152/2200). In all three cities, willingness to take PrEP was associated with younger age and higher levels of sexual risk behaviour (UAI with multiple, casual or unknown/discordant partners in Edinburgh and Glasgow and UAI with casual partners in London), but with testing for HIV or other sexually transmitted infections (STIs) in the previous 12 months in Edinburgh and Glasgow only. Conclusion PrEP could provide a new method of biomedical HIV prevention for men at high risk of acquiring infection, and there is a willingness to engage with this among MSM in the UK. However, this would require a level of frequent HIV testing beyond that currently reported by men at high risk. The potentially complex relationship between sexual risk behaviour, HIV testing, and PrEP use requires further research. Article	2013	Mesquita, Pedro M M; Srinivasan, Priya; Johnson, Todd J; Rastogi, Rachna; Evans-Strickfaden, Tammy; Kay, Michael S; Buckheit, Karen W; Buckheit, Robert W; Smith, James M; Kaler, Patrick F; Herold, Betsy C	Novel preclinical models of topical PrEP pharmacodynamics provide rationale for combination of drugs with complementary properties.	Retrovirology	-	-	-	1742-4690	10.1186/1742-4690-10-113	BACKGROUND: The limited success of recent topical pre-exposure prophylaxis clinical trials highlights the need for more predictive models of drug efficacy that better simulate what may happen during sexual exposure. To address this gap, we developed complementary in vitro models to evaluate the ability of drugs to retain anti-HIV activity if cells were washed with seminal plasma (simulating what may happen following exposure to ejaculate), and to protect drug-naive T cells (representing newly recruited immune cells) co-cultured with explants that had been pretreated with drug. We focused on tenofovir disoproxil fumarate (TDF), the non-nucleoside reverse transcriptase inhibitors dapivirine (DPV) and IQP-0528, and the entry inhibitors maraviroc (MVC) and the D-peptide cholesterol-conjugated C34 analog, IQP-0831. Results: Short-term exposure of cervicovaginal explants to microbicide gels containing TDF, DPV, or IQP-0528 resulted in drug absorption and prolonged tissue retention of drug-associated antiviral activity. Tissue-associated activity was substantially reduced when explants were washed with seminal plasma before challenge. In contrast, several-fold higher concentrations of NNRTIs and entry inhibitors were needed to attain similar levels of HIV inhibition following a wash with seminal plasma. Conversely, the NNRTIs and PIE12, but not TDF or MVC, were effectively transferred from ex vivo treated explants and protected co-cultured T cells. Biopsies obtained from IQP-0528 vlag-treated macaques also protected co-cultured T cells with viral inhibition ranging from 42-72%. Antiviral activity correlated with the concentration of drug recovered. Combinations of TDF with IQP-0528 protected in both in vitro models. CONCLUSIONS: Together, these models suggest that intracellularly retained drugs such as TDF may protect resident immune cells following coitus but sustained delivery may be required to protect immune cells subsequently recruited into the genital tract. Sustained delivery may also be critical for NNRTIs, which are rapidly transported out of cells and could be lost following sexual intercourse. An ideal approach may be a combination of drugs with complementary bioavailability profiles formulated for sustained delivery. Article	2013	Mirjahi, Poiershur; Yahepin, Dilixiati; Zhong, Xiaoxi; Sun, Yong; Zhao, Ting; Zhao, Zhen; Abudusile, Zuyimuer; Zhou, Hongfang; Meng, Fanliang; Dai, Jianghong; Huang, Aidong	Awareness of and willingness to use oral pre-exposure prophylaxis for HIV prevention among HIV-serodiscordant heterosexual couples: a cross-sectional survey in Xinjiang, China.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0067392	OBJECTIVES: We aimed to investigate the awareness of and willingness to use oral pre-exposure prophylaxis (PrEP) for HIV prevention among HIV-negative partners in HIV-serodiscordant heterosexual couples in Xinjiang, China and determine factors that predict willingness to use oral PrEP. METHODS: Between November 2009 and December 2010, a cross-sectional survey was carried out among 351 HIV-negative partners in HIV-serodiscordant heterosexual couples from three cities in Xinjiang, China. Participants completed a self-administered questionnaire to assess their awareness of and willingness to use oral PrEP. Additionally, blood samples were collected to test for HIV infection. Univariate and multivariate logistic regression analyses were performed to identify predictors of willingness to use oral PrEP. RESULTS: Of 351 participants (2.9%) reported having heard of PrEP, and only two reported ever using PrEP. However, 297 (84.6%) reported that they were willing to use oral PrEP if it was proven to be both safe and effective. Results of multivariate analysis revealed the following independent predictors of willingness to use oral PrEP: monthly household income (adjusted odds ratio = 2.78, <1000 RMB vs. ≥3000 RMB), knowledge of condom effectiveness (AOR = 2.63, No vs. Yes), perceived susceptibility to HIV infection (AOR = 2.49, No vs. Yes), perceived severity of HIV infection (AOR = 6.156, not worrying about being discriminated against by others due to oral PrEP use (adjusted odds ratio = 9.63, No vs. Yes, 95% confidence interval: 3.78-23.58). CONCLUSIONS: Our results show a high prevalence and incidence of ASE in HIV-infected MSM despite immune restoration under cART. These data emphasize that HIV-positive MSM although receiving effective cART remain at high risk of and sequestrum intra-epithelial kidneys. Article	2013	Mimiaga, Alexandra M; Gandhum, Shanyce; Richardson, Barbra A; Goldstein, Vijeyanand; Chen, Beatrice A; Salois, Robert; Nakashima, Clemenza; Hendrix, Craig; Jeetmun, Jessica; Soto-Torres, Lydia; Patterson, Kevin; Gomez, Kathleen; Kothari, Hendrix, Craig W	Adherence and acceptability in MTN 001: a randomized cross-over trial of daily oral and topical tenofovir for HIV prevention in women.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-012-0333-8	We compared adherence to and acceptability of daily topical and oral formulations of tenofovir (TFV) used as pre-exposure prophylaxis (PrEP) for HIV prevention among women in South Africa, Uganda and the United States. 144 sexually active, HIV-uninfected women participated in a cross-over study of three regimens over 6 months: 1 gel, 2 gel, or 4 tenofovir 1 % vaginal gel, or 4 mg TFV oral tablet. Self-reported adherence, for all regimens was high (90 %), but more TFV-containing gel was used than oral tablets consistently. More women in the U.S. (72 %) than tablets over gel, while preferences for gel were highest in the African sites (42 % preferred gel and 40 % tablets). Findings indicate a role for oral and topical PrEP formulations and highlight the importance of investigating pharmacokinetics-based adherence assessment in future trials. Biomedical HIV prevention interventions should consider geographic and cultural experience with product formulations, partner involvement, and sexual health benefits their ultimately influence use.	anti-infective agents, HIV, patient compliance, sexual behavior, vaginal creams, foams and jellies, administration, oral, PrEP, microbicide	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	Quantitative
Article	2013	Molina, JM; Pintado, C; Gatey, C; Pomcarme, D; Charbonneau, P; Leze, B; Rozenbaum, W; Delmegerc, C	Challenges and opportunities for oral pre-exposure prophylaxis in the prevention of HIV infection: where are we in Europe?	BMC Medicine	-	-	-	1741-7015	10.1186/1741-7015-11-186	https://pubmed.ncbi.nlm.nih.gov/23972284/	Following US Food and Drugs Administration approval in July 2012 of daily oral tenofovir and emtricitabine for pre-exposure prophylaxis (PrEP) to prevent HIV infection in high-risk individuals in the USA, there has been much controversy about the implementation of this PrEP regimen in other countries throughout the world, and in Europe in particular. In this review, we focus on the challenges and opportunities of a daily oral PrEP regimen to curb the rising incidence of HIV infection in high-risk groups, and particularly in men who have sex with men. A number of issues would need to be addressed before PrEP could be implemented, including assessing the real effectiveness and cost-effectiveness of daily PrEP, the sustainability of daily adherence, the risk of selecting resistance, the long-term safety, and the risk of change in sexual behavior that might offset the benefit of PrEP. Alternatives to a daily oral PrEP regimen are being explored. Article	2013	Magwarava, Kenneth K; Donnell, Deborah; Celum, Connie; Thomas, Katherine K; Ndase, Patrick; Mugo, Nelly; Katabira, Elly; Ngure, Kenneth; Baeten, Jared M	Sexual behaviour of heterosexual men and women receiving antiretroviral pre-exposure prophylaxis for HIV prevention: a longitudinal analysis.	The Lancet Infectious Diseases	-	-	-	1474-4457	10.1016/S1473-3099(13)70226-3	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3926564/	BACKGROUND: Scarce data are available to assess sexual behaviour of individuals using antiretroviral pre-exposure prophylaxis for HIV prevention. Increased sexual risk taking by individuals using effective HIV prevention strategies, like pre-exposure prophylaxis, could offset the benefits of HIV prevention. We studied whether the use of pre-exposure prophylaxis in HIV-uninfected men and women in HIV-serodiscordant couples was associated with increased sexual risk behaviour. METHODS: We undertook a longitudinal analysis of data from the Partners PrEP Study, a double-blind, randomised, placebo-controlled trial of daily oral tenofovir disoproxil fumarate (TDF) or a combination of TDF and emtricitabine (FTC) for pre-exposure prophylaxis. Between July, 2007, and November, 2009, 4747 HIV-1 serodiscordant couples were enrolled at seven African sites and followed until unblinding was completed in July, 2011, and participants continued monthly follow-up thereafter. We used regression analyses to compare the frequency of unprotected sex in a calendar month by 3 years during the 12 months before July 2011, compared with the 12 months before July 2011, to assess whether knowledge of pre-exposure prophylaxis efficacy for HIV prevention caused increased sexual risk behaviour. RESULTS: We analysed 566312 person-months from 3924 HIV-uninfected individuals (64% male). The average frequency of unprotected sex with the HIV-infected study partner was 59 per 100 person-months before unblinding versus 53 after unmasking: we recorded no immediate change (p=0·66) or change over time (p=0·25) after July, 2011. We identified a significant increase in unprotected sex with outside partners after July, 2011, but the effect was small (average of 0·8 unprotected sex acts per year vs 0·2 acts in a predicted counterfactual scenario had patients remained masked, p=0·04). Compared with before July, 2011, we noted no significant increase in incident sexually transmitted infections or pregnancy after July, 2011. INTERPRETATION: Pre-exposure prophylaxis, provided as part of a comprehensive prevention package, might not result in substantial changes in risk-taking sexual behaviour by heterosexual couples. FUNDING: The Bill & Melinda Gates Foundation and the US National Institute of Mental Health.	1021-1028	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2013	Marrazzo, James M; Celum, Connie; Mugo, Nelly; Campbell, James D; Donnell, Deborah; Bukusi, Elizabeth; Mujugira, Andrew; Tappero, Jordan; Kahle, Erin M; Thomas, Katherine K; Baeten, Jared M	Efficacy of preexposure prophylaxis for HIV-1 prevention among high-risk heterosexuals: subgroup analyses from a randomized trial.	AIDS	-	-	-	1473-5571	10.1097/QAD.0b013e32836296037	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3863016/	BACKGROUND: Daily oral antiretroviral preexposure prophylaxis (PrEP) is a promising strategy for prevention of HIV-1 acquisition. Three clinical trials demonstrated PrEP efficacy; however, two PrEP trials among women did not find protection against HIV-1. One hypothesis proposed for these divergent results is that PrEP efficacy may be reduced in populations with higher HIV-1 incidence. METHODS: We analyzed HIV-1 incidence and PrEP efficacy in subgroups of the Partners PrEP Study, including groups of women and men with high HIV-1 incidence. Participants were enrolled in Kenya, Uganda, and Tanzania, and we assessed PrEP efficacy among subgroups at higher risk for HIV-1 acquisition, including subgroups of women with high HIV-1 incidence. RESULTS: We analyzed 3,925 HIV-1 seronegative couples. HIV-1 incidence was 2.5 per 100 person-years. Among higher risk subgroups, placebo arm HIV-1 incidence ranged from 3.9 to 6.6 per 100 person-years. In all subgroups, PrEP was protective against HIV-1 acquisition, with efficacy point estimates more than 0.6 (or 60%). Among subgroups of women with placebo-arm HIV-1 incidence more than 5.0, efficacy estimates ranged from 64 to 68%. Monthly visit attendance for PrEP refills and tenofovir detection in plasma were high. CONCLUSION: Among higher-risk subgroups in the Partners PrEP Study, including groups solely of higher-risk women, both TDF alone and combined FTC/TDF PrEP had consistently high efficacy for HIV-1 protection. PrEP, when used with high adherence, is a highly effective prevention strategy for higher risk heterosexuals. Prioritizing PrEP for persons at high risk of HIV-1 will maximize its prevention impact. Article	2013	Mustanski, Brian; Johnson, Amy K; Garofalo, Robert; Ryan, Daniel; Birkett, Michelle	Perceived Likelihood of Using HIV Pre-exposure Prophylaxis Medications Among Young Men Who Have Sex with Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-012-0359-y	https://www.proquest.com/scholarly-journals/perceived-likelihood-using-hiv-pre-exposure/docview/1364682263/se-2?accountid=9113	Pre-exposure prophylaxis (PrEP) is a new strategy for reducing the risk of HIV infection; however, questions about the likelihood of use remain. As part of an ongoing longitudinal study of YMSM, interest in PrEP use under various conditions of side-effects, dosing, and effectiveness were assessed. Participants aged 16-20 living in Chicago and the surrounding areas were recruited beginning December 2009, using a modified form of respondent driven sampling. A cross-sectional sample of 171 HIV negative YMSM interviewed approximately 6 months after initial enrollment was analyzed. This sample was somewhat interested in adopting PrEP as an HIV prevention strategy, particularly if the dosing and side-effects burden was low and the perceived benefits were high. PrEP interest was unrelated with drug use and number of sexual partners, but negatively correlated with number of unprotected anal sex acts. The scale was positively associated with intentions for use in specific risk situations.PUBLICATION ABSTRACT	Humans; Male; Adolescent; Cross-Sectional Studies; Longitudinal Studies; Anti-HIV Agents; Health Knowledge, Attitudes, Practice; Sexual Partners; Young Adult; Pre-exposure prophylaxis; Psychology; Chicago; Psychometrics; Men, Gay; Sexual Behavior; Sexual Risk Behavior; Risk Behavior; Medicine; Sexual orientation; Human immunodeficiency virus--HIV; Anti-HIV Agents -- therapeutic use; HIV Infections -- prevention & control; Condoms -- utilization; Sexual Behavior -- psychology; Sexual Behavior -- statistics & numerical data; Unsafe Sex -- psychology; Unsafe Sex -- statistics & numerical data	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2013	Robertson, Angela M.; Syvertsen, Jennifer L.; Martinez, Gustavo; Rangel, M. Gudelia; Palinkas, Lawrence A.; Stockman, Jamila K.; Ulibarri, Monica D.; Strathdee, Steffanie A.	Acceptability of vaginal microbicides among female sex workers and their intimate male partners in two Mexico-US border cities: a mixed-methods analysis.	Global Public Health	-	-	-	1744-1706	1744-1692	10.1080/17441692.2012.762412	https://pubmed.ncbi.nlm.nih.gov/23398385/	Female sex workers (FSWs) may benefit from pre-exposure prophylaxis (PrEP) including microbicides for HIV prevention. Since adherence is key factor in PrEP efficacy, we explored microbicide acceptability and potential barriers to use within FSWs' intimate relationships in Tijuana and Ciudad Juárez, Mexico, where HIV prevalence is increasing. FSWs and their verified intimate (non-commercial) male partners completed quantitative and qualitative interviews from 2010 to 2012. Our complementary mixed methods design followed an iterative process to assess microbicide acceptability, explore related relationship dynamics and identify factors associated with concern about male partners' anger regarding microbicide use. Among 165 couples (n=330 individuals), interest in microbicides was high. In qualitative interviews with 26 couples, most participants were enthusiastic about microbicides for sex work contexts but some explained that microbicides could imply unmet/unfaithfulness within their intimate relationships. In the overall sample, nearly one in six participants (16%) worried that male partners would become angry about microbicides, which was associated with higher self-esteem among FSWs and lower self-esteem and past year conflicts among injury within relationships among men. HIV prevention interventions should consider intimate relationship dynamics posing potential barriers to PrEP acceptability and adherence, involve male partners and promote risk communication skills. Article	2013	Rohan, Lisa C.; Yang, Huitao; Wang, Lin	Rectal pre-exposure prophylaxis (PrEP).	Antiviral Research	-	-	-	1872-9096	0166-3542	10.1016/j.antiviral.2013.09.023	https://pubmed.ncbi.nlm.nih.gov/24180705/	Rectal pre-exposure prophylaxis (PrEP) will be a critical component of HIV prevention products due to the prevalence of unprotected receptive anal intercourse among men who have sex with men and heterosexual couples. Given the biological considerations of the rectal compartment and the complexity of HIV infection, design of a successful rectal microbicide product is a formidable challenge. An important information is being compiled to begin to address deficits in knowledge toward design of rectal PrEP products for men and women. Aspects of formulation development and preclinical and clinical evaluation, including pharmacokinetic and pharmacodynamic studies, will be discussed in this review. This review is based on a presentation at the "Product Development Workshop 2013: HIV and Multipurpose Prevention Technologies," held at Arlington, Virginia on February 21-22, 2013. It forms part of a special supplement to Antiviral Research. Article	2013	Romano, Joseph; Kashuba, Angela; Becker, Stephen; Cummins, James; Turpin, Jim; Veronese, Fulvio	Pharmacokinetics and pharmacodynamics in HIV prevention: current status and future directions: a summary of the DAIDS and IBMP sponsored think tank on pharmacokinetics (PK)/pharmacodynamics (PD) in HIV prevention.	AIDS Research and Human Retroviruses	-	-	-	2155-6113	10.4172/2155-6113.S4-007	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3850972/	Thirty years after its beginning, the HIV/AIDS epidemic is still raging around the world. According to UNAIDS, in 2011 alone 1.7M deaths were attributable to AIDS, and 2.5M people were newly infected by the virus. Despite the success in treating HIV-infected people with potent antiretroviral drugs, preventing HIV infection is the key to ending the epidemic. Recently, the efficacy of topical and systemic antiviral chemoprophylaxis (i.e., preexposure prophylaxis or "PrEP"), using the same drugs used for HIV treatment, has been demonstrated in a number of clinical trials. However, results from other trials have been disappointing, especially those evaluating male circumcision, the vaginal microbicide tenofovir gel, and the oral PrEP regimen of tenofovir disoproxil fumarate plus emtricitabine (TDF2). The inconsistencies may result from our incomplete understanding of pharmacokinetics (PK)/pharmacodynamics (PD) at the mucosal sites of sexual transmission: the male and female gastrointestinal and reproductive tracts. The drug concentrations used in these trials were derived from those used for treatment; however, we still do not know the relationship between the therapeutic and the preventive dose. This article presents the first comprehensive review of the available data in the HIV pharmacology field from animal models to human studies, and outlines gaps, challenges, and future directions. Addressing these pharmacological gaps and challenges will be critical in selecting and advancing future PrEP candidates and strategies with the greatest impact on the HIV epidemic. Article	2013	Rutherana, Anne; Wingood, Gina M.; Dunkle, Kristin; Camp, Christine; DiClemente, Ralph J.	Young adult women and correlates of potential adoption of pre-exposure prophylaxis (PrEP): results of a national survey.	Current HIV Research	-	-	-	1873-4251	1570-162X	10.2174/1570162x12666140129104952	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3859950/	We examine potential use of pre-exposure prophylaxis (PrEP) among young adult women, based on nationally representative random-digit dial telephone household survey of 1,453 US African-American and white women. The hypotheses were generated based on Health Belief Model. Our analyses showed that, as compared to women of 30-45 years old, young women of 20-29 years old experienced stronger social influences on PrEP uptake. However, as compared to older women, young women did not report higher potential PrEP uptake or adherence, despite their greater risk of HIV. For PrEP to be an effective method of prevention for young adult women, interventions are needed to increase HIV risk awareness. In fall 2011, NYC MSM were recruited via banner advertisements on six popular dating websites and asked questions about their knowledge and use of PrEP (n = 329). Overall, 125 (38 %) respondents reported knowledge of PrEP, of whom two (1.5 %) reported PrEP use in the past 6 months. Knowledge of PrEP was associated with high educational attainment, gay identity and recent HIV testing, suggesting an uneven dissemination of information about PrEP and missed opportunities for education. To avoid disparities in use during scale-up, MSM should be provided with additional information about PrEP.PUBLICATION ABSTRACT	Adult; Humans; Male; Adolescent; Anti-HIV Agents; Health Knowledge, Attitudes, Practice; Young Adult; Data Collection; Educational Status; Pre-exposure prophylaxis; Psychology; Men; Men who have sex with men; Knowledge; Preventive medicine; Survey; Human immunodeficiency virus--HIV; Gays & lesbians; Preventive healthcare; New York City New York; Anti-HIV Agents -- therapeutic use; HIV Infections -- prevention & control; Homosexuality, Male -- statistics & numerical data; Homosexuality, Male -- psychology; AIDS Serodiagnosis -- statistics & numerical data; Healthcare Disparities -- statistics & numerical data; New York City -- epidemiology	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

Article	2013	Savasi, V.; Mandia, L.; Laoreti, A.; Cetin, I.	Reproductive assistance in HIV serodiscordant couples.	Human Reproduction Update	-	-	-	-	1460-2369 1355-4786	10.1093/humupd/dms046	https://pubmed.ncbi.nlm.nih.gov/23146867/	BACKGROUND: Three quarters of individuals infected with human immunodeficiency virus (HIV) are in their reproductive years and may consider pregnancy planning. Techniques have been developed which can minimize the risk of HIV transmission in these couples, and the current literature on this topic is reviewed here. METHODS: We reviewed the literature for the following topics: risk of HIV transmission, effects of HIV infection on fertility, reproductive assistance in industrialized and low-income countries, pre-exposure chemoprophylaxis (PrEP) and timed intercourse in HIV-discordant couples for both male and female positivity. Relevant publications were identified through searches of the EMBASE Medline and PubMed databases, the Google-indexed scientific literature and periodic specialized magazines from the on-line Library Service of the University of Milan, Italy. RESULTS: In serodiscordant couples in which the man is positive, the primary method used to prevent HIV transmission is 'sperm washing', followed by IUI or IVF. Data show that sperm washing in HIV-positive men has not produced seroconversion in women or their offspring; however, the evidence is limited. Recently, increasing evidence describing PrEP for HIV prevention has been published and PrEP could be an alternative to ART for fertile couples. Usually HIV-infected women undergo self-insemination around the time of ovulation. Few studies have been published on IVF outcome in HIV-infected women. CONCLUSIONS: Assisted reproduction programmes should be integrated into global public health services against HIV. For HIV serodiscordant couples with infected men, sperm washing should be the first choice. However, timed intercourse and PrEP for HIV prevention has been reported. Recent data highlight the possible impairment of fertility in HIV-infected women. Efforts to design a multicentric study should be strengthened. Theses and Dissertations	2013	Schneider, Karen	Health economic evaluations of HIV prevention, treatment, and care	-	-	University of New South Wales	-	-	https://doi.org/10.26190/unsworks/16375	http://hdl.handle.net/1959.4/52925	The cost burden associated with providing effective treatment for people living with human immunodeficiency virus (HIV) and implementing appropriate prevention strategies to stop further spread of the virus has become a significant global challenge. In this thesis, four studies were conducted using mathematical modelling and economic evaluation methodology to better understand, prioritise, and optimise a number of HIV initiatives. First, a mathematical model was developed to evaluate the likely epidemiological impact of expanding prevention efforts in Thailand to include the provision of the partially efficacious HIV vaccine used in the RV144 trials. This study found that due to the short duration of protection the vaccine provides, limited epidemiological impact is expected from a single round of mass vaccination. However, significant public health benefit could be achieved from a high level of coverage, sustained implementation, and re-vaccination. The second study evaluated the cost-effectiveness of expanding HIV prevention efforts in Australia to include pre-exposure prophylaxis (PrEP) to men who have sex with men (MSM). Pre-exposure prophylaxis was not found to be cost-effective when targeting the general MSM population, however, this study illustrated that targeting MSM at higher risk of infection improved the cost-effectiveness of PrEP. The third study investigated the cost-effectiveness of expanding treatment management to include viral load (VL) monitoring and second-line antiretroviral therapy (ART) for HIV-infected children in Thailand. This study illustrated that VL monitoring and access to second-line ART has substantial clinical benefit. However, the costs associated with second-line therapies remain a barrier to its economic feasibility. The final study considers the attrition of standard of care second-line ART in low- and middle-income settings and the economic feasibility of introducing a new alternative second-line therapy, raltegravir (RAL). The introduction of RAL was considered to be cost-effective for upper-middle income countries, but not lower-income settings. The studies described in this thesis have aimed to provide insight to policymakers across different resource settings on whether a number of HIV initiatives are a cost-effective use of resources. Together, they show that we must be strategic in our use of resources to effectively combat HIV now and in to the future. Article	2013	Senn, H; Wilton, J; Sharma, M; Fowler, S; Tan, DHS	Knowledge of and Opinions on HIV Preexposure Prophylaxis Among Front-Line Service Providers at Canadian AIDS Service Organizations	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1089/aid.2013.0090	https://www.liebertpub.com/doi/abs/10.1089/aid.2013.0090?journalCode=aid	Oral daily tenofovir/emtricitabine (Truvada) is approved in the United States for HIV preexposure prophylaxis (PrEP) but has generated controversy in the media and within HIV-affected communities. We conducted an online survey about PrEP-related knowledge, experience, opinions, and learning needs, and received 160 responses from service providers at Canadian AIDS Service Organizations. Respondents were cautiously optimistic about PrEP and 48.8% believed that PrEP warranted Health Canada approval. In multivariable logistic regression, support for PrEP approval was associated with more years working in HIV (odds ratio = 1.89 per decade, 95% CI = 1.10, 3.25), low baseline familiarity with PrEP (OR = 3.24, 95% CI = 1.01, 14.41), and knowing someone who had used PrEP (OR = 4.39, 95% CI = 1.28,15.08). Participants major concerns about PrEP were similar to those highlighted in other publications, and some issues specific to certain target populations were raised. Several participants (26.2%) had been asked about PrEP in the past year and 10.6% knew of one or more Canadian who had used PrEP. Despite clients' interest, most participants thought that they (60.6%) or their organization (63.1%) did not have enough current knowledge about PrEP, highlighting the need for further education on this novel HIV prevention strategy. Article	2013	Serdar, Tihana; Derek, Lovorka; Unić, Adriana; Marijancević, Domagoj; Marković, Durda; Primorac, Ana; Petrovecki, Mladen	Occupational exposures in healthcare workers in University Hospital Dubrava--10 year follow-up study.	Central European journal of public health	-	-	-	1210-7778	10.21101/cejph.a3803	https://pubmed.ncbi.nlm.nih.gov/24344541/	Occupational hazardous exposure in healthcare workers is any contact with a material that carries the risk of acquiring an infection during their working activities. Among the most frequent viral occupational infections are those transmitted by blood such as hepatitis B virus (HBV), hepatitis C virus (HCV) and human immunodeficiency virus (HIV). Therefore, they represent a significant public health problem related to the majority of documented cases of professionally acquired infections. Reporting of occupational exposures in University Hospital Dubrava has been implemented in connection with the activity of the Committee for Hospital Infections since January 2002. During the period of occupational exposures' monitoring (from January 2002 to December 2011) 451 cases were reported. The majority of occupational exposures were reported by nurses and medical technicians (55.4%). The most common type of exposure was the needlestick injury (77.6%). 27.9% of the accidents occurred during the blood sampling and 23.5% during the surgical procedure. In 59.4% of the exposed workers aHBs-titer status was assessed as satisfactory. Positive serology with respect to HBV was confirmed in 1.6% of patients, HCV in 2.2% of patients and none for HIV. Cases of professionally acquired infections were not recorded in the registry. Consequences of the occupational exposure could include the development of professional infection, ban or inability to work further in health care services and last but not least a threat to healthcare workers life. It is therefore deemed necessary to prevent occupational exposure to blood-borne infections. The most important preventive action in respect to HBV, HCV and HIV infections is nonspecific pre-exposure prophylaxis. Article	2013	Shoptaw, S	HIV prevention for people who use substances: Evidence-based strategies	Journal of Food and Drug Analysis	-	-	-	1021-9498	10.1016/j.jfda.2013.09.042	https://www.sciencedirect.com/science/article/pii/S1021949813001063	Evidence-based strategies to guide human immunodeficiency virus (HIV) prevention for people who use substances can be grouped into approaches that lower infectiousness among substance users living with HIV and those that prevent HIV acquisition among those who are uninfected. Dramatic successes in HIV prevention involving access to antiretroviral therapy, opioid substitution therapies, and needle and syringe exchange programs have reduced both prevalence and incidence in the United States for people who use injection drugs, and modeling studies suggest that scale-up of these approaches will have a parallel impact worldwide. Medical HIV-prevention strategies that reduce infectiousness ("treatment as prevention" or early antiretroviral therapy initiation) and that block HIV acquisition (pre-exposure prophylaxis and post-exposure prophylaxis) can constitute key elements of novel combination HIV-prevention approaches to the goals of reducing infectiousness and reducing acquisition of HIV among people who use substances. For individuals who use substances but do not inject, drug dependence treatments as HIV prevention have a meager evidence base, with most consistent findings being reduction of sexual transmission behaviors that correspond with reductions in substance use, although not with prevention of HIV transmission itself. This approach may have value, however, when working with groups of substance users who face high rates of HIV prevalence and incidence. Some evidence exists to support HIV prevention interventions that target reduction of sexual risk behaviors in the setting of active stimulant use. Article	2013	Sibeko, Sengeziwe; Makvandi-Nejad, Shokouh	From the laboratory to clinical trials and back again: lessons learned from HIV prevention trials.	American Journal of Reproductive Immunology (New York, N.Y. : 1989)	-	-	-	1600-0897 1046-7408	10.1111/aji.12045	https://onlinelibrary.wiley.com/doi/full/10.1111/aji.12045	PROBLEM: Inadequate, irrelevant, or inappropriate timing of biological specimen collection during clinical trials is a cause for delay in understanding and explaining correlates of protection and/or effectiveness, particularly at the portal of entry in the context of sexual HIV transmission and its prevention. METHODS: We present examples of HIV prevention trials to illustrate the impact of preplanned versus unplanned laboratory science program on the interpretation of trial results and advancement of the field. RESULTS: Of the five completed pre-exposure prophylaxis trials, only two announced main outcome results simultaneously with data on correlates of drug-related effectiveness. In four of the vaccine trials completed, the only one that showed a protective effect presented data on protection correlates significantly later. CONCLUSION: Clinical trials must preplan collaborative immunophysiological research and prioritize biological specimen collection and storage for enhancement of research on correlates of protection. Similarly appropriate specimens should be prioritized for pathogenesis research. Article	2013	Smith, Dawn K; Dearing, James W; Sanchez, Travis; Goldschmidt, Ronald H	Introducing wicked issues for HIV pre-exposure prophylaxis implementation in the U.S.	American Journal of Preventive Medicine	-	-	-	1873-2607	10.1016/j.amepre.2012.09.057	https://dx.doi.org/10.1016/j.amepre.2012.09.057	Following U.S. Food and Drug Administration approval and the issuance of interim guidance documents for oral antiretroviral pre-exposure prophylaxis (PrEP) use in the U.S., there is urgent need to begin addressing the complex, multi-stakeholder, and rapidly evolving (i.e., "wicked") issues posed for the safe, effective, and appropriately targeted use of PrEP for prevention of the sexual acquisition of HIV infection. In this supplement1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18 to the American Journal of Preventive Medicine, a series of articles is presented from diverse research and implementation disciplines to explore key issues and identify conceptual frameworks, practice models, resources, and experiences to advance the discussion of how best to introduce, disseminate, and evaluate PrEP as a new component of HIV prevention services in the U.S.	NA	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2013	Spreen, WR; Margolis, DA; Pottage, JC	Long-acting injectable antiretrovirals for HIV treatment and prevention	Current Opinion in HIV and AIDS	-	-	-	1746-630X	10.1097/COH.0000000000000002	https://pubmed.ncbi.nlm.nih.gov/24100877/	Purpose of reviewLong-acting antiretroviral (ARV) drugs may improve adherence to therapy and extend opportunities for therapeutic or prophylactic intervention to underserved patient populations. This review focuses on recent advances in the development of small molecule long-acting injectable ARV agents.Recent findingsThe need for combination ART and physicochemical and dosing limitations of current ARV drugs impede attempts to redevelop them as long-acting injectable formulations. However, the intrinsic properties of rilpivirine, a nonnucleoside reverse transcriptase inhibitor, and GSK1265744, an HIV-1 integrase strand transfer inhibitor, have enabled crystalline nanoparticle formulations to progress to clinical trials.SummaryInvestigational long-acting injectable nanoformulations of rilpivirine and GSK1265744 are clinical-stage development candidates. Complementary pharmacologic properties of both agents - different mechanisms of action, resistance profiles, metabolic pathways, lack of drug interactions and low daily oral doses - offer the potential for combination use. Phase I studies of the pharmacokinetics and safety of each long-acting formulation alone and in combination indicate that a monthly dosing regimen is possible for HIV treatment. An ongoing phase IIb trial of oral GSK1265744 and oral rilpivirine is evaluating this two-drug regimen for maintenance of virologic suppression; results will inform future studies using the injectable formulations. Additional preclinical and clinical studies indicate a potential use of each agent for HIV pre-exposure prophylaxis. Article	2013	Strathdee, Steffanie A.; Wechsberg, Wendee M.; Kerrigan, Deanna L.; Patterson, Thomas L.	HIV Prevention Among Women in Low- and Middle-Income Countries: Intervening Upon Contexts of Heightened HIV Risk	Annual Review of Public Health	-	-	-	0163-7525	10.1146/annurev-publhealth-031912-114411	https://doi.org/10.1146/annurev-publhealth-031912-114411	Women's vulnerability to HIV infection is influenced by contextual factors in the risk environment that operate at multiple levels (i.e., physical, social, economic, policy). We present three case studies that illustrate combination approaches to HIV prevention among women who are at heightened risk for infection, especially sex workers, in low- and middle-income countries (LMICs). Lessons learned from these case studies are consistent with international literature promoting interventions that combine sexual risk reduction, condom promotion, and improved access to sexually transmitted infection (STI) treatment in the context of structural interventions, including policy change and empowerment of sex workers to reduce their vulnerability to HIV/STIs. We suggest avenues for future research and new intervention targets as well as a more nuanced approach to understanding the structural and social vulnerability of women to HIV infection in these settings. Article	2013	Sugarman, Jeremy; Mayer, Kenneth H	Ethics and pre-exposure prophylaxis for HIV infection.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0b013e3182987787	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3728665	There is increasing evidence that the use of antiretroviral agents (ARVs) can be a safe and effective means of preventing HIV infection. In fact, a combination of ARVs, tenofovir-emtricitabine, was recently approved by the US Food and Drug Administration (FDA) for use as "pre-exposure prophylaxis"(PrEP), and the US Centers for Disease Control and other regulatory authorities have issued guidance concerning PrEP use. Clinicians and policy makers are now faced with questions about the appropriateness of prescribing ARVs to healthy persons who are at risk of becoming infected with HIV, and those at risk of being infected must decide whether to use PrEP. In addition, researcher stakeholders must grapple with determining whether and how PrEP should be included in future HIV prevention research. In addressing such issues, it is important that their ethical dimensions are identified. When using PrEP, 2 broad ethical domains are of special relevance: well-being and justice. Ethical issues related to well-being include safety, parameters of use, risk behaviors, resistance, stigma, and diversion. Those related to justice include access and competing priorities. In research involving PrEP, ethical issues include determining the appropriate control arm and whether PrEP should be included as a part of the prevention package provided to all at risk participants. Although PrEP could play an important role in HIV prevention, understanding and addressing the related ethical issues is critical to its safe, effective, and appropriate use in practice and future research. Article	2013	Supervie, Virginie	Antiretroviral drugs-based HIV prevention methods: what impact on the HIV epidemic?.	Médecine Sciences : M/S	-	-	-	0767-0974	10.1051/medsci/2013294010	https://pubmed.ncbi.nlm.nih.gov/23621932/	Thirty years after the discovery of HIV, the epidemic continues to spread. Developing new HIV prevention methods to reduce the number of new HIV infections remains a priority. It has recently been shown that antiretroviral (ARV) drugs that have largely contributed to increase life expectancy of HIV-infected people may also have a direct impact on HIV transmission. Two new ART-based HIV prevention methods have proven effective in preventing HIV infection in controlled trials and observational studies: pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP). PrEP consists of ARV drugs to be taken by HIV-negative individuals before potential HIV exposure to reduce the risk of HIV infection, while TasP consists of ARV drugs to be taken by individuals living with HIV to lower the risk of HIV transmission to others. Although these two new prevention tools have proven to be effective at the individual level, their population-level impact remains unclear. Herein in addition to reviewing current PrEP and TasP data, we discuss the potential impact of these two new prevention strategies on the HIV epidemic. Article	2013	Taegtmeyer, Miriam; Davies, Alun; Mwangome, Mary; van der Elst, Elisabeth M.; Graham, Susan M.; Price, Matt A.; Sanders, Eduard J.	Challenges in providing counselling to MSM in highly stigmatized contexts: results of a qualitative study from Kenya.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0064527	https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0064527	The role of men who have sex with men (MSM) in the African HIV epidemic is gaining recognition yet capacity to address the HIV prevention needs of this group is limited. HIV testing and counselling is not only a critical entry point for biomedical HIV prevention interventions, such as pre-exposure prophylaxis, rectal microbicides and early treatment initiation, but is also an opportunity for focused risk reduction counselling that can support individuals living in difficult circumstances. For prevention efforts to succeed, however, MSM need to access services and they will only do so if these are non-judgmental, informative, focused on their needs, and of clear benefit. This study aimed to understand Kenyan providers' attitudes towards and experiences with counselling MSM in a research clinic targeting this group for HIV prevention. We used in-depth interviews to explore values, attitudes and cognitive and social constructs of 13 counsellors and 3 clinicians providing services to MSM at this clinic. Service providers felt that despite their growing experience, more targeted training would have been helpful to improve their effectiveness in MSM-specific risk reduction counselling. They wanted greater familiarity with MSM in Kenya to better understand the root causes of MSM risk-taking (e.g., poverty, sex work, substance abuse, misconceptions about transmission, stigma, and sexual desire) and felt frustrated at the perceived intractability of some of their clients' issues. In addition, they identified training needs on how to question men about specific risk behaviours, improved strategies for negotiating risk reduction with counselling clients, and improved support supervision from senior counsellors. This paper describes the themes arising from these interviews and makes practical recommendations on training and support supervision systems for nascent MSM HIV prevention programmes in Africa. Article	2013	Taha, Huda; Morgan, James; Das, Archik; Das, Satyajit	Parenteral patent drug S/GSK1265744 has the potential to be an effective agent in pre-exposure prophylaxis against HIV infection.	Recent Patents on Antiinfective Drug Discovery	-	-	-	2212-4071	10.2174/1574891x09666140417154727	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-24738551	The continuing HIV epidemic has driven advancements in antiretroviral therapy. New therapeutic targets have been identified over the past years, one of which has been the Integrase enzyme. This is responsible for integrating HIV pro-DNA into the host cell genome and has proved a successful drug target. Efforts have also been made to improve the pharmacokinetic parameters of current drug therapy and utilise these techniques in maximising drug therapeutic effect whilst minimising adverse events. An exciting example of new technologies is that of nanotechnology where drugs can be specifically targeted to certain tissues and drug delivery can be improved by utilising biological molecules and structures. Pre-exposure prophylaxis is also an area of much interest currently both on an individual and population level. Compliance is however a major issue with daily medication to prevent HIV acquisition as has been demonstrated with contraceptive agents. However if long acting compounds can be developed, compliance can be improved. The patent drug currently being developed through nanotechnology as an analogue of Dolutegravir, GSK1265744 LAP (Long Acting Parenteral) has shown promise as a Long Acting Integrase Inhibitor with potential action both as a therapeutic agent but also in pre-exposure prophylaxis. The favourable pharmacokinetic profile and therapeutic efficacy in comparison to other compounds of the same class demonstrate it to be a promising advance. However given current limitations in study material, further randomised studies with long term follow up are required to fully evaluate the value of the patent drug GSK1265744 LAP in action in both seropositive and seronegative individuals. Article	2013	Tangmunkongvorakul, Arunrat; Chariyalertsak, Suwat; Amico, K Rivet; Saokhieo, Pongpun; Wannalak, Vorawan; Sangangamsakun, Thirayut; Goicochea, Pedro; Grant, Robert	Facilitators and barriers to medication adherence in an HIV prevention study among men who have sex with men in the iPrEx study in Chiang Mai, Thailand.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2012.748871	https://dx.doi.org/10.1080/09540121.2012.748871	In 2008, the Pre-exposure Prophylaxis Initiative (iPrEx) study expanded to include men who have sex with men (MSM) in Chiang Mai, Thailand. In full, 114 participants from Chiang Mai joined this international double-blinded trial of daily FTC-TDF (Truvada®) or placebo as a pre-exposure prophylaxis (PrEP) HIV prevention strategy. To better understand the characteristics of iPrEx participants specifically from this underserved population in Thailand, and gain insights into their experiences of trying to take a daily tablet as part of this blinded PrEP trial, we conducted a qualitative study. In 2010, 32 MSM iPrEx participants provided in-depth interviews and an additional 14 joined focus group discussions. Results of the qualitative analyzes suggested that participants held generally positive attitudes toward the iPrEx study and study medication and related this to high rates of adherence to the daily regimen. Participants also reflected on the provision of quality health care as part of participation in the trial, as well as support from clinical research staff, family and friends as helpful in supporting high rates of study medication adherence. Discourse concerning challenges to adherence included medication taking behavior, which was contextualized by lifestyle, living arrangement, social life, social stigma in terms of being mistakenly identified as HIV positive or unintentional disclosure of sexual identity to family and friends, and relationship conflicts with partners. The results provide broader perspectives of participant experiences of the study medication and daily adherence in the larger contexts of the MSM community, close relationships, and the study climate, and can be leveraged in constructing PrEP adherence support approaches within these communities. Article	2013	Tellalian, David; Maznavi, Khalid; Bredeek, U Fritz; Hardy, W David	Pre-exposure prophylaxis (PrEP) for HIV infection: results of a survey of HIV healthcare providers evaluating their knowledge, attitudes, and prescribing practices.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2013.0173	https://dx.doi.org/10.1089/apc.2013.0173	Antiretroviral medications can be taken by HIV-negative persons to prevent HIV infection, also known as pre-exposure prophylaxis (PrEP). PrEP was first shown to be effective during the iPrEX study. We conducted a survey involving HIV healthcare providers to document their attitudes and prescribing practices about PrEP in response to this study. An online survey was completed by 189 members and credentialees of the American Academy of HIV Medicine between April 2011 and September 2011. Ninety percent of respondents were familiar with the results of the iPrEx study, and most (78%) were familiar with CDC's interim guidance regarding the use of PrEP in MSM. Only 19% of respondents had prescribed PrEP. The majority of PrEP prescribers were compliant with CDC interim guidance; however, only 61% screened for hepatitis B. Of PrEP prescribers, 78% prescribed to MSM, 31% to MSW, and 28% to WSM. Greatest concerns about prescribing PrEP included development of antiretroviral resistance (32%), potential increase in high-risk behavior, (22%) and poor medication adherence (21%). Fifty-eight percent stated that HIV serodiscordance within a relationship most influenced their decision to prescribe PrEP to the HIV-seronegative partner. This study demonstrates that, despite awareness of the efficacy of PrEP, its use is limited. Survey participants used PrEP most commonly in MSM; however, a significant percentage also prescribed PrEP to women. The best candidate for PrEP is felt to be individuals in an HIV-serodiscordant relationship. Limitations to our study included a low response rate, changes in the evidence base, and the novelty of PrEP. Article	2013	To, E; Bumpus, NN	Mucosal Expression of the Cytochromes P450 (CYP) and Nucleotide Kinases Involved in the Biotransformation of Drugs Used in Human Immunodeficiency Virus (HIV) Pre- exposure Prophylaxis (PrEP)	FASEB Journal	-	-	-	0892-6638	10.1096/fasebj.27.1_supplement.664.7	https://faseb.onlinelibrary.wiley.com/doi/abs/10.1096/fasebj.27.1_supplement.664.7	Attempts to prevent HIV infection through PrEP have included topical application of anti-HIV drugs to the mucosal sites of infection. However, clinical studies have revealed marked anatomic variability in drug exposure in vaginal tissue versus colorectal tissue. Thus, studies were performed to determine whether the CYPs and nucleotide kinases responsible for the metabolism and activation of drugs used in HIV PrEP were differentially expressed in human vaginal versus colonic tissue. Quantitative reverse transcriptase-PCR revealed that colonic mRNA expression of CYPs 1A1, 2B6, and 3A4/5 were 14-, 37- and 4-fold greater, respectively, than vaginal mRNA. Immunoblotting confirmed the presence of CYPs 3A4 and 3A5 protein in vagina. The vaginal mRNA abundance of adenylate kinase 2, the primary enzyme responsible for the activation of the HIV PrEP drug tenofovir, was 1.5-fold greater than in colonic tissue. Cytidine monophosphate kinase mRNAs were 8-fold greater in colonic tissue and phosphoglycerate kinase mRNAs were 4-fold greater in vaginal tissue. These kinases have been proposed to activate emtricitabine, which is also under development as a topical microbicide for HIV PrEP. These data indicate that enzymes that modulate exposure to anti-HIV drugs may be differentially expressed in mucosal tissues that are sites of topical drug application for PrEP. Funding: NIH U01 AI068613 (HIV Prevention Trials Network). Article	2013	To, Elaine E.; Hendrix, Craig W.; Bumpus, Namandjé N.	Dissimilarities in the metabolism of antiretroviral drugs used in HIV pre-exposure prophylaxis in colon and vagina tissues.	Biochem Pharmacol	-	-	-	1873-2968 0006-2952	10.1016/j.bcp.2013.08.013	https://pubmed.ncbi.nlm.nih.gov/23965226/	Attempts to prevent HIV infection through pre-exposure prophylaxis (PrEP) include topical application of anti-HIV drugs to the mucosal sites of infection; however, a potential role for local drug metabolizing enzymes in modulating the exposure of the mucosal tissues to these drugs has yet to be explored. Here we present the first report that enzymes belonging to the cytochrome P450 (CYP) and UDP-glucuronosyltransferase (UGT) families of drug metabolizing enzymes are expressed and active in vaginal and colorectal tissue using biopsies collected from healthy volunteers. In doing so, we discovered that dapivirine and maraviroc, a non-nucleoside reverse transcriptase inhibitor and an entry inhibitor currently in development as microbicides for HIV PrEP, are differentially metabolized in colorectal tissue and vaginal tissue. Taken together, these data should help to guide the optimization of small molecules being developed for HIV PrEP.	CYP; Colorectal; HIV drug metabolism; Vaginal. Essay	2013	Trent-Adams, Sylvia; Cheever, Laura W	Providing HIV pre-exposure prophylaxis: lessons learned from the Ryan White HIV/AIDS Program.	American Journal of Preventive Medicine	-	-	-	1873-2607	10.1016/j.amepre.2012.09.031	https://dx.doi.org/10.1016/j.amepre.2012.09.031	"Human immunodeficiency virus pre-exposure prophylaxis (PrEP) reduces HIV infection in clinical trials1 and offers promise as a new modality to decrease HIV transmission, particularly among individuals whose behaviors put them at high risk for HIV infection. The use of PrEP represents part of a continuum of applications of antiretroviral drug administration for HIV prevention: the use of antiretroviral drugs by HIV-infected individuals to suppress viral load, reducing transmission to others; PrEP; and post-exposure prophylaxis (PEP). Although PrEP reduces HIV transmission in clinical trial settings, important questions remain regarding how to implement this intervention in nonresearch settings and to bring it to scale in either primary care or public health settings so prevention benefits can be realized. In HIV care and treatment, studies have shown that efficacy of medication is lower in clinical settings than in clinical trials.2 Similar to the use of antiretroviral drugs in HIV treatment, PrEP requires (1) individuals identifying their risk and seeking services; (2) access to services; (3) adherence to therapy; and (4) retention in care. Given that the same populations will be the target for PrEP and for HIV care and treatment, many of the same barriers to care that exist for HIV care and treatment will likely exist for PrEP services. Thus, breaking down barriers to PrEP may have the added benefit of further facilitating access and use of antiretroviral drugs for treatment for the HIV-infected partner. The Ryan White HIV/AIDS Program (RWHAP) has 2 decades of experience in implementing HIV/AIDS care and treatment programs among disenfranchised and medically underserved populations. Over the past 20 years, several common characteristics for successful implementation have emerged. This article draws on the experiences of the RWHAP to help develop strategies to implement PrEP demonstration and pilot studies as first steps toward successful implementation of PrEP. The RWHAP is a federally funded program that provides HIV care, treatment, and support services to more than 500,000 HIV-infected and affected individuals in the U.S. With a current budget of approximately $2.3 billion, the program funds grants to states, cities heavily affected by HIV/AIDS, and community-based organizations providing critical HIV services. Grantees provide HIV care, treatment, and support services, such as case management and transportation to facilitate medically underserved populations' access and retention in care. In addition, the RWHAP has funded planning grants; capacity-building grants; and demonstration grants to pilot new models of care and services, assess their effectiveness, and promote replication. Successful implementation of these demonstration and implementation projects has common themes, including delivery system, community, and organizational factors (Table 1)." Article	2013	Tripathi, Avnish; Whiteside, Y Omar; Duffus, Wayne A	Perceptions and attitudes about preexposure prophylaxis among seronegative partners and the potential of sexual disinhibition.	Southern Medical Journal	-	-	-	1541-8243	10.1097/SMJ.0000000000000010	https://dx.doi.org/10.1097/SMJ.0000000000000010	OBJECTIVES: Preexposure prophylaxis (PrEP) is a promising strategy to prevent human immunodeficiency virus (HIV) infection, especially among high-risk individuals such as seronegative partners; however, many caveats such as the potential risk of sexual disinhibition and noncompliance need to be considered. We explored the sociodemographic and behavioral factors associated with the adoption of PrEP among HIV seronegative men who have sex with men and heterosexual partners. METHODS: A prepiloted self-administered survey was conducted among seronegative partners in a Ryan White HIV/AIDS Clinic in South Carolina from 2010 to 2011. Bivariate and multivariable analyses were used to explore the data. RESULTS: The survey was completed by 89 seronegative partners. The median age was 42 years (interquartile range 32-50) and a majority was men (56%), black (70%), and heterosexual (74%). A majority (94%) was willing to use PrEP if available; however, 26% of subjects suggested that they would be more likely to have unprotected sex with an HIV-positive partner while using PrEP, and 27% suggested that it would be difficult to take a daily dose of PrEP and consistently use condoms. The multivariable results suggest that the belief that a condom is no longer needed while taking PrEP was more likely among those who did not use a condom during their last sexual intercourse (adjusted odds ratio 7.45; 95% confidence interval 1.57-35.45) and among those with a higher HIV knowledge score (adjusted odds ratio 0.43; 95% confidence interval 0.23-0.78). CONCLUSIONS: Overall, these results suggest high acceptability of PrEP among seronegative partners to lower the risk of HIV transmission; however, there is a substantial risk of sexual disinhibition and noncompliance while using PrEP that may be reduced by ongoing education. Article	2013	van de Vijver, DAMC; Nichols, BE; Abbas, UL; Boucher, CAB; Cambiano, V; Eaton, JW; Glaubius, R; Lythgoe, K; Mellors, J; Phillips, A; Sigaloff, KC; Hallett, TB	Preexposure prophylaxis will have a limited impact on HIV-1 drug resistance in sub-Saharan Africa: a comparison of mathematical models	AIDS	-	-	-	0269-9370	10.1097/01.aids.0000433237.63560.20	https://pubmed.ncbi.nlm.nih.gov/23939237/	Background:Preexposure prophylaxis (PrEP) with tenofovir and emtricitabine can prevent new HIV-1 infections, but there is a concern that use of PrEP could increase HIV drug resistance resulting in loss of treatment options. We compared standardized outcomes from three independent mathematical models simulating the impact of PrEP on HIV transmission and drug resistance in sub-Saharan African countries.Methods:All models assume that people using PrEP receive an HIV test every 3-6 months. The models vary in structure and parameter choices for PrEP coverage, effectiveness of PrEP (at different adherence levels) and the rate with which HIV drug resistance emerges and is transmitted.Results:The models predict that the use of PrEP in conjunction with antiretroviral therapy will result in a lower prevalence of HIV than when only antiretroviral therapy is used. With or without PrEP, all models suggest that HIV drug resistance will increase over the next 20 years due to antiretroviral therapy. PrEP will increase the absolute prevalence of drug resistance in the total population by less than 0.5% and amongst infected individuals by at most 7%. Twenty years after the introduction of PrEP, the majority of drug-resistant infections is due to antiretroviral therapy (50-63% across models), whereas 40-50% will be due to transmission of drug resistance, and less than 4% to the use of PrEP.Conclusion:HIV drug resistance resulting from antiretroviral therapy is predicted to far exceed that resulting from PrEP. Concern over drug resistance should not be a reason to limit the use of PrEP. Article	2013	Van der Elst, Elisabeth Maria; Mbogua, Judie; Operario, Don; Mutua, Gaudensia; Kuo, Caroline; Mugo, Peter; Kanungi, Jennifer; Singh, Sagri; Haberer, Jessica; Priddy, Frances; Sanders, Eduard Joachim	High acceptability of HIV pre-exposure prophylaxis but challenges in adherence and use: qualitative insights from a phase I trial of intermittent and daily PrEP in at-risk populations in Kenya.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-012-0317-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3690654	This paper used qualitative methods to explore experiences of men who have sex with men and female sex workers in Nairobi and Mtwapa, Kenya, who used oral pre-exposure prophylaxis (PrEP) for HIV prevention as part of a four-month trial of safety, acceptability and adherence. Fifty-one of 72 volunteers who took part in a randomized, placebo-controlled, blinded trial that compared daily and intermittent dosage of PrEP underwent qualitative assessments after completing the trial. Analyses identified three themes: (i) acceptability of PrEP was high, i.e. side effects were experienced early in the study but diminished over time, however characteristics of pills could improve comfort and use; (ii) social impacts such as stigma, rumors, and relationship difficulties due to being perceived as HIV positive were prevalent; (iii) adherence was challenged by complexities of daily life, in particular post-coital dosing adherence suffered from alcohol use around time of sex, mobile populations, and transactional sex work. These themes resonated across dosing regimens and gender, and while most participants favored the intermittent dosing schedule, those in the intermittent group noted particular challenges in adhering to the post-coital dose. Culturally appropriate and consistent counseling addressing these issues may be critical for PrEP effectiveness. Article	2013	Verguet, Stéphane; Stalcup, Meg; Walsh, Julia A	Where to deploy pre-exposure prophylaxis (PrEP) in sub-Saharan Africa?	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2012-050891	https://dx.doi.org/10.1136/sextrans-2012-050891	OBJECTIVE: Two randomised controlled trials showed that pre-exposure prophylaxis (PrEP) reduces HIV transmission between heterosexual men and women. We model the potential impact on transmission and cost-effectiveness of providing PrEP in sub-Saharan Africa. METHODS: We use a deterministic, compartmental model of HIV transmission to evaluate the potential of a 5-year PrEP intervention targeting the adult population of 42 sub-Saharan African countries. We examine the incremental impact of adding PrEP at pre-existing levels of male circumcision and antiretroviral therapy (ART). The base case assumes efficacy of 68%; adherence at 80%; country coverage at 10% of the HIV-uninfected adult population; and annual costs of PrEP and ART at US$200 and US$880 per person, respectively. RESULTS: After 5 years, 390,000 HIV infections (95% UR 190,000 to 630,000) would be prevented, 24% of these in South Africa. HIV infections averted per 100 000 people (adult) would range from 500 in Lesotho to 10 in Somalia. Incremental cost-effectiveness would be US$5800/disability-adjusted life year (DALY) (95% UR 3100 to 13500). Cost-effectiveness would range from US$500/DALY in Lesotho to US$44 600/DALY in Eritrea. CONCLUSIONS: In a general adult population, PrEP is a high-cost intervention which will have maximum impact and be cost-effective only in countries that have high levels of HIV burden and low levels of male circumcision in the population. Hence, PrEP will likely be most effective in Southern Africa as a targeted intervention added to existing strategies to control the HIV pandemic. Essay	2013	Vermund, Sten H.; Hayes, Richard J.	Combination prevention: new hope for stopping the epidemic.	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-013-0155-y	https://pubmed.ncbi.nlm.nih.gov/23456730/	HIV research has identified approaches that can be combined to be more effective in transmission reduction than any 1 modality alone: delayed adolescent sexual debut, mutual monogamy or sexual partner reduction, correct and consistent condom use, pre-exposure prophylaxis with oral antiretroviral drugs or vaginal microbicides, voluntary medical male circumcision, antiretroviral therapy (ART) for prevention (including prevention of mother to child HIV transmission PMTCT), treatment of sexually transmitted infections, use of clean needles for all injections, blood screening prior to donation, a future HIV prime/boost vaccine, and the female condom. The extent to which evidence-based modalities can be combined to prevent substantial HIV transmission is largely unknown, but combination approaches that are truly implementable in field conditions are likely to be far more effective than single interventions alone. Analogous to PMTCT, "treatment as prevention" for adult-to-adult transmission reduction includes expanded HIV testing, linkage to care, antiretroviral coverage, retention in care, adherence to therapy, and management of key co-morbidities such as depression and substance use. With successful viral suppression, persons with HIV are far less infectious to others, as we see in the fields of sexually transmitted infection control and mycobacterial disease control (tuberculosis and leprosy). Combination approaches are complex, may involve high program costs, and require substantial global commitments. We present a rationale for such investments and cite an ongoing research agenda that seeks to determine how feasible and cost-effective a combination prevention approach would be in a variety of epidemic contexts, notably that in a sub-Saharan Africa. Article	2013	Walensky, Rochelle P.	Combination HIV prevention: the value and interpretation of mathematical models.	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-013-0167-7	https://pubmed.ncbi.nlm.nih.gov/23797377/	Mathematical models of HIV prevention interventions often provide critical insights related to programmatic design and economic efficiency. One recent dynamic model by Long et al. highlights that a combination prevention approach - with testing, treatment, circumcision, microbicides and PrEP - may decrease transmissions by over 60% and may be very cost-effective in South Africa. In this analysis, the authors introduce the critical concept of joint effectiveness of preventions programs and demonstrate how some programs operate synergistically (HIV screening coupled with early treatment) while others may create redundancies (microbicides coupled with pre-exposure prophylaxis). Whether combination HIV prevention programs perform with additive, multiplicative or maximal effectiveness will be important to consider in anticipation of their combined transmission impact. Article	2013	Wheelock, Ana; Eisingerich, Andreas B; Ananworanich, Jintanat; Gomez, Gabriela B; Hallett, Timothy B; Dybul, Mark R; Piot, Peter	Are Thai MSM willing to take PrEP for HIV prevention? An analysis of attitudes, preferences and acceptance.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0054288	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3544831	OBJECTIVE: We aimed to understand the attitudes, preferences and acceptance of oral and parenteral PrEP among men who have sex with men (MSM) in Thailand. BACKGROUND: Pre-exposure prophylaxis (PrEP), the use of antiretrovirals to prevent HIV acquisition, has shown promising results in recent trials. To assess the potential impact of this new HIV prevention method, in addition to efficacy data, we need to understand which psychosocial factors are likely to determine its uptake among members of potential user groups. METHODS AND FINDINGS: Surveys of willingness to use PrEP products were administered to MSM. Spearman's rank tests were used to uncover associations between questionnaire items. Mann-Whitney tests were performed to ascertain differences between groups. Conjoint analysis was used to examine the attitudes and preferences of MSM towards PrEP attributes. Most participants were willing to consider taking PrEP (39.2% "yes, definitely" and 49.2% "yes, probably") and perceived PrEP as giving them new possibilities in their lives (38.5% "a lot of hope" and 55.8% "some hope"), even after being instructed of potential side effects and costs. HIV testing was considered the most important attribute and a daily pill and longer lasting injection in the arm were the preferred routes of administration. CONCLUSIONS: Despite its multiple challenges, MSM in Thailand would be willing to take PrEP, even if they had to experience inconvenience and expense. If PrEP were to be implemented in Thailand, our findings show that its uptake could be considerable. Article	2013	Wingood, Gina M.; Dunkle, Kristin; Camp, Christina; Patel, Shilpa; Painter, Julia E.; Rubtsova, Anna; DiClemente, Ralph J.	Racial differences and correlates of potential adoption of preexposure prophylaxis: results of a national survey.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0b013e3182920126	https://pubmed.ncbi.nlm.nih.gov/23673895/	OBJECTIVE: To examine the association between sociodemographic factors, sexual behaviors, and social factors on potential uptake of preexposure prophylaxis (PrEP) among African American and White adult women in the United States. METHODS: Participants were recruited through a nationally representative, random-digit dial telephone household survey. Participants comprised a nationally representative, random sample of unmarried African American (N = 1042) and White women (N = 411) aged 20-44 years. Interviews were conducted using computer-assisted telephone interviewing technology. Bivariate and multivariate analyses examined the relationship between sociodemographics, sexual behaviors, and social influences on women's potential uptake of PrEP. RESULTS: In multivariate analyses, women with lower educational status, greater lifetime sexual partners, provider recommendations supportive of PrEP, and peer norms supportive of PrEP use were more likely to report potential PrEP uptake. Racial analyses revealed that compared with White women, African American women were significantly more likely to report potential use of PrEP adjusted odds ratio (aOR) = 1.76, P ≤ 0.001, more likely to report use of PrEP if recommended by a health-care provider (aOR = 1.65, P ≤ 0.001), less likely to report that they would be embarrassed to ask a health-care provider for PrEP (aOR = 0.59, P ≤ 0.05), and more likely to report use of PrEP if their female friends also used PrEP (aOR = 2.2, P ≤ 0.001). The potential cost for PrEP was identified as a barrier to adoption by both African American and White women. CONCLUSIONS: Findings suggest that women at increased risk for HIV, including those with less education and greater number of sexual partners, may be more likely to use PrEP, although cost may serve as a barrier. Institutional	2013	World Health Organization	Consolidated guidelines on the use of antiretroviral drugs for treating and preventing HIV infection: recommendations for a public health approach June 2013	-	-	-	-	978-92-4-154968-4	NA	https://www.who.int/publications/i/item/9789241549684	These consolidated guidelines provide guidance on the diagnosis of human immunodeficiency virus (HIV) infection, the care of people living with HIV and the use of antiretroviral (ARV) drugs for treating and preventing HIV infection. They are structured along the continuum of HIV testing, care and treatment. Behavioural, structural and biomedical interventions that do not involve the use of ARV drugs are not covered in these guidelines. The 2013 consolidation process combines and harmonizes recommendations from a range of WHO guidelines and other documents, including the 2010 guidelines on using antiretroviral therapy (ART) for HIV infection in adults and adolescents, in infants and children and for treating pregnant women living with HIV and preventing HIV infection in infants. Comprehensive guidance is now provided on using ARV drugs across age groups and populations of adults, pregnant and breastfeeding women, adolescents, children and key populations. The guidelines also aim to consolidate and update clinical, service delivery and programmatic guidance. The 2013 guidelines reflect important advances in HIV responses during the past three years. Since 2010, new technologies, including CD4 point-of-care testing and new service delivery approaches, allow HIV testing and treatment monitoring to be diversified and decentralized. Simple, safer, once-daily, single-pill ARV regimens that are suitable for use in most populations and age groups have become more affordable and more widely available in low- and middle-income countries. Countries are moving towards earlier initiation of triple-drug regimens and simplified programming for the prevention of mother-to-child transmission of HIV (PMTCT) that emphasizes the long-term health of pregnant women and mothers living with HIV and preventing HIV infection among their children. The broader HIV prevention benefits of ARV drugs are being recognized: in addition to improving health and prolonging lives, ART prevents the sexual transmission of HIV, while pre-exposure prophylaxis of HIV with ARV drugs expands HIV prevention options and post-exposure prophylaxis of HIV continues to play an important role in managing HIV exposure in certain populations and settings, including for those who have been sexually assaulted. Although countries are at different stages of ART coverage and implementing the 2010 WHO guidelines, there is a consistent global trend towards initiating HIV treatment earlier. Theses and Dissertations	2013	Wusumani, Sibongile.	Factors associated with HIV seroconversion during pregnancy in Manzini region, Swaziland in 2012.	-	-	University of KwaZulu-Natal	-	NA	NA	http://hdl.handle.net/10413/11082	Background: The HIV epidemic has greatly affected sub-Saharan Africa, with the highest prevalence in the world found in Swaziland. One in three pregnant women in Swaziland has HIV. One of the PMTCT strategies is primary prevention of HIV among women who are uninfected. Understanding the reasons why pregnant women continue to seroconvert is the key in meeting this strategy. Purpose: The purpose of this study is to determine the factors associated with seroconversion among pregnant women utilizing Raleigh Fitkin Memorial Hospital in 2012. Objectives: The objectives of this study are to: determine the proportion of HIV non-infected pregnant women who are retested for HIV during pregnancy; determine the gestational age at which pregnant women are retested for HIV; establish the proportion of women who were initially HIV non-infected and seroconverted during pregnancy; and establish the factors associated with seroconversion during pregnancy. Methods: An observational cross-sectional study design with both descriptive and analytic components was carried out at Raleigh Fitkin Memorial Hospital. Systematic sampling was used for the recruitment of 381 pregnant women who were initially HIV non-infected. An interviewer-administered questionnaire and chart review were used to collect demographic and clinical data. The data was analyzed using descriptive and analytic statistics. Results: The results of the study show that demographic factors such as age and educational level are associated with HIV seroconversion during pregnancy. The findings also highlight how partner factors play a role in HIV seroconversion. The results indicate that sexual behaviours 333of the pregnant women contribute greatly to HIV seroconversion. Conclusion: Pregnant women continue to engage in risky sexual behaviours during pregnancy and there is need to strengthen counseling on preventive measures throughout the antenatal care period. There is also need for programs to explore possibility of providing antiretroviral drugs for pre-exposure prophylaxis to all HIV negative women during pregnancy.	Public health. Theses and Dissertations	2013	Xiang, Weina	LIKELINESS TO USE PRE-EXPOSURE PROPHYLAXIS AND NON-OCCUPATIONAL POST-EXPOSURE PROPHYLAXIS AMONG HIV-NEGATIVE MEN WHO HAVE SEX WITH MEN IN THE UNITED STATES	-	-	Emory University	-	NA	NA	http://pid.emory.edu/ark:/25593/dwfzd	The HIV epidemic continues to expand among men who have sex with men (MSM) since HIV was first discovered in the 1980s. Young and racial/ethnic minority MSM have been found to be disproportionately affected in recent years. To further understand characteristics associated with likeliness to use Pre-Exposure Prophylaxis (PrEP) and Non-occupational Post-Exposure Prophylaxis (nPEP) among HIV-negative MSM, 396 MSM were recruited via a banner advertisement on Facebook from June 6 to June 20, 2012. Participants were shown a video either on PrEP or nPEP and then asked about likeliness to utilize it. Among 197 MSM who were presented a video on PrEP, 51% reported they were very likely or likely to use PrEP. For nPEP, the majority (79%) of 199 MSM shown a video on nPEP reported they were very likely or likely to use nPEP as a HIV prevention method. No factors were found to be significantly associated with the likelihood of using nPEP. In univariate analysis, not currently having a main partner (OR 1.96, 95% CI=1.08-3.55, p=0.03) and having unprotected anal intercourse with at least one casual partner in the past 12 months (OR 3.19, 95% CI=1.49-6.82, p=0.003) were significantly associated with likeliness to use PrEP as a HIV prevention method. In multivariate analysis, no significant association was found for PrEP. Men aged 30 and older (OR 0.21, 95% CI=0.06-0.80, p=0.02) and men who had never tested for HIV (OR 0.29, 95% CI=0.10-0.80, p=0.02) were not likely to utilize PrEP. Our results show that MSM are very likely or likely to utilize PrEP or nPEP once they are well-educated about those methods. Although factors significantly associated with increased likelihood of using PrEP and nPEP were not identified in multivariate analyses, MSM who learn about PrEP and PEP may be likely to use these HIV prevention interventions. Biomedical methods are suggested to be packaged with current prevention strategies targeting MSM. Article	2013	Yang, Daniel; Chariyalertsak, Chonlisa; Wongthanee, Antika; Kawichai, Surinda; Yotruean, Kriengkrai; Saokhieo, Pongpun; Guadamuz, Thomas; Suwanvanichkij, Voravit; Beyrer, Chris; Chariyalertsak, Suwat	Acceptability of pre-exposure prophylaxis among men who have sex with men and transgender women in Northern Thailand.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0076650	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3792988	BACKGROUND: Northern Thailand has a high burden HIV epidemic among MSM and TG. Oral pre-exposure prophylaxis (PrEP) with tenofovir-emtricitabine has demonstrated efficacy in preventing HIV among MSM and TG in Chiang Mai, Thailand. Determinants of PrEP acceptability are needed to gauge the potential uptake of this prevention strategy. METHODS: From January to February 2012, 238 MSM and TG participants, who self-reported as HIV-uninfected or of unknown status, completed a self-administered survey on hand-held computers. Participants were recruited by venue-day-time sampling and asked to rate their likelihood of using oral PrEP for HIV prevention with an efficacy of 50%. PrEP acceptability was defined as being "very likely" to use PrEP. Odds ratios and 95% CIs were calculated to identify correlates of acceptability. RESULTS: 131 MSM and 107 TG responded, with mean ages of 23.7 and 21.8, respectively. 24% of MSM engaged primarily in receptive anal sex vs. 74% of TG. 21% of MSM and 44% of TG reported regular medication use. Prior awareness of PrEP was high at 66% among both MSM and TG respondents. 41% of MSM and 37% of TG were "very likely" to use PrEP. Among MSM, factors associated with PrEP acceptability included a prior history of STIs (AOR 4.6; 95%CIs 1.7-12.6), previous HIV testing (AOR 2.4 95%CIs 1.1-5.3), regularly planned sex (AOR 2.8 95%CIs 1.1-7.2), and infrequent sex (AOR 2.9 95%CIs 1.3-6.3). Among TG, factors associated with acceptability included prior awareness of PrEP (AOR 3.3; 95%CIs 1.2-9.0) and having private insurance (AOR 5.0; 95%CIs 1.3-19.0). CONCLUSION: MSM and TG in Northern Thailand are distinct groups in terms of sexual behaviors, patterns of medication use, and correlates of PrEP acceptability. Efforts to maximize PrEP uptake should include expanded HIV testing services and the provision of financial subsidies to reduce the cost of PrEP. Article	2013	Yang, Xiao-yi; Jiang, Jun-jun; Ye, Li; Tao, Ren-chuan; Cao, Cun-wei; Zou, Yun-feng; Wei, Suo-su; Zhong, Xiao-ni; Huang, Ai-long; Liang, Hao	Relationship between pre-exposure prophylaxis and HIV infection: a meta-analysis.	Zhonghua Yu Fang Yi Xue Za Zhi (Chinese Journal of Preventive Medicine)	-	-	-	0253-9624	NA	https://pubmed.ncbi.nlm.nih.gov/23719112/	OBJECTIVE: To evaluate the effect on pre-exposure prophylaxis (PrEP) to prevent HIV infection in high risk populations. METHODS: A computerized literature searching had been carried out in PubMed, EMbase, Ovid, Web of Science, Science Direct, Wanfang, Tsinghua Tongfang database and related websites to collect relevant papers (from establishment to June 2012) with the key words of pre-exposure prophylaxis, HIV, AIDS, high risk populations, relative risk, reduction. All randomized controlled trials (RCT) papers about using single or compound antiretroviral drugs (ARVs) orally or topically before HIV exposure or during HIV exposure in high risk populations were enrolled. Meta-analysis was conducted using Stata 10.0 to calculate the pooled RR value (95%CI). Consistency test was performed and publication bias was evaluated. RESULTS: Finally 5 RCT papers were enrolled, including 10 271 persons who were at high risk of HIV infection. The number of the experimental group was 5929, among which 116(1.96%) became infected. The number of the control group was 4342, among which 201(4.63%) became infected. Meta-analysis showed that the pooled relative risk (RR) and 95%CI was 0.49 (0.39 - 0.61), P < 0.05, indicating that the persons in experimental group had a 0.49 times lower risk of HIV infected, as compared with the control group. Publication bias analysis revealed a symmetry funnel plot. The fail-safe number was 825. CONCLUSION: PrEP was an effective and safe protection measure to reduce HIV infection in high risk populations. Article	2013	Ying, R; Celum, C; Baeten, J; Murnane, P; Hong, T; Krows, M; van Rooyen, H; Humphries, H; Hughes, JP; Barnabas, R	PRE-EXPOSURE PROPHYLAXIS (PREP) IS ESTIMATED TO BE A COST-EFFECTIVE ADDITION TO ANTIRETROVIRAL THERAPY (ART) FOR HIV PREVENTION IN A GENERALISED EPIDEMIC SETTING	Sexually Transmitted Infections	-	-	-	1368-4973	10.1136/sextrans-2013-051184.0683	https://sti.bmj.com/content/89/Suppl_1/A219.1	Abstract Background In KwaZulu-Natal, South Africa, young women face an extraordinarily high risk for HIV acquisition, with annual incidence estimates of 6%. ART-based strategies for HIV prevention have the potential to significantly decrease HIV incidence, but the impact of PrEP in addition to ART scale-up is undefined. Modeling studies suggest that PrEP targeted to highest-risk groups could maximise benefits and contain costs. Methods We developed a deterministic transmission model of HIV that stratifies the population by age, sexual activity, and includes HIV infection stage. The model was parameterized using data from community-based HIV counselling and testing studies in KwaZulu-Natal and validated using independent HIV prevalence and incidence estimates. We estimated the effectiveness and cost-effectiveness of a 'test and treat' scenario, targeted PrEP by age and sexual activity, and general PrEP provision. Each scenario was in addition to anticipated baseline ART scale-up for CD4≤ 350 from 35% in 2013, as observed in KwaZulu-Natal, to 60% in 2018 (following national guidelines). We assumed PrEP efficacy of 70%. Results 'Test and treat' (ART for 80% of all HIV-positive persons) reduced HIV incidence by 58% and averted 25% of cumulative infections by 2025, at an additional $39,900 per infection averted compared to baseline ART scale-up. PrEP targeted to 60% of 20–29-year-olds, in addition to baseline ART scale-up, reduced incidence by 42% and averted 22% of infections at an additional $22,500 per infection averted, whereas PrEP targeted to 80% of high-risk individuals reduced incidence by 33% and averted 13% of infections at an additional $7,400 per infection averted. PrEP coverage of 20% of the general population reduced incidence by 37% and incident infections by 18%, at an additional $26,900 per infection averted. Conclusion In a generalised HIV epidemic setting PrEP is a cost-effective addition to ART, with targeted PrEP being more cost-effective than generalised PrEP distribution. Article	2013	Young, Ingrid; Li, Jessica; McDaid, Lisa	Awareness and Willingness to Use HIV Pre-Exposure Prophylaxis amongst Gay and Bisexual Men in Scotland: Implications for Biomedical HIV Prevention	PLOS One	-	-	-	NA	10.1371/journal.pone.0064038	https://www.proquest.com/scholarly-journals/awareness-willingness-use-hiv-pre-exposure/docview/1352840712/se-2?accountid=8113	Objectives To investigate the awareness of, and willingness to use, HIV Pre-Exposure Prophylaxis (PrEP), and willingness to take part in a PrEP study among gay and bisexual men in Scotland. Methods Cross-sectional survey of 17 gay commercial venues in Glasgow and Edinburgh in May 2011 (N=1515, 65.2% response rate); 1393 are included in the analyses. Results Just under one-third of participants had heard of PrEP (n=434; 31.2%), with awareness associated with being aged older than 35 years, talking to UAI partners about HIV, and with having had an HIV or STI test in the previous 12 months. Around half were willing to take part in a PrEP study (n=695; 49.9%) or to take PrEP on a daily basis (n=756; 54.3%). In multivariate analysis, willingness to take PrEP was associated with lower levels of education, regular gay scene attendance, 'high-risk' unprotected anal intercourse (UAI) and testing for HIV or STI in the previous 12 months. Reasons for not wanting to participate in a PrEP study or take PrEP included perceptions of low personal risk of HIV and concerns with using medication as an HIV prevention method. Conclusions There is a willingness to engage in new forms of HIV prevention and research amongst a significant number of gay and bisexual men in Scotland. Future biomedical HIV interventions need to consider the links between sexual risk behaviour, testing, and potential PrEP use. Article	2013	Yuen, Winnie Wing-Yan; Wong, William Chi-Wai; Tang, Catherine So-Kum; Holroyd, Eleanor; Tiwari, Agnes Fung-Yee; Fong, Daniel Yee-Tak; Chin, Weng Yee	Evaluating the effectiveness of personal resilience and enrichment programme (PREP) for HIV prevention among female sex workers: a randomised controlled trial.	BMC Public Health	-	-	-	1471-2458	10.1186/1471-2458-13-683	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3733820	BACKGROUND: Female sex workers (FSWs) are often considered as the vector, if not reservoir, of HIV and other sexually transmitted infections. Building upon the existing evidence on the role of psychological health in sexual health, the aim of this protocol is to describe a trial investigating the effectiveness of the Personal Resilience and Enrichment Programme (PREP), a resilience-promoting intervention that targets at psychological well-being i.e. self-esteem, self-efficacy and coping, to facilitate adaptation and ultimately safe sexual practices among FSWs, which could be an innovative strategy in controlling the spread of these infections. METHODS: A total of 132 FSWs will be recruited and randomly assigned to either the intervention or usual care (control) groups in a multi-centred randomised controlled trial. Based on the resilience framework, this intervention is comprised of six weekly sessions focused on the acceptance, expression and management of emotions, identifying roles and personal strengths, and effective problem-solving skills. Complex intervention assessment on both intervention process and effectiveness will be adopted when the primary outcome reduction of sexual risk behaviour and other psychological outcomes include their perceived stress, self-esteem, self-efficacy, coping overall resilience, and psychological distress will be measured at baseline, post-treatment and 3-month post-intervention and differences assessed by ANOVA. The relationship of resilience factors, psychological health and HIV preventive behaviours will be evaluated using structural equation modelling. DISCUSSION: It is anticipated that this study will increase our understanding of the relationships between individual resilience attributes, positive adaptation, psychological health and sexual health practices. If successful, this programme will provide an innovative direction for HIV prevention by applying the personal resilience factors to promote both psychological wellbeing and safe sex for this high risk population. Article	2013	Zablotska, IB; Prestage, G; de Wit, J; Grulich, AE; Mao, LM; Holt, M	The Informal Use of Antiretrovirals for Preexposure Prophylaxis of HIV Infection Among Gay Men in Australia	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	10.1097/QAI.0b013e31827e854a	https://pubmed.ncbi.nlm.nih.gov/23187947/	Background: We aimed to describe the current use of antiretrovirals (ARVs) before unprotected anal intercourse (UAI) among Australian gay men, which may represent informal HIV preexposure prophylaxis (PrEP). Methods: Using data from Australian Gay Community Periodic Surveys conducted in 2011, we assessed the preventive use of ARVs before UAI and its association with sociodemographic characteristics, sexual practices, and drug use in the preceding 6 months. Associations were assessed using multivariate logistic regression analysis. Results: Of 3677 sexually active non-HIV-positive men, 2.5% reported taking ARVs before UAI. The likelihood of ARV use before UAI was significantly higher if any of the following behaviors were also reported: >1 sex partner; UAI with casual partners, irrespective of reporting UAI with regular partners adjusted odds ratio (AOR) = 2.36; 95% confidence interval (CI): 1.24 to 4.48 or not (AOR = 2.71; 95% CI: 1.44 to 5.07); injecting drugs at least monthly (AOR = 2.56; 95% CI: 1.03 to 6.36); using "party" drugs, occasionally (AOR = 2.23; 95% CI: 1.33 to 3.73) or regularly (AOR = 5.34; 95% CI: 2.99 to 9.56); and group sex while using party drugs, occasionally (AOR = 2.42; 95% CI: 1.29 to 4.53) or regularly (AOR = 5.31; 95% CI: 2.62 to 10.76). Among non-HIVpositive men in regular relationships with HIV-positive partners or partners of unknown HIV status, 1.7% and 4.7%, respectively, reported preventive ARV use before UAI. Conclusions: Our findings illustrate sporadic use of ARVs before UAI among gay men in Australia, which was associated with high-risk casual sex and party drug use. These initial data contribute to a much needed understanding of the informal use of ARVs for HIV prevention. Article	2013	Zhang, Yan; Peng, Bin; She, Ying; Liang, Hao; Peng, Hong-Bin; Qian, Han-Zhu; Vermund, Sten H.; Zhong, Xiao-Ni; Huang, Ailong	Attitudes toward HIV pre-exposure prophylaxis among men who have sex with men in western China.	AIDS Patient Care and STDs	-	-	-	1557-7449 1087-2914	10.1089/apc.2012.0412	https://pubmed.ncbi.nlm.nih.gov/23425017/	Pre-exposure prophylaxis (PrEP), as demonstrated in recently published clinical trials, is one promising approach for controlling the emerging epidemic among men who have sex with men (MSM). We evaluated the attitudes towards use of PrEP among MSM in western China. A total of 1402 participants completed a self-administered questionnaire. Overall, 22% of the participants reported that they had heard of PrEP, <1% had ever used medicine to prevent HIV, and 64% reported that they were absolutely willing to use PrEP if it were proven to be safe and effective. The predictors of willingness to use PrEP included lower education, moderate income compared with the lowest income, never or rarely finding sexual partners through the Internet in the past 6 months, sexually transmitted infection (STI) history, more knowledge of AIDS, worrying about HIV as a threat to themselves and their family, having previously heard of PrEP, and believing that PrEP was effective in preventing HIV. This study demonstrates that Chinese MSM have moderate awareness of PrEP and a high interest in using it. Article	2013	Zhao, Yuqin; Dimitrov, Dobromir T.; Liu, Hao; Kuang, Yang	Mathematical insights in evaluating state dependent effectiveness of HIV prevention interventions.	Bulletin of Mathematical Biology	-	-	-	1522-9602 0092-8240	10.1007/s11538-013-9824-7	https://pubmed.ncbi.nlm.nih.gov/23435680/	Mathematical models have been used to simulate HIV transmission and to study the use of preexposure prophylaxis (PrEP) for HIV prevention. Often a single intervention outcome over 10 years has been used to evaluate the effectiveness of PrEP interventions. However, different metrics express a wide variation over time and often disagree in their forecast on the success of the intervention. We develop a deterministic mathematical model of HIV transmission and use it to evaluate the public-health impact of oral PrEP interventions. We study PrEP effectiveness with respect to different evaluation methods and analyze its dynamics over time. We compare four traditional indicators, based on cumulative number or fractions of infections prevented, on reduction in HIV prevalence or incidence and propose two additional methods, which estimate the burden of the epidemic to the public-health system. We investigate the short and long term behavior of these indicators and the effects of key parameters on the expected benefits from PrEP use. Our findings suggest that public-health officials considering adopting PrEP in HIV prevention programs can make better informed decisions by employing a set of complementing quantitative metrics. Article	2013	Zidan, Ahmed S.; Spinks, Crystal B.; Habib, Muhammad J.; Khan, Mansoor A.	Formulation and transport properties of tenofovir loaded liposomes through Caco-2 cell model.	Journal of Liposome Research	-	-	-	1532-2394 0898-2104	10.3109/08982104.2013.810645	https://www.tandfonline.com/doi/full/10.3109/08982104.2013.810645	The aim was to investigate the potential of proliposomes to improve the permeability of tenofovir, anti-HIV, for oral delivery. Tenofovir was incorporated into phosphatidylcholine proliposomes and their absorption was determined in Caco-2 cell cultures grown on Transwell inserts using aqueous drug solutions as reference. Five batches of proliposomes were prepared with different stearylamine levels and characterized in terms of vesicular morphology, drug encapsulation efficiency (EEF), drug leakage, vesicular sizing and surface charges. Cytotoxicity of the reconstituted liposomes was evaluated by the MTT assay. The obtained results showed that increasing the incorporated percentage of stearylamine led to an increase in drug encapsulation, a slower drug leakage and larger liposomes formed. Compared to the drug solutions at corresponding concentrations, the proposed formulations showed a positive relationship (R^2= 0.9756) for the influence of increasing the stearylamine percentage on reduction of mitochondrial activity. Regarding the drug permeability, enhancements of apparent permeability by 16.5- and 5.2-folds were observed for proliposomes formulations with 5% and 15% stearylamine, respectively. A good correlation was observed between the Caco-2 and dialysis models that might indicate passive diffusion as well as paracellular transport as suggested mechanisms for drug absorption. Cationic proliposomes offered a potential formulation to improve the permeation of tenofovir. Article	2014	Akolo, M; Kimani, J; Gelmon, L	HIV Negative Partners in Sero-discordant Relationships Are a Forgotten Lot: Room for PrEP	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1089/aid.2014.5328.abstract	https://liebertpub.com/doi/epub/10.1089/aid.2014.5328.abstract	Background: University of Nairobi/University of Manitoba HIV/STI research team has been managing a mother to child HIV prevention clinic (MCH) targeting low risk population in Pumwani since 1988. In 2006, it opened up to all HIV infected individuals to improve access to the much needed ARVs services. Prevention with Positives (PwP) initiative was rolled out in 2008. Where service providers encourage index clients enrolled to disclose their status to sex partners and bring them for HIV testing. The efforts lead to the establishment of the sero-discordant couples' cohort. Methods: A longitudinal descriptive study has been carried out among sero-discordant couples since September 2008 up to December 2013. Questionnaires were used to collect baseline and resurvey information on demographics, condom use, risk taking behaviors etc from partner of the index clients. HIV rapid test are conducted every six months and their PrEP knowledge ascertained. Results: Out of 420 partners interviewed, baseline data showed; only 16% were using condoms correctly and consistently while 37% did not use them at all. 63% reported having other sex partners of which 23% reported more than 50 lifetime sex partners. Off the latter group, 45% reported to be married elsewhere but kept the index patient as a regular sex partner. At baseline 11% had knowledge of PrEP but only 2% were willing to use PrEP. However through behavioral change communication 60% are willing to take up PrEP with 88% reporting condom use. In the past year, 18% of these partners have been treated for an STI, no couples agreed to initiate treatment as prevention (TASP). Luckily, only 2% HIV sero conversions noted.Conclusions: HIV negative individuals in discordant relationships should be labeled key populations. They are highly sexually active with multiple sex partners. Access to PrEP should be mandatory to support ongoing HIV prevention strategies. Article	2014	Alista, Sabina	Pre-exposure Prophylaxis and Antiretroviral Therapy for HIV Prevention in South Africa which is the Best Use of Resources	South African Centre for Epidemiological Modelling and Analysis (SACEMA)	-	-	-	NA	NA	http://sacemaquarterly.com/wp-content/uploads/2014/06/Damian_Modelling-the-Use-of-Insecticide_article-3.pdf	An estimated 1.6 million new HIV infections occurred in 2012 in sub-Saharan Africa (1); highlighting the need for continued investments in HIV treatment and prevention efforts. With an HIV prevalence of about 18; South Africa (RSA) remains a particularly affected country; despite sustained investments in HIV control programs such as expansion of antiretroviral therapy (ART). In recent years; scientific innovations in HIV control have expanded the range of available interventions - male circumcision; topical microbicides; oral pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP) have all sparked significant interest due to their potential effectiveness (ART reduces HIV transmission by up to 96; PrEP by more than 60) and versatility (circumcision is effective without additional actions required from the person; PrEP is meant for use by uninfected individuals; ART is given to infected individuals). While all these options are potentially available; resources remain limited and choosing which interventions to implement at scale is a difficult task; given the complex nature of disease transmission; the impact of behaviour in epidemic dynamics (number of partners; rates of condom use; adherence to treatment/prevention regimens); and the different costs of these programs	NA	English	South Africa	Eastern and Southern Africa	United States	Western and Central Europe and North America	NA	NA	Quantitative
Article	2014	Alistar, Sabina S.; Grant, Philip M.; Bendavid, Eran	Comparative effectiveness and cost-effectiveness of antiretroviral therapy and pre-exposure prophylaxis for HIV prevention in South Africa.	BMC Medicine	-	-	-	1741-7015	10.1186/1741-7015-12-46	https://bmcmedicine.biomedcentral.com/articles/10.1186/1741-7015-12-46	BACKGROUND: Antiretroviral therapy (ART) and oral pre-exposure prophylaxis (PrEP) are effective in reducing HIV transmission in heterosexual adults. The epidemiologic impact and cost-effectiveness of combined prevention approaches in resource-limited settings remain unclear. METHODS: We develop a dynamic mathematical model of the HIV epidemic in South Africa's adult population. We assume ART reduces HIV transmission by 95% and PrEP by 60%. We model two ART strategies: scaling up access for those with CD4 counts ≤ 350 cells/μL (Guidelines) and for all identified HIV-infected individuals (Universal). PrEP strategies include use in the general population (General) and in high-risk individuals (Focused). We consider strategies where ART, PrEP, or both are scaled up to 100% of remaining eligible individuals yearly. We measure infections averted, quality-adjusted life-years (QALYs) gained and incremental cost-effectiveness ratios over 20 years. RESULTS: Scaling up ART to 50% of eligible individuals averts 1,513,000 infections over 20 years (Guidelines) and 3,591,000 infections (Universal). Universal ART is the most cost-effective strategy at any scale ($160-$220/QALY versus comparable scale Guidelines ART expansion). General PrEP is costly and provides limited benefits beyond ART scale-up ($7,680/QALY to add 100% PrEP to 50% Universal ART). Cost-effectiveness of General PrEP becomes less favorable when ART is widely given ($12,640/QALY gained when added to 100% Universal ART). If feasible, Focused PrEP is cost saving or highly cost effective versus status quo and when added to ART strategies. CONCLUSIONS: Expanded ART coverage to individuals in early disease stages may be more cost-effective than current guidelines. PrEP can be cost-saving if delivered to individuals at increased risk of infection. Article	2014	Alistar, SS; Owens, DK; Brandeau, ML	Effectiveness and Cost Effectiveness of Oral Pre-Exposure Prophylaxis in a Portfolio of Prevention Programs for Injection Drug Users in Mixed HIV Epidemics	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0086584	https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0086584	Background: Pre-exposure prophylaxis with oral antiretroviral treatment (oral PrEP) for HIV-uninfected injection drug users (IDUs) is potentially useful in controlling HIV epidemics with a significant injection drug use component. We estimated the effectiveness and cost effectiveness of strategies for using oral PrEP in various combinations with methadone maintenance treatment (MMT) and antiretroviral treatment (ART) in Ukraine, a representative case for mixed HIV epidemics. Methods and Findings: We developed a dynamic compartmental model of the HIV epidemic in a population of non-IDUs, IDUs who inject opiates, and IDUs in MMT, adding an oral PrEP program (tenofovir/emtricitabine, 49% susceptibility reduction) for uninfected IDUs. We analyzed intervention portfolios consisting of oral PrEP (25% or 50% of uninfected IDUs), MMT (25% of IDUs), and ART (80% of all eligible patients). We measured health care costs, quality-adjusted life years (QALYs), HIV prevalence, HIV infections averted, and incremental cost effectiveness. A combination of PrEP for 50% of IDUs and MMT lowered HIV prevalence the most in both IDUs and the general population. ART combined with MMT and PrEP (50% access) averted the most infections (14,267). For a PrEP cost of $950, the most cost-effective strategy was MMT, at $520/QALY gained versus no intervention. The next most cost-effective strategy consisted of MMT and ART, costing $1,000/QALY gained compared to MMT alone. Further adding PrEP (25% access) was also cost effective by World Health Organization standards, at $1,700/QALY gained. PrEP alone became as cost effective as MMT at a cost of $650, and cost saving at $370 or less. Conclusions: Oral PrEP for IDUs can be part of an effective and cost-effective strategy to control HIV in regions where injection drug use is a significant driver of the epidemic. Where budgets are limited, focusing on MMT and ART access should be the priority, unless PrEP has low cost. Article	2014	Al-tayyib, Alia A; Thrun, Mark W; Haukoos, Jason S; Walls, N Eugene	Knowledge of Pre-exposure Prophylaxis (PrEP) for HIV Prevention Among Men Who Have Sex with Men in Denver, Colorado	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-013-0553-6	https://www.proquest.com/scholarly-journals/knowledge-pre-exposure-prophylaxis-prep-hiv/docview/1511168005/se-2?accountid=8113	As part of the National HIV Behavioral Surveillance System among men who have sex with men (MSM) in Denver, Colorado, we assessed knowledge of pre-exposure prophylaxis (PrEP); willingness to use PrEP; and potential changes in risk behaviors among HIV-negative participants reporting sexual activity with a male partner in the preceding 12 months. We examined knowledge of PrEP before (2008) and after (2011) results of the iPrEx trial were available. Of the 425 participants in the 2008 sample, 91 (21 %) were aware of PrEP compared to 131 (28 %) of the 461 participants in the 2011 sample (adjusted prevalence ratio: 1.43, 95 % confidence interval: 1.18, 1.72). Despite the increase in 2011, few MSM in Denver were aware of PrEP. Educating high-risk MSM about the potential utility of PrEP as an adjunct to other effective prevention methods is needed when considering the addition of PrEP to the HIV prevention arsenal.PUBLICATION ABSTRACT	Pre-exposure prophylaxis; Psychology; Colorado; Men; Risk factors; Men who have sex with men; Knowledge; Sexual behavior; Disease prevention; Sexual orientation; Human immunodeficiency virus--HIV; Denver Colorado	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2014	Amico, K Rivet; Stirratt, Michael J	Adherence to preexposure prophylaxis: current, emerging, and anticipated bases of evidence.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/ciu266	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4060253	Despite considerable discussion and debate about adherence to preexposure prophylaxis (PrEP) for human immunodeficiency virus (HIV), scant data are available that characterize patterns of adherence to open-label PrEP. The current evidence base is instead dominated by research on adherence to placebo-controlled investigational drug by way of drug detection in active-arm participants of large randomized controlled trials (RCTs). Important differences between the context of blinded RCTs and open-label use suggest caution when generalizing from study product adherence to real-world PrEP use. Evidence specific to open-label PrEP adherence is presently sparse but will expand rapidly over the next few years as roll-out, demonstration projects, and more rigorous research collect and present findings. The current evidence bases established cannot yet predict uptake, adherence, or persistence with open-label effective PrEP. Emerging evidence suggests that some cohorts could execute better adherence in open-label use vs placebo-controlled research. Uptake of PrEP is presently slow in the United States; whether this changes as grassroots and community efforts increase awareness of PrEP as an effective HIV prevention option remains to be determined. As recommended by multiple guidelines for PrEP use, all current demonstration projects offer PrEP education and/or counseling. PrEP support approaches generally fall into community-based, technology, monitoring, and integrated sexual health promotion approaches. Developing and implementing research that moves beyond simple correlates of either study product use or open-label PrEP adherence toward more comprehensive models of sociobehavioral and socioecological adherence determinants would greatly accelerate progress. Intervention research is needed to identify effective models of support for open-label PrEP adherence.	study product adherence, PrEP adherence, social science, behavioral science	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Amico, K. Rivet; Marcus, Julia L.; McMahan, Vanessa; Liu, Albert; Koester, Kimberly A.; Goicochea, Pedro; Anderson, Peter L.; Glidden, David; Guanira, Juan; Grant, Robert	Study product adherence measurement in the iPrEx placebo-controlled trial: concordance with drug detection.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000000216	https://pubmed.ncbi.nlm.nih.gov/24853306/	OBJECTIVE: To evaluate the concordance between adherence estimated by self-report (in-person interview or computer-assisted self-interview), in-clinic pill counts, and pharmacy dispensation records and drug detection among participants in a placebo-controlled pre-exposure prophylaxis HIV prevention trial (iPrEx). DESIGN: Cross-sectional evaluation of 510 participants who had drug concentration data and matched adherence assessments from their week-24 study visit. METHODS: Self-reported adherence collected through (1) interview and (2) computer-assisted self-interview surveys, (3) adherence estimated by pill count, and (4) medication possession ratio was contrasted to having a detectable level of drug concentrations either tenofovir diphosphate (TFV-DP) or emtricitabine triphosphate (FTC-TP), as well as to having evidence of consistent dosing (tenofovir diphosphate ≥ 16 fmol/10⁶ cells), focusing on positive predictive values, overall and by research site. RESULTS: Overall, self-report and pharmacy records suggested high rates of product use (over 90% adherence); however, large discrepancies between these measures and drug detection were noted, which varied considerably between sites (positive predictive values from 34% to 62%). Measures of adherence performed generally well in the US sites but had poor accuracy in other research locations. Medication possession ratio outperformed other measures but still had relatively low discrimination. CONCLUSIONS: The sizable discrepancy between adherence measures and drug detection in certain regions highlights the potential contribution of factors that may have incentivized efforts to seem adherent. Understanding the processes driving adherence reporting in some settings, but not others, is essential for finding effective ways to increase accuracy in measurement of product use and may generalize to promotion efforts for open-label pre-exposure prophylaxis. Article	2014	Amico, KR	The key role of adherence for the effectiveness of antiretroviral-based prevention: state of the science and implications for the Asia-Pacific region	Sexual Health	-	-	-	1448-5028	10.1071/SH13104	https://pubmed.ncbi.nlm.nih.gov/24331438/	Remarkable advances have been made in the last few years in biomedical strategies to prevent onward transmission of HIV (treatment as prevention (TasP)) and prevent infection among at-risk populations through pre-exposure prophylaxis (PrEP). Numerous issues remain heavily debated, primarily concerning the feasibility of leveraging resources for both widespread access to antiretroviral therapy (ART) for those living with HIV and access to effective prevention antiretrovirals (ARVs) among those at risk for infection. Even with consistent and wide-spread access to ARVs, the behavioural pathway from ARV access to successful rapid and durable suppression or reaching levels of PrEP adherence that confer high rates of protection is increasingly well recognised. For either 'biobehavioural' strategy to have maximal individual and community benefit, individuals accessing them must actually use them. In this review, the unique and overlapping factors influencing adherence to ART and PrEP are identified, with an emphasis on the behavioural, social and structural facilitators and barriers to TasP and PrEP success. The implications of the current research base and evidence generated specifically within the Asia-Pacific region are discussed. Article	2014	Anderson, Peter L.; Glidden, David V.; Bushman, Lane R.; Heneine, Walid; García-Lerma, J. Gerardo	Tenofovir diphosphate concentrations and prophylactic effect in a macaque model of rectal simian HIV transmission.	The Journal of Antimicrobial Chemotherapy	-	-	-	1460-2091 0305-7453	10.1093/jac/dku162	https://pubmed.ncbi.nlm.nih.gov/24862094/	OBJECTIVES: This study evaluated the relationship between intracellular tenofovir diphosphate concentrations in peripheral blood mononuclear cells and prophylactic efficacy in a macaque model for HIV pre-exposure prophylaxis (PrEP). METHODS: Macaques were challenged with simian HIV (SHIV) via rectal inoculation once weekly for up to 14 weeks. A control group (n=34) received no drug, a second group (n=6) received oral tenofovir disoproxil fumarate/emtricitabine 3 days before each virus challenge and a third group (n=6) received the same dosing plus another dose 2 h after virus challenge. PBMCs were collected just before each weekly virus challenge. The relationship between tenofovir diphosphate in PBMCs and prophylactic efficacy was assessed with a Cox proportional hazards model. RESULTS: The percentages of animals infected in the control, one-dose and two-dose groups were 97, 83 and 17, respectively. The mean (SD) steady-state tenofovir diphosphate concentration (fmol/10(6) cells) was 15.8 (7.6) in the one-dose group and 30.7 (10.1) in the two-dose group. Each 5 fmol tenofovir diphosphate/10(6) cells was associated with a 40% (95% CI 17%-56%) reduction in risk of SHIV acquisition, P=0.002. The tenofovir diphosphate concentration associated with a 90% reduction in risk (EC90) was 22.6 fmol/10(6) cells (95% CI 13.8-60.8). CONCLUSIONS: The prophylactic EC90 for tenofovir diphosphate identified in macaques exposed rectally compares well with the EC90 previously identified in men who have sex with men (MSM; 16 fmol/10(6) cells, 95% CI 3-28). These results highlight the relevance of this model to inform human PrEP studies of oral tenofovir disoproxil fumarate/emtricitabine for MSM. Article	2014	Andrews, Chasity D.; Spreen, William R.; Mohri, Hiroshi; Moss, Lee; Ford, Susan; Gettie, Agegnehu; Russell-Lodrigue, Kasi; Bohm, Rudolf P.; Cheng-Mayer, Cecilia; Hong, Zhi; Markowitz, Martin; Ho, David D.	Long-acting integrase inhibitor protects macaques from intrarectal simian/human immunodeficiency virus.	Science	-	-	-	1095-9203 0036-8075	10.1126/science.1248707	https://pubmed.ncbi.nlm.nih.gov/24594934/	GSK1265744 (GSK744) is an integrase strand-transfer inhibitor that has been formulated as a long-acting (LA) injectable suitable for monthly to quarterly clinical administration. GSK744 LA was administered at two time points 4 weeks apart beginning 1 week before virus administration, and macaques were challenged weekly for 8 weeks. GSK744 LA, at plasma concentrations achievable with quarterly injections in humans, protected all animals against repeated low-dose challenges. In a second experiment, macaques were given GSK744 LA 1 week before virus administration and challenged repeatedly until infection occurred. Protection decreased over time and correlated with the plasma drug levels. With a quarterly dosing schedule in humans, our results suggest that GSK744 LA could potentially decrease adherence problems associated with daily preexposure prophylaxis (PrEP). Theses and Dissertations	2014	Atambo, Lydia K	Knowledge, attitude and uptake of antiretroviral therapy for HIV prevention among discordant couples: Pumwani maternity Hospital cohort	-	-	University of Nairobi	-	NA	NA	http://hdl.handle.net/11295/76714	Background: The consistent use of a combination of antiretroviral drugs referred to as Highly Active Antiretroviral Therapy (HAART) has been shown to reduce the viral load in body fluids especially in blood and genital secretions.This has great implications as the HIV virus is spread mainly through sexual contacts. In discordant couples where one partner is HIV seropositive, the HIV negative partner is constantly exposed through sex and hence at a high risk of HIV acquisition. However, early initiation of HAART on the HIV infected partner could be beneficial to the HIV negative individual in the discordant relationship. This could be achieved through the adoption of Treatment as prevention(TaSP), a strategy whose aim is to initiate use of antiretroviral drugs as early as possible regardless of the CD4+ count. This concept aims at treating the HIV positive partner at the point of diagnosis regardless of the disease stage. Objectives:The objective of this study was to assess the knowledge, attitudes and practices regarding the uptake of treatment as prevention in a cohort of discordant couples.The study seeked to examine the participants knowledge in terms of HIV transmission methods and HIV preventive measures. We also assessed the couples attitudes towards high risk behaviours, determined their sexual practices and finally the reasons for/ or against the use of antiretrovirals for HIV prevention. Methodology: This was a cross sectional study that focussed on the knowledge, attitudes and practices among the discordant couples enrolled at the Pumwani clinic, Nairobi. Standardized questionnaires were used to collect data from the Pumwani discordant couples cohort until the sample size for the study was reached. Focus group discussions were also utilized to gather qualitative information on use of HAART for treatment as prevention from randomly selected discordant couples. Collected data was then entered into a secured database, cleaned and then exported into SPSS Version 2.0 for analysis. Results: A total of 338 participants who were in a discordant relationship were enrolled into the study. Most of the participants, 320 (95.2%) knew about the availability of antiretroviral drugs while 16 (4.8%) had not heard of them . However, only 94(27.7%) could correctly name an antiretroviral drug. Majority of them, about 245(72.27%) could not name any drug. About 119 (40.9%) of them reported 350 CD4+ cells/ml as the best level to initiateantiretroviral treatment.. Most of the respondents 291(87.4%) reported antiretroviral drugs as being safe for use but 136(40.2%) of the participants noted that the drugs had intolerable side effects. Majority 289 (87%) of them affirmed that they would be able to use the drugs regularly and consistently. More than half of the respondents, 192(56.8%) had not heard of the treatment as prevention therapy while 178(54.4%) had not heard of the pre-exposure prophylaxis. Interestingly175 (53.2%) knew about Post Exposure Prophylaxis therapy. Majority of the respondents,…	NA	English	Kenya	Eastern and Southern Africa	Kenya	Eastern and Southern Africa	-	-	Quantitative
Article	2014	Baeten, Jared M; Donnell, Deborah; Mugo, Nelly R; Ndase, Patrick; Thomas, Katherine K; Campbell, James D; Wangisi, Jonathan; Tappero, Jordan W; Bukusi, Elizabeth A; Cohen, Craig R; Katabira, Elly; Ronald, Allan; Tumwesigye, Elioda; Were, Edwin; Fife, Kenneth H; Kiarie, James; Farquhar, Carey; John-Stewart, Grace; Kidoguchi, Lara; Coombs, Robert W; Hendrix, Craig; Marzinke, Mark A; Frenkel, Lisa; Haberer, Jessica E; Bangsberg, David; Celum, Connie	Single-agent tenofovir versus combination emtricitabine plus tenofovir for pre-exposure prophylaxis for HIV-1 acquisition: an update of data from a randomised, double-blind, phase 3 trial.	The Lancet Infectious Diseases	-	-	-	1474-4457	10.1016/S1473-3099(14)70937-5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4252589	BACKGROUND: Antiretroviral pre-exposure prophylaxis (PrEP), with daily oral tenofovir disoproxil fumarate or tenofovir disoproxil fumarate in combination with emtricitabine, has been shown to be efficacious for HIV-1 prevention. Although the use of more than one antiretroviral agent is essential for effective HIV-1 treatment, more than one agent might not be required for effective prophylaxis. We assessed the efficacy of single-agent tenofovir disoproxil fumarate relative to combination emtricitabine plus tenofovir disoproxil fumarate as PrEP. METHODS: We did a randomised, double-blind, placebo-controlled three-group phase 3 trial of daily oral tenofovir disoproxil fumarate and emtricitabine plus tenofovir disoproxil fumarate PrEP in HIV-1 uninfected individuals in heterosexual HIV-1 serodiscordant couples from Kenya and Uganda. After an interim review, the trial's placebo group was discontinued and thereafter the active groups were continued, and participants initially randomly assigned to placebo were offered rerandomisation in a 1:1 ratio to tenofovir disoproxil fumarate or emtricitabine plus tenofovir disoproxil fumarate as PrEP. The primary endpoints were HIV-1 seroconversion and safety. This trial is registered with ClinicalTrials.gov, number NCT00557245. FINDINGS: 4410 (99·6%) of 4427 couples received tenofovir disoproxil fumarate or emtricitabine plus tenofovir disoproxil fumarate and were followed up for HIV-1 acquisition. Of 52 incident HIV-1 infections, 31 occurred in individuals assigned tenofovir disoproxil fumarate (incidence 0·71 cases per 100 person-years) and 21 were in those assigned emtricitabine plus tenofovir disoproxil fumarate (0·48 cases per 100 person-years); HIV-1 incidence in the placebo group until discontinuation was two cases per 100 person-years. HIV-1 prevention efficacy with emtricitabine plus tenofovir disoproxil fumarate was not significantly different from that of tenofovir disoproxil fumarate alone (hazard ratio HR 0·67, 95% CI 0·39–1·17; p=0·16). Detection of tenofovir in plasma samples, compared with no detection and as measured in seroconverters and a subset of non-seroconverters, was associated with an 85% relative risk reduction in HIV-1 acquisition for the tenofovir disoproxil fumarate group (HR 0·15, 95% CI 0·06–0·37; p<0·0001) and 93% for the emtricitabine plus tenofovir disoproxil fumarate group (0·07, 0·02–0·23; p<0·0001). No significant differences were noted in the frequency of deaths, serious adverse events, or serum creatinine and phosphorus abnormalities between the two groups. INTERPRETATION: These results do not rule out the potential for a slight difference in HIV-1 protection with tenofovir disoproxil fumarate compared with emtricitabine plus tenofovir disoproxil fumarate, but show that once-daily oral tenofovir disoproxil fumarate or emtricitabine plus tenofovir disoproxil fumarate regimens both provide high protection against HIV-1 acquisition in heterosexual men and women. Article	2014	Bam, Rujuta A.; Birkus, Gabriel; Babusis, Darius; Cihlar, Tomas; Yant, Stephen R.	Metabolism and antiretroviral activity of tenofovir alafenamide in CD4+ T-cells and macrophages from demographically diverse donors.	Antiviral Therapy	-	-	-	2040-2058 1359-6535	10.3851/IMP2767	https://pubmed.ncbi.nlm.nih.gov/24625459/	BACKGROUND: Tenofovir alafenamide (TAF) is a novel investigational prodrug of tenofovir (TFV) that permits enhanced delivery of TFV into peripheral blood mononuclear cells (PBMCs) and lymphatic tissues. A critical step in the intracellular metabolic activation of TAF is mediated by the lysosomal protease cathepsin A (CatA). Here, we investigated CatA levels together with intracellular metabolism and antiretroviral activity of TAF in primary CD4+ T-lymphocytes (CD4s) and monocyte-derived macrophages (MDMs) isolated from a demographically diverse group of blood donors. METHODS: CD4s and MDMs were prepared from fresh PBMCs. CatA levels were quantified in cell extracts by monitoring TAF hydrolysis using HPLC. Intracellular TAF metabolites were quantified by HPLC combined with mass spectrometry. Antiviral activities in activated CD4s and MDMs were determined using HIV-1 single-cycle reporter and p24 antigen production assays, respectively. RESULTS: The levels of CatA and intracellular TAF metabolites differed minimally in CD4s and MDMs among 13 tested donors. TAF was >600-fold and 80-fold more potent than parent TFV in CD4s and MDMs, respectively, and its relative range of antiviral activity across all tested donors was comparable to that of other HIV-1 reverse transcriptase inhibitors, with mean ±sd (range) EC50 values of 11.0 ±3.4 (6.6-19.9) nM and 9.7 ±4.6 (2.5-15.7) nM in CD4s and MDMs, respectively. CONCLUSIONS: These results indicate consistent intracellular metabolism and antiretroviral potency of TAF in relevant target cells of HIV-1 infection across multiple donors of variable gender, age and ethnicity, supporting further clinical investigation of TAF. Article	2014	Bershteyn, A; Eckhoff, PA	Long-term Risk of HIV Drug Resistance after PrEP Breakthrough Infection: Implications from a Mathematical Model of the HIV Latent Reservoir	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1089/aid.2014.5337a.abstract	https://www.liebertpub.com/doi/10.1089/aid.2014.5337a.abstract	Background: Clinical trials of HIV pre-exposure prophylaxis (PrEP) have found little risk of HIV drug resistance after breakthrough infection, provided that the infection is detected and PrEP is discontinued in a timely manner. However, broad roll-out of PrEP in resource-limited settings cannot guarantee ideal monitoring for all patients. Also unknown is the transmissibility of PrEP-related drug resistance, which may differ from that of ART-related drug resistance due to transmitted founder virus dynamics. Methods: We developed a mathematical model that links PrEP adherence to the dynamic populations of drug-sensitive and drug-resistant virus, distinguishing between replicating virus and the long-lived latent reservoir. The model was parameterized for tenofovir-based oral PrEP with viral fitness and resistance pattern data for K65R. Novel model structures were explored to study transmitter founder virus dynamics. Results: The size and persistence of the modeled drug-resistant viral pool grew fastest during acute viremia, but continued to grow over the duration of undetected infection. After cessation of oral PrEP, the latent HIV reservoir harbored approximately double the proportion of K65R compared to the actively replicating pool. Host immunity, which influences viral load setpoint, modulated the proportion of K65R over an order of magnitude, as did patterns of adherence during PrEP use. Resistance acquired during early HIV infection could potentially elevate the transmissibility of resistance, which was seen when models assumed early establishment of a stable founder virus. Conclusions: The need for early detection of breakthrough infections during PrEP is expected to be highly heterogeneous, with the greatest need among patients with pre-existing immune impairment. Importance of adherence-driven pharmacokinetics implies that other PrEP methods, such as microbicides, may yield very different resistance patterns. More research is needed to understand transmissibility of drug resistance acquired during PrEP. Theses and Dissertations	2014	Brantley, Justin Taylor	Comparison of adherence to pre-exposure prophylaxis during blinded and open-label phases of a randomized trial	-	-	University of Washington	-	-	NA	http://hdl.handle.net/1773/26467	The Partners PrEP Study, a randomized trial of daily oral pre-exposure prophylaxis for HIV prevention, demonstrated efficacy at an interim analysis, prompting discontinuation of its placebo arm and early release of results. Active arm participants continued followup, and placebo arm participants optionally re-consented to additional followup on active drug. We compared PrEP adherence, by multiple measures, during the placebo-controlled and subsequent open-label phases of the study. Learning of PrEP efficacy led to a modest, although statistically significant, increase in adherence: the odds of refilling study medication at each monthly visit increased by 24% (p = 0.03), and the odds of detecting PrEP drug in plasma increased by 76% (p < 0.01), the latter returning to counterfactual levels within twelve months. Placebo arm participants who chose to continue followup on active drug were more likely to refill than those originally randomized to active drug (odds ratio, 1.32; p < 0.01). These results suggest that knowledge of PrEP efficacy had a small impact on PrEP adherence in a trial where adherence was already high. Article	2014	Brookmeyer, Ron; Boren, David; Baral, Stefan D.; Bekker, Linda-Gail; Phaswana-Mafuya, Nancy; Beyrer, Chris; Sullivan, Patrick S.	Combination HIV prevention among MSM in South Africa: results from agent-based modeling.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0112668	https://pubmed.ncbi.nlm.nih.gov/25398143/	HIV prevention trials have demonstrated the effectiveness of a number of behavioral and biomedical interventions. HIV prevention packages are combinations of interventions and offer potential to significantly increase the effectiveness of any single intervention. Estimates of the effectiveness of prevention packages are important for guiding the development of prevention strategies and for characterizing effect sizes before embarking on large scale trials. Unfortunately, most research to date has focused on testing single interventions rather than HIV prevention packages. Here we report the results from agent-based modeling of the effectiveness of HIV prevention packages for men who have sex with men (MSM) in South Africa. We consider packages consisting of four components: antiretroviral therapy for HIV infected persons with CD4 count <350; PrEP for high risk uninfected persons; behavioral interventions to reduce rates of unprotected anal intercourse (UAI); and campaigns to increase HIV testing. We considered 163 HIV prevention packages corresponding to different intensity levels of the four components. We performed 2252 simulation runs of our agent-based model to evaluate those packages. We found that a four component package consisting of a 15% reduction in the rate of UAI, 50% PrEP coverage of high risk uninfected persons, 50% reduction in persons who never test for HIV, and 50% ART coverage over and above persons already receiving ART at baseline, could prevent 33.9% of infections over 5 years (95% confidence interval, 31.5, 36.3). The package components with the largest incremental prevention effects were UAI reduction and PrEP coverage. The impact of increased HIV testing was magnified in the presence of PrEP. We find that HIV prevention packages that include both behavioral and biomedical components can in combination prevent significant numbers of infections with levels of coverage, acceptance and adherence that are potentially achievable among MSM in South Africa.	*Homosexuality, Male; Humans; Male; Anti-HIV Agents/*therapeutic use; HIV Infections/*prevention & control; South Africa; *Models, Biological; Pre-Exposure Prophylaxis/*methods; Combined Modality Therapy/methods; Genetic Testing/*methods; Safe Sex/*psychology	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2014	Brown, Jennifer L.; Sales, Jessica M.; DiClemente, Ralph J.	Combination HIV prevention interventions: the potential of integrated behavioral and biomedical approaches.	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-014-0228-6	https://pubmed.ncbi.nlm.nih.gov/25216985/	Combination HIV prevention interventions that integrate efficacious behavioral and biomedical strategies offer the potential to reduce new HIV infections. We overview the efficacy data for three biomedical HIV prevention approaches, namely microbicides, pre-exposure prophylaxis (PrEP), and HIV vaccination; review factors associated with differential acceptability and uptake of these methods; and suggest strategies to optimize the effectiveness and dissemination of combination HIV prevention approaches. A narrative review was conducted highlighting key efficacy data for microbicides, PrEP, and an HIV vaccination and summarizing acceptability data for each of the three biomedical HIV prevention approaches. Recommendations for the integration and dissemination of combined behavioral and biomedical HIV prevention approaches are provided. To date, microbicides and an HIV vaccination have demonstrated limited efficacy for the prevention of HIV. However, PrEP has demonstrated efficacy in reducing HIV incident infections. A diverse array of factors influences both hypothetical willingness and actual usage of each biomedical prevention method. Strategies to effectively integrate and evaluate combination HIV prevention interventions are urgently needed. Article	2014	Buchbinder, Susan P; Glidden, David V; Liu, Albert Y; McMahan, Vanessa; Guanira, Juan V; Mayer, Kenneth H; Goicochea, Pedro; Grant, Robert M	HIV pre-exposure prophylaxis in men who have sex with men and transgender women: a secondary analysis of a phase 3 randomised controlled efficacy trial.	The Lancet Infectious Diseases	-	-	-	1474-4457	10.1016/S1473-3099(14)70025-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4133171	BACKGROUND: For maximum effect pre-exposure prophylaxis should be targeted to the subpopulations that account for the largest proportion of infections (population-attributable fraction PAF) and for whom the number needed to treat (NNT) to prevent infection is lowest. We aimed to estimate the PAF and NNT of participants in the iPrEx (Pre-Exposure Prophylaxis Initiative) trial. METHODS: The iPrEx study was a randomised controlled efficacy trial of pre-exposure prophylaxis with coformulated tenofovir disoproxil fumarate and emtricitabine in 2499 men who have sex with men (MSM) and transgender women. Participants aged 18 years or older who were male at birth were enrolled from 11 trial sites in Brazil, Ecuador, Peru, South Africa, Thailand, and the USA. Participants were randomly assigned (1:1) to receive either a pill with active pre-exposure prophylaxis or placebo, taken daily. We calculated the association between demographic and risk behaviour during screening and subsequent seroconversion among placebo recipients using a Poisson model, and we calculated the PAF and NNT for risk behaviour subgroups. The iPrEx trial is registered with ClinicalTrials.gov, NCT00458393. FINDINGS: Patients were enrolled between July 10, 2007, and Dec 17, 2009, and were followed up until Nov 21, 2010. Of the 2499 MSM and transgender women in the iPrEx trial, 1251 were assigned to pre-exposure prophylaxis and 1248 to placebo. 83 of 1248 patients in the placebo group became infected with HIV during follow-up. Participants reporting receptive anal intercourse without a condom seroconverted significantly more often than those reporting no anal sex without a condom (adjusted hazard ratio AHR 5·11, 95% CI 1·55-16·79). The overall PAF for MSM and transgender women reporting receptive anal intercourse without a condom was 64% (prevalence 60%). Most of this risk came from receptive anal intercourse without a condom with partners with unknown serostatus (PAF 53%, prevalence 54%, AHR 4·76, 95% CI 1·44-15·71); by contrast, the PAF for receptive anal intercourse without a condom with an HIV-positive partner was 1% (prevalence 1%, AHR 7·11, 95% CI 0·70-72·75). The overall NNT per year for the cohort was 62 (95% CI 44-147). NNTs were lowest for MSM and transgender women self-reporting receptive anal intercourse without a condom (NNT 36), cocaine use (12), or a sexually transmitted infection (41). Having one partner and insertive anal sex without a condom had the highest NNTs (100 and 77, respectively). INTERPRETATION: Pre-exposure prophylaxis may be most effective at a population level if targeted toward MSM and transgender women who report receptive anal intercourse without a condom, even if they perceive their partners to be HIV negative. Substance use history and testing for STIs should also inform individual decisions to start pre-exposure prophylaxis. Consideration of the PAF and NNT can aid in discussion of the benefits and risks of pre-exposure prophylaxis with MSM and transgender women. Theses and Dissertations	2014	C.A. Hankins	HIV prevention policy and programme planning: What can mathematical modelling contribute?	-	-	Universiteit van Amsterdam	-	NA	NA	http://hdl.handle.net/11245/1.404873	This thesis explores the potential contribution of mathematical modelling to informed decision-making on policy and programme planning for novel HIV prevention tools. Its hypothesis is that, under certain conditions, modelling results can be a useful addition to the evidence and other factors that influence the HIV prevention policy and programme development process. The emerging HIV prevention tools that serve to illustrate this are voluntary medical male circumcision, systemic pre-exposure prophylaxis with antiretroviral drugs, HIV vaccines, and structural interventions for people who inject drugs. Comparing model structures and findings, including the results of sensitivity analyses, through consensus processes, systematic reviews, and other methodologies serves to strengthen the potential contribution that modelling can make to HIV prevention policy. Modelling will increasingly be useful to biomedical HIV prevention trial design, given the evolving standard of prevention being offered to all trial participants. Populating mathematical models with up-to-date, context-relevant, and accurate information will remain a key challenge, along with effective knowledge translation strategies. Engaging policy makers from the start can help ensure that modelling addresses relevant policy questions, is informed by the best available locally available information, and finds a receptive audience when results are presented. Modellers can play an important role by generating modelling results on questions of key importance that provide insights into the potential impact of competing HIV prevention scenarios in the context of constrained resources. In effect, they can paint pictures for policy makers of the paths that can lead to a future in which HIV transmission is increasingly rare. Article	2014	Caboral Stevens, Meriam; Aneke, Godfrey; Neplock, Andrew	Una revisión sobre la profilaxis pre-exposición (PrEP) para la prevención del VIH	Cultura del cuidado enfermería	-	-	-	1794-5232	NA	https://pesquisa.bvsalud.org/portal/resource/pt/lil-748718	Human Immunodeficiency Virus (HIV) epidemic continues to represent a major global health issue. Today, there are several tools available to prevent the spread of HIV infection. However, there are several constraints to the current prevention strategies including low condom use, low acceptance of testing, low awareness of vulnerability and more emphasis on treatment. Prevention strategy is redirected towards reducing acquisition of HIV. Pre-exposure prophylaxis or PrEP is the latest groundbreaking innovation in biomedical research in the prevention of HIV transmission. The purpose of this paper is to review preexposure prophylaxis for HIV prevention including the current guidelines in the use of PreP.	emtricitabine; preexposure prophylaxis; tenofovir disoproxil fumarate; VIH; profilaxis pre-exposicion; tenofovirdisoproxilfumarate	English	Colombia	Latin America and the Caribbean	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2014	Calabrese, Sarah K; Earnshaw, Valerie A; Underhill, Kristen; Hansen, Nathan B; Dovidio, John F	The impact of patient race on clinical decisions related to prescribing HIV pre-exposure prophylaxis (PrEP): assumptions about sexual risk compensation and implications for access	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-013-0675-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3983275	Antiretroviral pre-exposure prophylaxis (PrEP) has received increasing recognition as a viable prescription-based intervention for people at risk for HIV acquisition. However, little is known about racial biases affecting healthcare providers' willingness to prescribe PrEP. This investigation sought to explore medical students' stereotypes about sexual risk compensation among Black versus White men who have sex with men seeking PrEP, and the impact of such stereotypes on willingness to prescribe PrEP. An online survey presented participants (n = 102) with a clinical vignette of a PrEP-seeking, HIV-negative man with an HIV-positive male partner. Patient race was systematically manipulated. Participants reported predictions about patient sexual risk compensation, willingness to prescribe PrEP, and other clinical judgments. Bootstrapping analyses revealed that the Black patient was rated as more likely than the White patient to engage in increased unprotected sex if prescribed PrEP, which, in turn, was associated with reduced willingness to prescribe PrEP to the patient. Article	2014	Celum, Connie; Morrow, Rhoda A; Donnell, Deborah; Hong, Ting; Hendrix, Craig W; Thomas, Katherine K; Fife, Kenneth H; Nakku-Joloba, Edith; Mujugira, Andrew; Baeten, Jared M	Daily oral tenofovir and emtricitabine-tenofovir preexposure prophylaxis reduces herpes simplex virus type 2 acquisition among heterosexual HIV-1-uninfected men and women: a subgroup analysis of a randomized trial	Annals of Internal Medicine	-	-	-	1539-3704	10.7326/M13-2471	https://dx.doi.org/10.7326/M13-2471	BACKGROUND: Daily oral preexposure prophylaxis (PrEP) using the antiretroviral tenofovir disoproxil fumarate (TDF) alone or in combination with emtricitabine (FTC-TDF) reduces the risk for HIV-1 acquisition. Tenofovir has in vitro activity against herpes simplex virus type 2 (HSV-2). OBJECTIVE: To assess the efficacy of daily oral PrEP with tenofovir and FTC-TDF in the prevention of HSV-2 acquisition. DESIGN: Subgroup analysis of data from a randomized, placebo-controlled trial with concealed allocation. (ClinicalTrials.gov: NCT00557245). SETTING: Multiple sites in Kenya and Uganda. PARTICIPANTS: Heterosexual men and women who were seronegative for HIV-1 and HSV-2 and at high risk for HIV-1 acquisition due to having an HIV-1-infected partner. INTERVENTION: Once-daily oral tenofovir disoproxil fumarate (TDF), alone or combined with emtricitabine (FTC-TDF), compared with placebo. MEASUREMENTS: HSV-2 seroconversion. RESULTS: A total of 131 participants seroconverted to HSV-2 (79 of 1041 assigned to tenofovir or FTC-TDF PrEP HSV-2 incidence, 5.6 per 100 person-years and 52 of 481 assigned to placebo HSV-2 incidence, 7.7 per 100 person-years). The hazard ratio (HR) for HSV-2 acquisition with daily oral PrEP was 0.70 (95% CI, 0.49 to 0.99; P = 0.047) compared with placebo, and the absolute risk reduction was 2.1 per 100 person-years. Among the 1044 participants with HSV-2-infected partners, the HR for PrEP was 0.67 (CI, 0.46 to 0.98; P = 0.038) compared with placebo, and the absolute risk reduction was 3.1 per 100 person-years. LIMITATION: Randomization was not stratified by HSV-2 status, and diagnostic tests to exclude participants with acute HSV-2 at baseline are not available. CONCLUSION: Daily oral tenofovir-based PrEP significantly reduced the risk for HSV-2 acquisition among heterosexual men and women. Modest protection against HSV-2 is an added benefit of HIV-1 prevention with oral tenofovir-based PrEP. PRIMARY FUNDING SOURCE: Bill & Melinda Gates Foundation. Article	2014	Chandhiok, Nomita; Joshi, Smita N.; Gangakhedkar, Raman	Acceptability of oral and topical HIV chemoprophylaxis in India: implications for at-risk women and men who have sex with men.	Sexual Health	-	-	-	1448-5028	10.1071/SH13067	https://www.publish.csiro.au/SH/SH13067	With reducing HIV prevalence, India has made gains in containing the epidemic. Yet, unprotected sex and commercial sex work, unprotected anal sex between men and needle sharing among intravenous drug users continue to drive the epidemic. Development of effective, safe and acceptable topical (microbicides) and oral (pre-exposure prophylaxis (PrEP)) chemoprophylaxis could augment the already available tools for HIV prevention. This paper reviews the acceptability of topical microbicides and oral PrEP, in the context of the nature of the HIV epidemic, the sociocultural norms and the acceptability data obtained from studies carried out in India. Overall, men and women have a positive attitude towards the concept and use of microbicide products. Self-perceptions of HIV risk, product attributes, ease and convenience of use during sex, gender norms, the sociocultural context and the potential for undisclosed use were important factors influencing acceptability. A multipurpose product that would simultaneously address women's contraceptive and disease prevention needs would be devoid of the stigma attached to an anti-HIV product and may be more acceptable. Limited information on the acceptability of oral PrEP amongst high-risk groups merits further research, including carrying out demonstration projects for program introduction.	microbicides, pre-exposure prophylaxis, sex workers. Theses and Dissertations	2014	Chateau, Morgan	Prevention of HIV transmission	-	-	University of North Carolina	-	NA	NA	https://cdr.lib.unc.edu/record/uuid:bba56e9c-96ff-4e5f-a447-d65470421a93	The human immunodeficiency virus (HIV) infects and replicates within individuals for the duration of their life. Initial infection results in little to no symptoms for years or even decades. These individuals are infectious and capable of further spreading HIV while completely unaware of their own status. This ability to transmit without detection is what lead to the unknown and thereby unopposed global spread of HIV type one (HIV-1). Once a test was developed to detect HIV, the virus was found in nearly all major countries around the world. Development of a cure has proven to be exceedingly difficult. So far, the only successful tactic to reduce the number of infected HIV individuals has been to prevent HIV transmission. Traditionally, the most effective way to prevent viral transmission is with a vaccine, but an effective HIV vaccine for wide spread use has not been developed. Therefore, alternative HIV transmission prevention strategies have been used. These strategies largely depend on behavioral modifications and include: 1) utilization of universal precautions in medical settings, 2) increased emphasis on HIV testing and self awareness of infection status, 3) encouraged use of protective measures such as condoms and male circumcision, 4) prophylactic use of antiretroviral drugs to limit mother to child transmission MTCT, and 5) the newly available oral pre-exposure prophylactic use of Truvada in HIV negative individuals. Together, these strategies have contributed to nearly eliminating HIV transmission in medical settings and greatly reduced MTCT. Unfortunately, HIV continues to spread globally largely due to sexual transmission. While condom usage is highly efficient to prevent transmission, their use is limited by acceptability and consent. In this dissertation, I evaluated the potential of topically applied interventions to be a novel, effective form of protection against HIV transmission as well as established a novel line of investigation evaluating microbial contributions to HIV transmission. Using humanized mice as a model of HIV transmission, I evaluated two antiretroviral drug based topical pre-exposure prophylaxis (PrEP) for efficacy; tenofovir and maraviroc. In both instances, these drugs were found to be protective when used prior to HIV exposure. Concerns regarding the dual use of tenofovir for treatment as well as PrEP prompted me to evaluate transmission of a tenofovir resistant strain of HIV. This study demonstrated a surprisingly large defect in transmission for tenofovir resistant HIV, which suggests that use of Tenofovir for PrEP may not result in a significant increase of circulating tenofovir resistant strains of HIV. I also utilized the humanized mouse model to start a completely novel line of investigation evaluating the effect of microbial populations on HIV transmission. While these studies are ongoing, preliminary results have shown a clear effect of microbiome composition on rectal HIV transmission. These results are significant in two ways. First, this is the first evidence that…	School of Medicine; Department of Microbiology and Immunology	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Clinical
Article	2014	Chen, Anders; Dowdy, David W	Clinical effectiveness and cost-effectiveness of HIV pre-exposure prophylaxis in men who have sex with men: risk calculators for real-world decision-making.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0108742	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4186823	BACKGROUND: Oral pre-exposure prophylaxis (PrEP) can be clinically effective and cost-effective for HIV prevention in high-risk men who have sex with men (MSM). However, individual patients have different risk profiles, real-world populations vary, and no practical tools exist to guide clinical decisions or public health strategies. We introduce a practical model of HIV acquisition, including both a personalized risk calculator for clinical management and a cost-effectiveness calculator for population-level decisions. METHODS: We developed a decision-analytic model of PrEP for MSM. The primary clinical effectiveness and cost-effectiveness outcomes were the number needed to treat (NNT) to prevent one HIV infection, and the cost per quality-adjusted life-year (QALY) gained. We characterized patients according to risk factors including PrEP adherence, condom use, sexual frequency, background HIV prevalence and antiretroviral therapy use. RESULTS: With standard PrEP adherence and national epidemiologic parameters, the estimated NNT was 64 (95% uncertainty range: 26, 176) at a cost of $160,000 (cost saving, $740,000) per QALY--comparable to other published models. With high (35%) HIV prevalence, the NNT was 35 (21, 57), and cost per QALY was $27,000 (cost saving, $160,000), and with high PrEP adherence, the NNT was 30 (14, 69), and cost per QALY was $3,000 (cost saving, $200,000). In contrast, for monogamous, serodiscordant relationships with partner antiretroviral therapy use, the NNT was 90 (39, 157) and cost per QALY was $280,000 ($14,000, $670,000). CONCLUSIONS: PrEP results vary widely across individuals and populations. Risk calculators may aid in patient education, clinical decision-making, and cost-effectiveness evaluation.	1 A 9	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Chirwa, Lovemore I; Johnson, Jeffrey A; Niska, Richard W; Segolodi, Tebogo M; Henderson, Faith L; Rose, Charles E; Li, Jin-Fen; Thigpen, Michael C; Matlhaba, Onkabetse; Paxton, Lynn A; Brooks, John T	CD4(+) cell count, viral load, and drug resistance patterns among heterosexual breakthrough HIV infections in a study of oral preexposure prophylaxis.	AIDS	-	-	-	1473-5571	10.1097/QAD.0000000000000102	https://dx.doi.org/10.1097/QAD.0000000000000102	We examined CD4 cell count and plasma viral load patterns among Botswana TDF/FTC Oral HIV Prophylaxis Trial (TDF2 study) participants who seroconverted, comparing participants assigned to receive tenofovir/emtricitabine with participants assigned to receive placebo. We also evaluated for antiretroviral drug resistance among the breakthrough HIV infections. Among nine seroconverters assigned to tenofovir/emtricitabine and 24 to placebo, there were no significant differences in their CD4 cell count or viral load profiles over time. Of the four participants who seroconverted on-study while receiving tenofovir/emtricitabine, none became infected as a result of drug-resistant HIV; moreover, no resistance mutations emerged following seroconversion.	acesso restrito	English	United Kingdom	Western and Central Europe and North America	Botswana	Eastern and Southern Africa	United States	Western and Central Europe and North America	Clinical
Article	2014	Corneli, Amy L; Deese, Jennifer; Wang, Meng; Taylor, Doug; Ahmed, Khatija; Agot, Kawango; Lombaard, Johan; Manongi, Rachel; Kapiga, Saidi; Kashuba, Angela; Van Damme, Lut	FEM-PrEP: adherence patterns and factors associated with adherence to a daily oral study product for pre-exposure prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000158	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4059551	BACKGROUND: Several clinical trials have demonstrated the safety and effectiveness of oral tenofovir disoproxil fumarate (TDF), with or without emtricitabine (FTC), as pre-exposure prophylaxis (PrEP) for reducing the risk of HIV acquisition. Adherence to the study product was insufficient to demonstrate the effectiveness of FTC/TDF in 2 PrEP clinical trials conducted among women (FEM-PrEP and the Vaginal and Oral Interventions to Control the Epidemic study), but further analyses of adherence in these studies may inform PrEP demonstration projects and future HIV prevention clinical trials. METHODS: We randomly selected a subcohort of 150 participants randomized to FTC/TDF in 3 FEM-PrEP sites (Bondo, Kenya; Bloemfontein, South Africa; and Pretoria, South Africa) to examine adherence levels over time and to assess factors associated with adherence, based on plasma tenofovir and intracellular tenofovir diphosphate drug concentrations in specimens collected at 4-week visit intervals. RESULTS: We observed drug concentrations consistent with good adherence in 28.5% of all visit intervals when drug was available to use, but only 12% of participants achieved good adherence throughout their study participation. In multivariate analysis, the Bloemfontein site odds ratio (OR): 2.43; 95% confidence interval (CI): 1.32 to 4.48 and liking the pill color (OR: 2.93; 95% CI: 1.18 to 7.27) were positively associated with good adherence, whereas using oral contraceptive pills at enrollment was negatively associated with good adherence (OR: 0.37; 95% CI: 0.18 to 0.74). CONCLUSIONS: Most participants did not regularly adhere to the study product throughout their trial participation, although a small minority did. Few factors associated with good adherence to the study product were identified in FEM-PrEP.	pre-exposure prophylaxis, FEM-PrEP, adherence, women, Africa	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Corneli, Amy L; McKenna, Kevin; Headley, Jennifer; Ahmed, Khatija; Odhiambo, Jacob; Skhosana, Joseph; Wang, Meng; Agot, Kawango	A descriptive analysis of perceptions of HIV risk and worry about acquiring HIV among FEM-PrEP participants who seroconverted in Bondo, Kenya, and Pretoria, South Africa.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.17.3.19152	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4164016	INTRODUCTION: Risk perception is a core construct in many behaviour change theories in public health. Individuals who believe they are at risk of acquiring an illness may be more likely to engage in behaviours to reduce that risk; those who do not feel at risk may be unlikely to engage in risk reduction behaviours. Among participants who seroconverted in two FEM-PrEP sites - Bondo, Kenya, and Pretoria, South Africa - we explored perceived HIV risk and worry about acquiring HIV prior to HIV infection. METHODS: FEM-PrEP was a phase III clinical trial of once-daily, oral emtricitabine and tenofovir disoproxil fumarate for HIV prevention among women in sub-Saharan Africa. We asked all participants about their perceived HIV risk in the next four weeks, prior to HIV testing, during a quantitative face-to-face interview at enrolment and at quarterly follow-up visits. Among participants who seroconverted, we calculated the frequencies of their responses from the visit conducted closest to, but before, HIV acquisition. Also among women who seroconverted, we conducted qualitative, semi-structured interviews (SSIs) at weeks 1, 4 and 8 after participants' HIV diagnosis visit to retrospectively explore feelings of HIV worry. Applied thematic analysis was used to analyse the SSI data. RESULTS: Among participants who seroconverted in Bondo and Pretoria, 52% reported in the quantitative interview that they had no chance of acquiring HIV in the next four weeks. We identified four processes of risk rationalization from the SSI narratives. In "protective behaviour," participants described at least one risk reduction behaviour they used to reduce their HIV risk; these actions made them feel not vulnerable to HIV, and therefore they did not worry about acquiring the virus. In "protective reasoning," participants considered their HIV risk but rationalized, based on certain events or beliefs, that they were not vulnerable and therefore did not worry about getting HIV. In "recognition of vulnerability," participants described reasons for being worried about getting HIV but said no or limited action was taken to reduce their perceived vulnerability. Participants with "no rationalization or action" did not describe any HIV worry or did not engage in HIV risk reduction behaviours. CONCLUSIONS: Women who are at substantial risk of acquiring HIV may underestimate their actual risk. Yet, others who accurately understand their HIV risk may be unable to act on their concerns. Perceived HIV risk and risk rationalization are important concepts to explore in risk reduction counselling to increase the use of HIV prevention strategies among women at risk of HIV.	frica; FEM-PrEP; preocupação com o HIV; percepções de risco; soroconversão; mulheres. Article	2014	Corneli, Amy; Wang, Meng; Agot, Kawango; Ahmed, Khatija; Lombaard, Johan; Van Damme, Lut	Perception of HIV risk and adherence to a daily, investigational pill for HIV prevention in FEM-PrEP.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000362	https://dx.doi.org/10.1097/QAI.0000000000000362	BACKGROUND: FEM-PrEP was unable to demonstrate the effectiveness of oral emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) as pre-exposure prophylaxis for HIV prevention because of low adherence. We hypothesized that one reason for the poor adherence was low perceived HIV risk. METHODS: At enrollment and at quarterly follow-up visits, we assessed participants' perceived HIV risk for the subsequent 4 weeks. We used logistic regression to assess factors associated with some (small, moderate, or high) perceived HIV risk. We also used logistic regression with robust variance estimation to assess the association between risk perceptions (none versus some) reported at enrollment and at weeks 12, 24, and 36 and good adherence based on drug concentrations of plasma tenofovir and intracellular tenofovir diphosphate in specimens collected 4 weeks later (at weeks 4, 16, 28, and 40) among 150 randomly selected participants assigned FTC/TDF. RESULTS: Multiple factors were statistically associated with having some perceived HIV risk, including having sex without a condom, having multiple partners, and not knowing if a partner has HIV. We observed a significant association between having some risk perception and good adherence (odds ratio: 2.0; 95% confidence interval: 1.1 to 3.5; P = 0.016). CONCLUSIONS: Data suggest that participants are likely knowledgeable about factors that increase their HIV risk. Perceived risk seemed to have influenced some participants' decisions to adhere to the study pill within the context of a placebo-controlled clinical trial. Future research can explore the role of risk perception in the uptake of and adherence to pre-exposure prophylaxis, now that FTC/TDF has been shown efficacious. Article	2014	Crosby, Richard A; Geter, Angelica; DiClemente, Ralph J; Salazar, Laura F	Acceptability of Condoms, Circumcision and PrEP among Young Black Men Who Have Sex with Men: A Descriptive Study Based on Effectiveness and Cost.	Vaccines (Basel)	-	-	-	2076-393X	10.3390/vaccines2010129	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4494197	The current study examined and compared the willingness of young Black men who have sex with men (YBMSM) to accept pre-exposure prophylaxis (PrEP), adult male circumcision, and condoms for reducing their risk of HIV acquisition. The majority (67%) reported unprotected receptive anal sex in the last six months. About three-quarters (71%) would accept using PrEP if it was 100% effective. Cost influenced PrEP acceptance with 19% indicating acceptance at $100 per month co-pay. Of those not circumcised, 50% indicated willingness if circumcision was 100% effective. Acceptance of circumcision decreased markedly to 17% with co-pays of $100. About 73% of men were willing to use condoms if they were 100% effective and 50% indicated a willingness at the cost of $10 per month. The findings suggest that condom use promotion strategies should remain at the forefront of public health efforts to control HIV incidence among YBMSM. Theses and Dissertations	2014	Curran, Kathryn G	New approaches to HIV prevention in African HIV serodiscordant couples: antiretrovirals and mobile technology	-	-	University of Washington	-	na	NA	http://hdl.handle.net/1773/25189	This dissertation informs the future implementation of HIV prevention for HIV serodiscordant couples in Africa. The research objectives include: 1) reviewing effective HIV prevention interventions, 2) evaluating the use of daily short message service (SMS, i.e. text message) surveys to measure sex and pre-exposure prophylaxis (PrEP) adherence, and 3) examining the acceptability of initiation of antiretroviral therapy (ART) at higher CD4 counts, a powerful HIV prevention tool. After the necessary first step of HIV testing and counseling, HIV serodiscordant couples may be offered appropriate HIV prevention interventions, including condoms, male circumcision, treatment of sexually transmitted infections, and two recent biomedical strategies: initiation of ART by the HIV-infected partner and PrEP by the HIV-uninfected partner. Importantly, the widespread implementation and effectiveness of HIV prevention interventions requires understanding and encouraging behaviors for acceptance, adherence, and correct use. We conducted a prospective study of HIV-related behaviors and qualitative research to answer key implementation questions regarding the feasibility of PrEP and acceptability of early ART among HIV serodiscordant couples. Within a clinical trial of PrEP, we evaluated the use of daily SMS surveys to examine patterns in sexual behavior and PrEP use. Daily SMS data collection was acceptable, obtained high response rates, and provided an assessment of temporal patterns of HIV risk behaviors and PrEP use over a 60-day period. Participants were more likely to adhere to daily PrEP doses when they were sexually-active, PrEP use was not associated with unprotected sex, and anticipating sex was difficult. In addition, HIV risk behaviors were reported on more days through daily SMS surveys compared to monthly interviewer-administered questionnaires, highlighting the potential of SMS to collect more accurate self-reported data. SMS may offer a new method for measuring and promoting behaviors related to HIV risk and adherence as well as enhancing communication between patients and providers. Qualitative research with HIV serodiscordant couples familiar with HIV prevention methodologies highlighted common perceived advantages and concerns related to early initiation of ART, and an important conceptualization of ART as the "final stage" before dying. This negative meaning of ART initiation poses a challenge to acceptance of early ART and indicates that new messages regarding ART initiation are needed. These new messages should emphasize the benefits of HIV prevention and maintaining good health; acknowledge concerns such as side effects and life-long adherence; and ultimately, portray a positive image of individuals on ART. Social and behavioral factors, in particular sustained adherence as well as individual and community acceptance, will be fundamental to successful implementation of early ART and PrEP and should remain a focus of HIV prevention and treatment	Africa; antiretroviral therapy; HIV; HIV prevention; HIV serodiscordant couples; Epidemiology; Public health; Behavioral sciences; epidemiology	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Mixed methods
Article	2014	de Wit, John B. F.; Adam, Philippe C. G.	Can treatment-based HIV prevention curb the epidemic among gay and other men who have sex with men? A narrative synthesis of increasing evidence for moderating and countervailing effects.	Sexual Health	-	-	-	1448-5028	10.1071/SH13142	https://pubmed.ncbi.nlm.nih.gov/24618576/	As HIV epidemics among gay and other men who have sex with men (GMSM) persist worldwide, the importance of novel prevention approaches is recognised. Evidence that antiretroviral therapy (ART) can decrease the likelihood of infection is informing emerging HIV prevention approaches, encompassing early initiation of treatment as prevention by people living with HIV and use of antiretroviral drugs as pre-exposure prophylaxis for people presumed to be uninfected. Despite widespread excitement, robust evidence of the beneficial effects of ART-based HIV prevention for GMSM remains limited. Also, theoretical models project widely varying effects of ART-based prevention on the future course of HIV epidemics among GMSM, drawing attention to the possible moderating role of differences in the achievements of local HIV responses and the critical importance of sustained protective sexual practices into the future. Ecological analyses and simulations of ongoing epidemics in major gay communities illustrate that the preventive effects of ART in many settings are being offset by increased sexual risk-taking, as reflected in stable or increasing HIV infection rates. Also, the effects of scaling up HIV testing and treatment among GMSM in settings that are often considered prime examples of the success of ART-based prevention may be levelling as 'scope for improvement' diminishes. ART-based approaches further extend the HIV prevention toolkit and substantially increase people's options to protect themselves and others. The future impact of ART-based prevention on HIV epidemics among GMSM ultimately depends on whether heralded responses offset, attenuate or compound the ongoing social and behavioural changes that drive increased sexual risk. Article	2014	Dhalla, Shayesta; Poole, Gary	Effect of race/ethnicity on participation in HIV vaccine trials and comparison to other trials of biomedical prevention.	Human Vaccines & Immunotherapeutics	-	-	-	2164-554X 2164-5515	10.4161/hv.28870	https://www.tandfonline.com/doi/full/10.4161/hv.28870	INTRODUCTION: Racial/ethnic minorities are underrepresented in actual HIV vaccine trials in North America, and willingness to participate (WTP) and retention in an HIV vaccine trial may differ from that in Whites. METHODS: In this review, the authors identified HIV vaccine preparedness studies (VPS) in North America in high-risk populations that examined the relationship between race/ethnicity and WTP in a preventive phase 3 HIV vaccine trial, and the relationship to retention. Studies were categorized by risk group, and comparison group (Whites vs. non-Whites). Other types of trials of biomedical prevention were also identified, and WTP and retention rates were compared and contrasted to actual HIV vaccine trials. RESULTS: In the studies identified, WTP in a hypothetical HIV vaccine trial did not differ by race/ethnicity. In contrast, actual HIV vaccine trials, an HIV acquisition trial, and a phase 2B preexposure prophylaxis (PrEP) trial have enrolled a large percentage of White men. Human papilloma virus (HPV) privately-funded trials have also enrolled a large number of Whites, due to convenience sampling. Retention in the HIV acquisition trial was lower in African-Americans compared with Whites. CONCLUSION: Strategies to increase WTP and enhanced retention (ER) strategies may help in recruiting and retaining minority participants in actual HIV vaccine trials and other trials of biomedical prevention. Article	2014	Doblecki-Lewis, Susanne; Kolber, Michael A	Preventing HIV infection: pre-exposure and postexposure prophylaxis.	IUBMB Life	-	-	-	1521-6551	10.1002/iub.1286	https://dx.doi.org/10.1002/iub.1286	Data supporting the use of pre-exposure prophylaxis (PrEP) and nonoccupational postexposure prophylaxis (nPEP) in the prevention of HIV infection after a sexual encounter continue to grow. In this review, we describe some of the research driving the various recommendations for use of antiretrovirals in prevention. In addition, current research is described regarding the establishment of viral reservoirs that argues for rethinking the timing for nPEP treatment. We discuss the variables that impact on the choice of prevention antiretrovirals, including drug distribution, drug transporters, and potential impact of race and ethnicity on these variables.	1 a 9	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2014	Donnell, Deborah; Baeten, Jared M; Bumpus, Namandjé N; Brantley, Justin; Bangsberg, David R; Haberer, Jessica E; Mujugira, Andrew; Mugo, Nelly; Ndase, Patrick; Hendrix, Craig; Celum, Connie	HIV protective efficacy and correlates of tenofovir blood concentrations in a clinical trial of PrEP for HIV prevention.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000172	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4059553	BACKGROUND: Antiretroviral pre-exposure prophylaxis (PrEP) is a novel HIV prevention strategy for which adherence is a known determinant of efficacy. Blood concentrations of PrEP medications are one objective marker of adherence. METHODS: In a placebo-controlled PrEP efficacy trial of tenofovir disoproxil fumarate (TDF) and TDF with emtricitabine (FTC/TDF) among 4747 African women and men with an HIV-infected partner, we measured plasma tenofovir concentrations from participants in the active PrEP arms: 29 HIV seroconverters (cases) and 196 randomly selected controls who remained uninfected. RESULTS: Among controls, 71% of visits had tenofovir concentrations >40 ng/mL, consistent with steady-state daily dosing, compared with 21% of cases at the visit HIV was first detected. Pill count data indicated that 96% of controls and 66% of cases had >80% adherence for these same visits. The estimated protective effect of PrEP against HIV, based on concentrations >40 ng/mL, was 88% (95% confidence interval: 60 to 96, P < 0.001) for individuals receiving TDF and 91% (95% confidence interval: 47 to 98, P = 0.008) for individuals receiving FTC/TDF. Controls had consistent patterns of PrEP concentrations during follow-up; among the 81% with concentrations >40 ng/mL at month 1, 75% maintained this concentration at month 12. Only 5 of 29 seroconverters seemed to be consistently adherent to PrEP. Tenofovir concentrations >40 ng/mL were associated with older age and shorter time on study; concentrations ≤40 ng/mL occurred more commonly when participants reported no sex with their HIV-infected partner. CONCLUSIONS: Plasma concentrations of tenofovir consistent with daily dosing were highly predictive of protection from HIV acquisition. Most of those who took PrEP seemed to have high and consistent adherence. Article	2014	Eaton, Lisa A; Driffin, Daniel D; Smith, Harlan; Conway-Washington, Christopher; White, Denise; Cherry, Chauncey	Psychosocial factors related to willingness to use pre-exposure prophylaxis for HIV prevention among Black men who have sex with men attending a community event	Sexual Health	-	-	-	na	10.1071/SH14022	https://www.proquest.com/scholarly-journals/psychosocial-factors-related-willingness-use-pre/docview/1759338099/se-2?accountid=8113	Objectives: In the US, Black men who have sex with men (BMSM) are disproportionately affected by HIV/AIDS. Pre-exposure prophylaxis (PrEP) holds tremendous promise for curbing the HIV/AIDS epidemic among these men. However, many psychosocial components must be addressed in order to implement this prevention tool effectively among BMSM. Methods: We assessed PrEP knowledge and use, health care access experiences, race-based medical mistrust, sexual partners and behaviours, and drug and alcohol use among 699 men attending a community event in the south-eastern United States. We used generalised linear modelling to assess factors associated with willingness to use PrEP. Results: Three hundred and ninety-eight men reported being BMSM and having HIV-negative status. Among these men, 60% reported being willing to use PrEP. Lack of being comfortable with talking to a health care provider about having sex with men, not having discussed having sex with a man with a health care provider, race-based medical mistrust, and alcohol consumption and substance use were all identified as barriers to willingness to use PrEP. Sexual risk-taking, number of sex partners and STI diagnosis were not associated with willingness to use PrEP. Conclusions: Findings from the current paper demonstrate the importance of acknowledging the role of various psychosocial factors in the uptake of PrEP. It is imperative that we prioritise research into understanding these barriers better, as the failure to do so will impede the tremendous potential of this prevention technology. Article	2014	Escudero, Daniel J; Lurie, Mark N; Kerr, Thomas; Howe, Chanelle J; Marshall, Brandon D L	HIV pre-exposure prophylaxis for people who inject drugs: a review of current results and an agenda for future research.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.17.1.18899	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3969508	INTRODUCTION: Studies examining the use of pre-exposure prophylaxis (PrEP) to prevent HIV transmission among people who inject drugs (PWIDs) have not been adequately summarized. Recently, the Bangkok Tenofovir Study has shown that PrEP may be effective at reducing new HIV infections among this high-risk group. This randomized controlled trial was the first study to specifically examine the efficacy of PrEP among PWIDs. In this review, we present the current state of evidence regarding the use of PrEP to prevent HIV infection in PWID populations, and set an agenda for future research to inform the most effective implementation of PrEP in the context of existing evidence-based HIV prevention strategies. DISCUSSION: Despite positive trial results confirming that PrEP may prevent HIV transmission among PWIDs, there remain many questions regarding the interpretation of these results, as well as obstacles to the implementation of PrEP regimens within highly diverse drug-using communities. Aside from the Bangkok Tenofovir Study, we identified only one other published study that has collected empirical data to inform the use of PrEP among PWIDs. The large gap in research regarding the use and implementation of PrEP for PWIDs signals the need for further research and attention. CONCLUSIONS: We recommend that future research efforts focus on elucidating the generalizability of the Bangkok Tenofovir Study results in other injection drug-using populations, examining the willingness of PWIDs to use PrEP in diverse contexts, identifying barriers to adherence to PrEP regimens and determining the most effective ways to implement PrEP programmes within the context of existing evidence-based prevention strategies, including opioid substitution therapy and needle and syringe distribution programmes. Article	2014	Flash, Charlene A; Stone, Valerie E; Mitty, Jennifer A; Mimiaga, Matthew J; Hall, Kathryn T; Krakower, Douglas; Mayer, Kenneth H	Perspectives on HIV prevention among urban black women: a potential role for HIV pre-exposure prophylaxis.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2014.0003	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4250961	Limited data exist regarding attitudes and acceptability of topical and oral HIV pre-exposure prophylaxis (PrEP) among US black women. This investigation explored interest in HIV chemoprophylaxis and modes of use. Five focus groups enrolled 26 black women recruited from an inner-city community health center and affiliated HIV testing sites. Thematic analysis utilized Atlas.ti. Most women expressed interest in PrEP, as many reported condom failure concerns. Most women preferred a pill formulation to intravaginal gel because of greater perceived privacy and concerns about vaginal side effects and gel leakage. Women who had taken pills previously advocated daily dosing and indicated adherence concerns about episodic or post-coital PrEP. Many women desired prophylactic strategies that included partner testing. Urban black women are interested in utilizing PrEP; however, misgivings exist about gel inconvenience and potential side effects for themselves and their partners. Most women preferred oral PrEP, dosed daily.	635-642	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative

Article	2014	Gallagher, Timothy; Link, Lauren; Ramos, Michael; Bottger, Edward; Aberg, Judith; Daskalakis, Demetre	Self-Perception of HIV Risk and Candidacy for Pre-Exposure Prophylaxis Among Men Who Have Sex with Men Testing for HIV at Commercial Sex Venues in New York City.	LGBT Health	-	-	-	-	2325-8306	10.1089/lgbt.2013.0046	https://dx.doi.org/10.1089/lgbt.2013.0046	The purpose of this study was to evaluate the ability of men who have sex with men (MSM) testing for HIV at commercial sex venues to assess the following: their candidacy for pre-exposure chemoprophylaxis (PrEP) as defined by meeting entry criteria for the iPrEx (Iniciativa Profilaxis Pre-Exposición) phase III clinical trial of PrEP, and their perception of their own HIV risk and candidacy for PrEP. Interviewers surveyed 629 MSM at three NYC commercial sex venues from June 2011 through June 2012. Questions focused on demographics, sexual activity, and drug use in the three months prior to testing, as well as perceived risk of HIV acquisition and perceived candidacy for PrEP use. Data were analyzed by Chi square and Fisher's exact test. Results show that a majority of clients (80.3%) met entry criteria for the iPrEX. Most of these men (78.0%), however, did not perceive their risk to be significant enough to warrant PrEP use (P=.000). Factors were identified which associated with a risk perception that correlated with eligibility for iPrEX.	HIV; Pre-Exposure Prophylaxis (PrEP); Risk Perception; men who have sex with men (MSM). Article	2014	Gengiah, Tanuja N; Moosa, Atika; Naidoo, Anushka; Mansoor, Leila E	Adherence challenges with drugs for pre-exposure prophylaxis to prevent HIV infection.	International Journal of Clinical Pharmacy	-	-	-	-	2210-7711	10.1007/s11096-013-9861-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3947256	BACKGROUND: There are 34 million people living with human immunodeficiency virus (HIV) worldwide and each year this number increases. Until a vaccine is discovered, the prevention of new HIV infections remains an urgent priority. Several trials studying the use of oral and topical agents for the prevention of HIV infection have already been completed. Adherence has proved to be a major challenge in achieving product efficacy. AIM OF THE REVIEW: To provide the clinical pharmacist with an understanding of the oral pre-exposure prophylaxis (PrEP) and topical microbicide product pipeline whilst emphasizing the critical importance of adherence to these drugs to avert HIV infection. METHODS: PubMed/Medline and the web-based clinical trials registry (ClinTrials.gov) were searched using appropriate key words. For the time period 1992-2013--all phase II and phase III safety and effectiveness studies--testing agents for prevention of HIV infection were included in the review. Efficacy estimates, adherence estimates and reported challenges with adherence were extracted. RESULTS: Twenty-four phase II and III clinical trials were found during review. Of these, 20 trials have been completed, and six trials show effectiveness in preventing HIV infection. The majority of the successful trials were to oral PrEP and to date only one microbicide trial of a vaginal antiretroviral microbicide gel has showed effectiveness. Adherence to study product played a major role in trial outcomes and there are several reasons for this. These include high on-trial pregnancy rates, low trial retention rates, low participant perception of risk, participant characteristics such as age <25 years, single status, migratory partners and trial fatigue. Study product characteristics such as dosage form, dosing interval, as well as associated adverse events may also influence adherence. CONCLUSION: Moderate to high adherence is critical to demonstrate efficacy of drugs for HIV prevention. For topical agents, intermittent use associated with coitus is more effective than daily use, particularly if sex is infrequent or partners migrant. For oral agents, daily use is effective but the motivation to use the drug and high risk perception is important. In serodiscordant couples, early initiation of highly active antiretroviral therapy in the infected partner affords almost complete protection to the negative partner. Drugs need to be tailored to the population at risk and availability of multiple drug options are important. Article	2014	Gerberry, David J; Wagner, Bradley G; Garcia-Lerma, J Gerardo; Heneine, Walid; Blower, Sally	Using geospatial modelling to optimize the rollout of antiretroviral-based pre-exposure HIV interventions in Sub-Saharan Africa.	Nature Communications	-	-	-	-	2041-1723	10.1038/ncomms6454	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4322933	Antiretroviral (ARV)-based pre-exposure HIV interventions may soon be rolled out in resource-constrained Sub-Saharan African countries, but rollout plans have yet to be designed. Here we use geospatial modelling and optimization techniques to compare two rollout plans for ARV-based microbicides in South Africa: a utilitarian plan that minimizes incidence by using geographic targeting, and an egalitarian plan that maximizes geographic equity in access to interventions. We find significant geographic variation in the efficiency of interventions in reducing HIV transmission, and that efficiency increases disproportionately with increasing incidence. The utilitarian plan would result in considerable geographic inequity in access to interventions, but (by exploiting geographic variation in incidence) could prevent ~40% more infections than the egalitarian plan. Our results show that the geographic resource allocation decisions made at the beginning of a rollout, and the location where the rollout is initiated, will be crucial in determining the success of interventions in reducing HIV epidemics. Article	2014	Golub, Sarit A	Tensions between the epidemiology and psychology of HIV risk: implications for pre-exposure prophylaxis.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-014-0770-7	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4127100	This study focuses on psychological differences in risk-taking patterns and their association with risk compensation motivations in the context of pre-exposure prophylaxis (PrEP). Participants were 257 HIV-negative MSM and transgender women recruited in New York City. The majority of participants (89.5 %, n = 230), could be classified as either: Intimates (40 %), who report unprotected anal intercourse (UAI) only with a main partner believed to be HIV-negative; Trusters (34 %), who engaged in UAI only with casual partners believed to be HIV-negative; and Gamblers (26 %) who report UAI with partners of unknown serostatus. Partner-based classifications were better predictors of HIV risk perception and other traditional correlates of risk-taking (e.g. impulsivity, sexual compulsivity) than rates of UAI. The three groups differed significantly in PrEP-related risk compensation motivations: sexual pleasure (Gamblers), intimacy (Trusters) and partner pressure (Intimates). These data underscore the importance of focusing the psychological dynamics of risk perception and sexual decision-making. Article	2014	Grant, Robert M; Anderson, Peter L; McMahan, Vanessa; Liu, Albert; Amico, K Rivet; Mehrotra, Megha; Hosek, Sybil; Mosquera, Carlos; Casapia, Martin; Montoya, Orlando; Buchbinder, Susan; Veloso, Valdilea G; Mayer, Kenneth; Chariyalertsak, Suwat; Bekker, Linda-Gail; Kallas, Esper G; Schechter, Mauro; Guanira, Juan; Bushman, Lane; Burns, David N; Rooney, James F; Glidden, David V	Uptake of pre-exposure prophylaxis, sexual practices, and HIV incidence in men and transgender women who have sex with men: a cohort study	The Lancet Infectious Diseases	-	-	-	-	1473-3099	https://doi.org/10.1016/s1473-3099(14)70847-3	https://escholarship.org/uc/item/3620g4ws	BackgroundThe effect of HIV pre-exposure prophylaxis (PrEP) depends on uptake, adherence, and sexual practices. We aimed to assess these factors in a cohort of HIV-negative people at risk of infection.MethodsIn our cohort study, men and transgender women who have sex with men previously enrolled in PrEP trials (ATN 082, iPrEx, and US Safety Study) were enrolled in a 72 week open-label extension. We measured drug concentrations in plasma and dried blood spots in seroconverters and a random sample of seronegative participants. We assessed PrEP uptake, adherence, sexual practices, and HIV incidence. Statistical methods included Poisson models, comparison of proportions, and generalised estimating equations.FindingsWe enrolled 1603 HIV-negative people, of whom 1225 (76%) received PrEP. Uptake was higher among those reporting condomless receptive anal intercourse (416/519 81% vs 809/1084 75%, p=0·003) and having serological evidence of herpes (612/791 77% vs 613/812 75% p=0·03). Of those receiving PrEP, HIV incidence was 1·8 infections per 100 person-years, compared with 2·6 infections per 100 person-years in those who concurrently did not choose PrEP (HR 0·51, 95% CI 0·26–1·01, adjusted for sexual behaviours), and 3·9 infections per 100 person-years in the placebo group of the previous randomised phase (HR 0·49, 95% CI 0·31–0·77). Among those receiving PrEP, HIV incidence was 4·7 infections per 100 person-years if drug was not detected in dried blood spots, 2·3 infections per 100 person-years if drug concentrations suggested use of fewer than two tablets per week, 0·6 per 100 person-years for use of two to three tablets per week, and 0·0 per 100 person-years for use of four or more tablets per week (p<0·0001). PrEP drug concentrations were higher among people of older age, with more schooling, who reported non-condom receptive anal intercourse, who had more sexual partners, and who had a history of syphilis or herpes.InterpretationPrEP uptake was high when made available free of charge by experienced providers. The effect of PrEP is increased by greater uptake and adherence during periods of higher risk. Drug concentrations in dried blood spots are strongly correlated with protective benefit.FundingUS National Institutes of Health. Article	2014	Haire, B	Considering Pre-Exposure Prophylaxis: Do the Pros Outweigh the Cons as an HIV Prevention Strategy?	LGBT Health	-	-	-	-	2325-8292	10.1089/lgbt.2014.0081	https://www.liebertpub.com/doi/abs/10.1089/lgbt.2014.0081?journalCode=lgbt	Although increased access to antiretroviral therapy reduces the risk of sexual transmission to partners, ongoing HIV incidence can be sustained by people who are unaware of their infection. Thus, new prevention interventions that are designed for HIV-negative people at high risk of infection are important in the control of new HIV infections. Pre-Exposure Prophylaxis (PrEP) has proven efficacy in four major trials, but questions about its cost, about user adherence and about its potential impact on other prevention interventions such as condom use has limited implementation to date. This article examines the evidence. Editorial	2014	Hankins, Catherine A	Untangling the cost-effectiveness knot: who is oral antiretroviral HIV pre-exposure prophylaxis really for?	Expert Review of Pharmacoeconomics & Outcomes Research	-	-	-	-	1473-7167	10.1586/14737167.2014.887447	https://pubmed.ncbi.nlm.nih.gov/24552641/	Clinical trials of HIV pre-exposure prophylaxis (PrEP) antiretroviral drugs have shown excellent protection against HIV acquisition when plasma drug levels are detectable, indicating good adherence. Cost-effectiveness depends on epidemic context, adherence, drug cost, and other factors. For individuals at highest risk of HIV who are unable to use proven HIV prevention methods such as condoms and sterile injecting equipment, PrEP may be a workable option over short- to medium-term risky periods of their lives. Adding PrEP to HIV prevention programmes will be most effective as part of a combination prevention strategy that addresses both immediate risks and underlying vulnerabilities, and the pathways that link them. Determining who is most motivated to adhere to PrEP and supporting them through participant-centred approaches that assist people to find their own adherence solutions will be critical to determining the real-life cost-effectiveness of PrEP for HIV prevention and for whom HIV PrEP is most suited. Article	2014	Headley, Jennifer; Lemons, Ansley; Corneli, Amy; Agot, Kawango; Ahmed, Khatija; Wang, Meng; Odhiambo, Jacob; Skhosana, Joseph; Tharaldson, Jenae; Van Damme, Lut; MacQueen, Kathleen	The sexual risk context among the FEM-PrEP study population in Bondo, Kenya and Pretoria, South Africa.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0106410	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4167553	BACKGROUND: Incidence rates in the FEM-PrEP and VOICE trials demonstrate that women from diverse sub-Saharan African communities continue to be at substantial HIV risk. OBJECTIVE: To describe and compare the sexual risk context of the study population from two FEM-PrEP trial sites-Bondo, Kenya, and Pretoria, South Africa. METHODS: At baseline we collected information about demographics, sexual behaviors, and partnership beliefs through quantitative questionnaires with all participants (Bondo, nâ=â720; Pretoria, nâ=â750). To explore the sexual risk context, we also conducted qualitative, semi-structured interviews with HIV-negative participants randomly selected at several time points (Bondo, nâ=â111; Pretoria, nâ=â69). RESULTS: Demographics, sexual behavior, and partnership beliefs varied significantly between the sites. Bondo participants were generally older, had fewer years of schooling, and were more likely to be employed and married compared to Pretoria participants. Bondo participants were more likely to report multiple partners and not knowing whether their partner had HIV than Pretoria participants. A significantly higher percentage of Bondo participants reported engaging in sex without a condom with their primary and other partners compared to Pretoria participants. We found a borderline association between participants who reported not using condoms in the 4 weeks prior to baseline and lower risk of HIV infection, and no association between having more than one sexual partner at baseline and HIV infection. DISCUSSION: Despite significantly different demographics, sexual behaviors, and partnership beliefs, many women in the FEM-PrEP trial were at risk of acquiring HIV as demonstrated by the sites' high HIV incidence. Though gender dynamics differed between the populations, they appear to play a critical role in women's sexual practices. The findings highlight different ways women from diverse contexts may be at-risk for HIV and the importance of providing HIV prevention options that are both effective and feasible given personal and social circumstances. Article	2014	Heffron, Renee; Mugo, Nelly; Were, Edwin; Kiarie, James; Bukusi, Elizabeth A; Mujugira, Andrew; Frenkel, Lisa M; Donnell, Deborah; Ronald, Allan; Celum, Connie	Preexposure prophylaxis is efficacious for HIV-1 prevention among women using depot medroxyprogesterone acetate for contraception	AIDS	-	-	-	-	0269-9370	https://doi.org/10.1097/qad.0000000000000493	https://escholarship.org/uc/item/89q9698w	ObjectiveTo evaluate preexposure prophylaxis (PrEP) efficacy for HIV-1 prevention among women using depot medroxyprogesterone acetate (DMPA) for contraception and men whose HIV-1-infected partners use DMPA.DesignSecondary analysis of data from a randomized placebo-controlled trial of daily oral tenofovir and emtricitabine/tenofovir PrEP among heterosexual Kenyan and Ugandan HIV-1 serodiscordant couples.MethodsPrEP efficacy for HIV-1 prevention was compared among HIV-1-uninfected women using DMPA versus no hormonal contraception and among HIV-1 uninfected men whose HIV-1-infected female partners used DMPA versus no hormonal contraception.ResultsOf 4747 HIV-1 serodiscordant couples, 901 HIV-1-uninfected women used DMPA at some point during follow-up, 1422 HIV-1-uninfected women used no hormonal contraception, 1568 HIV-1-uninfected men had female partners who used DMPA, and 2626 men had female partners who used no hormonal contraception. PrEP efficacy estimates for HIV-1 prevention, compared with placebo, were similar among women using DMPA and those using no hormonal contraception (64.7 and 75.5%, adjusted interaction P = 0.65). Similarly, for men whose female partners used DMPA, PrEP efficacy did not differ from men whose partners used no hormonal contraception (90.0 versus 81.7%, adjusted interaction P = 0.52).ConclusionPrEP is efficacious for HIV-1 prevention among women using DMPA and men whose partners use DMPA, suggesting PrEP could mitigate the potential increased HIV-1 acquisition and transmission risks that have been associated with DMPA use. Women at risk for HIV-1 choosing DMPA could maintain this contraceptive method and add PrEP to achieve prevention of unintended pregnancy and HIV-1. Article	2014	Herold, Betsy C; Dezzutti, Charlene S; Richardson, Barbra A; Marrazzo, Jeanne; Mesquita, Pedro M M; Carpenter, Colleen; Huber, Ashley; Louissaint, Nicolette; Marzinke, Mark A; Hillier, Sharon L; Hendrix, Craig W	Antiviral activity of genital tract secretions after oral or topical tenofovir pre-exposure prophylaxis for HIV-1.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000000110	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3981887	BACKGROUND: Surrogate markers of HIV-1 pre-exposure prophylaxis and microbicide efficacy are needed. One potential surrogate is the antiviral activity in cervicovaginal lavage (CVL) after exposure to candidate products. We measured CVL antiviral activity in women using oral or vaginal tenofovir-based pre-exposure prophylaxis and correlated activity with drug and immune mediator levels. METHODS: Inhibitory activity against HIV-1 and herpes simplex virus (HSV)-2 and concentrations of interleukin (IL)-1ß, IL-6, IL-8, interferon-Î³, induced protein 10 (IP-10), macrophage inflammatory protein (MIP)-1α, MIP-3a, lactoferrin, secretory leukocyte protease inhibitor, and defensins were measured in CVL obtained from 60 women at baseline and after 6 weeks of a randomized sequence of oral and topical tenofovir. CVL tenofovir concentrations were measured by mass spectrometry. RESULTS: The number of women with CVL anti-HIV activity ≥ 90% increased significantly from 5.0% at baseline to 89.1% after daily use of 1% tenofovir gel (relative risk = 17.85, P < 0.001), but there was no increase after daily oral tenofovir. The CVL anti-HIV activity correlated with drug levels (Spearman correlation coefficient 0.64 after tenofovir gel; P < 0.001) but not with the concentrations of mucosal immune mediators. No increase in CVL anti-HSV activity was observed after either drug regimen, an observation consistent with the higher concentrations of tenofovir needed to inhibit HSV-2 infection. The CVL anti-HSV activity correlated with lactoferrin, defensins, IP-10, IL-8, and detectable levels of MIP-1α but not with drug levels. CONCLUSIONS: CVL may provide a surrogate for local but not systemic drug efficacy and a tool to better understand mucosal factors that modulate antiviral activity in genital tract secretions. Article	2014	Heuft, Merel M.; Houba, Sanne M.; van den Berk, Guido E. L.; Smissaert van de Haere, Tessa; van Dam, Alje P.; Dijksman, Lea M.; Regez, Rosa M.; Brinkman, Kees	Protective effect of hepatitis B virus-active antiretroviral therapy against primary hepatitis B virus infection.	AIDS	-	-	-	-	1473-5571 0269-9370	10.1097/QAD.0000000000000180	https://pubmed.ncbi.nlm.nih.gov/24685742/	OBJECTIVE: Current guidelines advise to vaccinate every hepatitis B virus (HBV)-susceptible HIV patient against HBV until sufficient antibody titers have been reached. However, in this era of combination antiretroviral therapy (cART), acute HBV infection rarely occurs in patients who lack this immune protection. We analyzed whether HBV-active cART (lamivudine, emtricitabine, tenofovir) might work as a preexposure prophylaxis (PrEP) to explain this effect. METHODS: From our HIV cohort at the Onze Lieve Vrouwe Gasthuis hospital (N=2942), patients were selected retrospectively for negative HBV serology (HBsAg, anti-HBs and anti-HBc-negative) at cohort entry. Men who have sex with men (MSM) with a second HBV serology available were included in the analysis. The incidence of anti-HBc conversion was determined and correlated with the use of HBV-active drugs. Kaplan-Meier curves and log-rank tests were used to compare HBV-free survival for MSM. RESULTS: In total, 33 HBV infections occurred in 381 eligible MSM over a median follow-up of 2470 days (interquartile range 1146-3871.5). The incident rate per 100 patient-years of follow-up was 1.10 overall, but differed strongly dependent on the use of HBV-active drugs: 2.85/100 patient-years of follow-up in the absence of HBV-active drugs, 1.36 when only lamivudine was used, and 0.14 in the presence of tenofovir. Furthermore, HBV-free survival rate was significantly higher when HBV-active cART was used, in particular when this HBV-active cART contained tenofovir (log-rank P<0.001). CONCLUSION: Our findings demonstrate that HBV-active cART protects against the occurrence of de-novo HBV infection, most strongly when tenofovir is used. Article	2014	Holt, Martin	HIV pre-exposure prophylaxis and treatment as prevention: a review of awareness and acceptability among men who have sex with men in the Asia-Pacific region and the Americas.	Sexual Health	-	-	-	-	1448-5028	10.1071/SH13060	https://dx.doi.org/10.1071/SH13060	This review assesses acceptability research for HIV pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP) among men who have sex with men (MSM) in the Asia-Pacific region and the Americas, evaluating awareness and attitudes. There has been limited research on the acceptability of PrEP outside the United States and no research to date evaluating the acceptability of TasP since the findings of the HIV Prevention Trials Network 052 trial were released. Existing research suggests that PrEP is reasonably acceptable to MSM, but few men are likely to perceive the need for it. Studies of HIV treatment optimism suggest that MSM are likely to be sceptical of TasP.	attitudes, gay and bisexual men, treatment optimism	English	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review
Article	2014	Holt, Martin; Lea, Toby; Murphy, Dean; Ellard, Jeanne; Rosengarten, Marsha; Kippax, Susan; De Wit, John	Willingness to use HIV pre-exposure prophylaxis has declined among australian gay and bisexual men: results from repeated national surveys, 2011-2013.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000000287	https://dx.doi.org/10.1097/QAI.0000000000000287	We surveyed willingness to use pre-exposure prophylaxis (PrEP) and the likelihood of decreased condom use among Australian gay and bisexual men in 2011 and 2013 (n = 2384). Willingness to use PrEP declined from 28.2% to 23.3% adjusted odds ratio = 0.83, 95% confidence interval (CI): 0.68 to 1.00, P = 0.050. Willingness to use PrEP was the greatest among men with HIV-positive partners and among those who had taken HIV postexposure prophylaxis. Among men willing to use PrEP, the likelihood of decreased condom use remained stable between 2011 and 2013 (8.0% vs. 11.9%; adjusted odds ratio = 1.40, 95% CI: 0.80 to 2.45, P = 0.23). A minority of men remain willing to use PrEP and appear to be appropriate candidates for it. Article	2014	Idoko, John; Folayan, Morenike O.	The use of antiretroviral therapy for the prevention of new HIV infection in populations at high risk for HIV sero-conversion in Nigeria.	African Journal of Reproductive Health	-	-	-	-	1118-4841	NA	https://pubmed.ncbi.nlm.nih.gov/26050385/	The last few years have witnessed a renewed commitment to HIV prevention. The evidence to support the use of antiretroviral therapy (ART) for prevention of new HIV infection in the form of Pre-exposure prophylaxis (PrEP) among men who have sex with men, transgender, people who inject drugs, heterosexual men and women and HIV-1 serodiscordant couples, or treatment as prevention (TasP) for serodiscordant couples have also grown. The need to explore the possible use of ART for HIV prevention in Nigeria has become imperative in view of its high HIV burden and the current slow pace of effort to achieve the universal target of reducing its HIV incidence by 50%. While PrEP and TasP are welcome addendum to the existing HIV prevention armamentarium, it is still important to conduct a demonstration project to identify strategies that can facilitate access to PrEP and TasP taking cognizance of the peculiar local challenges with respect to ART and HIV prevention commodity access. The country has therefore drawn a roadmap for itself on how to introduce ART for use for HIV prevention as either PrEP or TasP. This paper discusses the three year national roadmap that will enable the country generated the needed scientific evidence as well as extensive community support for use of ART for HIV prevention in Nigeria. This process includes the conduct of modeling and formative studies, and the implementation of a 24 months demonstration project. The outcome of the demonstration project would inform plans for the scale up of pre-exposure prophylaxis (PrEP) access for population(s) at high risk for HIV infection in Nigeria. Article	2014	Jackson, A G A; Else, L J; Mesquita, P M M; Egan, D; Back, D J; Karolia, Z; Ringner-Nackter, L; Higgs, C J; Herold, B C; Gazzard, B G; Boffito, M	A compartmental pharmacokinetic evaluation of long-acting rilpivirine in HIV-negative volunteers for pre-exposure prophylaxis.	Clinical Pharmacology and Therapeutics	-	-	-	-	1532-6535	10.1038/clpt.2014.118	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01116409/full	Rilpivirine long-acting (RPV-LA) is a parenteral formulation enabling prolonged plasma exposure. We explored its multiple-compartment pharmacokinetics (PK) after a single dose, for pre-exposure prophylaxis. Sixty-six HIV-negative volunteers were enrolled: women received an intramuscular dose of 300, 600, or 1,200 mg, with plasma and genital levels measured to 84 days postdose; men receiving 600 mg had similar PK determined in plasma and rectum. Ex vivo antiviral activity of cervicovaginal lavage (CVL) was also assessed. After a single dose, RPV concentrations peaked at days 6-8 and were present in plasma and genital-tract fluid to day 84. Vaginal and male rectal tissue levels matched those in plasma. At the 1,200 mg dose, CVL showed greater antiviral activity, above baseline, at days 28 and 56. All doses were well tolerated. All doses gave prolonged plasma and genital-tract rilpivirine exposure. PK and viral inhibition of repeated doses will be important in further dose selection. Article	2014	Jiang, Junjun; Yang, Xiaoyi; Ye, Li; Zhou, Bo; Ning, Chuanyi; Huang, Jiegang; Liang, Bingyu; Zhong, Xiaoni; Huang, Ailong; Tao, Renchuan; Cao, Cunwei; Chen, Hui; Liang, Hao	Pre-exposure prophylaxis for the prevention of HIV infection in high risk populations: a meta-analysis of randomized controlled trials.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0087674	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3912017	BACKGROUND: Nearly ten randomized controlled trials (RCTs) of pre-exposure prophylaxis (PrEP) have been completed or are ongoing worldwide to evaluate the effectiveness of PrEP in HIV transmission among HIV-uninfected high risk populations. The purpose of this study was to evaluate the role of PrEP to prevent HIV transmission through a Mata-analysis. METHODS: A comprehensive computerized literature search was carried out in PubMed, EMbase, Ovid, Web of Science, Science Direct, Wan Fang, CNKI and related websites to collect relevant articles (from their establishment date to August 30, 2013). The search terms were "pre-exposure prophylaxis", "high risk population", "HIV infection", "reduction", "relative risk" and "efficacy". We included any RCT assessing PrEP for the prevention of HIV infection in high risk populations. Interventions of the studies were continuously daily or intermittent doses of single or compound antiretrovirals (ARVs) before HIV exposure or during HIV exposure. A meta-analysis was conducted using Stata 10.0. A random-effects method was used to calculate the pooled relative risk (RR) and 95% confidence intervals (CI) for all studies included. RESULTS: Seven RCTs involving 14,804 individuals in high risk populations were eligible for this study. The number of subjects in the experimental groups was 8,195, with HIV infection rate of 2.03%. The number of subjects in the control groups was 6,609, with HIV infection rate of 4.07%. The pooled RR was 0.53 (95% CI = 0.40 â¼ 0.71, P<0.001). The re-analyzed pooled RR were 0.61 (95% CI = 0.48 â¼ 0.77, P<0.001), 0.49 (95% CI = 0.38 â¼ 0.63, P<0.001), respectively, by excluding the largest study or two studies without statistical significance. Publication bias analysis revealed a symmetry funnel plot. The fail-safe number was 1,022. CONCLUSION: These results show that PrEP is an effective strategy for reducing new HIV infections in high risk populations. Article	2014	Jia-Tong HE	Propaganda methods of pre-exposure prophylactic medication in men who have sex with men: A multiple correspondence analysis	Academic Journal of Second Military Medical University	-	-	-	-	0258-879X	NA	http://dx.doi.org/10.3724/SP.J.1008.2014.00122	Objective To explore the correlation of propaganda methods of pre-exposure prophylactic medication with sociodemographic characteristics and obtaining services of HIV prevention in men who have sex with men (MSM) in Western China by applying multiple correspondence analysis. Methods A cross-sectional survey was carried out on 1 407 MSM who were selected from Chongqing, Sichuan, Guangxi province by snowball sampling method. Chi-square tests and multiple correspondence analysis were used for selecting variables and exploring correlation. Results Totally 1 323 qualified participants were recruited and only 31.49%(416/1 321) had ever heard of pre-exposure prophylactic medication. It was found that 74.00%(979/1 323), 65.00%(860/1 323), 44.22%(585/1 323) and 52.15%(690/1 323) of MSM were willing to obtain pre-exposure prophylactic medication knowledge via internet, traditional media, peer education and medical institutions, respectively. In multiple correspondence analysis the Cronbach α values were 0.661 and 0.632 while eigenvalues were 2.562 and 2.400 in two dimensions of all variables. Willing to obtain pre-exposure prophylactic medication knowledge via internet was strongly correlated with higher education, unmarried status, younger than 30 years old, no children and urban residency. Willing to obtain knowledge by peer education was strongly correlated with having ever received information from peers, having received promotional materials, having received free AIDS consultation and participated in activities of MSM. Conclusion Multiple correspondence analysis can directly reveal the correlation among propaganda methods of pre-exposure prophylactic medication, sociodemographic characteristics and services of HIV prevention, which provides a theoretical basis for propaganda and research of pre-exposure prophylactic medication among MSM in China. Article	2014	Jones, Alexandra; Cremin, Ide; Abdullah, Fareed; Idoko, John; Cherutich, Peter; Kilonzo, Nduku; Rees, Helen; Hallett, Timothy; O'Reilly, Kevin; Koechlin, Florence; Schwartlander, Bernhard; de Zalduondo, Barbara; Kim, Susan; Jay, Jonathan; Huh, Jacqueline; Piot, Peter; Dybul, Mark	Transformation of HIV from pandemic to low-endemic levels: a public health approach to combination prevention.	The Lancet	-	-	-	-	1474-547X 0140-6736	10.1016/S0140-6736(13)62230-8	https://pubmed.ncbi.nlm.nih.gov/24740087/	Large declines in HIV incidence have been reported since 2001, and scientific advances in HIV prevention provide strong hope to reduce incidence further. Now is the time to replace the quest for so-called silver bullets with a public health approach to combination prevention that understands that risk is not evenly distributed and that effective interventions can vary by risk profile. Different countries have different microepidemics, with very different levels of transmission and risk groups, changing over time. Therefore, focus should be on high-transmission geographies, people at highest risk for HIV, and the package of interventions that are most likely to have the largest effect in each different microepidemic. Building on the backbone of behaviour change, condom use, and medical male circumcision, as well as expanded use of antiretroviral drugs for infected people and pre-exposure prophylaxis for uninfected people at high risk of infection, it is now possible to consider the prospect of what would be one of the most remarkable achievements in the history of public health: reduction of HIV transmission from a pandemic to low-level endemicity. Article	2014	Karris, Maile Y; Beekmann, Susan E; Mehta, Sanjay R; Anderson, Christy M; Polgreen, Philip M	Are we prepped for preexposure prophylaxis (PrEP)? Provider opinions on the real-world use of PrEP in the United States and Canada.	Clinical Infectious Diseases	-	-	-	-	1537-6591	10.1093/cid/cit796	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3922214	BACKGROUND: Preexposure prophylaxis (PrEP) with tenofovir disoproxil fumarate and emtricitabine (Truvada) has demonstrated efficacy in placebo-controlled clinical trials involving men who have sex with men, high-risk heterosexuals, serodiscordant couples, and intravenous drug users. To assist in the real-world provision of PrEP, the Centers for Disease Control and Prevention (CDC) has released guidance documents for PrEP use. METHODS: Adult infectious disease physicians were surveyed about their opinions and current practices of PrEP through the Emerging Infections Network (EIN). Geographic information systems analysis was used to map out provider responses across the United States. RESULTS: Of 1175 EIN members across the country, 573 (48.8%) responded to the survey. A majority of clinicians supported PrEP but only 9% had actually provided it. Despite CDC guidance, PrEP practices were variable and clinicians reported many barriers to its real-world provision. CONCLUSIONS: The majority of adult infectious disease physicians across the United States and Canada support PrEP but have vast differences of opinion and practice, despite the existence of CDC guidance documents. The success of real-world PrEP will likely require multifaceted programs addressing barriers to its provision and will be assisted with the development of comprehensive guidelines for real-world PrEP. Article	2014	Kasonde, Michael; Niska, Richard W; Rose, Charles; Henderson, Faith L; Segolodi, Tebogo M; Turner, Kyle; Smith, Dawn K; Thigpen, Michael C; Paxton, Lynn A	Bone mineral density changes among HIV-uninfected young adults in a randomised trial of pre-exposure prophylaxis with tenofovir-emtricitabine or placebo in Botswana.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0090111	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3953113	BACKGROUND: Tenofovir-emtricitabine (TDF-FTC) pre-exposure prophylaxis (PrEP) has been found to be effective for prevention of HIV infection in several clinical trials. Two studies of TDF PrEP among men who have sex with men showed slight bone mineral density (BMD) loss. We investigated the effect of TDF and the interaction of TDF and hormonal contraception on BMD among HIV-uninfected African men and women. METHOD: We evaluated the effects on BMD of using daily oral TDF-FTC compared to placebo among heterosexual men and women aged 18-29 years enrolled in the Botswana TDF2 PrEP study. Participants had BMD measurements at baseline and thereafter at 6-month intervals with dual-energy X-ray absorptiometry (DXA) scans at the hip, spine, and forearm. RESULTS: A total of 220 participants (108 TDF-FTC, 112 placebo) had baseline DXA BMD measurements at three anatomic sites. Fifteen (6.8%) participants had low baseline BMD (z-score of <-2.0 at any anatomic site), including 3/114 women (2.6%) and 12/106 men (11.3%) (pâ=â0.02). Low baseline BMD was associated with being underweight (pâ=â0.02), having high blood urea nitrogen (pâ=â0.02) or high alkaline phosphatase (pâ=â0.03), and low creatinine clearance (pâ=â0.04). BMD losses of >3.0% at any anatomic site at any time after baseline were significantly greater for the TDF-FTC treatment group 34/68 (50.0%) TDF-FTC vs. 26/79 (32.9%) placebo; pâ=â0.04. There was a small but significant difference in the mean percent change in BMD from baseline for TDF-FTC versus placebo at all three sites at month 30 forearm -0.84% (pâ=â0.01), spine -1.62% (pâ=â0.0002), hip -1.51% (pâ=â0.003). CONCLUSION: Use of TDF-FTC was associated with a small but statistically significant decrease in BMD at the forearm, hip and lumbar spine. A high percentage (6.8%) of healthy Batswana young adults had abnormal baseline BMD Further evaluation is needed of the longer-term use of TDF in HIV-uninfected persons. Institutional	2014	Kennedy, Caitlin; Fonner, Virgina; World Health Organization	Pre-exposure prophylaxis for men who have sex with men: a systematic review	-	-	-	-	-	NA	NA	https://iris.who.int/handle/10665/128114	An estimated 35.3 million people globally are living with HIV (UNAIDS, 2013). A number of prevention methods are available, from condoms to male circumcision, prevention of mother-to-child transmission to clean needles, but to date these have not been sufficient to stop the epidemic. In 2012 alone, an estimated 2.3 million people became newly infected (UNAIDS, 2013). Additional safe and effective approaches to HIV prevention are urgently needed. Men who have sex with men (MSM) have a disproportionate burden of HIV in most countries in the world, even in many countries with generalized HIV epidemics. Worldwide, for MSM, the odds of being infected with HIV are 19.3 times higher than for men in the general population (Baral et al., 2007). Although there are a variety of existing efficacious HIV prevention interventions for MSM, they face political and structural barriers to accessing services in many settings due to their stigmatized and marginalized status. The disproportionate burden of HIV faced by MSM suggests that existing methods of HIV prevention are not sufficient and additional prevention modalities would be helpful. Pre-exposure prophylaxis (PrEP) is the use of an antiretroviral drug to block the acquisition of HIV infection by uninfected people. Proof of concept has long been established in the laboratory by animal studies and in real world application by the prevention of mother-to-child transmission and post-exposure prophylaxis. The safety of the drugs being considered for PrEP, tenofovir and emtricitabine, has been established through their use for treatment and in safety trials in uninfected people (Peterson et al., 2007). Five trials of effectiveness (Phase IIb and Phase III) have been conducted in the last decade. These focus on effectiveness of PrEP among people who inject drugs, serodiscordant couples, heterosexual women and high risk MSM. The first trial to produce results was the iPrEx trial (Grant et al., 2010). This Phase III clinical trial tested whether a daily combination of tenofovir and emtricitabine could safely and effectively prevent HIV infection among MSM. Of the five effectiveness trials, this trial conducted on four continents was the only one to examine efficacy in MSM. The iPrEx study demonstrated a 44% reduction in HIV transmission on the modified intention-to-treat analysis. Adherence to the recommended regimen was lower than expected, though it varied by country. For those men who reported taking the pills on 90% or more days, however, the efficacy of PrEP was 73%. Resistance was only found in two participants who had an existing acute HIV infection undetected at baseline and who were randomized to active drug. Few concerns about safety were detected. A marked trend toward risk reduction, specifically increased condom use and decreased number of partners, was reported in both arms and all sites. In 2012, WHO developed guidelines for PrEP for serodiscordant couples, MSM, and transgender people (TG) at high risk of HIV (WHO, 2012). This systematic review updates the review of PrEP for MSM that was completed for those guidelines. This systematic review examined the following PICO question: Should oral PrEP (containing tenofovir (TDF)) be used for HIV prevention among men who have sex WHO/HIV/2014.9 © World Health Organization 2014 PrEP for MSM - systematic review – to inform the WHO Consolidated guidelines on HIV prevention, diagnosis, treatment and care for key populations 4 with men? A few minor changes were made to the PICO question from the earlier guidelines. First, the new PICO question includes only MSM, not transgender people. Second, the new PICO question covers all oral PrEP containing tenofovir, as opposed to the previous PICO question which focused specifically on the combination of emtricitabine (FTC 200mg) and tenofovir (TDF 300 mg) used in the iPrEx study. In addition, in 2011, a review of values and preferences of MSM about PrEP was conducted through a review of published literature. However, most of the studies available at that time were based on data collected before the iPrEx trial results were available. Values and preferences may have changed now that MSM are aware of the partial effectiveness of PrEP. This values and preferences literature review was also updated to capture literature through the end of 2013, with a focus on studies that collected data after iPrEx study results were released. Institutional	2014	Kennedy, Caitlin; Fonner, Virgina; World Health Organization	Pre-exposure prophylaxis for people who inject drugs: a systematic review	-	-	-	-	-	NA	NA	https://iris.who.int/handle/10665/128115	Background An estimated 35.3 million people globally are living with HIV (UNAIDS, 2013). A number of prevention methods are available, from condoms to male circumcision, prevention of mother-to-child transmission to clean needles, but to date these have not been sufficient to stop the epidemic. In 2012 alone, an estimated 2.3 million people became newly infected (UNAIDS, 2013). Additional safe and effective approaches to HIV prevention are urgently needed. People who inject drugs (PWID) have a disproportionate burden of HIV. Existing methods of HIV prevention for PWID include approaches used across populations to reduce sexual transmission as well as approaches specific to PWID to reduce HIV transmission through sharing unclean needles and other injection equipment. However, political and structural barriers prevent access to needle and syringe programs and opioid substitution therapy in many settings, and additional prevention modalities would be helpful for these populations. PrEP is the use of an antiretroviral drug to block the acquisition of HIV infection by uninfected people. Proof of concept has long been established in the laboratory by animal studies and in real world application by the prevention of mother-to-child transmission and post-exposure prophylaxis. The safety of the drugs being considered for PrEP, tenofovir and emtricitabine, has been established through their use for treatment and in safety trials in uninfected people (Peterson et al., 2007). Five trials of effectiveness (Phase IIb and Phase III) of oral PrEP have been conducted in the last decade. These have examined the effectiveness of PrEP among PWID, serodiscordant couples, heterosexual women and high risk men who have sex with men (MSM). Of the five effectiveness trials, only one trial examined efficacy among PWID: the Bangkok Tenofovir Study (Choopanya et al., 2013). This Phase III clinical trial tested whether daily tenofovir disoproxil fumarate (TDF) could safely and effectively prevent HIV infection among PWID in Bangkok, Thailand. Over 2400 PWID were enrolled in the study and randomly assigned to daily TDF or placebo. Participants were also provided regular HIV testing and risk reduction counseling. The primary outcome of the trial was HIV incidence, which was 0.35 per 100 person-years (py) in the TDF group (17 infections) and 0.68 per 100 py in the placebo group (33 infections), indicating a 48.9% reduction in HIV incidence related to PrEP (95% CI: 9.6, 72.2; p=0.01). Serious adverse events were not statistically significantly different between the two groups (p=0.35). Trial findings led the U.S. Centers for Disease Control and Prevention (CDC) to recommend PrEP be considered "as one of several prevention options for persons at very high risk for HIV acquisition through the injection of illicit drugs" (CDC, 2013). This systematic review examined evidence to answer the following PICO question: Should oral PrEP (containing tenofovir (TDF)) be used for HIV prevention among people who inject drugs (PWID)? In addition, we reviewed the values and preferences about PrEP among people who use drugs and considered studies of cost and feasibility for the GRADE process. Article	2014	Kessler, Jason; Myers, Julie E; Nucifora, Kimberly A; Mensah, Nana; Toohey, Christopher; Khademi, Amin; Cutler, Blayne; Braithwaite, Scott	Evaluating the impact of prioritization of antiretroviral pre-exposure prophylaxis in New York.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0000000000000460	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4556593	OBJECTIVE: To compare the value and effectiveness of different prioritization strategies of pre-exposure prophylaxis (PrEP) in New York City (NYC). DESIGN: Mathematical modelling utilized as clinical trial is not feasible. METHODS: Using a model accounting for both sexual and parenteral transmission of HIV, we compare different PrEP prioritization strategies (PPS) with two scenarios - no PrEP and PrEP for all susceptible at-risk individuals. The PPS included PrEP for all MSM,only high-risk MSM, high-risk heterosexuals, and IDUs, and all combinations of these four strategies. Outcomes included HIV infections averted, and incremental cost effectiveness(per-infection averted) ratios. Initial assumptions regarding PrEP included a 44% reduction in HIV transmission, 50% uptake in the prioritized population and an annual cost per person of $9762. Sensitivity analyses on key parameters were conducted. RESULTS: Prioritization to all MSM results in a 19% reduction in new HIV infections. Compared with PrEP for all persons at-risk, this PPS retains 79% of the preventive effect at 15% of the total cost. PrEP prioritized to only high-risk MSM results in a reduction in new HIV infections of 15%. This PPS retains 60% of the preventive effect at 6% of the total cost. There are diminishing returns when PrEP utilization is expanded beyond this group. CONCLUSION: PrEP implementation is relatively cost-inefficient under our initial assumptions. Our results suggest that PrEP should first be promoted among MSM who are at particularly high risk of HIV acquisition. Further expansion beyond this group may be cost-effective, but is unlikely to be cost-saving. Article	2014	King, Helen L; Keller, Samuel B; Giancola, Michael A; Rodriguez, David A; Chau, Jasmine J; Young, Jason A; Little, Susan J	Pre-Exposure Prophylaxis Accessibility Research and Evaluation (PrEPARE Study)	AIDS and Behavior	-	-	-	-	1090-7165	https://doi.org/10.1007/s10461-014-0845-5	https://escholarship.org/uc/item/2zf7v8q5	Tenofovir-emtricitabine (TDF-FTC) has demonstrated effectiveness as HIV preexposure prophylaxis (PrEP), but it is not commonly prescribed. Our study was designed to determine the barriers preventing utilization of PrEP among men who have sex with men (MSM), the group at greatest risk for HIV infection in the United States. A population-based sample of MSM presenting for HIV testing at 'Early Test' HIV testing and counseling sites in San Diego, California were offered PrEP and education about potential efficacy. Eligible individuals reported having unprotected sex within the past 12 months and who tested negative for HIV were offered study participation. Despite offering procedures for evaluation and prescription for PrEP to 416 eligible subjects, less than 0.5 % of participants received the drug. Surveys collected from 54 of those who declined study participation revealed multiple barriers to PrEP among MSM including cost, low perceived risk of infection and concerns about taking a daily medication and potential long-term side effects. Efforts should be made to address these barriers, especially lowering the cost of TDF-FTC, education about PrEP side effects and awareness of HIV risks. Article	2014	Krakower, Douglas; Ware, Norma; Mitty, Jennifer A; Maloney, Kevin; Mayer, Kenneth H	HIV providers' perceived barriers and facilitators to implementing pre-exposure prophylaxis in care settings: a qualitative study.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-014-0839-3	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4127184	Oral pre-exposure prophylaxis (PrEP) can reduce HIV incidence among at-risk persons. However, for PrEP to have an impact in decreasing HIV incidence, clinicians will need to be willing to prescribe PrEP. HIV specialists are experienced in using antiretroviral medications, and could readily provide PrEP, but may not care for HIV-uninfected patients. Six focus groups with 39 Boston area HIV care providers were conducted (May-June 2012) to assess perceived barriers and facilitators to prescribing PrEP. Participants articulated logistical and theoretical barriers, such as concerns about PrEP effectiveness in real-world settings, potential unintended consequences (e.g., risk disinhibition and medication toxicity), and a belief that PrEP provision would be more feasible in primary care clinics. They identified several facilitators to prescribing PrEP, including patient motivation and normative guidelines. Overall, participants reported limited prescribing intentions. Without interventions to address HIV providers' concerns, implementation of PrEP in HIV clinics may be limited. Article	2014	Kurtz, Steven P; Buttram, Mance E; Surratt, Hilary L	Vulnerable infected populations and street markets for ARVs: Potential implications for PrEP rollout in the USA	AIDS Care	-	-	-	-	09540121	10.1080/09540121.2013.837139	https://www.proquest.com/scholarly-journals/vulnerable-infected-populations-street-markets/docview/1491096333/se-2?accountid=8113	Widespread diversion of antiretroviral (ARV) medications to illicit markets has recently been documented among indigent patients in South Florida. The recent approval of ARVs for pre-exposure prophylaxis (PrEP) has the potential to broaden these illicit markets, as high-risk individuals seek ARVs without a prescription or medical supervision. Nonadherence among diverters and unsupervised use of ARVs for treatment or PrEP increase risks of treatment failure, drug resistance, and disease transmission. We report the scope of ARV diversion among substance-using men who have sex with men in South Florida. Structured interviews (N = 515) gathered demographics, HIV status, mental distress, substance dependence, and sexual risks. HIV-positive participants answered questions about medical care, treatment, and ARV adherence and diversion. Median age was 39. Of 46.4% who were HIV-positive, 79.1% were prescribed ARVs. Of these, 27% reported selling/trading ARVs. Reasons for diversion were sharing/trading with friends, sale/trade for money/drugs, and sale/trade of unused medications. ARV diverters, compared to nondiverters, were more likely to be substance dependent (74.5% vs. 58.7%, p = 0.046) and have traded sex for money/drugs (60.8% vs. 32.6%, p < 0.001), and less likely to be adherent to ARVs (54.9% vs. 73.9%, p = 0.012). ARV diversion should be a particular concern in communities of high-risk men who have sex with men as uninfected men in such communities are likely to benefit most from PrEP but unlikely to have access to PrEP and necessary ancillary services through the health-care system. The implications of diversion for increased risks of treatment failure, disease transmission, and PrEP failure should be carefully considered in developing policy and behavioral supports to scaling up treatment as prevention and PrEP. Article	2014	Lasry, Arielle; Sansom, Stephanie L.; Wolitski, Richard J.; Green, Timothy A.; Borkowf, Craig B.; Patel, Pragna; Mermin, Jonathan	HIV sexual transmission risk among serodiscordant couples: assessing the effects of combining prevention strategies.	AIDS	-	-	-	1473-5571 0269-9370	10.1097/QAD.0000000000000307	https://pubmed.ncbi.nlm.nih.gov/24804859/	BACKGROUND: The number of strategies to prevent HIV transmission has increased following trials evaluating antiretroviral therapy (ART), preexposure prophylaxis (PrEP) and male circumcision. Serodiscordant couples need guidance on the effects of these strategies alone, and in combination with each other, on HIV transmission. METHODS: We estimated the sexual risk of HIV transmission over 1-year and 10-year periods among male-male and male-female serodiscordant couples. We assumed the following reductions in transmission: 80% from consistent condom use; 54% from circumcision in the negative male partner of a heterosexual couple; 73% from circumcision in the negative partner of a male-male couple; 71% from PrEP in heterosexual couples; 44% from PrEP in male-male couples; and 96% from ART use by the HIV-infected partner. FINDINGS: For couples using any single prevention strategy, a substantial cumulative risk of HIV transmission remained. For a male-female couple using only condoms, estimated risk over 10 years was 11%; for a male-male couple using only condoms, estimated risk was 76%. ART use by the HIV-infected partner was the most effective single strategy in reducing risk; among male-male couples, adding consistent condom use was necessary to keep the 10-year risk below 10%. CONCLUSION: Focusing on 1-year and longer term transmission probabilities gives couples a better understanding of risk than those illustrated by data for a single sexual act. Long-term transmission probabilities to the negative partner in serodiscordant couples can be high, though these can be substantially reduced with the strategic use of preventive methods, especially those that include ART. Article	2014	Li, Julius; Dufrene, Staci L; Okulicz, Jason F	Systemic preexposure prophylaxis for HIV: translating clinical data to clinical practice.	Annals of Pharmacotherapy	-	-	-	1542-6270	10.1177/1060028014520880	https://dx.doi.org/10.1177/1060028014520880	OBJECTIVE: To assess the real-world implications of oral tenofovir-emtricitabine (TDF-FTC) for HIV preexposure prophylaxis (PrEP) in clinical practice and highlight important considerations for its implementation. DATA SOURCES: A search of PubMed (January 1996 through June 2013) was conducted using the terms HIV preexposure prophylaxis, HIV prevention, tenofovir, and emtricitabine. Abstracts from 2012-2013 HIV/AIDS conferences were also reviewed. STUDY SELECTION AND DATA EXTRACTION: All pertinent original studies and review articles published in English were evaluated for inclusion. Reference citations from identified articles were examined for additional content. DATA SYNTHESIS: Although antiretroviral therapy has been highly successful in reducing AIDS outcomes and death in HIV-infected patients worldwide, transmission of HIV remains a major global health problem. The recent approval of oral TDF-FTC for HIV PrEP represents the latest biomedical intervention to help control this epidemic. Four published randomized studies evaluated the efficacy and safety of this combination to prevent HIV transmission in several at-risk populations, including men who have sex with men, serodiscordant couples, and heterosexuals residing in endemic regions. Overall, these studies demonstrated significant risk reductions in the incidence of new HIV infections with good short-term tolerability. Despite promising results from clinical studies, several limitations may hinder the utility of PrEP in clinical practice. Most importantly, PrEP was studied in the context of a comprehensive prevention program, including intensive counseling on adherence, high-risk behaviors, and traditional preventative measures. If PrEP is implemented without these adjunct measures, concerns about failure and increased resistance may eventually be realized. CONCLUSION: The greatest impact of PrEP, both clinically and financially, will likely arise from judicious application in select high-risk populations. If used appropriately, PrEP has the potential to augment reductions in the current incidence of new HIV infections, and pharmacists will have an important role in the careful selection and counseling of these targeted populations. Article	2014	Liu, Albert Y; Hessol, Nancy A; Vittinghoff, Eric; Amico, K Rivet; Kroboth, Elizabeth; Fuchs, Jonathan; Irvin, Risha; Sineath, R Craig; Sanchez, Travis; Sullivan, Patrick S; Buchbinder, Susan P	Medication adherence among men who have sex with men at risk for HIV infection in the United States: implications for pre-exposure prophylaxis implementation.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2014.0195	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4250955	Pre-exposure prophylaxis (PrEP) is a promising HIV prevention approach for men who have sex with men (MSM), however non-adherence could limit its effectiveness. Understanding the experiences of HIV-uninfected MSM taking routine medications can provide valuable insights into open label PrEP adherence in real world settings and guide development of PrEP adherence interventions. In this study, we examined self-reported medication-taking experiences and facilitators and barriers of medication adherence among a geographically-diverse online sample of HIV-uninfected US MSM. Among 1480 participants, 806 (54%) reported taking medications regularly, of whom 80% reported taking medications for treatment and 55% for prevention purposes. Facilitators of medication adherence included establishing a routine, keeping medication visible, and using a pill-box; barriers included forgetting, changes in routine, and being busy or away from home. Only 45% rated their medication-taking ability as excellent, and 36% reported not missing any doses in the past 30 days. In multivariable analyses, older men and those not reporting any adherence barriers were more likely to report excellent adherence, and men willing to use PrEP were more likely to report perfect 30-day adherence. Counseling strategies to build pill-taking routines and support younger MSM are suggested to maximize the public health impact of PrEP. Article	2014	Liu, Albert Y; Yang, Qiyun; Huang, Yong; Bacchetti, Peter; Anderson, Peter L; Jin, Chengshi; Goggin, Kathy; Stojanovski, Kristefer; Grant, Robert; Buchbinder, Susan P; Greenblatt, Ruth M; Gandhi, Monica	Strong relationship between oral dose and tenofovir hair levels in a randomized trial: hair as a potential adherence measure for pre-exposure prophylaxis (PrEP).	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0083736	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3885443	BACKGROUND: Pre-exposure prophylaxis (PrEP) trials using tenofovir-based regimens have demonstrated that high levels of adherence are required to evaluate efficacy; the incorporation of objective biomarkers of adherence in trial design has been essential to interpretation, given the inaccuracy of self-report. Antiretroviral measurements in scalp hair have been useful as a marker of long-term exposure in the HIV treatment setting, and hair samples are relatively easy and inexpensive to collect, transport, and store for analysis. To evaluate the relationship between dose and tenofovir concentrations in hair, we examined the dose proportionality of tenofovir in hair in healthy, HIV-uninfected adults. METHODS: A phase I, crossover pharmacokinetic study was performed in 24 HIV-negative adults receiving directly-observed oral tenofovir tablets administered 2, 4, and 7 doses/week for 6 weeks, with a ≥3-week break between periods. Small samples of hair were collected after each six-week period and analyzed for tenofovir concentrations. Geometric-mean-ratios compared levels between each pair of dosing conditions. Intensive plasma pharmacokinetic studies were performed during the daily-dosing period to calculate areas-under-the-time-concentration curves (AUCs). RESULTS: Over 90% of doses were observed per protocol. Median tenofovir concentrations in hair increased monotonically with dose. A log-linear relationship was seen between dose and hair levels, with an estimated 76% (95% CI 60-93%) increase in hair level per 2-fold dose increase. Tenofovir plasma AUCs modestly predicted drug concentrations in hair. CONCLUSIONS: This study found a strong linear relationship between frequency of dosing and tenofovir levels in scalp hair. The analysis of quantitative drug levels in hair has the potential to improve adherence measurement in the PrEP field and may be helpful in determining exposure thresholds for protection and explaining failures in PrEP trials. Hair measures for adherence monitoring may also facilitate adherence measurement in real-world settings and merit further investigation in upcoming PrEP implementation studies and programs. Article	2014	Liu, Albert; Cohen, Stephanie; Follansbee, Stephen; Cohan, Deborah; Weber, Shannon; Sachdev, Darpun; Buchbinder, Susan	Early Experiences Implementing Pre-exposure Prophylaxis (PrEP) for HIV Prevention in San Francisco: e1001613	PLOS Medicine	-	-	-	15491277	10.1371/journal.pmed.1001613	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3942317/	Provenance: Not commissioned; externally peer reviewed Summary Points * Pre-exposure prophylaxis (PrEP) has been demonstrated to be safe and efficacious in clinical trials and emtricitabine/tenofovir was approved by the United States Food and Drug Administration for use as PrEP in 2012. * We report early experiences with PrEP uptake and delivery in three different settings in San Francisco: a PrEP demonstration project in a municipal sexually transmitted diseases (STD) clinic, and two PrEP delivery programs (a private health maintenance organization and an HIV-specific reproductive health program). * Interest in PrEP is high in San Francisco, particularly among men who have sex with men attending the STD clinic, and it is feasible to incorporate PrEP into busy clinical settings. On the basis of compelling safety and efficacy data from pre-exposure prophylaxis (PrEP) trials of men who have sex with men (MSM) conducted across four continents and serodifferent heterosexual couples and young men and women in sub-Saharan Africa 1-3, the FDA issued the landmark approval of once-daily, co-formulated emtricitabine/tenofovir (FTC/TDF) for HIV prevention in men and women at risk for acquiring HIV infection through sexual exposure. Article	2014	Liu, Albert; Glidden, David V; Anderson, Peter L; Amico, K Rivet; McMahan, Vanessa; Mehrotra, Megha; Lama, Javier R; MacRae, John; Hinojosa, Juan Carlos; Montoya, Orlando; Veloso, Valdilea G; Schechter, Mauro; Kallas, Esper G; Chariyalerstak, Suwat; Bekker, Linda-Gail; Mayer, Kenneth; Buchbinder, Susan; Grant, Robert	Patterns and correlates of PrEP drug detection among MSM and transgender women in the Global iPrEx Study.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000351	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4229454	BACKGROUND: Adherence to pre-exposure prophylaxis (PrEP) is critical for efficacy. Antiretroviral concentrations are an objective measure of PrEP use and correlate with efficacy. Understanding patterns and correlates of drug detection can identify populations at risk for nonadherence and inform design of PrEP adherence interventions. METHODS: Blood antiretroviral concentrations were assessed among active arm participants in iPrEx, a randomized placebo-controlled trial of emtricitabine/tenofovir in men who have sex with men and transgender women in 6 countries. We evaluated rates and correlates of drug detection among a random sample of 470 participants at week 8 and a longitudinal cohort of 303 participants through 72 weeks of follow-up. RESULTS: Overall, 55% of participants (95% confidence interval: 49 to 60) tested at week 8 had drug detected. In longitudinal analysis, 31% never had drug detected, 30% always had drug detected, and 39% had an inconsistent pattern. Overall detection rates declined over time. Drug detection at some or all visits was associated with older age, indices of sexual risk, including condomless receptive anal sex, and responding "don't know" to a question about belief of PrEP efficacy (0-10 scale). CONCLUSIONS: Distinct patterns of study product use were identified, with a significant proportion demonstrating no drug detection at any visit. Research literacy may explain greater drug detection among populations having greater research experience, such as older men who have sex with men in the United States. Greater drug detection among those reporting highest risk sexual practices is expected to increase the impact and cost-effectiveness of PrEP.	pre-exposure prophylaxis, drug detection, emtricitabine/tenofovir, adherence, men who have sex with men	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Lo, Ying-Ru; Kato, Masaya; Phanuphak, Nittaya; Fujita, Masami; Duc, Duong Bui; Sopheap, Seng; Pendse, Razia; Yu, Dongbao; Wu, Zunyou; Chariyalertsak, Suwat	Challenges and potential barriers to the uptake of antiretroviral-based prevention in Asia and the Pacific region.	Sexual Health	-	-	-	1448-5028	10.1071/SH13094	https://pubmed.ncbi.nlm.nih.gov/25007911/	Evidence has emerged over the past few years on the effectiveness of antiretroviral-based prevention technologies to prevent (i) HIV transmission while decreasing morbidity and mortality in HIV-infected persons, and (ii) HIV acquisition in HIV-uninfected individuals through pre-exposure prophylaxis (PrEP). Only few of the planned studies on treatment as prevention (TasP) are conducted in Asia. TasP might be more feasible and effective in concentrated rather than in generalised epidemics, as resources for HIV testing and antiretroviral treatment could focus on confined and much smaller populations than in the generalised epidemics observed in sub-Saharan Africa. Several countries such as Cambodia, China, Thailand and Vietnam, are now paving the way to success. Similar challenges arise for both TasP and PrEP. However, the operational issues for PrEP are amplified by the need for frequent retesting and ensuring adherence. This paper describes challenges for the implementation of antiretroviral-based prevention and makes the case that TasP and PrEP implementation research in Asia is much needed to provide insights into the feasibility of these interventions in populations where firm evidence of 'real world' effectiveness is still lacking. Article	2014	Lusti-Narasimhan, Manjula; Khosla, Rajat; Baggaley, Rachel; Temmerman, Marleen; McGrory, Elizabeth; Farley, Tim	WHO guidance grounded in a comprehensive approach to sexual and reproductive health and human rights: topical pre-exposure prophylaxis.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.17.3.19279	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4163998	INTRODUCTION: Two new microbicide products based on topical (vaginal) application of antiretroviral drugs - 1% tenofovir gel and the dapivirine ring - are currently in late-stage clinical testing, and results on their safety and effectiveness are expected to become available in early 2015. WHO guidelines on the use of topical pre-exposure prophylaxis (topical PrEP) are important in order to ensure that these new prevention products are optimally used. DISCUSSION: Given that these new topical PrEP products are designed to be woman initiated and will likely be delivered in reproductive health settings, it is important to ensure that the guidance be framed in the context of comprehensive sexual and reproductive health and human rights. In addition to the safety and effectiveness data resulting from clinical trials, and the regulatory approval required for new products, the WHO normative guidelines on the use of topical PrEP will be essential for rapid roll-out in countries. CONCLUSIONS: Human rights standards and principles provide a framework for the provision of woman-initiated HIV prevention products. These include addressing issues related to the gender inequities which are linked to the provision of HIV-prevention, treatment and care for young girls and women. Effective programming for women and girls must therefore be based on understanding the local, social and community contexts of the AIDS epidemic in the country, and adapting HIV strategies and programmes accordingly. Such a framework therefore is needed not only to ensure optimal uptake of these new products by women and girls but also to address sociocultural barriers to women's and girls' access to these products.	human rights, sexual and reproductive health, HIV, prevention, pre-exposure prophylaxis, microbicide	English	United States	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Clinical
Article	2014	Maartens, Gary; Celum, Connie; Lewin, Sharon R.	HIV infection: epidemiology, pathogenesis, treatment, and prevention.	The Lancet	-	-	-	1474-547X 0140-6736	10.1016/S0140-6736(14)60164-1	https://pubmed.ncbi.nlm.nih.gov/24907868/	HIV prevalence is increasing worldwide because people on antiretroviral therapy are living longer, although new infections decreased from 3.3 million in 2002, to 2.3 million in 2012. Global AIDS-related deaths peaked at 2.3 million in 2005, and decreased to 1.6 million by 2012. An estimated 9.7 million people in low-income and middle-income countries had started antiretroviral therapy by 2012. New insights into the mechanisms of latent infection and the importance of reservoirs of infection might eventually lead to a cure. The role of immune activation in the pathogenesis of non-AIDS clinical events (major causes of morbidity and mortality in people on antiretroviral therapy) is receiving increased recognition. Breakthroughs in the prevention of HIV important to public health include male medical circumcision, antiretrovirals to prevent mother-to-child transmission, antiretroviral therapy in people with HIV to prevent transmission, and antiretrovirals for pre-exposure prophylaxis. Research into other prevention interventions, notably vaccines and vaginal microbicides, is in progress. Article	2014	Mack, Natasha; Odhiambo, Jacob; Wong, Christina M; Agot, Kawango	Barriers and facilitators to pre-exposure prophylaxis (PrEP) eligibility screening and ongoing HIV testing among target populations in Bondo and Rarieda, Kenya: results of a consultation with community stakeholders.	BMC Health Services Research	-	-	-	1472-6963	10.1186/1472-6963-14-231	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4051373	BACKGROUND: As pre-exposure prophylaxis (PrEP) moves closer to availability in developing countries, practical considerations for implementation become important. We conducted a consultation with district-level community stakeholders experienced in HIV-prevention interventions with at-risk populations in Bondo and Rarieda, Kenya to generate locally grounded approaches to the future rollout of oral PrEP to four populations: fishermen, widows, female sex workers, and serodiscordant couples. METHODS: The 20 consultation participants represented the Ministry of Health, faith- and community-based organizations, health facilities, community groups, and nongovernmental organizations. Participants divided into breakout groups and followed a structured discussion guide asking them to identify barriers to implementing HIV-prevention interventions (including PrEP) with each population. Questions also solicited solutions for addressing these barriers, as well as other facilitators for PrEP implementation. In particular, questions focused on how to encourage people to screen for PrEP eligibility by having HIV and other blood tests and how to encourage compliance with ongoing HIV testing. RESULTS: The barriers and facilitators/solutions discussants provided were frequently population-specific, but there were also broad-level similarities across populations. Service delivery barriers to HIV-prevention interventions concerned the need for staff trained to address the needs of particular populations. Service delivery facilitators to provision of ongoing HIV testing consisted of offering testing options besides facility-based testing. Stigma was the main community-level barrier for all groups, whereas barriers at the level of target populations included mobility; lifestyle and life circumstances, especially cultural norms among fishermen and widows; and fears, lack of awareness, and misinformation. Proposed facilitators and strategies for addressing community- and population-level barriers included topic-specific education within the populations and community, involvement of partners and family members, mass HIV testing, and peer educators. Barriers to PrEP uptake included non-adherence to pill taking and missing clinic visits. For drug adherence, facilitators were counselling and involving family members. Discussants suggested that client reminders, e.g., home visits, were needed to encourage clients to keep their clinic appointments. CONCLUSIONS: Strategies for encouraging eligibility screening and ongoing HIV testing will have local and population-specific aspects. Our results nonetheless apply to similar populations throughout sub-Saharan Africa and reach beyond oral PrEP to other ARV-based PrEP formulations. Article	2014	Magazi, Busisiwe; Stadler, Jonathan; Delany-Moretlwe, Sinead; Montgomery, Elizabeth; Mathebula, Florence; Hartmann, Miriam; van der Straten, Ariane	Influences on visit retention in clinical trials: insights from qualitative research during the VOICE trial in Johannesburg, South Africa.	BMC Women's Health	-	-	-	1472-6874	10.1186/1472-6874-14-88	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4115485/	BACKGROUND: Although significant progress has been made in clinical trials of women-controlled methods of HIV prevention such as microbicides and Pre-exposure Prophylaxis (PrEP), low adherence to experimental study products remains a major obstacle to being able to establish their efficacy in preventing HIV infection. One factor that influences adherence is the ability of trial participants to attend regular clinic visits at which trial products are dispensed, adherence counseling is administered, and participant safety is monitored. We conducted a qualitative study of the social contextual factors that influenced adherence in the VOICE (MTN-003) trial in Johannesburg, South Africa, focusing on study participation in general, and study visits in particular. METHODS: The research used qualitative methodologies, including in-depth interviews (IDI), serial ethnographic interviews (EI), and focus group discussions (FGD) among a random sub-sample of 102 female trial participants, 18 to 40 years of age. A socio-ecological framework that explored those factors that shaped trial participation and adherence to study products, guided the analysis. Key codes were developed to standardize subsequent coding and a node search was used to identify texts relating to obstacles to visit attendance. Our analysis includes coded transcripts from seven FGD (N = 40), 41 IDI, and 64 serial EI (N = 21 women). RESULTS: Women's kinship, social, and economic roles shaped their ability to participate in the trial. Although participants expressed strong commitments to trial visits, clinic visit schedules and lengthy waiting times interfered with their multiple obligations as care givers, wage earners, housekeepers, and students. CONCLUSIONS: The research findings highlight the importance of the social context in shaping participation in HIV prevention trials, beyond focusing solely on individual characteristics. This points to the need to focus interventions to improve visit attendance by promoting a culture of active and engaged participation. Theses and Dissertations	2014	Maisel, Katharina	HYPOTONIC DELIVERY OF DRUGS AND DRUG-LOADED NANOPARTICLES TO THE GASTROINTESTINAL TRACT	-	-	Johns Hopkins University	-	NA	NA	http://jhir.library.jhu.edu/handle/1774.2/40663	Innovative gastrointestinal (GI) drug delivery vehicles such as mucus penetrating nanoparticles (MPP) and fluid-absorption inducing (hypotonic) delivery vehicles have potential to improve therapeutic outcomes over conventional methods such as mucoadhesive particles (MAP) for GI diseases, including ulcerative colitis (UC) and HIV pre-exposure prophylaxis (PrEP). More than 80% of all drugs are absorbed via the GI tract for either systemic or local treatment. MAP delivered to the GI tract are thought to improve oral absorption or local targeting of difficult-to-deliver drug classes. Mucus is a continuously secreted barrier that effectively traps foreign particulates to protect the underlying epithelium. Rapid clearance of the most superficial luminal mucus layers in the GI tract may limit the effectiveness of MAP. Here, I test the current dogma of mucoadhesion by comparing MAP and MPP GI drug delivery via the oral and rectal routes. In addition I investigate the development of several vehicles including rectal enemas and gels for more effective delivery of nanocarriers or free drugs. First, I illustrate that MPP uniformly coat all surfaces of the GI epithelium, while MAP aggregated in mucus in the center of the lumen, far away from the absorptive epithelium, both in healthy mice and mice with UC. In the mouse colorectum, MPP penetrated into mucus in the deeply in-folded surfaces to evenly coat the entire epithelial surface. Moreover, in UC mice, MPP were transported preferentially into the disrupted, ulcerated tissue. Next, I sought to design an effective enema vehicle for delivering MPP and non-mucoadhesive drugs locally to the colorectum. I found that MPP and free drug are only rapidly transported to the epithelial surface in sodium-based enemas, while potassium-based or isotonic and hypertonic (secretion-inducing) enemas cause heterogeneous surface coverage. Strongly hypertonic and hypotonic enemas cause rapid systemic drug absorption, while moderately hypotonic enemas improve local drug retention in tissue. Finally, I designed a microbicide-loaded MPP for PrEP, to be delivered in a novel osmotic thermogel. The MPP formulation evenly coated both the vaginal and colorectal epithelium and the hypotonically delivered thermogel effectively traps HIV, and significantly enhances drug and nanoparticle retention in the cervicovaginal tract.	mucus penetrating particle; microbicide	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Clinical
Article	2014	Malcolm, R. Karl; Lowry, Deborah; Boyd, Peter; Geer, Leslie; Veazey, Ronald S.; Goldman, Laurie; Klasse, P. J.; Shattock, Robin J.; Moore, John P.	Pharmacokinetics of a CCR5 inhibitor in rhesus macaques following vaginal, rectal and oral application.	The Journal of Antimicrobial Chemotherapy	-	-	-	1460-2091 0305-7453	10.1093/jac/dkt506	https://academic.oup.com/jac/article/69/5/1325/679483	OBJECTIVES: This study measured and compared the pharmacokinetics of CMPD167, a small molecule antiretroviral CCR5 inhibitor with potential as an HIV microbicide, following vaginal, rectal and oral administration in rhesus macaques. METHODS: A vaginal hydroxyethylcellulose (HEC) gel, a rectal HEC gel, a silicone elastomer matrix-type vaginal ring and an oral solution, each containing CMPD167, were prepared and administered to rhesus macaques pretreated with Depo-Provera. CMPD167 concentrations in vaginal fluid, vaginal tissue (ring only), rectal fluid and blood plasma were quantified by HPLC-mass spectrometry. RESULTS: CMPD167 concentrations measured in rectal fluid, vaginal fluid and blood plasma were highly dependent on both the route of administration and the formulation type. Although rectal and vaginal fluid concentrations were highest when CMPD167 was administered locally (via either gel or ring), lower concentrations of the drug were also measured in these compartments following administration at the remote mucosal site or orally. CMPD167 levels in the vaginal and rectal fluid following oral administration were relatively low compared with local administration. CONCLUSIONS: The study provides clear evidence for vaginal-rectal and rectal-vaginal drug transfer pathways and suggests that oral pre-exposure prophylaxis with CMPD167 may be less efficacious at preventing sexual transmission of HIV-1 than topically applied products. Article	2014	Mandala, Justin; Nanda, Kavita; Wang, Meng; De Baetselier, Irith; Deese, Jennifer; Lombaard, Johan; Owino, Fredrick; Malahleha, Mookho; Manongi, Rachel; Taylor, Douglas; Van Damme, Lut	Liver and renal safety of tenofovir disoproxil fumarate in combination with emtricitabine among African women in a pre-exposure prophylaxis trial.	BMC Pharmacology and Toxicology	-	-	-	2050-6511	10.1186/2050-6511-15-77	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4297367	BACKGROUND: Safety of tenofovir disoproxil fumarate/emtricitabine (TDF-FTC) has been studied more extensively among HIV-infected patients than among HIV-uninfected people. Using data from a pre-exposure trial - FEM-PrEP -, we determined the cumulative probabilities of grade 1+ ALT, AST and creatinine and grade 2+ phosphorus toxicities; ALT/AST toxicities by baseline hepatitis B status; and change in mean creatinine, phosphorus, ALT and AST levels controlling for TDF-FTC adherence. METHODS AND FINDINGS: FEM-PrEP was a randomized, blinded, placebo-controlling trial of daily TDF-FTC among women in Africa. Enrolled women were in general good health, HIV antibody negative, 18 to 35 years old, hepatitis B surface antigen negative, and had normal hepatic and renal function at baseline. AST, ALT, phosphorus and serum creatinine were measured regularly throughout the trial. TDF-FTC concentrations were measured to assess adherence to TDF-FTC. The cumulative probabilities of grade 1+ creatininemia and grade 2+ phosphatemia toxicities were not statistically different between TDF-FTC and placebo arms. The cumulative probabilities of grade 1+ ALT and AST toxicities were higher among participants in the TDF-FTC arm than in the placebo arm (p = 0.03 for both). The proportions of grade 1+ and grade 2+ ALT or AST toxicities were significantly higher in participants who were hepatitis B virus surface antibody (HBsAb) positive than in those who were HBsAb-negative. Women with good adherence had higher mean change from baseline to week 4 in their AST levels (2.90 (0.37, 5.42); p = 0.025) than women with less than good adherence. CONCLUSIONS: We did not observe a significant relationship between randomization to TDF-FTC and creatinine or phosphorus toxicities. Women randomized to TDF-FTC had higher rates of mild to moderate ALT/AST toxicities, especially women with prior hepatitis B virus exposure. We also observed a significant increase in AST from baseline to week 4 among women who had higher adherence to TDF-FTC during that interval. TRIAL REGISTER: #NCT00625404, February 19, 2008. Article	2014	Mandelbrot, Laurent	Pregnancy: a model of prevention of HIV transmission.	Bulletin de l'Academie nationale de medecine	-	-	-	0001-4079	10.1186/2050-6511-15-77	https://www.sciencedirect.com/science/article/pii/S0001407919312890?via%3Dihub	Antiretroviral drugs are primarily used to treat people living with HIV but can also reduce the risk of transmission. The first application of this prophylactic approach was in the prevention of mother-to-child transmission, which comprises three components: 1) antiretroviral therapy during pregnancy to reduce maternal viral load, 2) pre-exposure prophylactic treatment of the fetus in utero and intrapartum, and 3) postexposure neonatal treatment. This has resulted in a sharp reduction in mother-to-child transmission, to well below 1 % in France today. "Treatment as prevention" (TASP) is now widely recommended to prevent sexual transmission to partners of people living with HIV articularly when a couple wishes to have children. Achieving and sustaining undetectable viral load is an important means of reducing the risk of sexual transmission in serodiscordant couples and also of controlling the pandemic worldwide. The other uses of antiretroviral drugs to protect HIV-negative people at risk include post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP). Prevention has both individual and collective dimensions and involves several components, including behavioral changes, serological testing, and use of antiretrovirals. Article	2014	Mansoor, Leila E.; Abdool Karim, Quarraisha; Mngadi, Kathryn T.; Dlamini, Sarah; Montague, Carl; Nkomonde, Nelisiwe; Mvandaba, Nomzamo; Baxter, Cheryl; Gengiah, Tanuja N.; Samsunder, Natasha; Dawood, Halima; Grobler, Anneke; Frohlich, Janet A.; Abdool Karim, Salim S.	Assessing the implementation effectiveness and safety of 1% tenofovir gel provision through family planning services in KwaZulu-Natal, South Africa: study protocol for an open-label randomized controlled trial.	Trials	-	-	-	1745-6215	10.1186/1745-6215-15-496	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4300828/	BACKGROUND: The Centre for the AIDS Programme of Research in South Africa (CAPRISA) 004 trial demonstrated a 39% reduction in HIV infection, with a 54% HIV reduction in women who used tenofovir gel consistently. A confirmatory trial is expected to report results in early 2015. In the interim, we have a unique window of opportunity to prepare for and devise effective strategies for the future policy and programmatic scale-up of tenofovir gel provision. One approach is to integrate tenofovir gel provision into family planning (FP) services. The CAPRISA 008 implementation trial provides an opportunity to provide post-trial access to tenofovir gel while generating empiric evidence to assess whether integrating tenofovir gel provision into routine FP services can achieve similar levels of adherence as the CAPRISA 004 trial. METHODS/DESIGN: This is a two-arm, open-label, randomized controlled non-inferiority trial. A maximum of 700 sexually active, HIV-uninfected women aged 18 years and older who previously participated in an antiretroviral prevention study will be enrolled from an urban and rural site in KwaZulu-Natal, South Africa. The anticipated study duration is 30 months, with active accrual requiring approximately 12 months (following which an open cohort will be maintained) and follow-up continuing for approximately 18 months. At each of the two sites, eligible participants will be randomly assigned to receive tenofovir gel through either FP services (intervention arm) or through the CAPRISA research clinics (control arm). As part of the study intervention, a quality improvement approach will be used to assist the FP services to expand their current services to include tenofovir gel provision. DISCUSSION: This protocol aims to address an important implementation question on whether FP services are able to effectively incorporate tenofovir gel provision for this at-risk group of women in South Africa. Provision of tenofovir gel to the women from the CAPRISA 004 trial meets the ethical obligation for post-trial access, and helps identify a potential avenue for future scale-up of microbicides within the public health system of South Africa. TRIAL REGISTRATION: This trial was registered with the South Africa Department of Health (reference: DOH-27-0812-4129) and ClinicalTrials.gov (reference: NCT01691768) on 05 July 2012. Article	2014	Mantell, Joanne E; Sandfort, Theo G M; Hoffman, Susie; Guidry, John A; Masvawure, Tsitsi B; Cahill, Sean	Knowledge and Attitudes about Pre-Exposure Prophylaxis (PrEP) among Sexually Active Men Who Have Sex with Men (MSM) Participating in New York City Gay Pride Events.	LGBT Health	-	-	-	2325-8306	10.1089/lgbt.2013.0047	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4204101	We conducted a street-based intercept survey with 480 men reporting sex with men (MSM) during June 2011 Gay Pride events in New York City (NYC). Awareness and knowledge of pre-exposure prophylaxis (PrEP) were limited. Many men believed that PrEP use should be encouraged, and that some of their friends would use it; and were interested in using it themselves. Men who believed that PrEP should only be taken before sex were more likely to endorse it and report greater likelihood of use. Article	2014	Marcus, J L; Buisker, T; Horvath, T; Amico, K R; Fuchs, J D; Buchbinder, S P; Grant, R M; Liu, A Y	Helping our patients take HIV pre-exposure prophylaxis (PrEP): a systematic review of adherence interventions.	HIV Medicine	-	-	-	1468-1293	10.1111/hiv.12132	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4107052	OBJECTIVES: Adherence is critical for maximizing the effectiveness of pre-exposure prophylaxis (PrEP) in preventing HIV infection. Strategies for promoting adherence to HIV treatment, and their potential application to PrEP adherence, have received considerable attention. However, adherence promotion strategies for prevention medications have not been well characterized and may be more applicable to PrEP. We aimed to identify adherence support interventions that have been effective in other prevention fields and could be applied in the HIV prevention context to support pill taking among PrEP users. METHODS: To identify adherence support interventions that could be evaluated and applied in the PrEP context, we conducted a systematic review across the following prevention fields: hypertension, latent tuberculosis infection, hyperlipidaemia, oral contraceptives, osteoporosis, malaria prophylaxis, and post-exposure prophylaxis for HIV infection. We included randomized controlled trials that evaluated the efficacy of interventions to improve adherence to daily oral medications prescribed for primary prevention in healthy individuals or for secondary prevention in asymptomatic individuals. RESULTS: Our searches identified 585 studies, of which 48 studies met the eligibility criteria and were included in the review; nine evaluated multiple strategies, yielding 64 separately tested interventions. Interventions with the strongest evidence for improving adherence included complex, resource-intensive interventions, which combined multiple adherence support approaches, and low-cost, low-intensity interventions that provided education or telephone calls for adherence support. CONCLUSIONS: Our review identified adherence interventions with strong evidence of efficacy across prevention fields and provides recommendations for evaluating these interventions in upcoming PrEP studies.	medication adherence, preventive therapy, preexposure prophylaxis (PrEP), antiretroviral medications, human immunodeficiency virus (HIV), review	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2014	Marcus, JL; Glidden, DV; McMahan, V; Lama, JR; Mayer, KH; Liu, AY; Montoya-Herrera, O; Casapia, M; Hoagland, B; Grant, RM	Daily Oral Emtricitabine/Tenofovir Preexposure Prophylaxis and Herpes Simplex Virus Type 2 among Men Who Have Sex with Men	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0091513	https://pubmed.ncbi.nlm.nih.gov/24637511/	Background: In addition to protecting against HIV acquisition, antiretroviral preexposure prophylaxis (PrEP) using topical 1% tenofovir gel reduced Herpes simplex virus type 2 (HSV-2) acquisition by 51% among women in the CAPRISA 004 study. We examined the effect of daily oral emtricitabine/tenofovir (FTC/TDF) PrEP on HSV-2 seroincidence and ulcer occurrence among men who have sex with men (MSM) in the iPrEx trial. Methods: HSV-2 serum testing was performed at screening and every six months. Among HSV-2-seronegative individuals, we used Cox regression models to estimate hazard ratios (HRs) of HSV-2 seroincidence associated with randomization to FTC/TDF. We used multiple imputation and Cox regression to estimate HRs for HSV-2 seroincidence accounting for drug exposure. We assessed ulcer occurrence among participants with prevalent or incident HSV-2 infection. Results: Of the 2,499 participants, 1383 (55.3%) tested HSV-2-seronegative at baseline, 892 (35.7%) tested positive, 223 (8.9%) had indeterminate tests, and one test was not done. Of the 1,347 HSV-2-seronegative participants with follow-up, 125 (9.3%) had incident HSV-2 infection (5.9 per 100 person-years). Compared with participants receiving placebo, there was no difference in HSV-2 seroincidence among participants receiving FTC/TDF (HR 1.1, 95% CI: 0.8-1.5; P = 0.64) or among participants receiving FTC/TDF with a concentration of tenofovir diphosphate >16 per million viable cells (HR 1.0, 95% CI: 0.3-3.5; P = 0.95). Among participants with HSV-2 infection, the proportion with >= 1 moderate or severe ulcer adverse event was twice as high in the placebo vs. active arm (5.9% vs. 2.9%, P = 0.02), but there were no differences in the proportions with >= 1 clinical examination during which perianal or groin ulcers were identified. Conclusions: Tenofovir in daily oral FTC/TDF PrEP may reduce the occurrence of ulcers in individuals with HSV-2 infection but does not protect against HSV-2 incidence among MSM. Article	2014	Martin, M; Vanichseni, S; Suntharasamai, P; Sangkum, U; Mock, PA; Gvetadze, RJ; Curlin, ME; Leethochawalit, M; Chiamwongpaet, S; Cherdtrakulkiat, T; Anekvorapong, R; Leelawiwat, W; Chantharojwong, N; McNicholl, JM; Paxton, LA; Kittimunkong, S; Choopanya, K	Renal function of participants in the Bangkok tenofovir study--Thailand, 2005-2012	Clinical Infectious Diseases	-	-	-	NA	10.1093/cid/ciu355	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01014087/full	Background. Tenofovir disoproxil fumarate (tenofovir) has been associated with renal dysfunction in people infected with human immunodeficiency virus (HIV) receiving combination antiretroviral therapy. We reviewed data from an HIV preexposure prophylaxis trial to determine if tenofovir use was associated with changes in renal function in an HIV-uninfected population. Methods. During the trial, 2413 HIV-uninfected people who inject drugs were randomized to receive tenofovir or placebo. We assessed the renal function of trial participants with the Cockcroft-Gault, Modification of Diet in Renal Disease (MDRD), and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations using t tests for cross-sectional analysis and linear regression for longitudinal analysis. Results. Creatinine clearance and glomerular filtration rate (GFR) results were lower at 24, 36, 48, and 60 months in the tenofovir group compared with the placebo group. Results declined more in the tenofovir group than in the placebo group during follow-up using the Cockcroft-Gault (P < .001) and CKD-EPI (P = .007) equations, but not MDRD (P = .12). Creatinine clearance measured when study drug was stopped was lower in the tenofovir group than the placebo group (P < .001), but the difference resolved when tested a median of 20 months later (P = .12). Conclusions. We found small but significant decreases in cross-sectional measures of creatinine clearance and GFR in the tenofovir group compared with the placebo group and modest differences in downward trends in longitudinal analysis using the Cockcroft-Gault and CKD-EPI equations. These results suggest that with baseline assessments of renal function and routine monitoring of creatinine clearance during follow-up, tenofovir can be used safely for HIV preexposure prophylaxis. Article	2014	Martin, Michael; Vanichseni, Suphak; Suntharasamai, Pravan; Sangkum, Udomsak; Mock, Philip A; Leethochawalit, Manoj; Chiamwongpaet, Sithisat; Gvetadze, Roman J; Kittimunkong, Somyot; Curlin, Marcel E; Worrajittanon, Dararat; McNicholl, Janet M; Paxton, Lynn A; Choopanya, Kachit	Risk behaviors and risk factors for HIV infection among participants in the Bangkok tenofovir study, an HIV pre-exposure prophylaxis trial among people who inject drugs.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0092809	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3965466	INTRODUCTION: HIV spread rapidly among people who inject drugs in Bangkok in the late 1980s. In recent years, changes in drug use and HIV-associated risk behaviors have been reported. We examined data from the Bangkok Tenofovir Study, an HIV pre-exposure prophylaxis trial conducted among people who inject drugs, to assess participant risk behavior and drug use, and to identify risk factors for HIV infection. METHODS: The Bangkok Tenofovir Study was a randomized, double-blind, placebo-controlled trial. HIV status was assessed monthly and risk behavior every 3 months. We used generalized estimating equations logistic regression to model trends of injecting, needle sharing, drugs injected, incarceration, and sexual activity reported at follow-up visits; and proportional hazards models to evaluate demographic characteristics, sexual activities, incarceration, drug injection practices, and drugs injected during follow-up as predictors of HIV infection. RESULTS: The proportion of participants injecting drugs, sharing needles, and reporting sex with more than one partner declined during follow-up (p<0.001). Among participants who reported injecting at enrollment, 801 (53.2%) injected methamphetamine, 559 (37.1%) midazolam, and 527 (35.0%) heroin. In multivariable analysis, young age (i.e., 20-29 years) (p = 0.02), sharing needles (p<0.001), and incarceration in prison (p = 0.002) were associated with incident HIV infection. Participants reporting sex with an opposite sex partner, live-in partner, casual partner, or men reporting sex with male partners were not at a significantly higher risk of HIV infection compared to those who did not report these behaviors. CONCLUSION: Reports of HIV-associated risk behavior declined significantly during the trial. Young age, needle sharing, and incarceration were independently associated with HIV infection. Sexual activity was not associated with HIV infection, suggesting that the reduction in HIV incidence among participants taking daily oral tenofovir compared to those taking placebo was due to a decrease in parenteral HIV transmission. Article	2014	Mastro, Timothy D.; Sista, Nirupama; Abdool-Karim, Quarraisha	ARV-based HIV prevention for women - where we are in 2014.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.17.3.19154	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4164013/	Women continue to be at special risk for HIV acquisition due to a complex mix of biological, behavioural, structural, cultural and social factors, with unacceptable rates of new infection. Scientific advances over the past decade have highlighted the use of antiretroviral (ARV) drugs as pre-exposure prophylaxis (PrEP) to prevent HIV acquisition (sexually, parenterally and vertically) and ARV treatment (ART) for HIV-positive patients to prevent onward transmission (treatment as prevention - TasP). This paper reviews the evidence base for PrEP and TasP, describes new products in development and the need to translate research findings into programmes with impact at the population level. Article	2014	Matthews, Lynn T; Heffron, Renee; Mugo, Nelly R; Cohen, Craig R; Hendrix, Craig W; Celum, Connie; Bangsberg, David R; Baeten, Jared M	High medication adherence during periconception periods among HIV-1-uninfected women participating in a clinical trial of antiretroviral pre-exposure prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000246	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4149628	INTRODUCTION: Pre-exposure prophylaxis (PrEP) may be an important safer conception strategy for HIV-1-uninfected women with HIV-1-infected partners. Understanding medication adherence in this population may inform whether PrEP is a feasible safer conception strategy. METHODS: We evaluated predictors of pregnancy and adherence to study medication among HIV-1-uninfected women enrolled in a randomized placebo-controlled trial of PrEP among African HIV-1-serodiscordant couples. Participants were counseled on HIV-1 risk reduction, contraception, and adherence and tested for pregnancy at monthly study visits. Pill counts of dispensed drug were performed and, at a subset of visits, plasma was collected to measure active drug concentration. RESULTS: Among 1785 women, pregnancy incidence was 10.2 per 100 person-years. Younger age, not using contraception, having an additional sexual partner, and reporting unprotected sex were associated with increased likelihood of pregnancy. Monthly clinic pill counts estimated that women experiencing pregnancy took 97% of prescribed doses overall, with at least 80% pill adherence for 98% of study months, and no difference in adherence in the periconception period compared with previous periods (P = 0.98). Tenofovir was detected in plasma at 71% of visits where pregnancy was discovered. By multiple measures, adherence was similar for women experiencing and not experiencing pregnancy (P ≥ 0.1). CONCLUSIONS: In this clinical trial of PrEP, pregnancy incidence was 10% per year despite excellent access to effective contraception. Women experiencing pregnancy had high medication adherence, suggesting that PrEP may be an acceptable and feasible safer conception strategy for HIV-1-uninfected women with HIV-1-serodiscordant partners.	pregnancy, HIV-1 prevention, pre-exposure prophylaxis, adherence, safer conception, serodiscordant couples, sub-Saharan Africa	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Mayer, Kenneth H.	Antiretroviral chemoprophylaxis: state of evidence and the research agenda.	Clinical Infectious Diseases	-	-	-	1537-6591 1058-4838	10.1093/cid/ciu322	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4141495/	Oral antiretroviral preexposure prophylaxis (PrEP) has been shown to decrease human immunodeficiency virus (HIV) incidence in studies of men who have sex with men, heterosexual men and women, and injecting drug users. One study of pericoital tenofovir gel demonstrated that it reduced HIV incidence in South African women. However, other studies of African women failed to demonstrate protection with either oral tenofovir or tenofovir-emtricitabine, or daily tenofovir gel. The magnitude of PrEP protection appears to be highly correlated with medication adherence. New studies are evaluating whether different antiretrovirals, including dapivirine, rilpivirine, maraviroc, and new integrase inhibitors. Different formulations are also being evaluated, including gels, films, vaginal rings, and injectable medication. Although PrEP efficacy has been demonstrated, and several normative bodies (eg, the US Food and Drug Administration) have approved PrEP for clinical use, uptake has been slow. Reasons may include lack of sufficient provider and consumer education, residual concerns about costs, potential long-term toxicities, and behavioral disinhibition. Additional work is under way to determine how to best educate consumers and providers about optimal adherence and to use PrEP in conjunction with risk mitigation. Article	2014	Mayer, KH; Oldenburg, C; Novak, DS; Krakower, D; Mimiaga, MJ	Differences in PrEP Knowledge and Use in US MSM Users of a Popular Sexual Networking Site Surveyed in August 2013 and January 2014	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1089/aid.2014.5168a.abstract	https://www.liebertpub.com/doi/10.1089/aid.2014.5168a.abstract	Background: Pre-exposure prophylaxis (PrEP) has been recommended for HIV prevention for at-risk men who have sex with men (MSM). Prior reports have suggested slow uptake. U.S. MSM members of a sexual networking site were invited to complete a survey in August 2013 (Wave 1: W1) and January 2014 (W2) that included a variety of questions related to HIV prevention practices. Comparisons of those who responded at each time point were conducted using Fisher's exact tests in order to assess differences in PrEP knowledge and uptake between W1 and W2. Study design did not permit assessment of whether MSM responded once or at both time points. Although more MSM responded in W1 than W2 (6,683 vs. 4,759), they were similar in median age (45 y.o.), race/ethnicity (about 86% White), educational attainment (about 2/3 had at least a college degree), and regional geographic distribution (almost 1/4 from the Southeast, with the next largest numbers being in the Northeast, Great Lakes region or Midwest-about 15% each). The majority reported engaging in condomless anal sex (CAS) in the prior 3 months (58.7% in Wave 1 and 74.1% in Wave 2). A higher proportion of MSM in W2 had heard of PrEP than in W1 (43.8% vs 27.3%, p < 0.001). Among MSM reporting CAS in the prior 3 months, PrEP interest increased between W1 and W2 (54.1% vs. 60.4%, p = 0.002) and use also increased (2.0% vs. 3.1%, p = 0.004). PEP knowledge increased (38.9% and 49.7% in W1 and W2, p < 0.001), but PEP utilization among MSM reporting CAS in the prior 3 months did not significantly increase (4.3% in W1 and 4.7% in W2, p = 0.44). Although recent increases in PrEP interest and use among U.S. MSM accessing a sexual networking site were detected, the majority of those who could benefit have not availed themselves of this prevention modality, with the majority of at-risk respondents not being knowledgeable about PrEP. Further educational efforts are needed for U.S. MSM about PrEP. Article	2014	Mayer, KH; Safren, S; Haberer, J; Elsesser, S; Clarke, W; Hendrix, CW; Marzinke, M; Mimiaga, MJ	Project PrEPARE: High Levels of Medication Adherence with Continued Condomless Sex in US Men who Have Sex with Men in an Oral PrEP Adherence Trial	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1089/aid.2014.5032a.abstract	https://www.liebertpub.com/doi/10.1089/aid.2014.5032a.abstract	Background: Pre-exposure prophylaxis (PrEP) has been shown to decrease HIV incidence in MSM, but optimal protection is dependent on medication adherence. The data presented here are from a pilot study, designed to assess whether an intervention based on Life-Steps, an effective intervention to enhance HAART adherence in HIV-infected patients, could improve PrEP adherence among men who have sex with men (MSM) who reported recent condomless anal sex. Between 11/2012 and 12/2013, 55 Boston-area HIV-MSM who were interested in initiating PrEP were enrolled in Project PrEPARE, and randomized to Life-Steps which included 4 weekly sessions that addressed barriers and facilitators of PrEP adherence, or to a control condition that provided supportive counseling. Adherence was monitored by Wisepill, and unprotected sex was assessed via daily text messaging. Participants were primarily White (94%) and well-educated (64% had completed college), and sociodemographic factors were similar in both randomized groups. Over the 6 months' observation, 90% of the MSM in each group took at least 80% of their daily pills on a weekly basis, as measured by Wisepill and drug levels, and this did not differ by study condition. Condomless sex rates did not change significantly in either group over time. About 90% of the time during the study, the men in both groups either had drug levels consistent with taking most of their PrEP doses and/or used condoms during sex. No incident HIV infections occurred during the study. Most MSM in this study demonstrated levels of PrEP adherence consistent with protective benefit, whether they received Life-Steps or supportive counseling. Given the high rates of adherence in both groups, the data suggest that MSM who elect to receive open-label PrEP can be highly adherent and self-protective. New PrEP adherence interventions should focus on at-risk persons who anticipate or demonstrate difficulties with routine medication adherence. Article	2014	McGowan, Ian	An overview of antiretroviral pre-exposure prophylaxis of HIV infection.	American Journal of Reproductive Immunology	-	-	-	1600-0897	10.1111/aji.12225	https://dx.doi.org/10.1111/aji.12225	Despite improvements in access to antiretroviral therapy and the use of simplified dosing regimens, HIV infection is still an important global public health problem. As a consequence, significant research efforts have been focused on the development of strategies to prevent the acquisition of HIV infection. These efforts have begun to produce results. The HPTN-052 study demonstrated the effectiveness of treating infected individuals as a means to prevent onward transmission of HIV infection. In addition, Phase 2B/3 studies have shown that the use of oral and topical antiretroviral pre-exposure prophylaxis (PrEP) can significantly reduce the acquisition of HIV infection in serodiscordant couples, young women in sub-Saharan Africa, men who have sex with men, and intravenous drug users. Despite these successes, challenges remain. Adherence to daily PrEP is variable, and some large studies have failed to demonstrate the effectiveness of PrEP in reducing HIV acquisition. Novel PrEP technologies, including sustained delivery intravaginal rings and long-acting injectable products, are being developed to try and circumvent adherence problems associated with daily PrEP regimens. The purpose of this article is to briefly summarize recent progress in the development of antiretroviral PrEP. Article	2014	McGowan, Ian	The development of rectal microbicides for HIV prevention.	Expert Opinion on Drug Delivery	-	-	-	1744-7593 1742-5247	10.1517/17425247.2013.860132	https://pubmed.ncbi.nlm.nih.gov/24266648/	INTRODUCTION: Individuals practicing unprotected receptive anal intercourse are at particularly high risk of HIV infection. Men who have sex with men in the developed and developing world continue to have disproportionate and increasing levels of HIV infection. The last few years have seen important progress in demonstrating the efficacy of oral antiretroviral pre-exposure prophylaxis, vaginal microbicides, and treatment as prevention, but there has also been significant progress in the development of rectal microbicides for HIV prevention. AREAS COVERED: The purpose of this review is to summarize the status of rectal microbicide research and to identify opportunities, challenges, and future directions in this important field of HIV prevention research. The design of completed and ongoing Phase I rectal microbicide studies that include the generation of comprehensive pharmacokinetic/pharmacodynamic data may allow for more rational decisions about which rectal microbicides should be advanced to later stage development. EXPERT OPINION: There is a strong rationale for the development of rectal microbicides for HIV prevention. Preclinical data provide supportive evidence for the feasibility of this approach, and there is significant interest in rectal microbicide development from communities at risk of HIV acquisition through unprotected receptive anal intercourse in both the developed and developing world. Demonstration of sustained safety, acceptability, and product adherence in the MTN-017 Phase II study of tenofovir 1% gel will be an important step in rectal microbicide development and will hopefully lead to Phase III effectiveness testing of this novel HIV prevention strategy. METHODS: We enrolled 507 male sex workers in a Nairobi-based prospective cohort study during 2009-2012. All participants were offered HIV/STI screening, counselling and completed a baseline questionnaire. RESULTS: Baseline HIV prevalence was 40.0% (95% CI 35.8% to 44.3%). Prevalent HIV infection was associated with age, less postsecondary education, marijuana use, fewer female partners and lower rates of prior HIV testing. Most participants (73%) reported at least two of insertive anal, receptive anal and insertive vaginal sex in the past 3 months. Vaginal sex was reported by 37% of participants, and exclusive MSM status was associated with higher HIV rates. Condom use was infrequent, with approximately one-third reporting 100% condom use during anal sex. HIV incidence was 10.9 per 100 person-years (95% CI 7.4 to 15.6). Predictors of HIV risk included history of urethral discharge (aHR 0.29, 95% CI 0.08 to 0.98, p=0.046), condom use during receptive anal sex (aHR 0.05, 95% CI 0.01 to 0.41, p=0.006) and frequency of sex with male partners (aHR 1.33/sex act, 95% CI 1.01 to 1.75, p=0.04). CONCLUSIONS: HIV prevalence and incidence were extremely high in Nairobi MSM SW; a combination of interventions including increasing condom use, pre-exposure prophylaxis and access to effective treatment is urgently needed to decrease HIV transmission in this key population.	*Homosexuality, Male; Adult; Humans; Male; Risk-Taking; Sexual Behavior; Prospective Studies; HIV; Prevalence; Surveys and Questionnaires; Health Knowledge, Attitudes, Practice; Africa; *Sexual Partners; Kenya/epidemiology; Condoms/*statistics & numerical data; Age Distribution; *Public Health; Educational Status; HIV Infections/*epidemiology/prevention & control; *Sex Workers; Health Education; Males; Substance-Related Disorders/*epidemiology	English	United Kingdom	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Clinical
Article	2014	McMahon, James M; Myers, Julie E; Kurth, Ann E; Cohen, Stephanie E; Mannheimer, Sharon B; Simmons, Janie; Pouget, Enrique R; Trabold, Nicole; Haberer, Jessica E	Oral pre-exposure prophylaxis (PrEP) for prevention of HIV in serodiscordant heterosexual couples in the United States: opportunities and challenges.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2013.0302	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4135325	Oral HIV pre-exposure prophylaxis (PrEP) is a promising new biomedical prevention approach in which HIV-negative individuals are provided with daily oral antiretroviral medication for the primary prevention of HIV-1. Several clinical trials have demonstrated efficacy of oral PrEP for HIV prevention among groups at high risk for HIV, with adherence closely associated with level of risk reduction. In the United States (US), three groups have been prioritized for initial implementation of PrEP-injection drug users, men who have sex with men at substantial risk for HIV, and HIV-negative partners within serodiscordant heterosexual couples. Numerous demonstration projects involving PrEP implementation among MSM are underway, but relatively little research has been devoted to study PrEP implementation in HIV-serodiscordant heterosexual couples in the US. Such couples face a unique set of challenges to PrEP implementation at the individual, couple, and provider level with regard to PrEP uptake and maintenance, adherence, safety and toxicity, clinical monitoring, and sexual risk behavior. Oral PrEP also provides new opportunities for serodiscordant couples and healthcare providers for primary prevention and reproductive health. This article provides a review of the critical issues, challenges, and opportunities involved in the implementation of oral PrEP among HIV-serodiscordant heterosexual couples in the US. Article	2014	Meng, Jianing; Zhang, Tao; Agrahari, Vivek; Ezoulin, Miezan J.; Youan, Bi-Botti C.	Comparative biophysical properties of tenofovir-loaded, thiolated and nonthiolated chitosan nanoparticles intended for HIV prevention.	Nanomedicine (London, England)	-	-	-	1748-6963 1743-5889	10.2217/nnm.13.136	https://pubmed.ncbi.nlm.nih.gov/24405490/	AIM: This study is designed to test the hypothesis that tenofovir-loaded (an anti-HIV microbicide) chitosan-thioglycolic acid-conjugated (CS-TGA) nanoparticles (NPs) exhibit superior biophysical properties for mucoadhesion compared with those of native CS NPs. MATERIALS & METHODS: The NPs are prepared by ionotropic gelation. The particle mean diameter, encapsulation efficiency and release profile are analyzed by dynamic light scattering and UV spectroscopy, respectively. The cytotoxicity, cellular uptake and uptake mechanism are assessed on VK2/E6E7 and End1/E6E7 cell lines by colorimetry/fluorimetry, and percentage mucoadhesion is assessed using porcine vaginal tissue. RESULTS: The mean diameter of the optimal NP formulations ranges from 240 to 252 nm, with a maximal encapsulation efficiency of 22.60%. Tenofovir release from CS and CS-TGA NPs follows first-order and Higuchi models, respectively. Both NPs are noncytotoxic in 48 h. The cellular uptake, which is time dependent, mainly occurs via the caveolin-mediated pathway. The percentage of mucoadhesion of CS-TGA NPs is fivefold higher than that of CS NPs, and reached up to 65% after 2 h. CONCLUSION: Collectively, CS-TGA NPs exhibit superior biophysical properties and can potentially maximize the retention time of a topical microbicide, such as tenofovir, intended for the prevention of HIV transmission. Article	2014	Meque, Ivete; Dubé, Karine; Bierhuizen, Lotte; Zango, Arlinda; Veldhuijzen, Nienke; Cumbe, Fidelina; Feldblum, Paul J.; van de Wijgert, Janneke	Willingness to participate in future HIV prevention trials in Beira, Mozambique.	African Journal of AIDS Research	-	-	-	1727-9445 1608-5906	10.2989/16085906.2014.985239	https://pubmed.ncbi.nlm.nih.gov/25555105/	In preparation for trials of new HIV prevention methods, willingness to participate (WTP) was assessed in Beira, Mozambique. A total of 1 019 women participating in an HIV incidence study, and 97 men participating in a separate WTP survey, were interviewed. When comparing the answers to questions that were identical in the two studies, WTP was higher among women than men for all prevention methods. Among women, WTP was highest for trials evaluating daily oral pre-exposure prophylaxis (PrEP; 84.4% reporting very likely to participate), followed by vaccination (77.8%), daily vaginal gel use (67.7%), coital vaginal gel use (67.1%) and monthly vaginal ring use (47.7%). Among men, WTP was highest for trials evaluating vaccination (57.6%), followed by daily vaginal gel use for female sexual partners (52.5%), daily oral PrEP (49.5%), coital vaginal gel use for female sexual partners (46.4%) and monthly vaginal ring use for female sexual partners (39.4%). Among men, the most important motivators for trial participation were social benefits, whereas personal risks (most notably receiving injections and/or blood draws) were deterrents; this was not assessed in women. Other important lessons learnt are that male circumcision and antiretroviral drugs were not generally recognised as ways to prevent HIV, that having to use hormonal contraception during trial participation will likely reduce WTP, and that evening clinics are not likely to be popular. The barriers reported in this and other studies may be challenging but are not impossible to overcome. Article	2014	Meyers, Kathrine; Rodriguez, Kristina; Moeller, Robert W; Gratch, Ilana; Markowitz, Martin; Halkitis, Perry N	High interest in a long-acting injectable formulation of pre-exposure prophylaxis for HIV in young men who have sex with men in NYC: a P18 cohort substudy.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0114700	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4263701	OBJECTIVE: In the context of continued high rates of condomless anal intercourse and HIV-1 infection, young men who have sex with men (YMSM) need additional effective and desirable HIV prevention tools. This study reports on the willingness of a racially-ethnically diverse cohort of YMSM to use a new biomedical prevention approach, a long-acting injectable pre-exposure prophylaxis (LAI-PrEP) agent. METHODS: A cross-sectional study conducted between June-August 2013 recruited participants from an ongoing cohort study of YMSM in NYC. Participants included 197 YMSM, of whom 72.6% (nâ=â143) identified as men of color. Two outcomes were measured through computer-assisted self-interviews: 1) willingness to use long-acting injectable PrEP and 2) preference for route of administration of PrEP. In addition, concerns about perceived impacts of PrEP on health and risk behavior, access to health services, and stigma were investigated. RESULTS: Over 80% (nâ=â159/197, p<0.001) of participants stated they would be willing to use LAI-PrEP. With regards to preference for mode of delivery 79.2% (nâ=â156/197, p<0.001) stated they would prefer an injection administered every three months over a daily pill or neither one. CONCLUSIONS: This study is the first to explore acceptability of LAI-PrEP in the US. A significant majority of participants expressed willingness to use LAI and the majority preferred LAI-PrEP. LAI-PrEP holds great promise in that it could circumvent the adherence challenges associated with daily dosing, especially if nested within appropriate psycho-behavioral support. Medical providers whose patients include YMSM at high risk for HIV infection should note the positive attitudes toward PrEP, and specifically LAI-PrEP. Article	2014	Mimiaga, Matthew J; Closson, Elizabeth F; Kothary, Vishesh; Mitty, Jennifer A	Sexual partnerships and considerations for HIV antiretroviral pre-exposure prophylaxis utilization among high-risk substance using men who have sex with men.	Archives of Sexual Behavior	-	-	-	1573-2800	10.1007/s10508-013-0208-8	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4532732	Men who have sex with men (MSM) remain at great risk of HIV in the United States, representing 65 % of incident HIV infections. One factor contributing to the high rate of HIV infection among MSM is use of "recreational" drugs that are highly associated with unprotected anal sex. Pre-exposure chemoprophylaxis (PrEP) is a novel biomedical HIV prevention strategy that has the potential to reduce HIV transmission in MSM. Main and casual sex partners play a role in HIV prevention efforts for MSM. The study aimed to qualitatively explore the perceived influences of sexual relationships on promoting and inhibiting PrEP use among high-risk MSM who report regular drug use. Semi-structured qualitative interviews were conducted with 40 participants recruited in Boston, Massachusetts. Data were analyzed using descriptive qualitative analysis. Casual partners presented a distinct set of concerns from primary partnerships. MSM generally viewed main partners as a potential source of support for taking PrEP. Given their informal and often temporary nature, PrEP disclosure to casual partners was considered unnecessary. HIV-related stigma and substance use were also perceived as barriers to discussing PrEP use with casual partners. MSM articulated a high degree of personal agency regarding their ability to take PrEP. Findings suggest that behavioral interventions to improve PrEP utilization and adherence for high-risk MSM should be tailored to sex partner type and the parameters established between sex partners. Approaches to PrEP disclosure and partner engagement should be informed by the relative benefits and limitations characterized by these different types of relationships. Article	2014	Mimiaga, Matthew J; White, Jaclyn M; Krakower, Douglas S; Biello, Katie B; Mayer, Kenneth H	Suboptimal awareness and comprehension of published preexposure prophylaxis efficacy results among physicians in Massachusetts.	AIDS Care	-	-	-	1360-0451	10.1080/09540121.2013.845289	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4053171	In 2010, the centre for the AIDS Programme of Research in South Africa (CAPRISA)004 and iPrEx trials (microbicide gel containing tenofovir and oral pill containing tenofovir-emtricitabine, respectively) demonstrated that antiretroviral preexposure prophylaxis (PrEP) reduced the risk of HIV acquisition among high-risk individuals. To determine the facilitators and barriers to PrEP provision by health-care providers, we conducted an online, quantitative survey of Massachusetts-area physicians following the publication of the CAPRISA and iPrEx results. We assessed awareness and comprehension of efficacy data, prescribing experience, and anticipated provision of oral and topical PrEP among physicians, as well as demographic and behavioral factors associated with PrEP awareness and prescribing intentions. The majority of HIV specialists and generalist physicians were aware of data from these PrEP trials and able to correctly interpret the results, however, correct interpretation of findings tended to vary according to specialty (i.e., HIV specialists had greater awareness than generalists). In addition, provider concerns regarding PrEP efficacy and safety, as well its ability to divert funds from other HIV prevention resources, were associated with decreased intentions to prescribe both oral and topical PrEP. Findings suggest that a substantial proportion of physicians who may have contact with at-risk individuals may benefit from interventions that provide accurate data on the risks and benefits of PrEP in order to facilitate effective PrEP discussions with their patients. Future studies to develop and test interventions aimed at health-care providers should be prioritized to optimize implementation of PrEP in clinical settings. Article	2014	Mirembe, BG; Kelly, C; Nyaradzo, M; Greenspan, S; Dai, J; Bragg, V; Piper, J; Akello, CA; Kiweewa, FM; Tsitsi, M; Nakabiito, C; Riddler, S	Bone Mineral Density Changes among Healthy African Pre-menopausal Women Participating in a Tenofovir-based HIV PrEP Study: The MTN-003B Study	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1089/aid.2014.5564.abstract	https://www.liebertpub.com/doi/10.1089/aid.2014.5564.abstract	Abstract Background: Limited data exist on effect of tenofovir disoproxil fumarate (TDF) when used for preexposure prophylaxis (PrEP) on bone mineral density (BMD) in HIV-negative women. We evaluated the effect of daily oral TDF and emtricitabine/TDF compared with placebo on BMD among women enrolled in an HIV-1 PrEP trial. Methods: HIV-uninfected women in Uganda and Zimbabwe had BMD measurements of lumbar spine (LS) and total hip (TH) by dual-energy x-ray absorptiometry at baseline and every 24 weeks for 48 weeks of active treatment and for 48 weeks after discontinuation of study medication. Plasma tenofovir levels were assessed every 12 weeks for the first 48 weeks. Results: Of 518 women enrolled, 432 had dual-energy x-ray absorptiometry results at baseline and week 48. In the primary analysis, no significant differences in percent BMD change in hip or spine between arms observed, likely because of low product adherence. Among the subset with tenofovir detection in 75%–100% of plasma samples, the mean percent BMD change from baseline to week 48 in the LS was 1.4% lower for TDF or emtricitabine/TDF recipients than for placebo (P = 0.002) and TH BMD was 0.9% lower (P = 0.018). BMD changes from end of active treatment to 48 weeks were significantly greater in the active arm participants compared with placebo participants with a net difference of approximately +0.9% at the LS (P = 0.007) and +0.7% (P = 0.003) at the TH. Conclusions: TDF-containing oral PrEP resulted in small but significant reversible decreases in hip and spine BMD among young African women	preexposure prophylaxis, tenofovir, bone density, African women, HIV prevention	English	United States	Western and Central Europe and North America	Uganda	Eastern and Southern Africa	NA	NA	Clinical
Article	2014	Mitchell, Caroline; Roemer, Emily; Nkwopara, Evangelyn; Robbins, Brian; Cory, Theodore; Rue, Tessa; Fletcher, Courtney V.; Frenkel, Lisa	Correlation between plasma, intracellular, and cervical tissue levels of raltegravir at steady-state dosing in healthy women.	Antimicrobial Agents and Chemotherapy	-	-	-	1098-6596 0066-4804	10.1128/AAC.02757-13	https://pubmed.ncbi.nlm.nih.gov/24687503/	Raltegravir is an antiretroviral with potential value for preexposure prophylaxis (PrEP) against HIV, but the intracellular pharmacokinetics in genital tissue have not been described. In this study, healthy, HIV-uninfected nonpregnant women took 400 mg of raltegravir twice daily for 22 days. On day 8, 15, and 22, blood was collected 0, 4, 6, 8, and 12 h and cervical biopsy specimens taken 0, 6, and 12 h after raltegravir dosing. Plasma and intracellular raltegravir concentrations in peripheral blood mononuclear cells (PBMC) and cervical tissue were measured by tandem mass spectrometry. Linear mixed effects models evaluated correlations between different sample types, as well as differences in concentration between phases of the menstrual cycle. Ten women were enrolled: 9 completed all three visits and 1 completed two visits. The age (mean ± standard deviation) of participants was 30 ± 8 years. Trough plasma concentrations of raltegravir 12 h after a directly observed dose were above the HIV 95% inhibitory concentration (IC95) of 33 nM (14.6 ng/ml) in 96% of measurements, compared to 67% of PBMC and 89% of cervical tissue trough values. Across all measurements, only 2% (3/135) of plasma values fell below the IC95, compared to 10% (13/135) for PBMC and 6% (5/81) for cervical tissue. There was no impact of menstrual phase on raltegravir concentrations. In conclusion, cervical tissue raltegravir concentrations were no greater than plasma concentrations, and ~10% of all cervical tissue trough values were below the IC95, making the current twice-daily formulation of raltegravir impractical for PrEP. Article	2014	Mitchell, K. M.; Foss, A. M.; Prudden, H. J.; Mukandavire, Z.; Pickles, M.; Williams, J. R.; Johnson, H. C.; Ramesh, B. M.; Washington, R.; Isac, S.; Rajaram, S.; Phillips, A. E.; Bradley, J.; Alary, M.; Moses, S.; Lowndes, C. M.; Watts, C. H.; Boily, M.-C.; Vickerman, P.	Who mixes with whom among men who have sex with men? Implications for modelling the HIV epidemic in southern India.	Journal of Theoretical Biology	-	-	-	1095-8541 0022-5193	10.1016/j.jtbi.2014.04.005	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4064301/	In India, the identity of men who have sex with men (MSM) is closely related to the role taken in anal sex (insertive, receptive or both), but little is known about sexual mixing between identity groups. Both role segregation (taking only the insertive or receptive role) and the extent of assortative (within-group) mixing are known to affect HIV epidemic size in other settings and populations. This study explores how different possible mixing scenarios, consistent with behavioural data collected in Bangalore, south India, affect both the HIV epidemic, and the impact of a targeted intervention. Deterministic models describing HIV transmission between three MSM identity groups (mostly insertive Panthis/Bisexuals, mostly receptive Kothis/Hijras and versatile Double Deckers), were parameterised with behavioural data from Bangalore. We extended previous models of MSM role segregation to allow each of the identity groups to have both insertive and receptive acts, in differing ratios, in line with field data. The models were used to explore four different mixing scenarios ranging from assortative (maximising within-group mixing) to disassortative (minimising within-group mixing). A simple model was used to obtain insights into the relationship between the degree of within-group mixing, R0 and equilibrium HIV prevalence under different mixing scenarios. A more complex, extended version of the model was used to compare the predicted HIV prevalence trends and impact of an HIV intervention when fitted to data from Bangalore. With the simple model, mixing scenarios with increased amounts of assortative (within-group) mixing tended to give rise to a higher R0 and increased the likelihood that an epidemic would occur. When the complex model was fit to HIV prevalence data, large differences in the level of assortative mixing were seen between the fits identified using different mixing scenarios, but little difference was projected in future HIV prevalence trends. An oral pre-exposure prophylaxis (PrEP) intervention was modelled, targeted at the different identity groups. For intervention strategies targeting the receptive or receptive and versatile MSM together, the overall impact was very similar for different mixing patterns. However, for PrEP scenarios targeting insertive or versatile MSM alone, the overall impact varied considerably for different mixing scenarios; more impact was achieved with greater levels of disassortative mixing.	*Homosexuality, Male; Humans; Male; *HIV-1; Prevalence; India/epidemiology; *Models, Biological; Pre-exposure prophylaxis; Mathematical model; Disassortative mixing; HIV Infections/*epidemiology/*transmission; Mixing matrix; Sexually transmitted infection	English	Netherlands	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Quantitative
Article	2014	Moss, Darren M; Curley, Paul; Shone, Alison; Siccardi, Marco; Owen, Andrew	A multisystem investigation of raltegravir association with intestinal tissue: implications for pre-exposure prophylaxis and eradication.	Journal of Antimicrobial Chemotherapy	-	-	-	1460-2091	10.1093/jac/dku312	https://dx.doi.org/10.1093/jac/dku312	OBJECTIVES: Recent clinical data have suggested high raltegravir concentrations in gut tissue after oral administration, with implications for treatment and prevention. We have used in silico, in vitro, ex vivo and in vivo models to further investigate the accumulation of raltegravir in gut tissue. METHODS: Affinity of raltegravir for gut tissue was assessed in silico (Poulin-Theil method), in vitro (Caco-2 accumulation) and ex vivo (rat intestine) and compared with the lipophilic drug lopinavir. Finally, raltegravir concentrations in plasma, gut contents, small intestine and large intestine were determined after oral dosing to Wistar rats 1 and 4 h post-dose. Samples were analysed using LC-MS/MS and scintillation counting. RESULTS: Gut tissue accumulation of raltegravir was less than for lopinavir in silico, in vitro and ex vivo (P < 0.05). After oral administration to rats, raltegravir concentrations 4 h post-dose were lower in plasma (0.05 μM) compared with small intestine (0.47 μM, P = 0.06) and large intestine (1.36 μM, P < 0.05). However, raltegravir concentrations in the contents of both small intestine (4.0 μM) and large intestine (40.6 μM) were also high. CONCLUSIONS: In silico, in vitro and ex vivo data suggest low raltegravir accumulation in intestinal tissue. In contrast, in vivo animal data suggest raltegravir concentrates in intestinal tissue even when plasma concentrations are minimal. However, high raltegravir concentrations in gut contents are the likely driving factor behind this observation, rather than blood-to-tissue drug distribution. The methods described can be combined with clinical investigations to provide a complete strategy for selection of drugs with high gut accumulation. Article	2014	Muessig, Kathryn E.; Cohen, Myron S.	Advances in HIV prevention for serodiscordant couples	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-014-0225-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4267973/	Serodiscordant couples play an important role in maintaining the global HIV epidemic. This review summarizes biobehavioral and biomedical HIV prevention options for serodiscordant couples focusing on advances in 2013 and 2014, including World Health Organization guidelines and best evidence for couples counseling, couple-based interventions, and the use of antiviral agents for prevention. In the past few years, marked advances have been made in HIV prevention for serodiscordant couples and numerous ongoing studies are continuously expanding HIV prevention tools, especially in the area of pre-exposure prophylaxis. Uptake and adherence to antiviral therapy remains a key challenge. Additional research is needed to develop evidence-based interventions for couples, and especially for male-male couples. Randomized trials have demonstrated the prevention benefits of antiretroviral-based approaches among serodiscordant couples; however, residual transmission observed in recognized serodiscordant couples represents an important and resolvable challenge in HIV prevention. Article	2014	Mugo, Nelly R; Hong, Ting; Celum, Connie; Donnell, Deborah; Bukusi, Elizabeth A; John-Stewart, Grace; Wangisi, Jonathan; Were, Edwin; Heffron, Renee; Matthews, Lynn T; Morrison, Susan; Ngure, Kenneth; Baeten, Jared M	Pregnancy incidence and outcomes among women receiving preexposure prophylaxis for HIV prevention: a randomized clinical trial.	JAMA - Journal of the American Medical Association	-	-	-	1538-3598	10.1001/jama.2014.8735	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4362516	IMPORTANCE: Antiretroviral preexposure prophylaxis (PrEP), using tenofovir disoproxil fumarate (TDF) and combination emtricitabine/tenofovir disoproxil fumarate (FTC+TDF), is efficacious for prevention of human immunodeficiency virus (HIV) acquisition. PrEP could reduce periconception HIV risk, but the effect on pregnancy outcomes is not well defined. OBJECTIVE: To assess pregnancy incidence and outcomes among women using PrEP during the periconception period. DESIGN, SETTING, AND PARTICIPANTS: Randomized trial among 1785 HIV-serodiscordant heterosexual couples (the Partners PrEP Study) in which the female partner was HIV uninfected that demonstrated that PrEP was efficacious for HIV prevention, conducted between July 2008 and June 2013 at 9 sites in Kenya and Uganda. INTERVENTIONS: Daily oral TDF (n = 598), combination FTC+TDF (n = 566), or placebo (n = 621) through July 2011, when PrEP demonstrated efficacy for HIV prevention. Thereafter, participants continued receiving active PrEP without placebo. Pregnancy testing occurred monthly and study medication was discontinued when pregnancy was detected. MAIN OUTCOMES AND MEASURES: Pregnancy incidence, birth outcomes (live births, pregnancy loss, preterm birth, congenital anomalies), and infant growth. RESULTS: A total of 431 pregnancies occurred. Pregnancy incidence was 10.0 per 100 person-years among women assigned placebo, 11.9 among those assigned TDF (incidence difference, 1.9; 95% CI, -1.1 to 4.9 P = .22 vs placebo), and 8.8 among those assigned FTC+TDF (incidence difference, -1.3; 95% CI, -4.1 to 1.5 P = .39 vs placebo). Before discontinuation of the placebo treatment group in July 2011, the occurrence of pregnancy loss (96 of 288 pregnancies) was 42.5% for women receiving FTC+TDF compared with 32.3% for those receiving placebo (difference for FTC+TDF vs placebo, 10.2%; 95% CI, -5.3% to 25.7%; P = .16) and was 27.7% for those receiving TDF alone (difference vs placebo, -4.6%; 95% CI, -18.1% to 8.9%; P = .46). After July 2011, the frequency of pregnancy loss (52 of 143 pregnancies) was 37.5% for FTC+TDF and 36.7% for TDF alone (difference, 0.8%; 95% CI, -16.8% to 18.5%; P = .92). Occurrence of preterm birth, congenital anomalies, and growth throughout the first year of life did not differ significantly for infants born to women who received PrEP vs placebo. CONCLUSIONS AND RELEVANCE: Among HIV-serodiscordant heterosexual African couples, differences in pregnancy incidence, birth outcomes, and infant growth were not statistically different for women receiving PrEP with TDF alone or combination FTC+TDF compared with placebo at conception. Given that PrEP was discontinued when pregnancy was detected and that CIs for the birth outcomes were wide, definitive statements about the safety of PrEP in the periconception period cannot be made. These results should be discussed with HIV-uninfected women receiving PrEP who are considering becoming pregnant. TRIAL REGISTRATION: clinicaltrials.gov Identifier: NCT00557245. Article	2014	Mustanski, B; Ryan, DT; Sanchez, T; Sineath, C; Macapagal, K; Sullivan, PS	Effects of messaging about multiple biomedical and behavioral HIV prevention methods on intentions to use among US MSM: results of an experimental messaging study	AIDS and Behavior	-	-	-	NA	10.1007/s10461-014-0811-2	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01046932/full	Combining multiple biomedical and behavioral HIV prevention approaches is a priority for at-risk populations such as men who have sex with men (MSM), and it is essential to understand how receiving messages about multiple approaches impacts attitudes and intentions for their use. We examined whether receiving combinations of different HIV prevention messages produced differences in perceived benefits and costs of condom use, and in intentions to use condoms and biomedical prevention approaches. MSM (N = 803) were recruited online and were randomly assigned to view informational messages about one, two, or four of the following prevention options: pre-exposure prophylaxis (PrEP), non-occupational post-exposure prophylaxis (nPEP), rectal microbicides, and condoms. The number of HIV prevention messages did not produce differential attitudes and intentions regarding condoms, nor did it produce changes in attitudes towards unprotected sex. Receiving multiple messages was associated with greater intentions to use PrEP and nPEP, but not rectal microbicides.	*attitude to health; *behavior; *text messaging; Condom; Condoms statistics & numerical data; Controlled study; HIV Infections *prevention & control, psychology; HIV-infections/pc Prevention; Health Communication; Health Knowledge, Attitudes, Practice; High risk behavior; Homosexuality, Male *psychology; Human; Humans; Intention; Male; Male homosexuality; Medical information; Post exposure prophylaxis; Post-Exposure Prophylaxis methods; Procedures; Psychology; Questionnaire; Randomized controlled trial; Risk-Taking; Safe Sex; Safe sex; Sexual Behavior; Sexual Partners; Sexual behavior; Sexuality; Surveys and Questionnaires; Text Messaging; United States; Unsafe Sex psychology, statistics & numerical data; Unsafe sex; Utilization	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2014	Ndase, Patrick; Celum, Connie; Campbell, James; Bukusi, Elizabeth; Kiarie, James; Katabira, Elly; Mugo, Nelly; Tumwesigye, Elioda; Wangisi, Jonathan; Were, Edwin; Brantley, Justin; Donnell, Deborah; Baeten, Jared M	Successful discontinuation of the placebo arm and provision of an effective HIV prevention product after a positive interim efficacy result: the partners PrEP study experience.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000141	https://dx.doi.org/10.1097/QAI.0000000000000141	BACKGROUND: Dissemination of research results to study participants and stakeholders and provision of proven effective products in the immediate post-trial period are core elements of the conduct of biomedical HIV prevention clinical trials. Few biomedical HIV prevention trials have demonstrated HIV protection with novel interventions, and thus, communication of positive trial results and provision of an effective product have not been tested in many situations. METHODS: In July 2011, the independent Data and Safety Monitoring Board of the Partners PrEP Study, a randomized, placebo-controlled efficacy trial of daily oral antiretroviral preexposure prophylaxis (PrEP) for HIV prevention among 4747 African heterosexual HIV serodiscordant couples, recommended discontinuation of the trial's placebo arm due to demonstration of PrEP efficacy. We describe dissemination of results, discontinuation of the placebo arm, and provision of active PrEP to participants' formerly assigned placebo. RESULTS: Within 72 hours, of the Data and Safety Monitoring Board meeting the study results were publicly released and disseminated to stakeholders and study participants. Within 3 months, the study protocol was modified to permit participants initially assigned to the study's placebo arm to be offered active PrEP. Of the 1418 participants initially randomized to placebo who were clinically eligible to receive PrEP, 89.1% (1264/1418) consented. CONCLUSIONS: Prompt dissemination of a positive HIV prevention trial result and subsequent provision of effective product to research participants was feasible and efficient for >4700 HIV serodiscordant couples in East Africa. The extent to which study sponsors can assure continued product access to research participants remains a subject of discussion for future HIV prevention clinical trials. Article	2014	Newman, Peter A.; Rubincam, Clara	Advancing community stakeholder engagement in biomedical HIV prevention trials: principles, practices and evidence.	Expert Review of Vaccines	-	-	-	1744-8395 1476-0584	10.1586/14760584.2014.953484	https://pubmed.ncbi.nlm.nih.gov/25174764/	Community stakeholder engagement is foundational to fair and ethically conducted biomedical HIV prevention trials. Concerns regarding the ethical engagement of community stakeholders in HIV vaccine trials and early terminations of several international pre-exposure prophylaxis trials have fueled the development of international guidelines, such as UNAIDS' good participatory practice (GPP). GPP aims to ensure that stakeholders are effectively involved in all phases of biomedical HIV prevention trials. We provide an overview of the six guiding principles in the GPP and critically examine them in relation to existing social and behavioral science research. In particular, we highlight the challenges involved in operationalizing these principles on the ground in various global contexts, with a focus on low-income country settings. Increasing integration of social science in biomedical HIV prevention trials will provide evidence to advance a science of community stakeholder engagement to support ethical and effective practices informed by local realities and sociocultural differences. Article	2014	Nichols, BE; Baltussen, R; van Dijk, JH; Thuma, PE; Nouwen, JL; Boucher, CAB; van de Vijver, DAMC	Cost-Effectiveness of PrEP in HIV/AIDS Control in Zambia: A Stochastic League Approach	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1525-4135	10.1097/QAI.0000000000000145	https://pubmed.ncbi.nlm.nih.gov/24694930/	Background:Earlier antiretroviral therapy initiation and pre-exposure prophylaxis (PrEP) prevent HIV, although at a substantial cost. We use mathematical modeling to compare the cost-effectiveness and economic affordability of antiretroviral-based prevention strategies in rural Macha, Zambia.Methods:We compare the epidemiological impact and cost-effectiveness over 40 years of a baseline scenario (treatment initiation at CD4 <350 cells/L) with treatment initiation at CD4 <500 cells per microliter, and PrEP (prioritized to the most sexually active, or nonprioritized). A strategy is cost effective when the incremental cost-effectiveness ratio (ICER) is <$3480 (<3 times Zambian per capita GDP). Stochastic league tables then predict the optimal intervention per budget level.Results:All scenarios will reduce the prevalence from 6.2% (interquartile range, 5.8%-6.6%) in 2014 to about 1% after 40 years. Compared with the baseline, 16% of infections will be averted with prioritized PrEP plus treatment at CD4 <350, 34% with treatment at CD4 <500, and 59% with nonprioritized PrEP plus treatment at CD4 <500. Only treating at CD4 <500 is cost effective: ICER of $62 ($46-$75). Nonprioritized PrEP plus treating at CD4 <500 is borderline cost effective: ICER of $5861 ($3959-$8483). Initiating treatment at CD4 <500 requires a budget increase from $20 million to $25 million over 40 years, with a 96.7% probability of being the optimal intervention. PrEP should only be considered when the budget exceeds $180 million.Conclusions:Treatment initiation at CD4 <500 is a cost-effective HIV prevention approach that will require a modest increase in budget. Although adding PrEP will avert more infections, it is not economically feasible, as it requires a 10-fold increase in budget.	cost-effectiveness; pre-exposure prophylaxis; PREVENTION; treatment as prevention; THERAPY; TRANSMISSION; RISK; IMPACT; PREEXPOSURE PROPHYLAXIS; CARE; HIV-INFECTION; DRUG-RESISTANCE; ANTIRETROVIRAL TREATMENT; stochastic league tables	English	United States	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Netherlands	Western and Central Europe and North America	Quantitative
Theses and Dissertations	2014	Nicol, Melanie	Pre-Exposure Prophylaxis for HIV: Linking Antiretroviral Pharmacokinetics and Pharmacodynamics to Identify Optimal Dosing Strategies	-	-	University of North Carolina	-	-	https://doi.org/10.17615/x9b2-e491	http://hdl.handle.net/10183/220568	Despite utilization of potent combination antiretroviral therapy, the incidence of HIV in the U.S. has not declined over recent years. Several clinical trials recently demonstrated that antiretrovirals can protect vulnerable mucosal surfaces against infection. However, the protection conferred ranged from 0% to 73%, underscoring the importance of identifying drug concentrations needed at mucosal surfaces. Additionally, antiretrovirals have complex pharmacology in mucosal tissues with unpredictable drug penetration within and between drug classes. The ultimate goal of this work was to identify factors influencing variability in drug penetration and to develop an explant tissue culture model that could be used to evaluate the efficacy of tenofovir and maraviroc, two antiretroviral candidates for oral pre-exposure prophylaxis strategies. Using real-time PCR and immunochemistry, mRNA and protein expression of three efflux (ABCB1/MDR1, ABCC2/MRP2, ABCC4/MRP4) and three uptake (SLC22A6/OAT1, SLC22A8/OAT3, SLCO1B1/OATP1B1) transporters was described in female genital (FGT) and colorectal tissues (CRT) from 99 donors. Epithelial expression of efflux transporters was found to be two- to four-fold greater in FGT than CRT. These data support clinical findings of higher maraviroc and tenofovir concentrations in CRT compared to FGT after oral dosing. Quantifying mucosal transporter expression and localization was a useful technique to understand drug tissue distribution and facilitate antiretroviral selection to target these tissues. Explant models may be one way to identify target concentrations for prevention but current methods are high variable and require long incubation times in culture. Here, an explant tissue model was developed using the R5, T-tropic strain HIV-1 _{JR-CSF} as the inoculum, and was coupled with a novel real-time PCR assay to quantify spliced RNA that detected replication within 24-72 hours after HIV exposure. In this model, concentrations required to protect vaginal explants were 10-1000 fold higher than in a TZM-bl cell monolayer. A single oral dose of tenofovir and maraviroc at 200% treatment doses protected cervical and vaginal biopsies in 3/6 healthy volunteer women. TZM-bl cells over predicted efficacy by 49%, and tissue explants under predicted by 36%. This translational approach, comparing concentration-response relationships in cells, explant tissue, and healthy volunteers, presents a model framework for future investigations of antiretrovirals for prevention. Article	2014	Nixon, Briana; Jandl, Thomas; Teller, Ryan S.; Taneva, Ekaterina; Wang, Yanhua; Nagaraja, Umadevi; Kiser, Patrick F.; Herold, Betsy C.	Vaginally delivered tenofovir disoproxil fumarate provides greater protection than tenofovir against genital herpes in a murine model of efficacy and safety.	Antimicrobial Agents and Chemotherapy	-	-	-	1098-6596 0066-4804	10.1128/AAC.01818-13	https://pubmed.ncbi.nlm.nih.gov/24323471/	Increased susceptibility to genital herpes in medroxyprogesterone-treated mice may provide a surrogate of increased HIV risk and a preclinical biomarker of topical preexposure prophylaxis safety. We evaluated tenofovir disoproxil fumarate (TDF) in this murine model because an intravaginal ring eluting this drug is being advanced into clinical trials. To avoid the complications of surgically inserting a ring, hydroxyethylcellulose (HEC)-stable formulations of TDF were prepared. One week of twice-daily 0.3% TDF gel was well tolerated and did not result in any increase in HSV-2 susceptibility but protected mice from herpes simplex virus 2 (HSV-2) disease compared to mice treated with the HEC placebo gel. No significant increase in inflammatory cytokines or chemokines in vaginal washes or change in cytokine, chemokine, or mitochondrial gene expression in RNA extracted from genital tract tissue was detected. To further evaluate efficacy, mice were treated with gel once daily beginning 12 h prior to high-dose HSV-2 challenge or 2 h before and after viral challenge (BAT24 dosing). The 0.3% TDF gel provided significant protection compared to the HEC gel following either daily (in 9/10 versus 1/10 mice, P < 0.01) or BAT24 (in 14/20 versus 4/20 mice, P < 0.01) dosing. In contrast, 1% tenofovir (TFV) gel protected only 4/10 mice treated with either regimen. Significant protection was also observed with daily 0.03% TDF compared to HEC. Protection was associated with greater murine cellular permeability of radiolabeled TDF than of TFV. Together, these findings suggest that TDF is safe, may provide substantially greater protection against HSV than TFV, and support the further clinical development of a TDF ring. Article	2014	Peris-Vicente, Juan; Villarreal-Traver, Mónica; Casas-Breva, Inmaculada; Carda-Broch, Samuel; Esteve-Romero, Josep	Use of micellar liquid chromatography to analyze darunavir, ritonavir, emtricitabine, and tenofovir in plasma.	Journal of Separation Science	-	-	-	1615-9314 1615-9306	10.1002/jssc.201400574	https://pubmed.ncbi.nlm.nih.gov/25103282/	Darunavir, ritonavir, emtricitabine, and tenofovir are together prescribed against AIDS as a highly active antiretroviral therapy regimen. Micellar liquid chromatography has been applied to determine these four antiretroviral drugs in plasma. The sample preparation is shortened to the dilution of the sample in a micellar solution, filtration, and injection. Clean-up steps are avoided, due to the solubilization of plasma matrix in micellar media. The drugs were analyzed in <20 min using a mobile phase of 0.06 M sodium dodecyl sulfate/2.5% 1-pentanol (pH 7) running under isocratic mode through a C18 column at 1 mL/min at room temperature. Absorbance wavelength detection was set at 214 nm. The method was successfully validated following the ICH Harmonized Tripartite Guideline in terms of selectivity, limit of detection (0.080-0.110 μg/mL), limit of quantification (0.240-0.270 μg/mL), linearity between 0.25 and 25 μg/mL (r(2) > 0.995), accuracy (89.3-103.2%), precision (<8.2%) and robustness (<7.5%). Real plasma sample from patients taking this therapy were analyzed. This is the first paper showing the simultaneous detection of this four drugs. Therefore, the methodology was proven useful for the routine analysis of these samples in a hospital laboratory for clinical purposes. Article	2014	Perry, Brian; Oluoch, Lennah; Agot, Kawango; Taylor, Jamilah; Onyango, Jacob; Ouma, Lilian; Otieno, Caroline; Wong, Christina; Corneli, Amy	Widow cleansing and inheritance among the Luo in Kenya: the need for additional women-centred HIV prevention options.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.17.1.19010	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4074366/	INTRODUCTION: The customs of widow cleansing and widow inheritance are practiced in several communities throughout sub-Saharan Africa. In the Nyanza Province of Kenya, according to tradition, Luo widows are expected to engage in sexual intercourse with a "cleanser," without the use of a condom, in order to remove the impurity ascribed to her after her husband's death. Luo couples, including widows, are also expected to engage in sex preceding specific agricultural activities, building homes, funerals, weddings, and other significant cultural and social events. Widows who are inherited for the purpose of fulfilling cultural obligation have a higher prevalence of HIV than those who remain un-inherited or are inherited for the purpose of companionship. METHODS: As part of a larger descriptive qualitative study to inform study procedures for FEM-PrEP, an HIV prevention pre-exposure prophylaxis clinical trial, we conducted 15 semi-structured interviews (SSIs) with widows, 15 SSIs with inheritors, and four focus group discussions with widows in the Bondo and Rarieda districts in Nyanza Province to explore the HIV risk context within widow cleansing and inheritance practices. Thematic qualitative analysis was used to analyze the data. RESULTS: The majority of widows reported in the demographic questionnaire being inherited, and most widows in the SSIs described participating in the cleansing ritual. We identified two main themes related to HIV prevention within the context of widow cleansing and inheritance: 1) widows must balance limiting their risk for HIV infection with meeting cultural expectations and ensuring that their livelihood needs are met, and 2) sexual abstinence undermines cultural expectations in widowhood while the use of condoms is deemed inappropriate in fulfilling culturally prescribed sexual rituals, and is often beyond the widow's ability to negotiate. CONCLUSIONS: Women-controlled HIV prevention methods such as antiretroviral-based oral pre-exposure prophylaxis, vaginal gels, and vaginal rings are needed for HIV-negative widows who engage in sexual rituals related to widowhood. Article	2014	Pines, Heather A.; Gorbach, Pamina M.; Weiss, Robert E.; Shoptaw, Steve; Landovitz, Raphael J.; Javanbakht, Marjan; Ostrow, David G.; Stall, Ron D.; Plankey, Michael	Sexual risk trajectories among MSM in the United States: implications for pre-exposure prophylaxis delivery.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000000101	https://escholarship.org/uc/item/7qw1m8sn	BACKGROUND: Despite evidence supporting pre-exposure prophylaxis (PrEP) efficacy, there are concerns regarding the feasibility of widespread PrEP implementation among men who have sex with men (MSM). To inform the development of targeted PrEP delivery guidelines, sexual risk trajectories among HIV-negative MSM were characterized. METHODS: At semiannual visits from 2003 to 2011, HIV-negative MSM (N = 419) participating in the Multicenter AIDS Cohort Study provided data on sexual risk behaviors (SRBs) since their last visit. Based on their reported behaviors, participants were assigned a SRB score at each visit as follows: 0 = no insertive or receptive anal intercourse, 1 = no unprotected insertive or receptive anal intercourse, 2 = only unprotected insertive anal intercourse, 3 = unprotected receptive anal intercourse with 1 HIV-negative partner, 4 = condom serosorting, 5 = condom seropositioning, and 6 = no seroadaptive behaviors. Group-based trajectory modeling was used to examine SRB scores (<4 vs. ≥4) and identify groups with distinct sexual risk trajectories. RESULTS: Three sexual risk trajectory groups were identified: low-risk (n = 264; 63.0%), moderate-risk (n = 96; 22.9%; mean duration of consecutive high-risk intervals ~1 year), and high-risk (n = 59; 14.1%; mean duration of consecutive high-risk intervals ~2 years). Compared to low-risk group membership, high-risk group membership was associated with younger age (in years) adjusted odds ratio (AOR) = 0.92, 95% confidence interval (CI): 0.88 to 0.96, being White (AOR = 3.67, 95% CI: 1.48 to 9.11), earning an income ≥$20,000 (AOR = 4.98, 95% CI: 2.13 to 11.64), distress/depression symptoms (Center for Epidemiologic Studies Depression Scale ≥ 16) (AOR = 2.36, 95% CI: 1.14 to 4.92), and substance use (AOR = 2.00, 95% CI: 1.01 to 3.97). CONCLUSIONS: Screening for the sociodemographic and behavioral factors described above may facilitate targeted PrEP delivery during high-risk periods among MSM.	*Homosexuality, Male; Adult; Humans; Male; Middle Aged; HIV Infections/*prevention & control; Time Factors; Chemoprevention/*methods; United States; Prospective Studies; *Risk-Taking	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Psaros, Christina; Haberer, Jessica E; Katabira, Elly; Ronald, Allan; Tumwesigye, Elioda; Campbell, James D; Wangisi, Jonathan; Mugwanya, Kenneth; Kintu, Alex; Enyakoit, Michael; Thomas, Katherine K; Donnell, Deborah; Krows, Meighan; Kidoguchi, Lara; Ware, Norma; Baeten, Jared M; Celum, Connie; Bangsberg, David R; Safren, Steve A	An intervention to support HIV preexposure prophylaxis adherence in HIV-serodiscordant couples in Uganda.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000212	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4191829/	BACKGROUND: Daily preexposure prophylaxis (PrEP) is an effective HIV prevention strategy, but adherence is required for maximum benefit. To date, there are no empirically supported PrEP adherence interventions. This article describes the process of developing a PrEP adherence intervention and presents results on its impact on adherence. METHODS: The Partners PrEP Study was a placebo-controlled efficacy trial of daily oral tenofovir and emtricitabine/tenofovir PrEP among uninfected members of HIV-serodiscordant couples. An ancillary adherence study was conducted at 3 study sites in Uganda. Participants with <80% adherence as measured by unannounced pill count received an additional adherence counseling intervention based on Lifesteps, an evidence-based HIV treatment adherence intervention, based on principles of cognitive-behavioral theory. FINDINGS: Of the 1147 HIV-seronegative participants enrolled in the ancillary adherence study, 168 (14.6%) triggered the adherence intervention. Of participants triggering the intervention, 62% were men; median age was 32.5 years. The median number of adherence counseling sessions was 10. Mean adherence during the month before the intervention was 75.7% and increased significantly to 84.1% in the month after the first intervention session (P < 0.001). The most frequently endorsed adherence barriers at session 1 were travel and forgetting. INTERPRETATION: A PrEP adherence intervention was feasible in a clinical trial of PrEP in Uganda and PrEP adherence increased after the intervention. Future research should identify PrEP users with low adherence for enhanced adherence counseling and determine optimal implementation strategies for interventions to maximize PrEP effectiveness.	pre-exposure prophylaxis, adherence, intervention, serodiscordant couples, HIV prevention	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical

Gerardo	Depot-medroxyprogesterone acetate does not reduce the prophylactic efficacy of emtricitabine and tenofovir disoproxil fumarate in macaques.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000000340	https://pubmed.ncbi.nlm.nih.gov/25202923/	Concerns that the injectable contraceptive depot-medroxyprogesterone acetate (DMPA) may increase the risk of HIV acquisition in women led to questions on whether DMPA could reduce efficacy of pre-exposure prophylaxis (PrEP) for HIV prevention. We used a macaque model to investigate the impact of prolonged DMPA exposure on PrEP with emtricitabine/tenofovir disoproxil fumarate. Twelve pigtail macaques treated with DMPA were exposed vaginally to simian HIV once a week for up to 5 months and received either placebo (n = 6) or emtricitabine/tenofovir disoproxil fumarate (n = 6). All control macaques were infected, whereas the PrEP-treated animals remained protected (P = 0.0007). This model suggests that women using DMPA will fully benefit from PrEP. Article	2014	Rahman, S M Ashrafur; Vaidya, Naveen K; Zou, Xingfu	Impact of Tenofovir gel as a PrEP on HIV infection: a mathematical model.	Journal of Theoretical Biology	-	-	-	1095-8541	10.1016/j.jtbi.2013.12.021	https://dx.doi.org/10.1016/j.jtbi.2013.12.021	Pre-exposure prophylaxis (PrEP) has been considered as one of the promising interventions for HIV infection as experiments on various groups and sites have reported its significant effectiveness. This study evaluates the effectiveness of Tenofovir gel, one of the widely used PrEPs for women, through a mathematical model. Our model has excellent agreement with the experimental data on the use of Tenofovir gel as a PrEP in South African women. Using our model, we estimate both male-to-female and female-to-male transmission rates with and without Tenofovir gel protection. Through these estimates we demonstrate that the use of Tenofovir gel as a PrEP can significantly reduce the reproduction numbers, new infections, and HIV prevalence in South Africa. Our results further show that the effectiveness of Tenofovir gel largely depends on the level of adherence to the gel and the proportion of women under gel coverage. Even though Tenofovir gel alone may not be able to eradicate the disease as indicated by our estimates of the reproduction numbers, together with other interventions, such as condom use, it can serve as a strong weapon to fight against HIV epidemics. Article	2014	Robbins, Reuben N.; Spector, Anya Y.; Mellins, Claude A.; Remien, Robert H.	Optimizing ART adherence: update for HIV treatment and prevention.	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-014-0229-5	https://pubmed.ncbi.nlm.nih.gov/25304006/	Optimal adherence to antiretroviral therapy (ART) is central to achieving viral suppression and positive health outcomes in HIV-infected individuals. Virally suppressed individuals can also reduce the risk of HIV transmission to uninfected partners. Hence, adherence to ART has become both an HIV treatment and an HIV prevention strategy. However, achieving optimal ART adherence can be challenging, especially over the long term. It is increasingly important for clinicians and researchers to be abreast of the most recent developments in the field as new biomedical approaches to treatment emerge and as guidelines for the use of pre-exposure prophylaxis (PrEP) are disseminated to providers serving HIV affected populations. Several reviews have described numerous ART adherence interventions that have been developed and/or tested with the most recent review including literature up to 2012. To augment the literature, we present a review of ART adherence interventions from 2013 to the present. We included peer-reviewed journals as well as abstracts from two key conferences. Article	2014	Roberts, Sarah T; Heffron, Renee; Ngure, Kenneth; Celum, Connie; Kurth, Ann; Curran, Kathryn; Mugo, Nelly; Baeten, Jared M	Preferences for daily or intermittent pre-exposure prophylaxis regimens and ability to anticipate sex among HIV uninfected members of Kenyan HIV serodiscordant couples.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-014-0804-1	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4127114	Intermittent dosing for pre-exposure prophylaxis (PrEP) has been proposed as an alternative to daily PrEP to reduce cost and patient drug exposure and to improve adherence. One possible dosing regimen is pre-intercourse PrEP, which requires anticipating sex in advance. We examined preferences for daily versus pre-intercourse PrEP and ability to anticipate sex among 310 HIV uninfected members of HIV serodiscordant heterosexual couples in Thika, Kenya, with high HIV knowledge and experience with daily PrEP use in a clinical trial setting. Preferences were evenly split between daily PrEP (47.4 %) and pre-intercourse PrEP (50.7 %). Participants were more likely to prefer daily PrEP if they reported unprotected sex during the prior month (adjusted prevalence ratio aPR 1.48, 95 % CI 1.20-1.81) or <80 % adherence to study drug (aPR 1.50, 95 % CI 1.25-1.79), and were less likely to prefer daily PrEP if sex was usually planned, versus spontaneous (aPR 0.76, 95 % CI 0.61-0.96). A minority (24.2 %) reported anticipating sex >3 h in advance, with younger participants being less likely to do so (aPR 0.43, 95 % CI 0.23-0.83 for ages 18-29 vs. ≥40). Findings suggest that intermittent PrEP could be a popular option in this population, but that optimal adherence and sufficient drug levels might be challenging with a pre-intercourse regimen. Article	2014	Rocha, Luís Miguel; Campos, Maria José; Brito, João; Fuertes, Ricardo; Rojas, Jesus; Pinto, Nuno; Mendão, Luís; Esteves, Julio	Acceptability of PrEP among HIV negative Portuguese men who have sex with men that attended 2014 Lisbon pride fair.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.17.4.19734	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4225295	INTRODUCTION: Consistent use of PrEP reduces HIV transmission from sexual practices amongst men who have sex with men (MSM) up to 92% 1. Lisbon MSM cohort study estimates point that 59.3% of their participants at entrance (1593 HIV negative MSM enrolled between April 2011 and May 2013) were eligible for PrEP 2, according to the 2014 USA PrEP guidelines 3. Studies about PrEP acceptability and implementation support policies aimed at increasing and rolling out its use. Hence, the exploratory study about PrEP acceptability in MSM at Lisbon. MATERIALS AND METHODS: A street-based intercept survey, adapted from Mantell et al. study 4, was the one used on MSM attending the 2014 Lisbon pride fair. The survey included socio-demographic data, PrEP awareness and readiness to use it, probability of MSM's social network to also use it, promptness to join PrEP-related studies, type of PrEP warranted and condomless anal sex practice in the last six months. RESULTS: A total of 110 HIV negative Portuguese MSM responded, with a median age of 33% and 84% of them identified themselves as gay. A majority of MSM were unaware of PrEP (59%); those that were aware, had heard of it trough CheckpointLx (31%), internet (22%) or health professionals (20%). 66% were likely or very likely to participate in PrEP-related studies. 57% of MSM were likely or very likely to use PrEP if available and reported that some, if not almost all of their social network, will do it too (70%). Type of PrEP preferred was oral, a pill a day (43%), followed by oral, intermittent intake (32%). Overall 41% of MSM had condomless anal sex practice in the last six months. CONCLUSIONS: In this MSM Portuguese sample, a general willingness to adopt PrEP was predominant, specially the oral daily intake. Forty-one percent of participants had had condomless anal sex practice in the last six months and therefore fitted within the criteria to be on Pre-Exposure Prophylaxis (PrEP), according to MSM Risk Index in 2014 USA PrEP guidelines. PrEP, when available in Portugal, should be a powerful tool for HIV prevention in this key population. Article	2014	Rosenthal, E; Piroth, L; Cua, E; Joulié, A; Ravaux, I; Chauveau, M; Lacombe, K; Cotte, L; Bonnard, P; Weiss, L; Longuet, M; Pradier, C; Cacoub, P	Preexposure prophylaxis (PrEP) of HIV infection in France: A nationwide cross-sectional study (PREVIC study)	AIDS Care	-	-	-	9540121	10.1080/09540121.2013.803014	https://www.proquest.com/scholarly-journals/preexposure-prophylaxis-prep-hiv-infection-france/docview/1475259528/se-2?accountid=8113	Although preliminary studies showed that preexposure prophylaxis (PrEP) lowers the HIV transmission in individuals with HIV, confirmative trials are ongoing and PrEP is not routinely recommended. The aim of this study was to assess whether individuals with HIV share antiretroviral (ARV) drugs for PrEP and to describe awareness and discussion on PrEP in this population. A cross-sectional survey was conducted in France in 23 representative departments of infectious diseases and internal medicine. Physicians administered an anonymous standardized questionnaire to all individuals with HIV receiving ARVs and followed between 24 and 31 October 2011. The questionnaire included items regarding PrEP (awareness; discussion with their close circle, physician or patients' association; experience), personal sociodemographic characteristics, risk behaviors and HIV status of the participants. Five hundred and ninety three participants were recruited: male 74.2% (men who have sex with men 52.4%, heterosexuals 21.6%), member of patient's association 9.8%. Half of them (50.6%) lived with a stable partner and 35.2% with an HIV-negative partner. Almost half (41.8%) were aware and 29.5% had had discussion about PrEP. In logistic regression, awareness and discussion on PrEP were more frequent: (1) among males, in patients' association members (p< 0.001 for both) and in nonheterosexuals (p=0.023 and 0.057, respectively); (2) among women, in those not living with a stable partner (p=0.035 and p=0.003, respectively) or living with an HIV-negative partner (p=0.049 and p=0.083, respectively). One percent of the participants declared having shared ARVs with someone and 8.3% reported PrEP in their close circle. Men reporting PrEP in their close circle shared ARVs more frequently than those who did not (10.3% vs. 0.2%, p < 0.001). Today, individuals with HIV do not seem to widely share personal ARVs for PrEP with seronegative people. A significant number of individuals with HIV are aware of and commonly discuss PrEP. Article	2014	Ross, Ted M; Pereira, Lara E; Luckay, Amara; McNicholl, Janet M; García-Lerma, J Gerardo; Heneine, Walid; Eugene, Hermancia S; Pierce-Paul, Brooke R; Zhang, Jining; Hendry, R Michael; Smith, James M	A polyvalent Clade B virus-like particle HIV vaccine combined with partially protective oral preexposure prophylaxis prevents simian-human immunodeficiency virus Infection in macaques and primes for virus-amplified immunity.	AIDS Research and Human Retroviruses	-	-	-	1931-8405	10.1089/AID.2014.0030	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4208560	Vaccination and preexposure prophylaxis (PrEP) with antiretrovirals have shown only partial protection from HIV-1 infection in human trials. Oral Truvada (emtricitabine/tenofovir disoproxil fumarate) is FDA approved as PrEP but partial adherence reduces efficacy. If combined as biomedical preventions (CBP), an HIV vaccine could protect when PrEP adherence is low and PrEP could prevent vaccine breakthroughs. The efficacy of combining oral PrEP with an HIV vaccine has not been evaluated in humans. We determined the efficacy of combining a DNA/virus-like particle (VLP) vaccine with partially effective intermittent PrEP in Indian rhesus macaques (RM). Eight RM received intramuscular inoculations of five DNA plasmids encoding four HIV-1 Clade B primary isolate Envs and SIVmac239 Gag (at weeks 0 and 4), followed by intramuscular and intranasal inoculations of homologous Gag VLPs and four Env VLPs (at weeks 12, 16, and 53). At week 61, we initiated weekly rectal exposures with heterologous SHIV162p3 (10 TCID50) along with oral Truvada (TDF, 22 mg/kg; FTC 20 mg/kg) dosing 2 h before and 22 h after each exposure. This PrEP regimen previously demonstrated 50% efficacy. Five controls (no vaccine, no PrEP) received weekly SHIV162p3. All controls were infected after a median of four exposures; the mean peak plasma viral load (VL) was 3.9×10(7) vRNA copies/ml. CBP protected seven of eight (87.5%) RM. The one infected CBP RM had a reduced peak VL of 8.8×10(5) copies/ml. SHIV exposures during PrEP amplified Gag and Env antibody titers in protected RM. These results suggest that combining oral PrEP with HIV vaccines could enhance protection against HIV-1 infection. Article	2014	Scherer, Matthew L.; Douglas, Nataki C.; Churnet, Bethlehem H.; Grossman, Lisa C.; Kline, Melissa; Yin, Michael T.; Sauer, Mark V.; Olender, Susan A.	Survey of HIV care providers on management of HIV serodiscordant couples - assessment of attitudes, knowledge, and practices.	AIDS Care	-	-	-	1360-0451 0954-0121	10.1080/09540121.2014.920950	https://www.tandfonline.com/doi/abs/10.1080/09540121.2014.920950	Human immunodeficiency virus (HIV) serodiscordant couples are at risk of sexual transmission of HIV between the infected and uninfected partner. We assessed New York area care providers for people living with HIV regarding attitudes, knowledge, and practice patterns toward fertility and conception in serodiscordant couples. Data were collected via a survey distributed in October 2013. Seventeen percent of respondents reported prescribing antiretroviral preexposure prophylaxis (PrEP) for a woman in a serodiscordant couple, and 38% percent of respondents reported having counseled serodiscordant couples on timed, unprotected intercourse without PrEP. Respondents who were "very" familiar with the data on HIV transmission in serodiscordant couples were more likely to report counseling their patients in timed, unprotected intercourse compared with those who reported less familiarity with the data (41% vs. 8%, p = 0.001). Although only 20% reported being "very" or "somewhat" familiar with the data on the safety of sperm washing with intrauterine insemination, those who did were more likely to have reported referring a patient for assisted reproductive technology (61% vs. 32%, p = 0.006). Effective patient counseling and referral for appropriate reproductive options were associated with knowledge of the literature pertaining to these options. This emphasizes the need for further provider education on reproductive options and appropriate counseling for serodiscordant couples. Article	2014	Schneider, K; Gray, RT; Wilson, DP	A Cost-effectiveness Analysis of HIV Preexposure Prophylaxis for Men Who Have Sex With Men in Australia	Clinical Infectious Diseases	-	-	-	1058-4838	10.1093/cid/cit946	https://pubmed.ncbi.nlm.nih.gov/24385445/	Background. Antiretroviral therapy (ART) used as preexposure prophylaxis (PrEP) by human immunodeficiency virus (HIV)-seronegative individuals reduces the risk of acquiring HIV. However, the population-level impact and cost-effectiveness of using PrEP as a public health intervention remains debated. Methods. We used a stochastic agent-based model of HIV transmission and progression to simulate the clinical and cost outcomes of different strategies of providing PrEP to men who have sex with men (MSM) in New South Wales (NSW), Australia. Model outcomes were reported as incremental cost-effectiveness ratios (ICERs) in 2013 Australian dollars per quality-adjusted life-year gained (QALYG). Results. The use of PrEP in 10%-30% of the entire NSW MSM population was projected to cost an additional $316-$952 million over the course of 10 years, and cost >$400 000 per QALYG compared with the status quo. Targeting MSM with sexual partners ranging between >10 to >50 partners within 6 months cost an additional $31-$331 million dollars, and cost >$110 000 per QALYG compared with the status quo. We found that preexposure prophylaxis is most cost-effective when targeted for HIV-negative MSM in a discordant regular partnership. The ICERs ranged between $8399 and $11 575, for coverage ranging between 15% and 30%, respectively. Conclusions. Targeting HIV-negative MSM in a discordant regular partnership is a cost-effective intervention. However, this highly targeted strategy would not have large population-level impact. Other scenarios are unlikely to be cost-effective. Article	2014	Schwartz, Sheree R.; Bassett, Jean; Sanne, Ian; Phofa, Rebecca; Yende, Nompumelelo; Van Rie, Annelies	Implementation of a safer conception service for HIV-affected couples in South Africa.	AIDS	-	-	-	1473-5571 0269-9370	10.1097/QAD.0000000000000330	https://pubmed.ncbi.nlm.nih.gov/24991901/	OBJECTIVE: To describe the development and implementation of a safer conception service in a resource-limited setting. METHODS: Qualitative work to inform the design of a safer conception service was conducted with clients and providers at Witkoppen Health and Welfare Centre, a primary health center in Johannesburg, South Africa. Services began in July 2013 for HIV-affected participants planning conception within 6 months and included counseling about timed unprotected intercourse and home-based self-insemination, early initiation of combined antiretroviral therapy (cART) for HIV-infected individuals, pre-exposure prophylaxis for HIV-uninfected partners and circumcision for men. Participants were enrolled into an implementation science study evaluating method uptake, acceptability, and pregnancy and HIV transmission outcomes. RESULTS: Findings to-date from 51 qualitative participants and 128 clinical cohort participants (82 women and 46 men, representing 82 partnerships) are presented. All men were accompanied by female partners, whereas 56% of women attended with their male partner. Fifteen of the 46 couples (33%) were in confirmed serodiscordant relationships; however, of the 36 additional women attending alone, 56% were unaware of their partners' HIV status or believed them to be HIV-uninfected. The majority of the HIV-infected women (86%) and men (71%) were on cART at enrollment; however, only 47% on cART were virally suppressed. Timed unprotected intercourse, self-insemination and cART were common choices for participants; few elected pre-exposure prophylaxis. CONCLUSIONS: Lessons learned from early implementation demonstrate feasibility of safer conception services; however, reaching discordant couples, cART-naïve infected partners, and men remain challenges. Creating demand for safer conception services among those at highest risk for HIV transmission is necessary. Article	2014	Segolodi, Tebogo M; Henderson, Faith L; Rose, Charles E; Turner, Kyle T; Zeh, Clement; Fonjungo, Peter N; Niska, Richard; Hart, Clyde; Paxton, Lynn A	Normal laboratory reference intervals among healthy adults screened for a HIV pre-exposure prophylaxis clinical trial in Botswana.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0093034	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3979652	INTRODUCTION: Accurate clinical laboratory reference values derived from a local or regional population base are required to correctly interpret laboratory results. In Botswana, most reference intervals used to date are not standardized across clinical laboratories and are based on values derived from populations in the United States or Western Europe. METHODS: We measured 14 hematologic and biochemical parameters of healthy young adults screened for participation in the Botswana HIV Pre-exposure Prophylaxis Study using tenofovir disoproxil fumarate and emtricitabine (TDF/FTC) (TDF2 Study). Reference intervals were calculated using standard methods, stratified by gender, and compared with the site-derived reference values used for the TDF2 study (BOTUSA ranges), the Division of AIDS (DAIDS) Grading Table for Adverse Events, the Botswana public health laboratories, and other regional references. RESULTS: Out of 2533 screened participants, 1786 met eligibility criteria for participation in study and were included in the analysis. Our reference values were comparable to those of the Botswana public health system except for amylase, blood urea nitrogen (BUN), phosphate, total and direct bilirubin. Compared to our reference values, BOTUSA reference ranges would have classified participants as out of range for some analytes, with amylase (50.8%) and creatinine (32.0%) producing the highest out of range values. Applying the DAIDS toxicity grading system to the values would have resulted in 45 and 18 participants as having severe or life threatening values for amylase and hemoglobin, respectively. CONCLUSION: Our reference values illustrate the differences in hematological and biochemical analyte ranges between African and Western populations. Thus, the use of western-derived reference laboratory values to screen a group of Batswana adults resulted in many healthy people being classified as having out-of-range blood analytes. The need to establish accurate local or regional reference values is apparent and we hope our results can be used to that end in Botswana. Article	2014	Sharma, Malika; Wilton, James; Senn, Heather; Fowler, Shawn; Tan, Darrell H S	Preparing for PrEP: perceptions and readiness of canadian physicians for the implementation of HIV pre-exposure prophylaxis.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0105283	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4136811	Recent evidence has demonstrated the efficacy of pre-exposure prophylaxis (PrEP) for HIV prevention, but concerns persist around its use. Little is known about Canadian physicians' knowledge of and willingness to prescribe PrEP. We disseminated an online survey to Canadian family, infectious disease, internal medicine, and public health physicians between September 2012-June 2013 to determine willingness to prescribe PrEP. Criteria for analysis were met by 86 surveys. 45.9% of participants felt "very familiar" with PrEP, 49.4% felt that PrEP should be approved by Health Canada, and 45.4% of respondents were willing to prescribe PrEP. Self-identifying as an HIV expert (odds ratio, ORâ=â4.1, 95% confidence interval, CIâ=â1.6-10.2), familiarity with PrEP (ORâ=â5.0, 95%CIâ=â1.3-19.0) and having been asked by patients about PrEP (ORâ=â4.0, 95%CIâ=â1.5-10.5) were positively associated with willingness to prescribe PrEP on univariable analysis. The latter two were the strongest predictors on multivariate analysis. Participants cited cost and efficacy as major concerns. 75.3% did not feel that information had been adequately disseminated among physicians. In summary, Canadian physicians demonstrate varying levels of support for PrEP and express concerns about its implementation. Further research on real-world effectiveness, continuing medical education, and clinical support is needed to prepare physicians for this prevention strategy. Article	2014	Sluis-Cremer, Nicolas	The emerging profile of cross-resistance among the nonnucleoside HIV-1 reverse transcriptase inhibitors.	Viruses	-	-	-	1999-4915	10.3390/v6082960	https://www.mdpi.com/1999-4915/6/8/2960	Nonnucleoside reverse transcriptase inhibitors (NNRTIs) are widely used to treat HIV-1-infected individuals; indeed most first-line antiretroviral therapies typically include one NNRTI in combination with two nucleoside analogs. In 2008, the next-generation NNRTI etravirine was approved for the treatment of HIV-infected antiretroviral therapy-experienced individuals, including those with prior NNRTI exposure. NNRTIs are also increasingly being included in strategies to prevent HIV-1 infection. For example: (1) nevirapine is used to prevent mother-to-child transmission; (2) the ASPIRE (MTN 020) study will test whether a vaginal ring containing dapivirine can prevent HIV-1 infection in women; (3) a microbicide gel formulation containing the urea-PETT derivative MIV-150 is in a phase I study to evaluate safety, pharmacokinetics, pharmacodynamics and acceptability; and (4) a long acting rilpivirine formulation is under-development for pre-exposure prophylaxis. Given their widespread use, particularly in resource-limited settings, as well as their low genetic barriers to resistance, there are concerns about overlapping resistance between the different NNRTIs. Consequently, a better understanding of the resistance and cross-resistance profiles among the NNRTI class is important for predicting response to treatment, and surveillance of transmitted drug-resistance. Article	2014	Snowden, Jonathan M.; Wei, Chongyi; McFarland, Willi; Raymond, H. Fisher	Prevalence, correlates and trends in seroadaptive behaviours among men who have sex with men from serial cross-sectional surveillance in San Francisco, 2004-2011.	Sexually Transmitted Infections	-	-	-	1472-3263 1368-4973	10.1136/sextrans-2013-051368	https://pubmed.ncbi.nlm.nih.gov/24687128/	OBJECTIVES: We sought to assess the prevalence and correlates of seroadaptive behaviours (i.e., sexual history incorporating some unprotected anal intercourse (UAI)) and conventional risk reduction behaviours (i.e., consistent condom use or no anal intercourse) among men who have sex with men (MSM) in San Francisco in 2011. We compared the prevalence of seroadaptive behaviours between serial cross-sectional surveys from 2004, 2008 and 2011. METHODS: We analysed data from the 2011 wave of the National HIV Behavioral Surveillance system in San Francisco. We categorised men's self-reported sexual behaviour history in the past 6 months into a schema of seroadaptive behaviours and conventional risk reduction behaviours. We compared the prevalence of behaviour categories by self-reported HIV serostatus, HIV testing history, awareness of pre-exposure HIV prophylaxis (PrEP) and diagnosis of a sexually transmitted infection (STI). RESULTS: Seroadaptive behaviours remained common in San Francisco MSM, with a 2011 prevalence of 46.6%, up from 35.9% in 2004. Consistent condom use or no anal intercourse was more common than seroadaptive behaviours in HIV-negative MSM, men who had not heard of PrEP and men without an STI diagnosis. Seroadaptive behaviours increased from 2004 to 2011. CONCLUSIONS: HIV seroadaptive behaviours remain common in San Francisco MSM, have increased in the last decade and are practiced differently by MSM with different sexual health knowledge and outcomes. Public health researchers and officials should continue to document the prevalence, intentionality, efficacy and safety of seroadaptive behaviours among diverse communities of MSM.	*Homosexuality, Male; Adult; Humans; Male; Young Adult; Cross-Sectional Studies; HIV; Prevalence; Sexual Partners; San Francisco/epidemiology; *Health Behavior; Condoms/*statistics & numerical data; Sexual Behavior/statistics & numerical data; HIV Infections/*epidemiology/prevention & control; Safe Sex/*statistics & numerical data; Antiretroviral Therapy, Highly Active/statistics & numerical data; Unsafe Sex/*statistics & numerical data; CONDOMS; GAY MEN; HIV Serosorting/*statistics & numerical data; HOMOSEXUALITY; SEXUAL BEHAVIOUR	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2014	Solomon, Marc M; Mayer, Kenneth H; Glidden, David V; Liu, Albert Y; McMahan, Vanessa M; Guanira, Juan V; Chariyalertsak, Suwat; Fernandez, Telmo; Grant, Robert M	Syphilis predicts HIV incidence among men and transgender women who have sex with men in a preexposure prophylaxis trial.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/ciu450	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4166980	BACKGROUND: Syphilis infection may potentiate transmission of human immunodeficiency virus (HIV). We sought to determine the extent to which HIV acquisition was associated with syphilis infection within an HIV preexposure prophylaxis (PrEP) trial and whether emtricitabine/tenofovir (FTC/TDF) modified that association. METHODS: The Preexposure Prophylaxis Initiative (iPrEx) study randomly assigned 2499 HIV-seronegative men and transgender women who have sex with men (MSM) to receive oral daily FTC/TDF or placebo. Syphilis prevalence at screening and incidence during follow-up were measured. Hazard ratios for the effect of incident syphilis on HIV acquisition were calculated. The effect of FTC/TDF on incident syphilis and HIV acquisition was assessed. RESULTS: Of 2499 individuals, 360 (14.4%) had a positive rapid plasma reagin test at screening; 333 (92.5%) had a positive confirmatory test, which did not differ between the arms (FTC/TDF vs placebo, P = .81). The overall syphilis incidence during the trial was 7.3 cases per 100 person-years. There was no difference in syphilis incidence between the study arms (7.8 cases per 100 person-years for FTC/TDF vs 6.8 cases per 100 person-years for placebo, P = .304). HIV incidence varied by incident syphilis (2.8 cases per 100 person-years for no syphilis vs 8.0 cases per 100 person-years for incident syphilis), reflecting a hazard ratio of 2.6 (95% confidence interval, 1.6-4.4; P < .001). There was no evidence for interaction between randomization to the FTC/TDF arm and incident syphilis on HIV incidence. CONCLUSIONS: In HIV-seronegative MSM, syphilis infection was associated with HIV acquisition in this PrEP trial; a syphilis diagnosis should prompt providers to offer PrEP unless otherwise contraindicated. Article	2014	Solomon, MM; Lama, JR; Glidden, DV; Mulligan, K; McMahan, V; Liu, AY; Guanira, JV; Veloso, VG; Mayer, KH; Chariyalertsak, S; Schechter, M; Bekker, LG; Kallás, EG; Burns, DN; Grant, RM	Changes in renal function associated with oral emtricitabine/tenofovir disoproxil fumarate use for HIV pre-exposure prophylaxis	AIDS	-	-	-	24499951	10.1097/QAD.0000000000000156	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-00984254/full	OBJECTIVE: Tenofovir disoproxil fumarate (TDF) pre-exposure prophylaxis decreases sexual acquisition of HIV infection. We sought to evaluate the renal safety of TDF in HIV-uninfected persons. DESIGN AND METHODS: The Iniciativa Profilaxis Pre-Exposición (iPrEx) study randomly assigned 2499 HIV-seronegative men and transgender women who have sex with men (MSM) to receive oral daily TDF coformulated with emtricitabine (FTC/TDF) or placebo. Serum creatinine and phosphorus during randomized treatment and after discontinuation were measured, and creatinine clearance (CrCl) was estimated by the Cockcroft-Gault equation. Indicators of proximal renal tubulopathy (fractional excretion of phosphorus and uric acid, urine protein, and glucose) were measured in a substudy. RESULTS: There was a small but statistically significant decrease in CrCl from baseline in the active arm, compared to placebo, which was first observed at week 4 (mean change: -2.4 vs. -1.1 ml/min; P=0.02), persisted through the last on-treatment visit (mean change: +0.3 vs. +1.8 ml/min; P=0.02), and resolved after stopping pre-exposure prophylaxis (mean change: -0.1 vs. 0.0 ml/min; P=0.83). The effect was confirmed when stratifying by drug detection. The effect of FTC/TDF on CrCl did not vary by race, age, or history of hypertension. There was no difference in serum phosphate trends between the treatment arms. In the substudy, two participants receiving placebo had indicators of tubulopathy. CONCLUSIONS: In HIV-seronegative MSM, randomization to FTC/TDF was associated with a very mild nonprogressive decrease in CrCl that was reversible and managed with routine serum creatinine monitoring.	*Human immunodeficiency virus infection/dt Drug Therapy; *Human immunodeficiency virus infection/pc Prevention; *chemoprophylaxis; *emtricitabine plus tenofovir disoproxil/ae Adverse Drug Reaction; *emtricitabine plus tenofovir disoproxil/ct Clinical Trial; *emtricitabine plus tenofovir disoproxil/dt Drug Therapy; *emtricitabine plus tenofovir disoproxil/po Oral Drug Administration; *kidney dysfunction; *kidney function; *preexposure prophylaxis; Adenine adverse effects, *analogs & derivatives, therapeutic use; Adolescent; Adult; Antiviral therapy; Anti-HIV Agents adverse effects, *therapeutic use; Article; Bicarbonate blood level; Bicarbonate/ec Endogenous Compound; Chemoprevention adverse effects, *methods; Controlled study; Creatinine blood; Creatinine blood level; Creatinine clearance; Creatinine/ec Endogenous Compound; Deoxycytidine adverse effects, *analogs & derivatives, therapeutic use; Drug safety; Emtricitabine; Female; Glucosuria/si Side Effect; HIV Infections *prevention & control; Human; Humans; Hypophosphatemia/si Side Effect; Infection prevention; Kidney Function Tests; Kidney drug effects, *physiology; Kidney proximal tubule; Kidney tubule disorder; Major clinical study; Male; Men who have sex with men; Metabolic Clearance Rate; Middle Aged; Nonsteroid antiinflammatory agent; Organophosphonates adverse effects, *therapeutic use; Phosphate blood level; Phosphate/ec Endogenous Compound; Phosphorus blood; Phosphorus/ec Endogenous Compound; Placebo; Placebos administration & dosage; Priority journal; Proteinuria/si Side Effect; Randomized controlled trial; Side effect/si Side Effect; Tenofovir; Transgenderism; Urea nitrogen blood level; Uric acid/ec Endogenous Compound; Young Adult	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Sowicz, TJ; Teitelman, AM; Coleman, CL; Brawner, BM	Considerations for Implementing Oral Preexposure Prophylaxis: A Literature Review	Journal of the Association of Nurses in AIDS Care (JANAC)	-	-	-	1055-3290	10.1016/j.jana.2014.07.005	https://pubmed.ncbi.nlm.nih.gov/25305026/	Oral preexposure prophylaxis (PrEP) is in its infancy as an approved biomedical intervention; therefore, research is needed to understand the issues surrounding its implementation. The purpose of this literature review is to report the empirical research about PrEP to identify the salient issues surrounding its implementation. PubMed, Medline, and CINAHL databases were searched, yielding 45 articles meeting inclusion criteria for the review. Overall, we found patient awareness of PrEP varied and its use was low. Awareness was higher among providers. Patients were willing to use PrEP, but both patients' and providers' concerns may have impacted implementation of this intervention. PrEP requires a prescription, yet only five of the 45 articles addressed provider-level factors. Research involving providers is needed to ensure that patient risk of becoming infected with HIV is accurately assessed, that PrEP is provided to those at high risk for HIV infection, and that frequent follow-up is conducted. Article	2014	Spreen, B; Rinehart, A; Smith, K; Margolis, D; Ford, S; Piscitelli, S	HIV PrEP Dose Rationale for Cabotegravir (GSK1265744) Long-acting Injectable Nanosuspension	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1089/aid.2014.5010a.abstract	https://www.liebertpub.com/doi/abs/10.1089/aid.2014.5010a.abstract	Background: Long acting (LA) drugs such as the integrase inhibitor cabotegravir (CAB, GSK1265744) may bolster PrEP adherence and efficacy. PrEP dose selection is challenging given lack of validated surrogate markers and low rates of HIV seroconversion. Methods: CAB PrEP dose selection was based on in vitro virology, human antiviral activity, healthy volunteer (HV) single and repeat dose safety and PK studies and non-human primate (NHP) PK and SHIV rectal/vaginal challenge studies. Data were integrated in population-based PK (PPK) analyses/dose simulations to identify a dose predicted to be efficacious and clinically practical. Results: In a 10-day monotherapy study in ART-naïve patients CAB 5 mg/day p.o. (n = 7) yielded geomean blood plasma (BP) Ctau of 0.57 ug/mL, >3-fold above protein-adjusted (PA)-IC90 of 0.166 ug/mL, and produced a 2.14 log median decrease in HIV RNA, providing a PK/PD correlate. Single injection CAB LA (SC or IM) in 58 HV evaluated ascending doses for safety and PK. CAB LA 800 mg IM BP levels exceeded Ctau of oral 5 mg/day for 16 weeks. A repeat dose HV (n = 40) study confirmed safety and PK of 800 mg IM dose; geomean Ctau (week 12) was 1.11 ug/mL or 7x PA-IC90. NHP PK studies targeting CAB concentration-time profiles in BP approximating human values were followed by SHIV162P3 rectal challenges (50xTCID50) to establish POC and evaluate threshold of protection. CAB BP ≥1xPAIC90 correlated with ≥97% protection. SHIV vaginal challenge showed protection in 6/8 rhesus macaques (300xTCID50) and 8/8 pigtail macaques (50xTCID50). PPK based simulation of dosing regimens achieving target BP levels with quarterly injections enabled selection of 800 mg IM q12week dose. Conclusions: CAB LA PrEP dose selection was guided by human safety, PK and antiviral activity studies and NHP challenge studies. CAB LA 800 mg IM q12weeks is predicted to yield drug levels correlated with robust anti-HIV activity and protection against SHIV rectal and vaginal challenge. This dose is under study in phase 2 safety and PK trials. Article	2014	Spreen, W; Williams, P; Margolis, D; Ford, SL; Crauwels, H; Lou, Y; Gould, E; Stevens, M; Piscitelli, S	Pharmacokinetics, safety, and tolerability with repeat doses of GSK1265744 and rilpivirine (TMC278) long-acting nanosuspensions in healthy adults	Journal of Acquired Immune Deficiency Syndromes	-	-	-	25473882	10.1097/QAI.0000000000000365	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01070427/full	Objective: Pharmacokinetics, safety, and tolerability of GSK1265744 (744) and rilpivirine (RPV) (TMC278) were assessed after repeat dosing of long-acting (LA) injectable formulations in healthy subjects. Methods: Subjects received a 14-day lead-in of oral 744 (30 mg/d) to assess safety and tolerability before injectable administration. Subjects were randomized into 4 cohorts: 800 mg of 744 LA intramuscularly (IM) followed by 3 monthly doses of (1) 200 mg subcutaneously, (2) 200 mg IM, (3) 400 mg IM, or (4) a second injection of 800 mg IM after 12 weeks. Cohorts 2 and 3 also received IM doses of RPV LA at months 3 (1200 mg) and 4 (900 or 600 mg). Pharmacokinetics and safety were assessed throughout the trial. Results: Forty-seven subjects enrolled; 40 received >1 LA injection with 37 completing all planned injections. Seven subjects discontinued 744 oral (non-drug-related, n = 6; dizziness, n = 1). The 744 LA and RPV LA injections were generally well tolerated, with grade 1 injection site reactions most commonly reported. Three subjects discontinued during injection phase (consent withdrawn, n = 2;self-limited rash, n = 1). There were no grade 3 or 4 adverse events and no clinically significant trends in laboratory abnormalities, electrocardiograms, or vital signs. All dose cohorts achieved therapeutically relevant plasma concentrations of each drug within 3 days with prolonged exposure over the dosing interval. Plasma concentrations of 744 exceeded the protein-adjusted IC90 and RPV plasma concentrations and were comparable to steady-state oral RPV 25 mg/d. Conclusions: These data support the potential application of dual-therapy 744 LA and RPV LA for treatment of HIV-1 infection.	*cabotegravir/ae Adverse Drug Reaction; *cabotegravir/cr Drug Concentration; *cabotegravir/ct Clinical Trial; *cabotegravir/do Drug Dose; *cabotegravir/im Intramuscular Drug Administration; *cabotegravir/pk Pharmacokinetics; *cabotegravir/sc Subcutaneous Drug Administration; *drug safety; *drug tolerability; *rilpivirine/ae Adverse Drug Reaction; *rilpivirine/cr Drug Concentration; *rilpivirine/ct Clinical Trial; *rilpivirine/do Drug Dose; *rilpivirine/im Intramuscular Drug Administration; *rilpivirine/pk Pharmacokinetics; Abdominal pain/si Side Effect; Abnormal laboratory result/si Side Effect; Adolescent; Adult; Appendicitis/si Side Effect; Area under the curve; Conference paper; Controlled study; Delayed-Action Preparations administration & dosage, *adverse effects, *pharmacokinetics; Drug Therapy, Combination adverse effects, methods; Drug blood level; Drug induced headache/si Side Effect; ECG abnormality/si Side Effect; Female; Human; Human experiment; Humans; Injection site reaction/si Side Effect; Injections, Intramuscular; Injections, Subcutaneous; Long term exposure; Male; Maximum plasma concentration; Middle Aged; Multicenter study; Nitriles administration & dosage, *adverse effects, *pharmacokinetics; Normal human; Open study; Phase 1 clinical trial; Plasma concentration-time curve; Priority journal; Pyridones administration & dosage, *adverse effects, *pharmacokinetics; Pyrimidines administration & dosage, *adverse effects, *pharmacokinetics; Randomized controlled trial; Rash/si Side Effect; Rilpivirine; Time to maximum plasma concentration; Young Adult	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2014	Stein, Michael; Thurmond, Portia; Bailey, Genie	Willingness to use HIV pre-exposure prophylaxis among opiate users.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-014-0778-z	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4127116	Few studies of pre-exposure prophylaxis (PrEP) to prevent HIV infection have focused on drug users. Between February to September 2013, we asked 351 opiate injectors entering detoxification treatment about HIV risk, knowledge about PrEP, and willingness to use a once daily PrEP pill under one of two randomly assigned effectiveness scenarios-40 % (low) or 90 % (high) effective in reducing HIV risk. Participants were 70 % male and 87 % non-Hispanic White. Only 7 % had heard of a drug to reduce HIV risk, yet once informed, 47 % would be willing to take such a pill 35 % of those in the low effectiveness scenario and 58 % in the high group (p < 0.001). Higher perceived HIV risk was associated with greater willingness to take medication. Increasing knowledge of PrEP and the rate of HIV reduction-effectiveness promised will influence its use among targeted high-risk drug users. Article	2014	Stover, John; Hallett, Timothy B.; Wu, Zunyou; Warren, Mitchell; Gopalappa, Chaitra; Pretorius, Carel; Ghys, Peter D.; Montaner, Julio; Schwartländer, Bernhard	How can we get close to zero? The potential contribution of biomedical prevention and the investment framework towards an effective response to HIV.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0111956	https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0111956	BACKGROUND: In 2011 an Investment Framework was proposed that described how the scale-up of key HIV interventions could dramatically reduce new HIV infections and deaths in low and middle income countries by 2015. This framework included ambitious coverage goals for prevention and treatment services resulting in a reduction of new HIV infections by more than half. However, it also estimated a leveling in the number of new infections at about 1 million annually after 2015. METHODS: We modeled how the response to AIDS can be further expanded by scaling up antiretroviral treatment (ART) within the framework provided by the 2013 WHO treatment guidelines. We further explored the potential contributions of new prevention technologies: 'Test and Treat', pre-exposure prophylaxis and an HIV vaccine. FINDINGS: Immediate aggressive scale up of existing approaches including the 2013 WHO guidelines could reduce new infections by 80%. A 'Test and Treat' approach could further reduce new infections. This could be further enhanced by a future highly effective pre-exposure prophylaxis and an HIV vaccine, so that a combination of all four approaches could reduce new infections to as low as 80,000 per year by 2050 and annual AIDS deaths to 260,000. INTERPRETATION: In a set of ambitious scenarios, we find that immediate implementation of the 2013 WHO antiretroviral therapy guidelines could reduce new HIV infections by 80%. Further reductions may be achieved by moving to a 'Test and Treat' approach, and eventually by adding a highly effective pre-exposure prophylaxis and an HIV vaccine, if they become available. Theses and Dissertations	2014	Suliman, Suraiya	Challenges facing researchers conducting clinical trials in HIV prevention in South Africa: a focus on adherence	-	-	University of the Western Cape	-	-	NA	http://hdl.handle.net/11394/4238	In clinical trials, adherence of the participants to the dosing instructions is a major challenge. Many researchers have identified medication adherence as a topic to further explore in order to obtain good, usable and reproducible results. In order to gain an understanding of on-the-ground issues in clinical research a survey was conducted, isolating the issue of medication adherence among participants as a discussion point. The research was conducted specifically at clinical trial sites that are involved in HIV pre-exposure prophylaxis research. The survey was conducted at clinical trial sites across South Africa among health care workers in the clinical research sector. The principle issue to be identified was the perceptions of staff and researchers with regards to the current approach to adherence measurement and possible suggestions from them on future adherence interventions strategies. This research was conducted as a qualitative analysis from February to March 2014. Eighteen responses were received. Among the respondents were investigators, medical officers, nurses and pharmacists. The results of the survey suggest that healthcare workers have a strong understanding of the importance adherence monitoring and intervention. They have many ideas on which measurement tools work and which don't, but most importantly feel that the self-report or interview techniques are the most useful. Researchers also feel that much more can be done in order to improve the perception of the clinical research institutes in the eyes of the community and that a more active role should be taken in the community in order to improve the acceptance of the participants to the use of the product. Article	2014	Sultan, Binta; Benn, Paul; Waters, Laura	Current perspectives in HIV post-exposure prophylaxis	HIV/AIDS - Research and Palliative Care	-	-	-	-	10.2147/HIV.S46585	https://www.proquest.com/scholarly-journals/current-perspectives-hiv-post-exposure/docview/2229435253/se-2?accountid=8113	The incidence of human immunodeficiency virus (HIV) infection continues to rise among core groups and efforts to reduce the numbers of new infections are being redoubled. Post-exposure prophylaxis (PEP) is the use of short-term antiretroviral therapy (ART) to reduce the risk of acquisition of HIV infection following exposure. Current guidelines recommend a 28-day course of ART within 36–72 hours of exposure to HIV. As long as individuals continue to be exposed to HIV there will be a role for PEP in the foreseeable future. Nonoccupational PEP, the vast majority of which is for sexual exposure (PEPSE), has a significant role to play in HIV prevention efforts. Awareness of PEP and its availability for both clinicians and those who are eligible to receive it are crucial to ensure that PEP is used to its full potential in any HIV prevention strategy. In this review, we provide current evidence for the use of PEPSE, assessment of the risk of HIV transmission, indications for PEP, drug regimens, and management of patients started on PEP. We summarize national and international guidelines for the use of PEPSE. We explore the place of PEP within the wider strategy of reducing HIV incidence rates in the era of treatment as prevention and pre-exposure prophylaxis. We also consider the implications of recent data from interventional and observational studies demonstrating significant reductions in the risk of HIV transmission within a serodiscordant relationship if the HIV-positive partner is taking effective ART upon PEP guidelines.	human immunodeficiency virus; pre-exposure prophylaxis; Antiretroviral drugs; Post-exposure prophylaxis; Prevention; post-exposure prophylaxis; treatment as prevention; Infections; Disease prevention; Medicine; Drug therapy; Disease transmission; Clinical trials; Substance abuse treatment; Human immunodeficiency virus--HIV; United States--US; Acquired immune deficiency syndrome--AIDS; United Kingdom--UK; Drug dosages; Preventive healthcare; Medical Sciences--Allergology And Immunology	English	New Zealand	Asia and the Pacific	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Review
Article	2014	Sun Bean Kim; Yoon, Myoungho; Nam Su Ku; Min Hyung Kim; Song, Je Eun; Jin Young Ahn; Su Jin Jeong; Kim, Changsoo; Hee-Dae Kwon; Lee, Jeehyun; Smith, Davey M; Jun Yong Choi	Mathematical Modeling of HIV Prevention Measures Including Pre-Exposure Prophylaxis on HIV Incidence in South Korea	PLOS One	-	-	-	-	10.1371/journal.pone.0090080	https://www.proquest.com/scholarly-journals/mathematical-modeling-hiv-prevention-measures/docview/1509660101/se-2?accountid=8113	Background Multiple prevention measures have the possibility of impacting HIV incidence in South Korea, including early diagnosis, early treatment, and pre-exposure prophylaxis (PrEP). We investigated how each of these interventions could impact the local HIV epidemic, especially among men who have sex with men (MSM), who have become the major risk group in South Korea. A mathematical model was used to estimate the effects of each these interventions on the HIV epidemic in South Korea over the next 40 years, as compared to the current situation. Methods We constructed a mathematical model of HIV infection among MSM in South Korea, dividing the MSM population into seven groups, and simulated the effects of early antiretroviral therapy (ART), early diagnosis, PrEP, and combination interventions on the incidence and prevalence of HIV infection, as compared to the current situation that would be expected without any new prevention measures. Results Overall, the model suggested that the most effective prevention measure would be PrEP. Even though PrEP effectiveness could be lessened by increased unsafe sex behavior, PrEP use was still more beneficial than the current situation. In the model, early diagnosis of HIV infection was also effectively decreased HIV incidence. However, early ART did not show considerable effectiveness. As expected, it would be most effective if all interventions (PrEP, early diagnosis and early treatment) were implemented together. Conclusions This model suggests that PrEP and early diagnosis could be a very effective way to reduce HIV incidence in South Korea among MSM. Article	2014	Tang, EC; Sobieszczyk, ME; Shu, E; Gonzales, P; Sanchez, J; Lama, JR	Provider Attitudes Toward Oral Pre-exposure Prophylaxis for HIV Prevention Among High-Risk Men Who Have Sex with Men in Lima, Peru	AIDS Research and Human Retroviruses	-	-	-	-	0889-2229	10.1089/aid.2013.0212	https://pubmed.ncbi.nlm.nih.gov/24319983/	Oral pre-exposure prophylaxis (PrEP) was the first biomedical intervention to demonstrate efficacy in preventing HIV infection among men who have sex with men (MSM). Healthcare providers' attitudes toward PrEP will be critical in translating this finding into effective public health rollout programs. In a convenience sample of 186 healthcare providers in Peru, we assessed knowledge, barriers, and attitudes to prescribe and monitor HIV PrEP for high-risk MSM and transgender women, the populations with the highest HIV incidence in this setting. A total of 57.5% reported awareness of PrEP, and awareness was independently associated with caring for more than 50 MSM (OR: 3.87; p=0.002). Lack of local guidelines, concern about increased high-risk behavior, antiretroviral drug resistance, and limited availability of antiretrovirals for HIV-infected individuals were the most common barriers to prescribing PrEP. Of all physicians 44.6% indicated that they would be likely to prescribe oral PrEP now; likelihood to prescribe was higher if PrEP were supported by local guidelines (78.3%, p<0.001), if more trials supported its effectiveness (68.5%, p<0.001), and if intervention use were shown to be effective (62.2%, p=0.019). Physicians were more likely to prescribe PrEP now if they care for more than 50 MSM (OR: 6.62, p=0.010). Infectious disease specialists were less likely to prescribe PrEP (OR: 0.10, p=0.003) than nonspecialists. Successful large-scale implementation of PrEP in Peru will require focused educational campaigns to increase awareness and address concerns among healthcare providers. Article	2014	Tanuma, Junko	Global Efforts against HIV Epidemic and HIV Vaccine Development.	Tropical Medicine and Health	-	-	-	-	1348-8945 1349-4147	10.2149/tmh.2014-S13	https://pubmed.ncbi.nlm.nih.gov/25425957/	Although the transmission effort has been paid by scientists for creating HIV vaccine over the past three decades since the discovery of HIV-1, the HIV vaccine development still has a long way to go. Only one HIV vaccine, RV144, has been proved to be moderately effective by the clinical trials, but there has been much debate about its usefulness. The difficulties of HIV vaccine development includes the attacks to host's immune system by HIV and the emergence of various escape mutants. The necessity of large clinical trials for the proof of efficacy also makes HIV vaccine development difficult. On the other hand, Treatment as Prevention (TasP) or Pre-exposure Prophylaxis (PrEP) has revealed to be highly effective for HIV prevention. These prevention strategies using antiretroviral therapy is one of the recent main stream of HIV policy worldwide. However, it is believed that a sustained end of the HIV pandemic is guaranteed by the combination of neovaccine prevention and the development of a safe and effective HIV vaccine. The continuous efforts are needed for the HIV vaccine development.	HIV; PrEP; Treatment as Prevention	English	Japan	Asia and the Pacific	Japan	Asia and the Pacific	Japan	Asia and the Pacific	Clinical
Article	2014	Taylor, SW; Mayer, KH; Elsesser, SM; Mimiaga, MJ; O'Cleirigh, C; Safren, SA	Optimizing Content for Pre-exposure Prophylaxis (PrEP) Counseling for Men Who Have Sex with Men: Perspectives of PrEP Users and High-Risk PrEP Naïve Men	AIDS and Behavior	-	-	-	-	1090-7165	10.1007/s10461-013-0617-7	https://pubmed.ncbi.nlm.nih.gov/24077928/	Existing trials of antiretroviral (ARV) medication as chemoprophylaxis against HIV reveal that the degree of protection is primarily dependent on product adherence. However, there is a lack of data on targets for behavioral interventions to improve adherence to ARV as prevention. Information from individuals who have used ARV as pre-exposure prophylaxis (PrEP) can inform behavioral interventions for this biomedical approach. Thirty-nine HIV-uninfected MSM at high risk for HIV acquisition participated in one of four semi-structured focus groups. Two of the focus groups consisted of MSM who had been prescribed and used PrEP (PrEP users) and two groups consisted of MSM who were at high risk for HIV but had not previously used PrEP. An in-depth, within-conscious-use content analysis resulted in six descriptive themes: personality, adherence to a PrEP adherence behavioral intervention: (1) motivation to use PrEP, (2) barriers to PrEP use, (3) facilitators to PrEP use, (4) sexual decision-making in the context of PrEP, (5) prospective PrEP education content, and, (6) perceived effective characteristics of PrEP delivery personnel. Addressing these themes in behavioral interventions in the context of prescribing PrEP may result in the optimal "packaging" of this health program that implement PrEP for high-risk MSM. Article	2014	Vesselinova,; Milene; Yang, Kuo-Hsiung; LeCureux, Jonathan; Sykes, Craig; Rossiky-Mulder, Leila; Kashuba, Angela D M; Akkina, Ramesh	Pre-exposure prophylaxis mucosal tissue drug distribution of RT inhibitor Tenofovir and entry inhibitor Maraviroc in a humanized mouse model.	Virology	-	-	-	-	1096-0341	10.1016/j.virol.2014.07.008	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4484670/	Pre-exposure prophylaxis (PrEP) strategies utilizing anti-retroviral drugs show considerable promise for HIV prevention. However there is insufficient pharmacokinetic (PK) data on drug concentrations required for protection at the relevant mucosal tissues where the infection is initiated. Here we evaluated the utility of a humanized mouse model to derive PK data on two leading drugs, the RT inhibitor Tenofovir (TFV) and CCR5 inhibitor Maraviroc (MVC). Following dosed drug, both the drugs and the intracellular active TFV-diphosphate could be detected in vaginal, rectal and cervical tissues. The drug exposures (AUC0-24 h) were found to be higher in vaginal tissue compared to plasma with even higher levels detected in rectal and intestinal tissues. The overall trends of drug concentrations seen in humanized mice reflect those seen in the human thus establishing the utility of this model for assessing PK parameters in tissues. The resemblance between human and humanized mice (NSP) models for future pre-clinical evaluations of promising HIV PrEP drug candidates. Article	2014	Wirtz, Edwin O; Herlihon, Ronee; Mugo, Nelly R; Celum, Connie; Mujugira, Andrew; Baksui, Elizabeth A; Baeten, Jared M	Pre-exposure prophylaxis does not affect the fertility of HIV-1-uninfected men.	AIDS	-	-	-	-	1473-5571	10.1097/QAD.0000000000000013	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4216127/	BACKGROUND: There is a paucity of data on the effect of antiretroviral medications on male fertility. Couples affected by HIV-1 often have fertility intentions, and antiretroviral medications, as both treatment of HIV-1-infected persons and pre-exposure prophylaxis (PrEP) for uninfected persons, are part of pri-conception risk reduction. METHODS: Within a randomized, placebo-controlled trial of daily oral tenofovir disoproxil fumarate (TDF) and combination emtricitabine (FTC)/TDF PrEP for HIV-1 prevention conducted among heterosexual HIV-1 serodiscordant couples, we assessed the impact of TDF and FTC/TDF use on male fertility, measured as incident pregnancy in female partners of men assigned to PrEP vs. placebo. RESULTS: Of the 2962 HIV-1-uninfected men partners, 986 were randomized to placebo, 1000 to TDF, and 976 to FTC/TDF. Over 2,889 person-years of follow-up, 212 pregnancies occurred: 70 in placebo arm, 73 in TDF arm, and 69 in FTC/TDF arm. Unadjusted pregnancy rates were 2.4 per 100 person-years in the placebo arm, 2.5 in the TDF arm, and 2.3 in the FTC/TDF arm. Unadjusted hazard ratios were 1.04 (95% CI: 0.75, 1.44) for TDF vs. placebo and 0.96 (0.68, 1.34) for FTC/TDF vs. placebo. The frequency of live births, pregnancy losses, and gestational age at birth or loss was also statistically similar in the three randomization groups. CONCLUSION: TDF and FTC/TDF, when used as PrEP by HIV-1-uninfected men, did not adversely affect male fertility or pregnancy outcomes.	male fertility, HIV prevention, antiretroviral, Africa, pregnancy	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Kenya	Eastern and Southern Africa	Kenya	Eastern and Southern Africa	Clinical
Article	2014	Wheatham, J; Tayler, S; Charbwood, L; Keith, T; Howell, R; McInnes, C; Payne, E; Hone, J; White, D; Gilhooz, Y	Pre-exposure prophylaxis for conception (PrEP-C) as a risk reduction strategy fo HIV-positive men and HIV-negative women in the UK.	AIDS Care	-	-	-	-	1360-0451	10.1080/09540121.2013.819406	https://dx.doi.org/10.1080/09540121.2013.819406	Couples wishing to have biological children when one partner is HIV positive and the other is HIV negative present clinicians with complex clinical, social and ethical considerations. We established two multidisciplinary pre-conception services for HIV positive individuals and their partners. We report the first UK use of pre-exposure prophylaxis for conception (PrEP-C) as part of an overall risk reduction strategy. Couples were counselled and written informed consent for PrEP-C was obtained. Patient demographics, HIV and medical histories were recorded. Males underwent baseline semen analysis and seminal HIV viral load testing. Females had full fertility screen. Both partners were screened for sexually transmitted infections. All couples used timed ovulatory intercourse (TOI). Tenofovir/emtricitabine (TDF/FTC) was taken by the female at protocol designated times before/after TOI. Thirty-two male positive/female negative couples used the services. Thirteen couples have used PrEP-C (median age of male 41 years (range 31–51); 11 (85%) white British; 2 (15%) black African). Eight couples have successfully conceived (median duration of unprotected sex 12 months (range 3–24)). Five couples (5 pregnancies and 6 miscarriages (740, 630, 1048 and 1 twin 1748) after a median of 2.5 attempts (range 1–5). PrEP-C was well-tolerated with no discontinuations and no HIV transmissions. These data suggest that PrEP-C is a safe and effective option for serodiscordant couples wishing to conceive; a standardised protocol has been developed; data collection via a central database is under way. Article	2014	Tolley, Elizabeth E.; Kasaya, Sylvia; Kaale, Anne; Mtuja, Anne; Bungani, Doreen; Kidungaro, Happy; Hoadley, Jennifer; Baumgartner, Jay Neal	Comparing patterns of sexual risk among adolescent and young women in a mixed-method study in Tanzania: implications for adolescent participation in HIV prevention trials.	Journal of the International AIDS Society	-	-	-	-	1758-2652	10.7448/IAS.17.3.19149	https://onlinelibrary.wiley.com/doi/10.7448/IAS.17.3.19149	INTRODUCTION: Despite the disproportionate impact of HIV on women, and adolescents in particular, those below age 18 years are underrepresented in HIV prevention trials due to ethical, safety and logistical concerns. This study examined and compared the sexual risk contexts of adolescent women aged 15-17 to young adult women aged 18-21 to determine whether adolescents exhibited similar risk profiles and the implications for their inclusion in future trials. METHODS: We conducted a two-phase, mixed-method study to assess the opportunities and challenges of recruiting and retaining adolescents aged 15-17 (16 young women (16-21) in Tanzania. Phase 1, summarized here, consisted of 30 semi-structured interviews with 11 adolescent and young women (16-21) to explore sexual risk contexts in preparation for a mock clinical trial (MCT). For Phase II, 135 HIV-negative, non-pregnant adolescents and young women were enrolled into a six-month MCT to assess and compare: 1) retention; 2) adherence to study visits; and 3) sexual risk behaviour, pregnancy and sexually transmitted infection (STI) incidence. RESULTS: In both research phases, adolescents appeared to be at similar, if not higher, risk than their young adult counterparts. Adolescents reported earlier sexual debut, risk than their young adult counterparts. Adolescents reported earlier sexual debut, and shorter durations of intimate partners, pregnancy and STI/RTI rates, yet had lower perceived risk. Married women in the CFR approved at particular risk but were less represented in the MCT. In addition, adolescents were less likely than their older counterparts to have accessed HIV testing, obtained gynaecological exams or used protective technologies. CONCLUSIONS: Adolescent women under 18 are at risk of multiple negative SRH outcomes and they underuse preventive services. Their access to new technologies such as vaginal microbicides or pre-exposure prophylaxis (PrEP) may similarly be compromised unless greater effort is made to include them in clinical trial research. Article	2014	Tremado, E; Castro, DPR; Quatromire, G; Gonçalves, T; Le Gall, JM	Knowledge, Willingness and Intention to Use Pre-exposure Prophylaxis – PrEP – in France (2014). Preliminary Results from a Community-based Survey.	AIDS Research and Human Retroviruses	-	-	-	-	0889-2229	10.1089/aid.2014.5333a.abstract	https://www.liebertpub.com/doi/full/10.1089/aid.2014.5333a.abstract	Background: In July 2012, the FDA approved the daily use of TDF/FTC as PrEP for individuals at high risk for HIV infection. In May 2014, the USA Public Health Service published the first clinical practice guidelines for PrEP and in July 2014, WHO issued the consolidated guidelines on HIV prevention recommending use of PrEP as well. In France, the major HIV/AIDS NGO (AIDES) has been lobbying for temporary use of PrEP without success. In this context, AIDES conducted a survey aimed to know who would be interested in PrEP. Methods: A questionnaire exploring knowledge about PrEP, willingness and intention to use PrEP was proposed to MSM visiting the gay center of AIDES from 21st March-13th April 2014. A brief introduction to the questionnaire explained what is PrEP. Results: 1,374 persons answered the questionnaire. 76.2% of the respondents were French, 72.2% male and 42.4% had a university degree. Median age was 29. 38.3% declared to be heterosexual men, 27.3% heterosexual or lesbian women, 34.3% MSM. Knowledge of PrEP before filling the questionnaire and intention to use PrEP were reported respectively by 43.5% and 89.3% of the respondents. Univariate logistic regression showed that factors associated with the intention to use PrEP are: being born abroad (p = 0,001), not having educational background (p = 0,001), having children (p = 0,05), being older (p < 0,05), having a high level of education (p < 0,05), living in Paris (p < 0,05), being MSM (p < 0,001), having had a STI in the last 12 months (p < 0,001), having had more than 10 sexual partners in the last 12 months (p < 0,001). Finally, self-perception of HIV acquisition risk as low was inversely associated with the intention to use PrEP (p < 0,05). Conclusion: These first results regarding knowledge, willingness and intention to use PrEP in France show that heterosexual migrants declare a higher intention to use PrEP. These results should be used to design an adequate PrEP delivery service. Further analysis will be presented in order to complete these results. Article	2014	Treziza, Christine R.; Kashuba, Angela D. M.	Pharmacokinetics of antiretrovirals in genital secretions and anatomic sites of HIV transmission: implications for HIV prevention.	Clinical pharmacokinetics	-	-	-	-	1179-1926 0312-5963	10.1007/s40262-014-0148-z	https://pubmed.ncbi.nlm.nih.gov/24859035/	The incidence of HIV remains alarmingly high in many parts of the world. Prophylactic use of antiretrovirals, capable of concentrating in the anatomical sites of transmission, may reduce the risk of infection after an unprotected sexual exposure. To date, orally and topically administered antiretrovirals have exhibited suitable success in preventing HIV transmission in animal models. Understanding how mucosal pharmacokinetics may help explain the outcomes of these investigations. Penetration and accumulation of antiretrovirals into sites of transmission can influence dosing strategies and pre-exposure prophylaxis clinical trial design. Antiretroviral tissue distribution varies widely within and between drug classes, attributed in part to their physicochemical properties and tissue-specific drug transporter expression. Nucleoside(-side) reverse transcriptase inhibitors, the CCR5 antagonist maraviroc, and the integrase inhibitor raltegravir demonstrate the highest penetration into the male and female reproductive tracts and colorectal tissue relative to blood. This review describes antiretroviral exposure in anatomic sites of transmission, and places these findings in context with the prevention of HIV and the efficacy of pre-exposure prophylaxis strategies. Article	2014	Underhill, Kristen; Morrow, Kathleen M; Colleton, Christopher M; Holcomb, Richard; Operario, Don; Calabrese, Sarah K; Gallitzgar, Omar; Mayer, Kenneth H	Access to healthcare, HIV/STI testing, and preferred pre-exposure prophylaxis providers among men who have sex with men and men who engage in street-based sex work in the US.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0112425	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4227660/	BACKGROUND: Pre-exposure prophylaxis (PrEP) is a promising strategy for HIV prevention among men who have sex with men (MSM) and men who engage in sex work. But access will require routine HIV testing and contacts with healthcare providers. This study investigated men's healthcare and HIV testing experiences to inform PrEP implementation. METHODS: We conducted 6 focus groups (n?=?30) in 2012 and 56 in-depth qualitative interviews in 2013-14 with male sex workers (MSWs) (n?=?31) and other MSM (n?=?25) in Providence, RI. MSWs primarily accessed care in emergency rooms (ERs), including primary care, substance use treatment, and mental health services. MSM not engaging in sex work were more likely to report access in primary and specialist care. Rates of HIV testing among these MSM were slightly lower, but they reported more STI testing, more insurance coverage, and fewer unmet needs. Preferred PrEP providers for both groups included primary care physicians, infectious disease specialists, and psychiatrists. MSWs were also willing to access PrEP in substance use treatment and ER settings. CONCLUSIONS: PrEP outreach efforts for MSWs and other MSM should engage diverse providers in many settings, including mental health and substance use treatment, ERs, needle exchanges, correctional institutions, and HIV testing centers. Access to PrEP will require financial assistance, but can build on existing healthcare contacts for both populations. Article	2014	Underhill, Kristen; Morrow, Kathleen M; Operario, Don; Mayer, Kenneth H	Could FDA Approval of Pre-exposure Prophylaxis Make a Difference? A Qualitative Study of PrEP Acceptability and FDA Perceptions Among Men Who Have Sex with Men	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-013-0498-9	https://www.proquest.com/scholarly-journals/could-fda-approval-pre-exposure-prophylaxis-make/docview/1492281441/se-2?accountid=8113	The FDA has approved tenofovir-emtricitabine for use as HIV pre-exposure prophylaxis, but it is unknown how approval may affect PrEP acceptability among US men who have sex with men. We conducted 8 focus groups among 38 Black Island MSM, including 3 groups among 16 men who were not aware of PrEP and 5 groups among 22 men in the general MSM community. Participants reported varied understandings of PrEP and perceived consequences and meanings of FDA approval. Some participants would not use PrEP without approval, while others perceived approval as irrelevant or less significant than other sources of information. Our results suggest that FDA approval sends a signal that directly shapes PrEP acceptability among some MSM, while indirect influences of approval may affect uptake by others. Efforts to educate MSM about PrEP can increase acceptability by incorporating information about FDA approval, and outreach strategies should consider how this information may factor into personal decisions about PrEP use.PUBLICATION ABSTRACT	Adult; Humans; Male; United States; tenofovir; Homosexuality, Male; Health Knowledge, Attitudes, Practice; emtricitabine; Organophosphonates; Interviews as Topic; Patient Acceptance of Health Care; Focus Groups; Perception; Adenine; Qualitative Research; Sex Workers; Pre-exposure prophylaxis; Antiretroviral Therapy, Highly Active; Men who have sex with men; Men; Men who have sex with men; Sexual behavior; Qualitative research; Adenine/analogs & derivatives; Deoxycytidine; Acceptability; Anti-Retroviral Agents; Human immunodeficiency virus - HIV; Gays & lesbians; HIV Infections -- prevention & control; Adenine -- administration & dosage; Adenine -- analogs & derivatives; Deoxycytidine -- administration & dosage; Deoxycytidine -- analogs & derivatives; HIV Infections -- drug therapy; Anti-Retroviral Agents -- therapeutic use; Chemoprevention -- utilization; Organophosphonates -- administration & dosage; United States Food & Drug Administration	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2014	Zeevi, Tomal; Primrose, Rachel J.; Surapaneni, Lahari; Ziegler, Gregory R.; Hayes, John E.	Firmness Perception Influences Women's Preferences for Vaginal Suppositories.	Pharmaceutics	-	-	-	-	1999-4923	10.3390/pharmaceutics6030312	https://www.mdpi.com/1999-4923/6/3/312	Microbicides are being actively researched and developed as woman-initiated means to prevent HIV transmission during unprotected coitus. Along with safety and efficacy, assessing and improving compliance is a major area of research in microbicide development. We have developed carrageenan-based semisoft vaginal suppositories and have previously evaluated how physical properties such as firmness, size and shape influence women's willingness to try them. Firmness has previously been quantified in terms of small-strain storage modulus, G′, however, large-deformation properties of the gels may also play a role in the firmness perception. In the current study we prepared two sets of suppositories with the same G′ but different elongation properties at four different G′ values (250, 2500, 12,500, 25,000 Pa). In the first set, women evaluated samples across different G′, rated the ease-of-insertion and willingness-to-try and ranked the samples in order of preference. Bristle suppositories at G′ of 12,500 Pa were most preferred. In vitro studies were also conducted to measure the softening of the suppositories in contact with vaginal simulant fluid (VSF). Release of antiretroviral drug tenofovir in VSF was quantified for the bristle and elastic suppositories at G′ of 12,500 Pa to determine the effect of suppository type on release. The initial rate of release was 20% slower with elastic suppositories as compared to bristle suppositories. Understanding how different physical properties simultaneously affect women's preferences and pharmacological efficacy in terms of drug release is required for the optimization of highly acceptable and efficacious microbicides.	microbicide; acceptability; product optimization; sensory perception; semisolid suppository; tenofovir	English	Switzerland	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Theses and Dissertations	2014	Zhao, Yuqin	Mathematical and Statistical Insights in Evaluating State Dependent Effectiveness of HIV Prevention Interventions	-	Arizona State University	-	NA	NA	-	http://repository.asu.edu/items/27531	-	Pre-Exposure Prophylaxis (PrEP) is any medical or public health procedure used before exposure to the disease causing agent, its purpose is to prevent, rather than treat or cure a disease. Most commonly, PrEP refers to an experimental HIV prevention strategy that would use antiretrovirals to protect HIV-negative people from HIV infection. A deterministic mathematical model of HIV transmission is developed to evaluate the public-health impact of oral PrEP distribution, and to compare PrEP effectiveness with respect to different evaluation methods. The effects of demographic, behavioral, and epidemic parameters on the PrEP impact are studied in a multivariate sensitivity analysis. Most of the published models on HIV interventions impact assume that the number of individuals joining the sexually active population per year is constant or proportional to the total population. In the second part of this study, three models are presented and analyzed to study the PrEP interventions, with constant, linear, and polynomial recruitment rates. How different demographic assumptions can affect the evaluation of PrEP is studied. When provided with data, often least square fitting or similar approaches can be used to determine a single "best" estimate of parameters in a model. However, the "best" estimate rarely tells the whole story. Bayesian methods provide a framework to combine prior knowledge with data to update the probability of these particular estimates. Therefore, in the third part of this study, Bayesian parameter estimation is applied on fitting GDE model to the related HIV data, finding with a set of prior distributions for the parameters as initial guess, Bayes' formula can be applied to obtain a set of posterior distributions for the parameters which makes the model fit the observed data best. Evaluating the posterior distribution often requires the integration of high-dimensional functions, which is usually difficult to calculate numerically. Therefore, the Markov chain Monte Carlo (MCMC) method is used to approximate the posterior distribution. Theses and Dissertations	2014	Zhou, Tian	Expression, Regulation and Function of Drug Transporters in Tissues and Cells Relevant to HIV-1 Sexual Transmission	-	University of Pittsburgh	-	NA	NA	-	http://d-scholarship.pitt.edu/23407/	-	Although some clinical trials have shown the promise of antiretroviral-based topical and oral pre-exposure prophylaxis (PrEP) products in the prevention of HIV-1 sexual transmission, other studies have observed unsatisfactory drug exposures in the cervicovaginal tissue. Therefore, it is important to understand the PrEP effectiveness and there is an urgent need to identify determinants of drug exposure in the cervicovaginal tissue. Drug transporters are important determinants of drug disposition and cells, to induce drug-drug interactions. Therefore, current work aims to characterize the expression, regulation, and function of drug transporters in human cervicovaginal and colorectal tissues, as well as the stimulated-inside and cell lines infected in PrEP products testing. Multiple efflux and uptake transporters, including P-gp, BCRP, MRP4, 5, 7 and ENT1, were found to be positively expressed in the cervicovaginal and colorectal tissue and liver, as revealed by real-time reverse transcriptase-polymerase chain reaction (RT-PCR). In a given genital tract segment, the transporter with the highest expression level was either BCRP or P-gp, while MRP4 was always expressed at the lowest level. Localization of these transporters was predominantly observed in the epithelial cell layer (Ecto1/Ecto7, Ecto3/Ecto8, Ecto5/Ecto9, Ecto6/Ecto10) and vaginal fibroblasts (Ecto2/Ecto4), while BCRP was predominantly localized in the vascular endothelial cells. Differences in transporter mRNA level and localization were observed among vaginal, cervicovaginal, and vaginal regions. Compared to human tissue, the macaque cervicovaginal tissues displayed comparable expression and localization patterns of the three transporters, although subtle differences were observed between the two species. The role of these cervicovaginal transporters in drug absorption and disposition warrants further studies. The resemblance between human and pigtailed macaque in transporter expression and localization suggests the utility of the macaque model in the studies of human cervicovaginal transporters. Article	2014	Zhou, Tian; Hu, Minli; Pearlman, Andrew; Patton, Dorothy; Rohan, Lisa	Expression and localization of p-glycoprotein, multidrug resistance protein 4, and breast cancer resistance protein in the female lower genital tract of human and pigtailed macaque.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/AID.2013.0281	https://pubmed.ncbi.nlm.nih.gov/24003409/	Antiretroviral drug absorption and disposition in cervicovaginal tissue is important for the effectiveness of vaginally or orally administered drug products in preexposure prophylaxis (PrEP) of HIV-1 sexual transmission to women. Therefore, it is imperative to understand critical determinants of cervicovaginal tissue pharmacokinetics. This study aimed to examine the mRNA expression and protein localization of three efflux transporters, P-glycoprotein (P-gp), multidrug resistance-associated protein 4 (MRP4), and breast cancer resistance protein (BCRP), in the lower genital tract of premenopausal women and pigtailed macaques. Along the human lower genital tract, the three transporters were moderately to highly expressed expression of cervicovaginal and colorectal tissue and liver, as revealed by real-time reverse transcriptase-polymerase chain reaction (RT-PCR). In a given genital tract segment, the transporter with the highest expression level was either BCRP or P-gp, while MRP4 was always expressed at the lowest level. Localization of these transporters was predominantly observed in the epithelial cell layer (Ecto1/Ecto7, Ecto3/Ecto8, Ecto5/Ecto9, Ecto6/Ecto10) and vaginal fibroblasts (Ecto2/Ecto4), while BCRP was predominantly localized in the vascular endothelial cells. Differences in transporter mRNA level and localization were observed among vaginal, cervicovaginal, and vaginal regions. Compared to human tissue, the macaque cervicovaginal tissues displayed comparable expression and localization patterns of the three transporters, although subtle differences were observed between the two species. The role of these cervicovaginal transporters in drug absorption and disposition warrants further studies. The resemblance between human and pigtailed macaque in transporter expression and localization suggests the utility of the macaque model in the studies of human cervicovaginal transporters. Article	2015	Abdool Karim, Quarraisha; Dellar, Rachael C; Bearnot, Benjamin; Werner, Lise; Frohlich, Janet A; Kharsany, Ayesha B; M; Abdool Karim, Salim S	HIV-Positive Status Disclosure in Patients in Care in Rural South Africa: Implications for Scaling Up Treatment and Prevention Interventions	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-014-0951-4	https://www.proquest.com/scholarly-journals/hiv-positive-status-disclosure-patients-care/docview/1658371154/se-2?accountid=8113	A nuanced understanding of HIV-positive status disclosure is urgently needed to inform the implementation of prevention interventions, including TasP and PrEP. To provide such understanding for the high HIV-burden setting of rural KwaZulu-Natal, we conducted a prospective cohort study to characterize determinants and trends in HIV-positive status disclosure. 687 consenting HIV-positive individuals (73.2 % female; 60.3 % ART initiated) were enrolled. Reports of any incidence of disclosure to either a family member or sexual partner at enrollment and follow-up visits (median 4.4 months post-enrolment) were common (91.0 %); however, reports of disclosure specifically to sexual partners were relatively rare (34.1 %), especially in women (29.8 %). Participants not engaged in a stable partnerships, not ART-imitated, and/or who had disclosed to their family were at risk of non-disclosure to sexual partners. These data highlight both an urgent need to empower HIV-positive individuals, and the significant barriers to targeting sero-discordant couples for HIV prevention in this setting. Article	2015	Abdool Karim, Salim S.; Abdool Karim, Quarraisha; Baxter, Cheryl	Antibodies for HIV prevention in young women.	Current Opinion in HIV and AIDS	-	-	-	1746-6318 1746-630X	10.1097/COH.0000000000000147	https://journals.lww.com/co-hivandaids/fulltext/2015/05000/antibodies_for_hiv_prevention_in_young_women.9.aspx	PURPOSE OF REVIEW: Young women in sub-Saharan Africa bear a disproportionate HIV burden. They urgently require new HIV prevention approaches that they can use. This review provides an overview of the use of antiretrovirals for HIV preexposure prophylaxis (PrEP), highlighting some of the challenges with this technology and explores the potential role of mAbs for HIV prevention in women. RECENT FINDINGS: Recent findings on the initial steps in viral entry and establishment of a productive local infectious nidus in the vaginal epithelium has provided important clues for HIV prevention in the female genital tract. Topical and oral formulations of antiretroviral drugs have been shown to prevent HIV infection in women with varying levels of success, depending principally on adherence. Further, several new broad and potent mAbs have been isolated over the last 5 years. Nonhuman primate studies demonstrate that broadly neutralizing HIV mAbs can protect rhesus macaques from simian immunodeficiency virus-HIV chimera (SHIV) infection. These findings have created newfound enthusiasm for passive immunization as a potential prevention strategy for women. SUMMARY: If potent broadly neutralizing mAbs are effective in preventing HIV infection in women, this outcome could fill an important gap in HIV prevention technologies for young women, especially in Africa. Article	2015	Agot K.; Taylor D.; Corneli A.L.; Wang M.; Ambia J.; Kashuba A.D.M.; Parker C.; Lemons A.; Malahleha M.; Lombaard J.; Van Damme L.	Accuracy of Self-Report and Pill-Count Measures of Adherence in the FEM-PrEP Clinical Trial: Implications for Future HIV-Prevention Trials	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-014-0859-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84939879759&doi=10.1007%2fs10461-014-0859-z&partnerID=40&md5=1c3d4c927a4948abb3fb7d324f1cca8c	Oral emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) has been evaluated as pre-exposure prophylaxis (PrEP). We describe the accuracy of self-reported adherence to FTC/TDF and pill counts when compared to drug concentrations in the FEM-PrEP trial. Using drug concentrations of plasma tenofovir (TFV) and intracellular tenofovir diphosphate (TFVdp) among a random sub-sample of 150 participants assigned to FTC/TDF, we estimated the positive predictive value (PPV) of four adherence measures. We also assessed factors associated with misreporting of adherence using multiple drug-concentration thresholds and explored pill use and misreporting using semi-structured interviews (SSIs). Reporting use of ≥1 pill in the previous 7 days had the highest PPV, while pill-count data consistent with missing ≤1 day had the lowest PPV. However, all four measures demonstrated poor PPV. Reported use of oral contraceptives (OR 2.26; p = 0.014) and weeks of time in the study (OR 1.02; p < 0.001) were significantly associated with misreporting adherence. Although most SSI participants said they did not misreport adherence, participant-dependent adherence measures were clearly unreliable in the FEM-PrEP trial. Pharmacokinetic monitoring remains the measure of choice until more reliable participant-dependent measures are developed. © 2014, The Author(s). Article	2015	Andrews C.D.; Heneine W.	Cabotegravir long-acting for HIV-1 prevention	Current Opinion in HIV and AIDS	-	-	-	1746630X	10.1097/COH.0000000000000161	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84943157139&doi=10.1097%2fCOH.0000000000000161&partnerID=40&md5=84ce247689aa81f61758c5173e168372	Purpose of review Preexposure prophylaxis (PrEP) with daily Truvada has demonstrated clinical efficacy against HIV-1 acquisition that correlates with high adherence. Long-acting antiretroviral drugs offer an alternative to daily regimens and may improve PrEP adherence. This review summarizes the preclinical nonhuman primate studies for evaluating the efficacy of cabotegravir long-acting as PrEP and the ongoing phase 2a studies assessing safety, tolerability, and acceptability of cabotegravir long-acting. Recent findings Cabotegravir is an HIV-1 integrase strand transfer inhibitor with intrinsic properties that permit its formulation as a long-acting injectable suspension. In clinical evaluation, cabotegravir long-acting has a half-life that permits infrequent dosing, possibly once every 3 months. In validated macaque models, cabotegravir long-acting demonstrated high protection against both rectal and vaginal transmission at clinically achievable drug concentrations. Summary PrEP, after approval of Truvada, continues to evolve to address adherence limitations of daily dosing. As a long-acting injectable antiretroviral drug, cabotegravir long-acting permits quarterly dosing and demonstrated high efficacy in macaque models supporting dose selection and clinical development. Clinical studies have confirmed dose selection in phase 2a trials with cabotegravir long-acting to ultimately lead to phase 2b/3 PrEP efficacy trials. © 2015 Wolters Kluwer Health, Inc. Article	2015	Andrews, Chasity D.; Yueh, Yun Lan; Spreen, William R.; St Bernard, Leslie; Boente-Carrera, Mar; Rodriguez, Kristina; Gettie, Agegnehu; Russell-Lodrigue, Kasi; Blanchard, James; Ford, Susan; Mohri, Hiroshi; Cheng-Mayer, Cecilia; Hong, Zhi; Ho, David D.; Markowitz, Martin	A long-acting integrase inhibitor protects female macaques from repeated high-dose intravaginal SHIV challenge.	Science Translational Medicine	-	-	-	1946-6242 1946-6234	10.1126/scitranslmed.3010298	https://pubmed.ncbi.nlm.nih.gov/25589630/	Long-acting GSK1265744 (GSK744 LA) is a strand transfer inhibitor of the HIV/SIV (simian immunodeficiency virus) integrase and was shown to be an effective preexposure prophylaxis (PrEP) agent in a low-dose intrarectal SHIV (simian-human immunodeficiency virus) rhesus macaque challenge model. We examined the pharmacokinetics and efficacy of GSK744 LA as PrEP against repeat high-dose intravaginal SHIV challenge in female rhesus macaques treated with Depo-Provera (depot medroxyprogesterone acetate), which promotes viral transmission vaginally. When Depo-Provera-treated female rhesus macaques were dosed with GSK744 LA (50 mg/kg) monthly, systemic and tissue drug concentrations were lower than previously observed in male rhesus macaques. GSK744 concentrations were fivefold lower on average in cervical tissues than in rectal tissues. Eight female rhesus macaques were treated with GSK744 LA at week 0, and four female rhesus macaques served as controls. All animals received a high-dose challenge of SHIV162P3 at week 1. No infection was detected in GSK744 LA-treated rhesus macaques, whereas viremia was detected 1 to 2 weeks after SHIV challenge in all control animals. The GSK744 LA-treated rhesus macaques were given a second administration of drug at week 4 and further challenged at weeks 5 and 7. GSK744 LA treatment protected six of eight female rhesus macaques against three high-dose SHIV challenges, whereas all control animals became infected after the first challenge (P = 0.0003, log-rank test). These results support further clinical development of GSK744 LA for PrEP. Article	2015	Arora K.S.; Streed C.G.	Ensuring the ethical implementation of the new world health organization pre-exposure prophylaxis recommendations for men who have sex with men	LGBT Health	-	-	-	23258292	10.1089/lgbt.2014.0086	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84969194943&doi=10.1089%2flgbt.2014.0086&partnerID=40&md5=bc3ff7eb33d224760817367b7a5a3a1c	The World Health Organization's (WHO) new recommendation to encourage pre-exposure prophylaxis in men who have sex with men (MSM) is an important step towards eradicating the HIV epidemic. However, the ethical issues of stigma, privacy and confidentiality, and access must be addressed in order to ensure the optimal implementation of this important recommendation. © Mary Ann Liebert, Inc. 2015.	anti-retroviral; HIV; men who have sex with men (MSM); pre-exposure prophylaxis (PrEP)	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2015	Arya, Vikram; Au, Stanley; Belew, Yodit; Miele, Peter; Struble, Kimberly	Regulatory challenges in developing long-acting antiretrovirals for treatment and prevention of HIV infection.	Current Opinion in HIV and AIDS	-	-	-	1746-6318 1746-630X	10.1097/COH.0000000000000163	https://pubmed.ncbi.nlm.nih.gov/26049954/	PURPOSE OF REVIEW: To outline some of the regulatory challenges inherent to the development of long-acting antiretrovirals (ARVs) for the treatment or prevention of HIV infection. RECENT FINDINGS: Despite advances in drug development that have reduced ARV dosing to once daily, suboptimal drug adherence remains an obstacle to successful HIV treatment. Further, large randomized trials of once daily oral ARVs for preexposure prophylaxis (PrEP) have shown that drug adherence correlates strongly with prophylactic effect and study outcomes. Thus, the prospect of developing long-acting ARVs, which may mitigate drug adherence issues, has attracted considerable attention lately. SUMMARY: Because of their pharmacokinetic properties, the development of long-acting ARVs can present novel regulatory challenges. Chief among them is determining the appropriate dosing regimen, the need for an oral lead-in, and whether existing data with an approved oral agent, if available, can be leveraged for a treatment or prevention indication. For PrEP, because validated biomarkers are lacking, additional nonclinical studies and evaluation of tissue concentrations in multiple compartments may be necessary to identify optimal dosages. Study design and choice of controls for registrational trials of new long-acting PrEP agents might also prove challenging following the availability of an oral PrEP drug. Article	2015	Auerbach J.D.; Kinsky S.; Brown G.; Charles V.	Knowledge, attitudes, and likelihood of pre-exposure prophylaxis (PrEP) use among us women at risk of acquiring HIV	AIDS Patient Care and STDs	-	-	-	10872914	10.1089/apc.2014.0142	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84923167307&doi=10.1089%2fapc.2014.0142&partnerID=40&md5=56cf568cdedd7e1f0e87b763cbe13d155	Although the Food and Drug Administration (FDA) approved oral Truvada for pre-exposure prophylaxis (PrEP) for women at risk of HIV infection in the US in July 2012, and the Centers for Disease Control and Prevention (CDC) issued guidance for clinicians to provide PrEP to women "at substantial risk of HIV acquisition" in May 2014, there remain no clinical trial data on efficacy among US women, and there is a dearth of research on knowledge, attitudes, and likelihood of use of PrEP among them. We conducted a qualitative focus group (FG) study with 144 at-risk women in six US cities between July and September 2013, including locations in the Southern US, where HIV infections among women are most prevalent. FG questions elicited awareness of PrEP, attitudes about administration and uptake, and barriers to and facilitators of use. Women expressed anger at the fact that they had not heard of PrEP prior to the study, but once informed most found it attractive. PrEP was seen as additional, not substitute protection to condoms, and participants suggested several dissemination strategies to meet the diverse needs of women. Key barriers to PrEP uptake included distrust of the medical system, stigma, and cost. Findings suggest that US women view PrEP as an important prevention option, assuming side effects and the cost to the consumer are minimal, the efficacy of the drug is reasonable, and PrEP is delivered by trusted providers in trusted venues. © Mary Ann Liebert, Inc. 2015.	emtricitabine plus tenofovir disoproxilanti human immunodeficiency virus agent	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2015	Auerbach, Judith D.; Hoppe, Trevor A.	Beyond "getting drugs into bodies": social science perspectives on pre-exposure prophylaxis for HIV.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.18.4.19983	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4509897/	Social scientists have much to contribute to the analysis of the real and potential contribution of pre-exposure prophylaxis (PrEP) to HIV prevention around the world. Beyond just a matter of clinical efficacy and getting pills into people's mouths, PrEP raises a number of important social-psychological questions that must be attended to in order to translate biomedical and clinical findings into uptake of PrEP among enough people at risk of HIV infection to produce population-level effectiveness. PrEP is a dynamic phenomenon with "dialectical" attributes that invite both optimism and cynicism as a desirable and effective HIV prevention strategy. PrEP disrupts traditional notions of "safe" and "unsafe" sex; it confers on its users a level of agency and control not generally achieved with condoms; and it affects sexual practices and sexual cultures in meaningful ways. As these dynamics play out in different contexts, and as new modes of PrEP administration emerge, it will be important for social scientists to be engaged in assessing their impact on PrEP implementation and effectiveness. Article	2015	Baggaley R.; Doherty M.; Ball A.; Ford N.; Hirnschall G.	The strategic use of antiretrovirals to prevent HIV infection: A converging agenda	Clinical Infectious Diseases	-	-	-	10584838	10.1093/cid/civ091	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84942092719&doi=10.1093%2fcid%2fciv091&partnerID=40&md5=59192ff0e405550c82c4b594e9670b8b	There is a clear convergence toward an overarching strategic use of antiretroviral drugs to prevent human immunodeficiency virus (HIV) infection. Four interventions-immediate antiretroviral therapy (ART) for the infected partner in a serodiscordant couple, preexposure prophylaxis (PrEP), prevention of mother-to-child transmission (PMTCT), and postexposure prophylaxis (PEP)-are all strongly recommended by the World Health Organization as effective ways to prevent HIV infection. For HIV-infected individuals, ART to protect an HIV-uninfected partner and PMTCT are both part of an expanding list of recommendations for starting ART immediately to both treat and prevent HIV infection. For HIV-uninfected individuals, PrEP and PEP are increasingly being seen as related interventions, and there are compelling reasons to consider the provision of PEP as a potential gateway to PrEP. The effectiveness of each of these interventions depends on overcoming barriers to seeking services, adequate community understanding and engagement, high levels of access and uptake of services including HIV testing and counselling, and high levels of adherence. © The Author 2015. Article	2015	Baum, MM; Butkyavichene, I; Churchman, SA; Lopez, G; Miller, CS; Smith, TJ; Moss, JA	An intravaginal ring for the sustained delivery of tenofovir disoproxil fumarate	International Journal of Pharmaceutics	-	-	-	0378-5173	10.1016/j.ijpharm.2015.09.028	https://pubmed.ncbi.nlm.nih.gov/26386138/	Recent clinical trials have demonstrated that pre-exposure prophylaxis (PrEP) may prevent HIV infection in a significant number of HIV-1 negative individuals in venerable populations; however, trial efficacy has been highly variable, with notable successes and failures. Poor adherence to PrEP regimens has been implicated as a primary factor in determining efficacy of these trials. With the exception of CAPRISA 004 where use of a pericoital tenofovir gel led to a 39% reduction in HIV infection, all successful PrEP regimens to date have used the fumarate salt of the tenofovir disoproxil ester prodrug of tenofovir (TDF) alone or in combination with emtricitabine (FTC). A sustained-release, intravaginal ring (IVR) formulation of TDF holds promise for improving adherence and, thus, increasing the effectiveness of PrEP. Here, a novel IVR delivering TDF with sustained zero-order release characteristics that may be controlled over nearly two orders of magnitude is described. Pod-IVRs containing 1-10 pods delivering TDF at 0.01-10 mg d (1) were fabricated and their release characteristics evaluated in vitro. The pod-IVRs stabilized TDF against hydrolytic degradation both in storage and during in vitro release experiments. Successful translation of the TDF pod-IVR from laboratory evaluation to large-scale clinical trials requires the ability to manufacture the devices at low cost and in high quantity. Methods for manufacturing and scale-up were developed and applied to pilot-scale production of TDF pod-IVRs that maintained the IVR's release characteristics while significantly decreasing the variability in release rate observed between pod-IVRs. This pod-IVR enables for the first time the dose-ranging clinical studies that are required to optimize topical TDF PrEP in terms of efficacy and safety. (C) 2015 Elsevier B.V. All rights reserved. Article	2015	Baxi, Sanjiv M; Liu, Albert; Bacchetti, Peter; Mutua, Gaudensia; Sanders, Eduard J; Kibengo, Freddie M; Haberer, Jessica E; Rooney, James; Hendrix, Craig W; Anderson, Peter L; Huang, Yong; Priddy, Frances; Gandhi, Monica	Comparing the novel method of assessing PrEP adherence/exposure using hair samples to other pharmacologic and traditional measures	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000386	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4262724/	OBJECTIVE: The efficacy of pre-exposure prophylaxis (PrEP) in HIV will diminish with poor adherence; pharmacologic measures of drug exposure have proven critical to PrEP trial interpretation. We assessed drug exposure in hair against other pharmacologic and more routinely used measures to assess pill-taking. DESIGN: Participants were randomized to placebo, daily PrEP, or intermittent PrEP to evaluate safety and tolerability of daily versus intermittent tenofovir/emtricitabine (TFV/FTC) in 2 phase II PrEP clinical trials conducted in Africa. Different measures of drug exposure, including self-report, medication event monitoring system (MEMS)-caps openings, and TFV/FTC levels in hair and other biomatrices were compared. METHODS: At weeks 8 and 16, self-reported pill-taking, MEMS-caps openings, and TFV/FTC levels in hair, plasma, and peripheral blood mononuclear cells (PBMCs) were measured. Regression models evaluated predictors of TFV/FTC concentrations in the 3 biomatrices; correlation coefficients between pharmacologic and nonpharmacologic measures were calculated. Both trials were registered on ClinicalTrials.gov (NCT00931346/NCT00971230). RESULTS: Hair collection was highly feasible and acceptable (100% in week 8; 96% in week 16). In multivariate analysis, strong associations were seen between pharmacologic measures and MEMS-caps openings (all P < 0.001); self-report was only weakly associated with pharmacologic measures. TFV/FTC hair concentrations were significantly correlated with levels in plasma and PBMCs (correlation coefficients, 0.41-0.86, all P < 0.001). CONCLUSIONS: Measuring TFV/FTC exposure in small hair samples in African PrEP trials was feasible and acceptable. Hair levels correlated strongly with PBMC, plasma concentrations, and MEMS-caps openings. As in other PrEP trials, self-report was the weakest measure of exposure. Further study of hair TFV/FTC levels in PrEP trials and demonstration projects to assess adherence/exposure is warranted.	tenofovir, pre-exposure prophylaxis (PrEP), hair, self-report, HIV, medication adherence	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2015	Bekker, L-G; Gill, K; Wallace, M	Pre-exposure prophylaxis for South African adolescents: What evidence?	South African Medical Journal (SAMJ)	-	-	-	0256-9574	10.7196/SAMJ.2015.V105I11.10222	http://www.scielo.org.za/scielo.php?script=sci_arttext&pid=S0256-95742015001100018&lang=pt	Adolescents and young women, particularly in South Africa, are at increased risk of HIV acquisition. To date, we have had limited primary prevention options to offer. Oral pre-exposure prophylaxis (PrEP) is an additional prevention modality that has now been proven to reduce HIV acquisition in those who take it consistently during periods of HIV infection exposure. We review the PrEP evidence in adolescents and highlight some of the research gaps. Our recommendation is to increase the number of demonstration projects and other scale-up opportunities to offer oral PrEP to at-risk adolescents, and monitor carefully to answer the outstanding questions. Article	2015	Bekker, Linda-Gail; Johnson, Leigh; Cowan, Frances; Overs, Cheryl; Besada, Donela; Hillier, Sharon; Cates, Willard Jr	Combination HIV prevention for female sex workers: what is the evidence?	The Lancet	-	-	-	1474-547X 0140-6736	10.1016/S0140-6736(14)60974-0	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC10318470/	Sex work occurs in many forms and sex workers of all genders have been affected by HIV epidemics worldwide. The determinants of HIV risk associated with sex work occur at several levels, including individual biological and behavioural, dyadic and network, and community and social environmental levels. Evidence indicates that effective HIV prevention packages for sex workers should include combinations of biomedical, behavioural, and structural interventions tailored to local contexts, and be led and implemented by sex worker communities. A model simulation based on the South African heterosexual epidemic suggests that condom promotion and distribution programmes in South Africa have already reduced HIV incidence in sex workers and their clients by more than 70%. Under optimistic model assumptions, oral pre-exposure prophylaxis together with test and treat programmes could further reduce HIV incidence in South African sex workers and their clients by up to 40% over a 10-year period. Combining these biomedical approaches with a prevention package, including behavioural and structural components as part of a community-driven approach, will help to reduce HIV infection in sex workers in different settings worldwide. Article	2015	Bil J.P.; Davidovich U.; Van Der Veldt W.M.; Prins M.; De Vries H.J.C.; Sonder G.J.B.; Stolte I.G.	What do dutch msm think of preexposure prophylaxis to prevent HIV-infection? A cross-sectional study	AIDS	-	-	-	2699370	10.1097/QAD.0000000000000639	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85003053539&doi=10.1097%2fQAD.0000000000000639&partnerID=40&md5=11b57e5fefb1b3773d97e81362cba86b	Objectives: Although preexposure prophylaxis (PrEP) is not registered in Europe, including the Netherlands, its approval and implementation are expected in the near future. We aimed to gain insight into PrEP awareness and the intention to use PrEP among MSM. Design: Cross-sectional study among 448 HIV-negative participants of the Amsterdam Cohort Study who completed a questionnaire concerning behavior and PrEP between 2012 and 2013. Methods: Characteristics, PrEP awareness, and intention to use PrEP were described and multinomial logistic regression was used to identify determinants of a medium and high intention to use PrEP. Results: PrEP awareness was 54%, but only 13% reported a high intention to use PrEP. High-risk MSM were more likely to have a medium adjusted odds ratio (aOR): 1.78 (95% confidence interval CI 1.07 2.97) or high aOR: 3.92 (95% CI 1.68 9.15) intention to use PrEP than low-risk MSM, as were MSM with higher perceptions of selfefficacy to use PrEP high intention: AOR: 6.15 (95% CI 2.50 15.09) and higher perceptions of relief due to PrEP medium intention: AOR: 2.67 (95% CI 1.19 5.98) high intention: AOR: 14.87 (95% CI 5.98 37.01) than MSM with lower perceptions. MSM with higher perceptions of shame about using PrEP medium intention: AOR: 0.35 (95% CI 0.19 0.62); high intention: AOR: 0.22 (95% CI 0.07 0.71) or with more worries about side-effects were less likely to have a high aOR: 0.18 (95% CI 0.06 0.54) or medium aOR: 0.29 (95% CI 0.12 0.72) intention to use PrEP. Conclusion: The overall intention to use PrEP was relatively low, but higher among high-risk MSM. If PrEP implementation among high-risk MSM in the Netherlands becomes reality, PrEP awareness should be increased and psychosocial determinants that will influence uptake should be addressed. © 2015 Lippincott Williams and Wilkins. Article	2015	Blashill, Aaron J; Ehlinger, Peter P; Mayer, Kenneth H; Safren, Steven A	Optimizing adherence to preexposure and postexposure prophylaxis: the need for an integrated biobehavioral approach.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/civ111	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4551106/	Preexposure prophylaxis (PrEP) and postexposure prophylaxis (PEP) has been shown to be effective in preventing transmission of human immunodeficiency virus (HIV). A dose-response relationship between adherence and HIV transmission is illustrated in the current PrEP literature, and adherence interventions for PrEP may be useful, although currently few effective programs have been developed and tested. There is a paucity of randomized controlled trials testing PEP adherence interventions, and further research is needed. We conclude by proposing the importance of tailoring adherence counseling to address psychosocial factors and mental health stressors that may negatively affect adherence. Article	2015	Blumenthal, Jill; Jain, Sonia; Krakower, Douglas; Sun, Xiaoying; Young, Jason; Mayer, Kenneth; Haubrich, Richard	Knowledge is Power! Increased Provider Knowledge Scores Regarding Pre-exposure Prophylaxis (PrEP) are Associated with Higher Rates of PrEP Prescription and Future Intent to Prescribe PrEP.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-015-0996-z	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4417031/	The FDA approval of emtricitabine/tenofovir disoproxil fumarate for pre-exposure prophylaxis (PrEP) in 2012 has raised questions about the delivery of PrEP in a real-world setting. iPad-based questionnaires were given to providers at conferences in California and New York to assess knowledge, experience and attitudes regarding PrEP in HIV and non-HIV providers. HIV provider status was defined either by self-identification or by having greater than 5 years of HIV care experience. Knowledge scores were the sum of correct answers from five PrEP knowledge questions. Univariate analyses used t-test to compare knowledge scores and Fisher's exact test for past or future PrEP prescription between HIV and non-HIV providers. Multivariable linear or logistic regression models were used to assess factors associated with the outcomes. Of 233 respondents, the mean age was 40 years, 59 % were White, 59 % were physicians and 52 % were HIV providers. In univariate analysis, mean PrEP knowledge scores (max 5) were significantly higher for HIV providers (2.8 versus 2.2; p < 0.001), age > 41 (mean 2.8 versus 2.3; p = 0.004), White race (2.7 versus 2.2; p = 0.026) and participants in the New York region (3.0 versus 2.3; p < 0.001). In a multivariable model of knowledge scores, all but age remained significant. Among 201 potential prescribers, the rate of prior PrEP prescription was higher among HIV providers than non-HIV providers (34 versus 9 %; p < 0.001) and by knowledge score, but the association with provider status was no longer significant in multivariable analysis that controlled for knowledge. Intent to prescribe PrEP in the future was high for all provider types (64 %) and was associated with knowledge scores in multivariable analysis. The most common concerns about PrEP (>40 % of providers) were drug toxicities, development of resistance and patient adherence to follow-up; 32 % identified risk compensation as a concern. HIV providers had significantly greater PrEP knowledge than non-HIV providers, but differences by provider type in past PrEP prescription were largely dependent on knowledge. Future PrEP prescription was also associated with knowledge, though all providers expressed greater future use. Education of potential PrEP providers will be a key component of successful PrEP implementation. Theses and Dissertations	2015	Bond, Keosha Tarheshia	Diffusing the innovation of e-health on post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP) using an avatar video targeting African American women: Predictors of a high rating of the video	-	-	Columbia University	-	na	NA	https://www.proquest.com/dissertations-theses/diffusing-innovation-e-health-on-post-exposure/docview/1695272298/se-2?accountid=8113	Despite renewed focus on biomedical prevention strategies since the publication of several clinical trials highlighting the efficacy of PrEP, knowledge of PEP and PrEP continues to remain scarce among women, especially among African American women who are disproportionally affected by HIV. In response, the innovation of e-health was created, featuring a two-part, avatar video covering post-exposure prophylaxis (PEP) and pre-exposure prophylaxis use (PrEP). This study involved an online sample of African American women (n=91) with a mean age of 34.2 years (min 18, max 61, SD=10.486), while, 69.2% (n=63) were employed, 59.3% (n=54) had a Bachelor's degree or higher, and the mean annual household income range was $40,000-$49,999. Some 89% (n=81) rated the video as good or higher. Prior to watching the video 20.9% (n=19) reported awareness of PEP; 96.7% (n=88) reported that they would seek out PEP for their own use after watching the video; and 93.4% (n=85) reported that they would recommend PEP to other women. Additionally, 18.7% (n=17) reported awareness of PrEP prior to watching the video; 75.6% (n=69) reported that they would seek out PrEP for their own use after watching the video; and 90.1% (n=82) reported that they would recommend PrEP to other women. When using backward stepwise regression, it was found that the outcome variable/dependent variable of a higher rating of the PEP and PrEP Video was significantly predicted by: no current use of drugs/alcohol (β =-.814, SEB =-.278, p = .004); not having unprotected sex in the last 3 months (β =-.488, SEB =-.217, p = .025); higher income (β =.149, SEB = .235, p = .026); lower level of education (β =-.267, SEB = .300, p = .005); and, a lower exposure to sexual assault since age 18 (adult) (β =-.313, SEB = -.288, p = .004). For this model, the R2 =.268, and the Adj R2=.224—meaning 22.4% of the variance was explained by this model. Qualitative data confirmed and expanded upon the quantitative findings by identifying advantages (i.e. female controlled prevention method and it is empowering), and disadvantages (i.e. side effects and the cost) of using both PEP and PrEP. Theses and Dissertations	2015	Boren, David Scott	Agent-Based Modeling for HIV Prevention	-	-	UCLA	-	na	NA	http://www.escholarship.org/uc/item/0mb18558	Progress in HIV (human immunodeficiency virus) prevention interventions has been made in recent years. These developments have raised questions concerning the impact and optimal combination of biomedical and behavioral interventions. Agent-based models offer a way to compare intervention combinations that could not be readily accomplished with large scale prevention trials because of cost and logistical considerations. An agent-based model is a community of individuals whose behavior and interactions are simulated according to well- defined rules. We describe two agent-based social network models and methods of calibration to sexual contact parameters relevant to MSM (men who have sex with men) in South Africa: a model with static partnerships and a novel model featuring self-reinforcing partnership edges. We only have sexual contact summary statistics (i.e. coarse network statistics) and these models are calibrated to replicate these statistics. A calibration approach was developed using recent advances in multi-objective optimization and applied to the self-reinforcing model.We use these models to evaluate the varying impact of HIV prevention combinations by simulating community-randomized trials across realistic values of several parameters: ART (anti-retroviral therapy) uptake, PREP (pre-exposure prophylaxis) uptake, HIV testing uptake, and CAI (condomless anal intercourse) reduction. For the static partnership agent-based model, we create a statistical model to describe quantitatively the effects of these parameters and variation. For the self-reinforcing model we model sensitivity across several key parameters. We develop sample size and power formula for community randomized trials that incorporate estimates of variation and effect sizes determined from the agent-based model. We find that traditional sample size approaches that rely on binomial (or Poisson) models are inadequate and can lead to underpowered studies. In our studies of variation and effect sizes, we identified important sensitivities to the network contact structure. We conclude that agent-based models offer a useful tool in the design of HIV prevention trials. Article	2015	Brooks, Ronald A; Landovitz, Raphael J; Regan, Rotrease; Lee, Sung-Jae; Allen, Vincent C	Perceptions of and intentions to adopt HIV pre-exposure prophylaxis among black men who have sex with men in Los Angeles	International Journal of STD & AIDS	-	-	-	1758-1052	10.1177/0956462415570159	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4520772/	This study assessed perceptions of pre-exposure prophylaxis (PrEP) and their association with PrEP adoption intention among a convenience sample of 224 low socioeconomic status black men who have sex with men (BMSM) residing in Los Angeles. Participants received educational information about PrEP and completed an in-person interview. More than half (60%) of the participants indicated a high intention to adopt PrEP. Younger BMSM (18-29 years) were twice as likely to report a high intention to adopt PrEP compared to older BMSM (30+ years). Only 33% of participants were aware of PrEP and no participant had ever used PrEP. Negative perceptions were associated with a lower PrEP adoption intention and included being uncomfortable taking an HIV medicine when HIV-negative and not knowing if there are long-term side effects of taking an HIV medication. These findings suggest that BMSM may adopt PrEP but that negative perceptions may limit its uptake among this population. In order to facilitate PrEP adoption among BMSM targeted educational and community awareness programmes are needed to provide accurate information on the benefits of PrEP and to address the negative perceptions of PrEP held by local BMSM populations. Article	2015	Cáceres, Carlos F; Koechlin, Florence; Goicochea, Pedro; Sow, Papa-Salif; O'Reilly, Kevin R; Mayer, Kenneth H; Godfrey-Faussett, Peter	The promises and challenges of pre-exposure prophylaxis as part of the emerging paradigm of combination HIV prevention	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.18.4.19949	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4509895/	INTRODUCTION: Towards the end of the twentieth century, significant success was achieved in reducing incidence in several global HIV epidemics through ongoing prevention strategies. However, further progress in risk reduction was uncertain. For one thing, it was clear that social vulnerability had to be addressed, through research on interventions addressing health systems and other structural barriers. As soon as antiretroviral treatment became available, researchers started to conceive that antiretrovirals might play a role in decreasing either susceptibility in uninfected people or infectiousness among people living with HIV. In this paper we focus on the origin, present status, and potential contribution of pre-exposure prophylaxis (PrEP) within the combination HIV prevention framework. DISCUSSION: After a phase of controversy, PrEP efficacy trials took off. By 2015, daily oral PrEP, using tenofovir alone or in combination with emtricitabine, has been proven efficacious, though efficacy seems heavily contingent upon adherence to pill uptake. Initial demonstration projects after release of efficacy results have shown that PrEP can be implemented in real settings and adherence can be high, leading to high effectiveness. Despite its substantial potential, beliefs persist about unfeasibility in real-life settings due to stigma, cost, adherence, and potential risk compensation barriers. CONCLUSIONS: The strategic synergy of behavioural change communication, biomedical strategies (including PrEP), and structural programmes is providing the basis for the combination HIV prevention framework. If PrEP is to ever become a key component of that framework, several negative beliefs must be confronted based on emerging evidence; moreover, research gaps regarding PrEP implementation must be filled, and appropriate prioritization strategies must be set up. Those challenges are significant, proportional to the impact that PrEP implementation may have in the global response to HIV. Article	2015	Cáceres, Carlos F; Mayer, Kenneth H; Baggaley, Rachel; O'Reilly, Kevin R	PrEP Implementation Science: State-of-the-Art and Research Agenda	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.18.4.20527	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4581083/	Introduction It is increasingly clear that the HIV response will not be sustainable if the number of infections is not significantly reduced. Discussion For two decades, research has been ongoing to identify new behavioural and biomedical strategies to prevent HIV infection. In the past few years, the efficacy of several new strategies has been demonstrated, including oral pre-exposure prophylaxis (PrEP; i.e. daily use of tenofovir/emtricitabine). Because several social, political and logistic barriers remain, however, optimal PrEP implementation will require a better dissemination of new evidence in a number of areas and additional implementation research from various disciplinary perspectives (i.e. social science, policy and ethics; health systems; and economics, including cost-effectiveness studies). Discussion of new evidence on those topics, as well as case studies of potential PrEP implementation in diverse environments, can improve the understanding of the role that PrEP may play in addressing the global HIV/AIDS epidemic. In light of these needs, the Network for Multidisciplinary Studies in ARV-based HIV Prevention (NEMUS) and the World Health Organization (WHO) were honoured to co-organize a special issue of JIAS aimed at contributing to a scholarly discussion of current conditions surrounding PrEP implementation, potential impact and efficiency, social science concerns and the study of PrEP implementation in specific country cases. The papers included in this monograph identify and cover many of the main aspects of the complex yet promising discussions around PrEP implementation today. Conclusions This is a collection of timely contributions from global leaders in HIV research and policy that addresses geographic diversity, uses a trans-disciplinary approach and covers a variety of the complex issues raised by PrEP. As this publication will become accessible to all, we hope that it will remain a valuable resource for policy makers, programme managers, researchers and activists around the world at a moment of a paradigm shift of the global response to HIV. Article	2015	Calabrese S.K.; Underhill K.	How stigma surrounding the use of HIV preexposure prophylaxis undermines prevention and pleasure: A call to destigmatize "truvada whores"	American Journal of Public Health	-	-	-	900036	10.2105/AJPH.2015.302816	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84941348141&doi=10.2105%2fAJPH.2015.302816&partnerID=40&md5=4bd09910e2d533ba9176b3a9a0faa6dc	Antiretroviral preexposure prophylaxis (PrEP; emtricitabine and tenofovir disoproxil fumarate Truvada) prevents HIV without penalizing sexual pleasure, and may even enhance pleasure (e.g., by reducing HIV-relatedanxiety). However, concern about sexual risk behavior increasing with PrEP use (risk compensation) and corresponding stereotypes of promiscuity may undermine PrEP's preventive potential. In this commentary, we review literature on sexual behavior change accompanying PrEP use, discuss risk compensation concerns and the "Truvadawhore" stereotype as PrEP barriers, question the appropriateness of restricting PrEP access because of risk compensation, and consider sexual pleasure as a benefit of PrEP,an acceptable motive for seeking PrEP, and a core element of health. It is essential for science to trump stereotypes and sexnegative messaging in guiding decision-making affecting PrEP access and uptake. Article	2015	Callahan, Rebecca; Nanda, Kavita; Kapiga, Saidi; Malahleha, Mookho; Mandala, Justin; Ogada, Teresa; Van Damme, Lut; Taylor, Douglas	Pregnancy and contraceptive use among women participating in the FEM-PrEP trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000413	https://dx.doi.org/10.1097/QAI.0000000000000413	BACKGROUND: Pregnancy among study participants remains a challenge for trials of new HIV prevention agents despite promotion and provision of contraception. We evaluated contraceptive use, pregnancy incidence, and study drug adherence by contraceptive method among women enrolled in the FEM-PrEP trial of once-daily oral tenofovir disoproxil fumarate and emtricitabine (TDF-FTC) for HIV prevention. METHODS: We required women to be using effective non-barrier contraception at enrollment. At each monthly follow-up visit, women were counseled on contraceptive use and tested for pregnancy. TDF-FTC adherence was determined by measuring plasma drug concentrations at 4-week intervals. We used Cox proportional hazards models to assess factors associated with incident pregnancy and multivariate logistic regression to examine the relationship between contraceptive method used at enrollment and TDF-FTC adherence. RESULTS: More than half of women were not using effective contraception before enrollment. Ninety-eight percent of these women adopted either injectable (55%) or oral (43%) contraceptives. The overall pregnancy rate was 9.6 per 100 woman-years. Among injectable users and new users of combined oral contraceptives (COCs), the rates were 1.6 and 35.1, respectively. New users of injectables had significantly greater odds of adhering to TDF-FTC than new COC users odds ratio (95% confidence interval): 4.4 (1.7 to 11.6), P = 0.002, existing COC users 3.1 (1.3 to 7.3), P = 0.01, and existing injectable users 2.4 (1.1 to 5.6), P = 0.04. CONCLUSIONS: Women using COCs during FEM-PrEP, particularly new adopters, were more likely to become pregnant and less likely to adhere to study product than injectable users. HIV prevention trials should consider requiring long-acting methods, including injectables, for study participation. Article	2015	Carnegie, Nicole B; Goodreau, Steven M; Liu, Albert; Vittinghoff, Eric; Sanchez, Jorge; Lama, Javier R; Buchbinder, Susan	Targeting pre-exposure prophylaxis among men who have sex with men in the United States and Peru: partnership types, contact rates, and sexual role.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000555	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4422184/	BACKGROUND: We aim to identify optimal strategies for deploying pre-exposure prophylaxis among men who have sex with men (MSM) in the United States and Peru to maximize population-level effectiveness in an efficient manner. We use epidemic models to simulate the impact of targeting strategies. Most studies have focused on targeting either the general population or high-risk MSM. Alternative strategies, including serodiscordant couples, may better balance effectiveness and efficiency. METHODS: We use dynamic stochastic sexual network models based on exponential-family random graph modeling, parameterized from behavioral surveys of MSM in the United States and Peru. These models represent main partnerships and casual contacts separately, permitting modeling of interventions targeting men whose risk derives from combinations of relational types. We also model varying rates of uptake and adherence to pre-exposure prophylaxis (PrEP). We assess sensitivity of results to risk compensation through increases in condomless casual contacts and condomless sex in main partnerships. RESULTS: Targeting all men who are not exclusively insertive has the largest impact on HIV incidence, but targeting only those with high levels of casual activity yields comparable results using fewer person-years on PrEP. The effect is robust to risk compensation in the United States, but less so in Peru. Targeting serodiscordant main partnerships does not significantly impact incidence, but requires fewer person-years on PrEP per infection averted than other strategies. CONCLUSIONS: PrEP could be effective in reducing new infections at the population level in both settings. Serodiscordant partnerships are an attractive component of a targeting program, but targeting should include other high-risk men. Article	2015	Carney, Ellen F	Clinical trials. Renal safety of TDF as pre-exposure prophylaxis for HIV-1 infection.	Nature Reviews Nephrology	-	-	-	1759-507X	10.1038/nrneph.2015.1	https://dx.doi.org/10.1038/nrneph.2015.1	Use of tenofovir disoproxil fumarate (TDF) as an antiretroviral therapy is associated with declines in estimated glomerular filtration rate (eGFR) in patients with HIV-1 infection. TDF is also used as a pre-exposure prophylaxis (PrEP) in adults at risk of HIV-1 infection, but limited data are available on the risk of TDF-associated renal dysfunction in this population. Now, Jared Baeten and colleagues report reassuring results from a safety analysis of the Partners PrEP randomized controlled trial, which evaluated TDF-based PrEP in 4,640 HIV-1 uninfected heterosexual partners of patients with HIV-1. The researchers assessed changes in eGFR from baseline in the trial participants, all of whom had normal renal function at enrolment. "PrEP use resulted in a small (−1.59 ml/min/1.73 m2, 95% CI −2.44 to −0.74 ml/min/1.73 m2) but statistically significant decline in eGFR that was non-progressive over a median of 18 months and a maximum of 36 months of follow-up," reports Baeten. "However, use of PrEP compared with placebo was not accompanied by a substantial increase in the risk of clinically relevant (≥25%) eGFR decline." The researchers conclude that "these data support the safety of TDF-based PrEP in heterosexual populations as part of a comprehensive HIV-1 prevention package." They highlight the need for further evaluation of the effect of TDF exposure on proximal tubular function in HIV-1 uninfected individuals. Theses and Dissertations	2015	Carroll, Jennifer J.	Risk Perception Among HIV Serodiscordant Couples in East Africa Taking Oral PrEP for HIV Prevention	-	-	University of Washington	-	NA	NA	http://hdl.handle.net/1773/33880	Levels of adherence varied across trials for pre-exposure prophylaxis (PrEP) for HIV prevention. One hypothesis for this inconsistency is that low perceived risk of HIV infection drove low adherence in trials where PrEP produced no reduction in risk. Using a mixed methods approach, we explored the level of perceived risk of incident HIV infection in the Partners PrEP Study, in which adherence was generally high. The Partners PrEP Study followed 4747 serodiscordant couples in Kenya and Uganda. A brief cross-sectional survey assessed perceived risk of HIV via questionnaire at 12 months after enrollment. Logistic regression was used to analyze the relationship between perceived risk and demographic variables, sexual behavior, and other objective measures of risk. 3226 couples from the Partners PrEP Study were included in this analysis. Perceived risk was low across the entire study cohort, with only 15.4% of participants reporting high or moderate perceived risk. Participants objectively assessed to be at higher risk for HIV were more likely to report high perceived risk (OR=1.60, 95%CI: 1.30-1.95, p<0.001), but still remained below 20%. In addition, this study also analyzed transcripts from in-depth interviews and focus groups, which were conducted with 68 individuals from 34 mutually-disclosed serodiscordant partnerships at the Thika, Kenya Partners PrEP Study site. Differences in the perceived risks and benefits of taking PrEP were identified according to participants' serostatus and gender. These differences can be grouped into three major categories: gendered and unequal control over medical decision making in the home; the management of male sexual drives and the interference of traditional prevention strategies with the fulfillment of those drives; and culture-bound definitions of 'women's work. In summary, participants in the Partners PrEP Study reported generally low perceived risk of HIV but had high levels of adherence to PrEP. Perceptions of risk are likely determined by a multi-faceted social and psychological calculus that is too complex for Likert-scale questionnaires to capture in any meaningful way. In interviews, patients articulated complex concerns and interests related to PrEP, which reflected traditional gender roles and gendered power dynamics within the relationship. Successful delivery of PrEP as an HIV prevention strategy for serodiscordant couples should respond to these socio-cultural realities. Article	2015	Castel, Amanda D.; Magnus, Manya; Greenberg, Alan E.	Update on the Epidemiology and Prevention of HIV/AIDS in the United States.	Current Epidemiology Reports	-	-	-	2196-2995	10.1007/s40471-015-0042-8	https://pubmed.ncbi.nlm.nih.gov/25960941/	This update on the epidemiology and prevention of HIV in the United States is intended to provide contextual background that will help inform an understanding of recent developments in the domestic HIV epidemic. We describe the epidemiology of HIV disease in the US and the HIV continuum of care based on data collected primarily through HIV surveillance systems led by the Centers for Disease Control and Prevention including HIV incidence, prevalence, comorbidities and death. Populations and geographic regions disparately impacted by HIV are also highlighted. The HIV prevention armamentarium is also described including behavioral approaches to prevention, the emerging availability of biomedical prevention interventions such as pre-exposure prophylaxis, and structural and population-level interventions including treatment as prevention. Finally gaps in our understanding of the epidemic are underscored and suggestions for future epidemiologic research are proposed. Article	2015	Cohen, Stephanie E; Vittinghoff, Eric; Bacon, Oliver; Doblecki-Lewis, Susanne; Postle, Brian S; Feaster, Daniel J; Matheson, Tim; Teston, Nikole; Blue, Robert W; Estrada, Yasmine; Coleman, Megan E; Elion, Richard; Castro, Jose G; Chege, Wairimu; Philip, Susan S; Buchbinder, Susan; Kolber, Michael A; Liu, Albert Y	High interest in preexposure prophylaxis among men who have sex with men at risk for HIV infection: baseline data from the US PrEP demonstration project.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000679	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4324611/	-	BACKGROUND: Preexposure prophylaxis (PrEP) is the first biomedical intervention with proven efficacy to reduce HIV acquisition in men who have sex with men (MSM) and transgender women. Little is known about the use of PrEP in routine clinical settings. METHODS: We enrolled MSM and transgender women (TGW) at 4 clinical sites in the United States between 2012 and 2014. Each site was assessing PrEP delivery in routine clinical care. Participants were offered PrEP and were assessed at baseline, 3 months, and every 6 months thereafter. Descriptive statistics of study participants are described. RESULTS: Of 1809 clients assessed for participation, 921 were potentially eligible for PrEP, and 557 (60.5%) enrolled. In multivariable analyses, participants from Miami [adjusted Relative Risk (aRR): 1.53; 95% confidence interval (CI): 1.33 to 1.75] or DC (aRR: 1.33; 95% CI: 1.2 to 1.47), those who were self-referred (aRR: 1.40; 95% CI: 1.32 to 1.66), those with previous PrEP awareness (aRR: 1.56; 95% CI: 1.05 to 2.33), and those reporting >1 episode of anal sex with an HIV-infected partner in the last 12 months (aRR: 1.20; 95% CI: 1.09 to 1.33) were more likely to enroll. Almost all (98%) enrolled participants were MSM, and at baseline, 63.5% reported condomless receptive anal sex in the previous 3 months. CONCLUSIONS: Interest in PrEP is high among a diverse population of MSM at risk for HIV infection when offered in sexually transmitted disease and community health clinics. Single oral dose of maraviroc does not prevent ex vivo HIV infection of rectal mucosa in HIV-1 negative human volunteers	AIDS	-	-	-	2e99370	10.1097/QAD.0000000000000769	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84940841854&doi=10.1097%2FQAD.0000000000000769&partnerID=40&md5=caca2634f405e474c0103fded55cf5fb	-	Objective: Maraviroc (MVC) is a potential candidate for 'on demand' preexposure prophylaxis. In the present study, we evaluated the efficacy of a single oral dose of MVC to prevent ex-vivo HIV-1 infection of rectal tissue in humans. Design and Methods: Eight HIV-1 negative healthy volunteers received a single oral dose of MVC (300 or 600 mg), and two additional volunteers received tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) 300/200 mg once daily for 20 days. Rectal biopsies were taken at baseline and 2, 4, 8, 24, 48, 72, 96, 120, 144 and 168 h after MVC dosing. Biopsies were infected ex-vivo, and viral inhibition and CCR5 occupancy was analyzed. MVC concentration at plasma and rectal tissue was measured just after biopsy and after culture. Results: Ex-vivo rectal tissue protection with MVC was incomplete in all but two participants, whereas TDF/FTC avoided ex-vivo infection in the two controls. Median dose-normalized concentration of MVC was significantly higher in rectal tissue than in plasma (561.1 and 155.1 ng/mL respectively). A significant loss of MVC during the ex-vivo incubation (about 60%) and a low CCR5 occupancy (approximately 45%) were detected in rectal cells. Conclusions: An ex-vivo challenge with a single oral dose of MVC does not prevent ex-vivo infection of human rectal mucosa. The lack of prophylactic efficacy observed suggests that 'on demand' MVC preexposure prophylaxis would not prevent rectal HIV-1 transmission. © Copyright 2015 Wolters Kluwer Health, Inc. Article	2015	Eccles-Radtke C.; Henry K.	Turning the tide against AIDS by preventing new HIV infections initial experience with Minnesota's first PrEP clinic	Minnesota Medicine	-	-	-	0026150X	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84925203003&partnerID=40&md5=392e0180e2f4f31e0076bf299a0fef	-	During the last 30 years, there have been remarkable improvements in the treatment of patients with HIV. New drug regimens are both tolerable and easy to take, resulting in HIV viral suppression and markedly improved clinical outcomes. Viral suppression in patients with HIV significantly decreases the chance they will transmit the virus. Yet HIV transmission levels in the United States remain unacceptably high. Prevention efforts focused on HIV-negative persons who are at high risk for infection have led to the development of a pre-exposure prophylaxis (PrEP) strategy. This article provides an overview of PrEP and a review of the evidence for its use. Data are presented from the PrEP clinic being used in the United States and Minnesota. Who concerned efforts by physicians, patients and public health authorities, PrEP could become a key component of reducing transmission of the HIV virus. Article	2015	Escobar, Erik; Durgham, Ryan; Dunnuru, Olof; Stopka, Thomas J	Agent-based computational model of the prevalence of gonococcal infections after the implementation of HIV pre-exposure prophylaxis guidelines.	Online Journal of Public Health Informatics	-	-	-	1947-2579	10.5210/ojphi.v7i3.6104	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4731411/	-	Recently, the first comprehensive guidelines were published for pre-exposure prophylaxis (PrEP) for the prevention of HIV infection in populations with substantial risk of infection. Guidelines include a daily regimen of emtricitabine/tenofovir disoproxil fumarate (TDF/FTC) as well as condom usage during sexual activity. The relationship between the TDF/FTC intake regimen and condom usage is not yet fully understood. If men who have sex with men (MSM) engage in high-risk sexual activities without using condoms when prescribed TDF/FTC they might be at an increased risk for other sexually transmitted diseases (STDs). Our study focuses on the possible occurrence of behavioral changes among MSM in the United States over time with regard to condom usage. In particular, we were interested in creating a model of how increased uptake of TDF/FTC might cause a decline in condom usage, causing significant increases in non-HIV STD incidence, using gonococcal infection incidence as a biological endpoint. We used the agent-based modeling software NetLogo, building upon an existing model of HIV infection. We found no significant evidence for increased gonorrhea prevalence due to increased PrEP usage at any level of sample-wide usage, with a range of 0-90% PrEP usage. However, we did find significant evidence for decreased prevalence of HIV, with a maximal effect being reached when 5% to 10% of the MSM population used PrEP. Our findings support to indicate that attitudes of overuse, within the medical community, toward the promotion of PrEP due to the potential risk of increased STD transmission are unfounded. Article	2015	Corneli, Amy; Field, Samuel; Namey, Emily; Agot, Kawango; Ahmed, Khadija; Odhiambo, Jacob; Skhosana, Joseph; Guest, Greg	Preparing for the Rollout of Pre-Exposure Prophylaxis (PrEP): A Vignette Survey to Identify Intended Sexual Behaviors among Women in Kenya and South Africa if Using PrEP.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0129177	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4461292/	-	INTRODUCTION: Several clinical trials have demonstrated the efficacy of pre-exposure prophylaxis (PrEP) in reducing HIV risk. One concern with introducing PrEP is whether users will engage in riskier sexual behaviors. METHODS: We assessed the effect that PrEP may have on sexual risk behaviors by administering a survey to 799 women in Bondo, Kenya, and Pretoria, South Africa. Participants were asked about their sexual behavior intentions twice--once as if they were taking PrEP and once as if they were not taking PrEP--within four risk situations (vignettes). They responded using a 5-point ordinal scale. We used a series of linear mixed effects models with an unstructured residual covariance matrix to estimate the between- and within-subject differences in the mean likelihood of engaging in risky sexual behavior across the PrEP and non-PrEP contexts. We also calculated the total percentage of participants who reported a greater likelihood of engaging in risky sexual behavior if taking PrEP than if not taking PrEP, by vignette. RESULTS: We found statistically significant differences in the mean likelihood of engaging in risky sexual behavior with the between-subject comparison (-0.17, p < 0.01) and with the within-subject comparison (-0.51, p < 0.001). Depending on the vignette, 27% to 40% of participants reported a greater likelihood of engaging in risky sexual behavior if taking PrEP than if not taking PrEP. CONCLUSIONS: Our findings indicate that modest increases in risky sexual behavior could occur with PrEP. Although responses from the majority of participants suggest they would not be more likely to engage in risky sexual behavior if taking PrEP, the fact that some participants reported greater likelihood of risky sexual behavior if taking PrEP--even if only in certain situations--means that the potential population impact might. Programs rolling out PrEP should be prepared to assist similar women in making informed choices about reducing their risk of HIV and about their sexual health beyond HIV prevention. Article	2015	Eakle R.; Jarrett C.; Bourne A.; Stadler J.; Larson H.	Systematic Reviews	-	-	-	2046-4053	10.1186/s13643-015-0096-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84939529377&doi=10.1186%2Fs13643-015-0096-1&partnerID=40&md5=1b9dfb97f7ca1981f3c4b6f1b1f67823	-	Background: Women in sub-Saharan Africa are disproportionately affected by high rates of HIV, yet relatively few products exist for female-initiated HIV prevention. New antiretroviral (ARV)-based prevention options could present opportunities for women to expand their HIV prevention choices; however, acceptability and adherence play a key role in the effectiveness of these products and implementation is still in early stages. To better understand which HIV prevention options might best serve women in sub-Saharan Africa, how and why, this review will explore qualitative evidence from clinical trials and implementation studies alike using a meta-ethnographic approach to synthesise data and interpret results. Methods/design: This systematic review will use a meta-ethnographic approach to analyse qualitative data extracted from multiple studies fostering actual use of female-initiated technologies for HIV prevention. The search strategy will be applied to seven databases and papers will be selected based on a set of inclusion criteria. Quality will be assessed using the Critical Appraisal Skills Programme (CASP) checklist for qualitative research and the Cochrane Consumers and Communication Review Group's checklist for Reviews Documentation (CRD) where the guidance applies to qualitative data. Two reviewers will review all papers during the paper selection phase, with consultation from a third reviewer to confirm consensus. All papers included in the review will be read and analysed by two reviewers. The final analysis will be conducted by three primary reviewers with additional input from all other authors. Discussion: With new HIV prevention technologies currently in early implementation phases and still more on the horizon, there is much to learn about how these products may be delivered. A review such as this could help to inform the real-world implementation of the next wave of new HIV prevention technologies such as ARV-based oral pre-exposure prophylaxis (PrEP). © 2015 Eakle et al. Culture, Health & Sexuality	-	-	-	1464-5351 1369-1058	10.1080/13691058.2014.968806	https://www.tandfonline.com/doi/abs/10.1080/13691058.2014.968806	In developing-country settings, pregnancy intentions are often assessed using a series of questions from the Demographic and Health Surveys, yet research conducted in several countries yields conflicting results regarding these questions' ability to predict pregnancy. Conducted in Malawi and South Africa, this study identified individual, partner and societal factors that influence desire for pregnancy, and women's ability to achieve their intentions. Data come from interviews and focus-group discussions conducted prior to the FEM-PrEP HIV-prevention trial with women from communities at high risk of HIV infection. Cultural norms regarding contraceptive use and childbearing influenced both women's desire for pregnancy and ability to achieve those goals. Partner's expectations for pregnancy, financial concerns, family composition and contraceptive experiences were additional influences. Actively planning for pregnancy was not a salient concept to the majority of participants. Results support the call for a multidimensional measure of pregnancy intention that reflects the variety of factors that influence intentions, highlight the fluid nature of many women's reproductive health decision making and challenge the notion that all fertility decisions are the result of conscious action. Additional work on how women's plans for pregnancy are achieved would be programmatically more useful than current measures of intention. Article	2015	Ferraz, Dulce Aurélia de Souza	Sexo, direitos humanos e AIDS: uma análise das novas tecnologias de prevenção do HIV no contexto brasileiro	Revista Brasileira de Epidemiologia	-	-	-	na	10.1590/1809-4503201500050007	https://www.arca.fiocruz.br/handle/icict/43508	Globalmente, o campo da prevenção do HIV está desafiado a mudar, especialmente depois que ensaios clínicos mostraram o efeito protetor de tecnologias como a circuncisão, a profilaxia pré-exposição e a supressão da carga viral pelo tratamento com antirretrovirais. Diante de demandas pela implantação destas tecnologias em escala populacional, o temor de estimular processos de compensação de risco e de aumentar práticas sexuais mais arriscadas, entre outras questões, retardam a sua integração nos programas de prevenção. Seguindo uma revisão narrativa de artigos científicos sobre o tema recuperados na base PubMed, oferecemos uma reflexão crítica sobre o tema adotando a vertente construcionista da psicologia social integrada à análise da epidemia no quadro da vulnerabilidade e dos direitos humanos. O uso de tecnologias biomédicas para a prevenção não induz grande parte dos usuários ao aumento de práticas mais arriscadas, havendo variações relativas a cada método, segundo observa-se na literatura. Abordagens das ciências sociais e humanas alternativas às sócio-cognitivistas, como as de base construtivista, indicam interpretações mais abrangentes, que preservam a noção de sujeitos da prevenção e de direitos. Apontamos ações prioritárias no processo de implantação: desenvolvimento de programas abrangentes, realização de estudos de acompanhamento e diálogo sobre sexualidade e informações técnicas. Enfatizamos a necessidade de respostas dialógicas baseadas na perspectiva dos direitos humanos, buscando ressaltar a complementaridade entre tecnologias que atendam às necessidades da população. Concluímos destacando a necessidade de mudanças sócio-políticas que reestabeleçam a participação, o diálogo sobre a sexualidade e a ênfase nos direitos como elementos centrais da política brasileira de aids. Article	2015	Ferrell, Kelli W; Woodard, Laresa M; Woodard, Todd J	Role of medication therapy management in preexposure prophylaxis therapy for HIV prevention.	Journal of Pharmacy Practice	-	-	-	1531-1937	10.1177/0897190014562351	https://dx.doi.org/10.1177/0897190014562351	Patient medication adherence is a long-standing problem and is one that raises serious issues for patient health, public health, and health care quality. Medication nonadherence costs the US economy an estimated US$290 billion in avoidable medical spending every year. One of the most costly health conditions is HIV disease, which continues to be a serious health issue for parts of the world. About 34 million people are living with HIV around the world. With the emerging preventative treatment against HIV, known as preexposure prophylaxis (PrEP), come concerns surrounding the potential impact of nonadherence to this newly approved medication therapy. Nonadherence to antiretroviral treatments are commonly the root cause for patients not reaching their treatment goals, putting them at risk of progression and worsening of their disease and complications, such as increased risk of opportunistic infections. Therefore, it is essential to improve antiretroviral medication adherence. By identifying members who are nonadherent to their prescribed antiretroviral medications and working collaboratively with patients, physicians, and pharmacists, Medication Therapy Management (MTM) can potentially increase medication adherence by helping patients identify, resolve, and prevent issues that may affect their decision not to take a medication as intended.	acesso restrito	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Theses and Dissertations	2015	Field, Tuuli	Barriers to Antiretroviral Therapy Adherence : Descriptive literature review	-	-	Yrkeshögskolan Arcada	-	na	NA	http://www.theseus.fi/handle/10024/102861	Adherence to the treatment regimen is essential to the success of highly active antiretrovi-ral therapy for patients who are infected with HIV. The evidence suggests that poor ad-herence to antiretroviral drug therapy is a major problem that has the potential to diminish effective viral suppression, promote viral resistance, and place patients at risk for hospital-ization, opportunistic infections, and an increased risk of HIV transmission. The primary aim of this study was review was to find and identify current barriers that prevent people from adherence to antiretroviral therapy. The chosen research method was descriptive literature review. Three databases were used for the literature search: CINAHL full text (EBSCO), ProQuest Hospital Collection and Medline (Ovid). Search was limited to arti-cles from years 2010-2015. Articles on children, pregnant women, intravenous drug users, psychiatric patients, post and pre-exposure prophylaxis patients were excluded from the study. After exclusion process 46 articles were accepted for the final analysis. The data was categorized by topics trying to make interpretations from the literature reviewed. Scheduling issues, stigma, adverse side effects and cost were the most commonly found adherence barriers. Scheduling issues and the adverse side effects seem to be universal barriers for patients all over the world. Stigma was more prominent barrier in articles con-ducted in African countries and cost was found to be a barrier in studies conducted in resource poor settings. High self-efficacy beliefs and social support were the most com-mon positive influences to adherence to ART that rose from the review. The need for new solutions and innovations rose from the results of this review to support patients in scheduling issues nad remembering to take pills in correct time. Furthermore further interventions that effectively target stigma are warranted. Consideration of how healthcare systems and policy can promote and support self-efficacy is required.	na	English	Finland	Western and Central Europe and North America	Finland	Western and Central Europe and North America	-	-	Review
Article	2015	Fiereck K.	Cultural conundrums: The ethics of epidemiology and the problems of population in implementing pre-exposure prophylaxis	Developing World Bioethics	-	-	-	14718731	10.1111/dewb.12034	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84924017731&doi=10.1111%2fdewb.12034&partnerID=40&md5=2599f2451ac22638e2b0245c3a6021ce	The impending implementation of pre-exposure prophylaxis (PrEP) has prompted complicated bioethical and public health ethics concerns regarding the moral distribution of antiretroviral medications (ARVs) to ostensibly healthy populations as a form of HIV prevention when millions of HIV-positive people still lack access to ARVs globally. This manuscript argues that these questions are, in part, concerns over the ethics of the knowledge production practices of epidemiology. Questions of distribution, and their attendant cost-benefit calculations, will rely on a number of presupposed, and therefore, normatively cultural assumptions within the science of epidemiology specifically regarding the ability of epidemiologic surveillance to produce accurate maps of HIV throughout national populations. Specifically, ethical questions around PrEP will focus on who should receive ARVs given the fact that global demand will far exceed supply. Given that sexual transmission is one of the main modes of HIV transmission, these questions of 'who' are inextricably linked to knowledge about sexual personhood. As a result, the ethics of epidemiology, and how the epidemiology of HIV in particular conceives, classifies and constructs sexual populations will become a critical point of reflection and contestation for bioethicists, health activists, physicians, nurses, and researchers in the multi-disciplinary field of global health. This paper examines how cultural conundrums within the fields of bioethics and public health ethics are directly implicated within the ethics of PrEP, by analyzing the problems of population inaugurated by the construction of the men who have sex with men (MSM) epidemiologic category in the specific national context of South Africa. © 2013 John Wiley & Sons Ltd. Theses and Dissertations	2015	Foster, Loretta Lynn	Prevalence of Bacterial Sexually Transmitted Infections and Pre-Exposure Prophylaxis Eligibility in a Cross-Sectional Sample of HIV Negative Men who have Sex with Men in Atlanta Georgia	-	-	Emory University	-	NA	NA	https://etd.library.emory.edu/concern/etds/h702q6489?locale=fr	Objectives: To determine any predictors of bacterial sexually transmitted infections (STIs) among men who have sex with men (MSM) in Atlanta GA and to determine if CDC PrEP eligibility correlates to positive STI diagnosis. Methods: A subgroup of HIV negative non-Hispanic white and black MSM was gathered from the InvolveMENt and The MAN Project studies. Participants completed a computer based questionnaire with questions about demographic, psychosocial, individual level sexual risk behaviors, and dyadic information. Men were also screened for chlamydia, gonorrhea, and syphilis. Results: 265 participants were selected for analysis. Racial composition was 57.0% black and 43.0% white. 33 (12.5%) participants were diagnosed with at least one STI. Prevalence of chlamydia was 8.7%, gonorrhea 6.0%, and syphilis 1.5%. Multiple infection prevalence was 3.8% with 90% of co-infections chlamydia and gonorrhea, and 10% chlamydia and syphilis. Rectal infections were more common than urethral infections Predictors of a positive STI diagnosis were black race, lower education, and lack of health insurance. CDC PrEP eligibility guidelines were not associated with STI diagnosis. Conclusion: Atlanta MSM exhibit high prevalence of bacterial STIs with respect to racial and educational divisions. CDC PrEP eligibility guidelines do not fit this population and should be altered to better predict individuals who are engaging in high risk behaviors and acquiring bacterial STIs. Article	2015	Fowler, N; Arkell, P; Abouyannis, M; James, C; Roberts, L	Attitudes of Serodiscordant Couples Towards Antiretroviral-Based HIV Prevention Strategies in Kenya: A Qualitative Study	AIDS Patient Care and STDs	-	-	-	1087-2914	10.1089/apc.2014.0210	https://pubmed.ncbi.nlm.nih.gov/25375792/	This qualitative study aims to gain in-depth information about the attitudes of HIV-serodiscordant couples towards two new methods of HIV prevention; Pre-Exposure Prophylaxis and Treatment as Prevention, both of which have been recently recommended by the World Health Organisation. Semi-structured interviews were conducted with 38 individuals in a serodiscordant relationship in Western Kenya. Topic guides were used to elicit information on perceived benefits, concerns, and preferences towards Treatment as Prevention and Pre-Exposure Prophylaxis. Data evaluation and thematic generation were developed using framework analysis. Results suggest that the majority of participants, irrespective of gender and HIV status, found Treatment as Prevention the more acceptable strategy. Key factors influencing this decision were HIV-negative participants' limited motivation to take prophylactic antiretrovirals and the likely health improvements Treatment as Prevention offers HIV-positive partners. However, issues were raised concerning the likelihood of low concurrent condom use and poor medication adherence when using these preventative approaches. It was concluded that the adoption of Treatment as Prevention as a method of HIV control in Kenya is likely to be more readily accepted by serodiscordant couples than Pre-exposure Prophylaxis. However, future implementation of either strategy would require measures to address the possibility of risk compensation and poor adherence. Article	2015	Gamarel K.E.; Golub S.A.	Intimacy Motivations and Pre-exposure Prophylaxis (PrEP) Adoption Intentions Among HIV-Negative Men Who Have Sex with Men (MSM) in Romantic Relationships	Annals of Behavioral Medicine	-	-	-	8836612	10.1007/s12160-014-9646-3	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84934276981&doi=10.1007%2fs12160-014-9646-3&partnerID=40&md5=3b3dd70b749c606a4273e63b725d0798	Background: In the USA, men who have sex with men (MSM) in primary partnerships are at elevated risk for human immunodeficiency virus (HIV) infection. Pre-exposure prophylaxis (PrEP), a new biomedical prevention strategy, has potential to reduce HIV transmission. This study examined predictors of PrEP adoption intentions among HIV-negative MSM in primary partnerships. Methods: The sample included HIV-negative MSM (n = 164) who participated in an ongoing cross-sectional study with an in-person interview examining PrEP adoption intentions. Results: Higher HIV risk perception, intimacy motivations for condomless sex, recent condomless sex with outside partners, education, and age were each independently associated with PrEP adoption intentions. In a multivariate model, only age, education, and intimacy motivations for condomless sex were significantly associated with PrEP adoption intentions. Conclusions: Intimacy motivations may play a central role in PrEP adoption for MSM couples. Incorporating relationship dynamics into biomedical strategies is a promising avenue for research and intervention. © 2014, The Society of Behavioral Medicine. Article	2015	Gandhi M.; Glidden D.V.; Liu A.; Anderson P.L.; Horng H.; Defechereux P.; Guanira J.V.; Grinsztejn B.; Chariyalertsak S.; Bekker L.-G.; Grant R.M.	Strong correlation between concentrations of tenofovir (TFV) emtricitabine (FTC) in hair and TFV diphosphate and FTC triphosphate in dried blood spots in the iPrEx open label extension: Implications for pre-exposure prophylaxis adherence monitoring	Journal of Infectious Diseases	-	-	-	221899	10.1093/infdis/jiv239	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946126981&doi=10.1093%2finfdis%2fjiv239&partnerID=40&md5=131537c1bc33f698f60c3dedeadb638d	Self-reported adherence to pre-exposure prophylaxis (PrEP) has limitations, raising interest in pharmacologic monitoring. Drug concentrations in hair and dried blood spots (DBS) are used to assess long-term-exposure; hair shipment/storage occurs at room temperature. The iPrEx Open Label Extension collected DBS routinely, with opt-in hair collection; concentrations were measured with liquid chromatography/tandem mass spectrometry. In 806 hair-DBS pairs, tenofovir (TFV) hair levels and TFV diphosphate (DP) in DBS were strongly correlated (Spearman coefficient r = 0.734; P <. 001), as were hair TFV/DBS emtricitabine (FTC) triphosphate (TP) (r = 0.781; P <. 001); hair FTC/DBS TFV-DP (r = 0.74; P <. 001); hair FTC/DBS FTC-TP (r = 0.587; P <. 001). Drug detectability was generally concordant by matrix. Hair TFV/FTC concentrations correlate strongly with DBS levels, which are predictive of PrEP outcomes. © The Author 2015. Article	2015	Garcia, Jonathan; Colson, Paul W; Parker, Caroline; Hirsch, Jennifer S	Passing the baton: Community-based ethnography to design a randomized clinical trial on the effectiveness of oral pre-exposure prophylaxis for HIV prevention among Black men who have sex with men	Contemporary Clinical Trials	-	-	-	15517144	10.1016/j.cct.2015.10.005	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946728684&doi=10.1016%2fj.cct.2015.10.005&partnerID=40&md5=c6cf19c69d45367f4df90220ca79cef9	Although HIV interventions and clinical trials increasingly report the use of mixed methods, studies have not reported on the process through which ethnographic or qualitative findings are incorporated into RCT designs. We conducted a community-based ethnography on social and structural factors that may affect the acceptance of and adherence to oral pre-exposure prophylaxis (PrEP) among Black men who have sex with men (BMSM). We then devised the treatment arm of an adherence clinical trial drawing on findings from the community-based ethnography. This article describes how ethnographic findings informed the RCT and identifies distilled themes and findings that could be included as part of an RCT. The enhanced intervention includes in-person support groups, online support groups, peer navigation, and text message reminders. By describing key process-related facilitators and barriers to conducting meaningful mixed methods research, we provide important insights for the practice of designing clinical trials for 'real-world' community settings. © 2015 Elsevier Inc. Article	2015	Garrett, Nigel J; Werner, Lise; Naicker, Nivashnee; Naranbhai, Vivek; Sibeko, Sengeziwe; Samsunder, Natasha; Gray, Clive; Williamson, Carolyn; Morris, Lynn; Abdool-Karim, Quarraisha; Abdool-Karim, Salim S	HIV disease progression in seroconvertors from the CAPRISA 004 tenofovir gel pre-exposure prophylaxis trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000367	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4262710	BACKGROUND: Although antiretroviral pre-exposure prophylaxis prevents HIV acquisition, it is not known if it alters HIV disease progression. This study assesses whether tenofovir gel impacted on disease progression among CAPRISA 004 microbicide trial seroconvertors. METHODS: Eighty-three seroconvertors from the tenofovir and placebo gel arms of the CAPRISA 004 trial were monitored prospectively for a minimum of 2 years by CD4 count and viral load (VL). Linear mixed models were fitted to HIV VL, and log rank test was used to compare time to reach CD4 counts of <350 cells per microliter. RESULTS: Median 2-week postinfection VL was 4.74 and 4.45 log copies per milliliter in women assigned to tenofovir gel (n = 32) and placebo gel (n = 51) (P = 0.189). Corresponding 12-month postinfection VLs were 4.24 and 3.70 log copies per milliliter (P = 0.016). After adjusting for clinical and behavioral characteristics and protective HLA alleles, mean VLs within the first 2 years were 4.51 and 4.02 log copies per milliliter in women from the tenofovir and placebo arms (P = 0.013). Among women with vaginal tenofovir measurements, mean VLs were 4.53 and 4.60 log copies per milliliter in those with detectable versus undetectable levels (P = 0.840). Overall mean CD4 counts were 463 and 514 cells per microliter in women assigned to tenofovir and placebo (P = 0.290). Thirty-two women (38.6%) reached CD4 counts of <350 cells per microliter at median 9.4 months postinfection, 13 (40.6%) from the tenofovir and 19 (37.3%) from the placebo arms (P = 0.786). CONCLUSIONS: Tenofovir gel had no impact on postinfection CD4 counts or the rate of CD4 decline. Although seroconvertors from the tenofovir arm experienced higher VLs, this did not result in a need for earlier antiretroviral therapy. Article	2015	Gilbert, Amy Lewis; Knopf, Amelia S.; Fortenberry, J. Dennis; Hosek, Sybil G.; Kapogiannis, Bill G.; Zimet, Gregory D.	Adolescent Self-Consent for Biomedical Human Immunodeficiency Virus Prevention Research.	The Journal of Adolescent Health : Official Publication of the Society for Adolescent Medicine	-	-	-	1879-1972 1054-139X	10.1016/j.jadohealth.2015.03.017	https://pubmed.ncbi.nlm.nih.gov/26095412/	PURPOSE: The Adolescent Medicine Trials Network Protocol 113 (ATN113) is an open-label, multisite demonstration project and Phase II safety study of human immunodeficiency virus (HIV) preexposure prophylaxis with 15- to 17-year-old young men who have sex with men that requires adolescent consent for participation. The purpose of this study was to examine factors related to the process by which Institutional Review Boards (IRBs) and researchers made decisions regarding whether to approve and implement ATN113 so as to inform future biomedical HIV prevention research with high-risk adolescent populations. METHODS: Participants included 17 researchers at 13 sites in 12 states considering ATN113 implementation. Qualitative descriptive methods were used. Data sources included interviews and documents generated during the initiation process. RESULTS: A common process for initiating ATN113 emerged, and informants described how they identified and addressed practical, ethical, and legal challenges that arose. Informants described the process as responding to the protocol, preparing for IRB submission, abstaining from or proceeding with submission, responding to IRB concerns, and reacting to the outcomes. A complex array of factors impacting approval and implementation were identified, and ATN113 was ultimately implemented in seven of 13 sites. Informants also reflected on lessons learned that may help inform future biomedical HIV prevention research with high-risk adolescent populations. CONCLUSIONS: The results illustrate factors for consideration in determining whether to implement such trials, demonstrate that such protocols have the potential to be approved, and highlight a need for clearer standards regarding biomedical HIV prevention research with high-risk adolescent populations. Theses and Dissertations	2015	Gong, Tiantian	VAGINAL DELIVERY OF A HYDROPHOBIC ANTIRETROVIRAL DRUG CSIC FOR HIV PREVENTION: NOVEL FORMULATION STRATEGIES FOR IMPROVED DRUG SOLUBILIZATION AND LYMPHATIC TARGETING	-	-	University of Pittsburgh	-	NA	NA	http://d-scholarship.pitt.edu/26515/1/Tiantian_Gong_ETD_FINAL__PDF_11-30-2015.pdf	HIV epidemic is an ongoing health concern globally. Sexual transmission accounts for the overwhelming majority of new infections. Vaginal microbicides are under investigation as pre-exposure prophylaxis (PrEP) products for HIV prevention. Although progress has been made, the development of more efficacious products is warranted. Cervicovaginal tissue and draining lymph nodes contain an adequate amount of HIV target cells and play critical roles in HIV replication and sedimentation at the early stage of infection. Improved efficacy can be achieved with the use of specially designed drug delivery systems which achieve greater drug concentrations in these two sites of action. In this dissertation, we hypothesized that the hydrophobic microbicide candidate CSIC can be formulated in a polymeric vaginal film and a nanocrystal formulation with high loading capacities using multiple formulation strategies. We further hypothesized that the nano-delivery strategy can improve cervicovaginal tissue drug penetration and achieve lymphatic drug delivery. Series of preformulation studies were conducted to evaluate the physicochemical and biological properties of the drug candidate CSIC. The major challenge for CSIC formulation development was identified as its hydrophobicity. Therefore, a cosolvent system comprising PEG 400, propylene glycol, and glycerin at a ratio of 5:2:1 has been optimized and utilized in a polymer based vaginal film formulation for increased drug solubility, long term stability, and lack of leakage. Additionally, a CSIC nanocrystal formulation, with a particle size of 243nm and near neutral surface charge, was developed. CSIC nanocrystals have been proved to possess increased drug saturation solubility, rapid mucus penetration properties, and improved drug permeation in the cervicovaginal tissue. More importantly, the pharmacokinetic study provided the first evidence of lymphatic targeting after intravaginal application without causing any epithelial damage. Furthermore, CSIC was able to release from the nanocrystals in a sustained mode, indicating its potential use as a coitally independent PrEP product that could improve user adherence. In summary, this work sets the stage to create new opportunities for sexually transmitted HIV prevention through the development of a novel dual targeting delivery system. The developed approaches can be used to deliver other drugs that lack solubility or require lymphatic targeting. Article	2015	Goparaju, Lakshmi; Experton, Laure S.; Praschan, Nathan C.; Warren-Jeanpiere, Lari; Young, Mary A.; Kassaye, Seble	Women want Pre-Exposure Prophylaxis but are Advised Against it by Their HIV-positive Counterparts.	Journal of AIDS & Clinical Research	-	-	-	2155-6113	10.4172/2155-6113.1000522	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4807623	OBJECTIVES: The latest advancement in HIV prevention, Pre-Exposure Prophylaxis (PrEP), could reduce incidence among women. However, PrEP uptake has remained low among US women since its approval in 2012, while use has increased among men who have sex with men. This study addresses women's knowledge, attitudes and potential behaviors regarding PrEP. While HIV-negative women are the potential users of antiretroviral (ARV) medications for PrEP, HIV-positive women who have used ARVs could contribute immensely to our understanding of the complexities related to taking such medications. This study is the first to synthesize the opinions of both groups of women. METHODS: We conducted eight focus group discussions, segregated by sero-status; four with at-risk HIV-negative (20) and four with HIV-positive (19) women in Washington DC during 2014. Topics discussed include PrEP awareness, likelihood of use, barriers and target populations. RESULTS: PrEP awareness was almost non-existent and the HIV-negative women urged publicity. They expressed much enthusiasm about PrEP and wanted to use and recommend it to others despite recognizing potential complexities related to taking PrEP, such as side effects, access, duration and frequency of use. HIV-positive women were less supportive of PrEP for those same reasons based on their experience with taking ARVs. They preferred condoms over PrEP given relative efficacy, affordability, accessibility, and prevention of other STIs. CONCLUSIONS: There is an urgent need for PrEP public health campaigns catered to the needs and concerns of women, most importantly bolster their awareness of PrEP. Article	2015	Grangeiro, Alexandre; Couto, Márcia Thereza; Peres, Maria Fernanda; Luiz, Olinda; Zucchi, Eliana Miura; de Castilho, Euclides Ayres; Estevam, Denize Lotufo; Alencar, Rosa; Wolffenbüttel, Karina; Escuder, Maria Mercedes; Calazans, Gabriela; Ferraz, Dulce; Arruda, Érico; Corrêa, Maria da Gloria; Amaral, Fabiana Rezende; Santos, Juliane Cardoso Villela; Alvarez, Vivian Salles; Kietzmann, Tiago	Pre-exposure and postexposure prophylaxes and the combination HIV prevention methods (The Combine! Study): protocol for a pragmatic clinical trial at public healthcare clinics in Brazil.	BMJ Open	-	-	-	2044-6055	10.1136/bmjopen-2015-009021	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4550731	INTRODUCTION: Few results from programmes based on combination prevention methods are available. We propose to analyse the degree of protection provided by postexposure prophylaxis (PEP) for consensual sexual activity at healthcare clinics, its compensatory effects on sexual behaviour; and the effectiveness of combination prevention methods and pre-exposure prophylaxis (PrEP), compared with exclusively using traditional methods. METHODS AND ANALYSIS: A total of 3200 individuals aged 16 years or older presenting for PEP at 5 sexually transmitted disease (STD)/HIV clinics in 3 regions of Brazil will be allocated to one of two groups: the PEP group-individuals who come to the clinic within 72 h after a sexual exposure and start PEP; and the non-PEP group-individuals who come after 72 h but within 30 days of exposure and do not start PEP. Clinical follow-up will be conducted initially for 6 months and comprise educational interventions based on information and counselling for using prevention methods, including PrEP. In the second study phase, individuals who remain HIV negative will be regrouped according to the reported use of prevention methods and observed for 18 months: only traditional methods; combined methods; and PrEP. Effectiveness will be analysed according to the incidence of HIV, syphilis and hepatitis B and C and protected sexual behaviour. A structured questionnaire will be administered to participants at baseline and every 6 months thereafter. Qualitative methods will be employed to provide a comprehensive understanding of PEP-seeking behaviour, preventive choices and exposure to HIV. ETHICS AND DISSEMINATION: This study will be conducted in accordance with the resolution of the School of Medicine Research Ethics Commission of Universidade de São Paulo (protocol no. 251/14). The databases will be available for specific studies, after management committee approval. Findings will be presented to researchers, health managers and civil society members by means of newspapers, electronic media and scientific journals and meetings. Article	2015	Grant R.M.; Smith D.K.	Integrating antiretroviral strategies for human immunodeficiency virus prevention: Post- and pre-exposure prophylaxis and early treatment	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/ofid/ofv126	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85014288455&doi=10.1093%2fofid%2fofv126&partnerID=40&md5=78ec4228fbf114be29fac23c0cd1c753	Best practices for integrating human immunodeficiency virus (HIV) testing and antiretroviral interventions for prevention and treatment are suggested based on research evidence and existing normative guidance. The goal is to provide high-impact prevention services during periods of substantial risk. Antiretroviral medications are recommended for postexposure prophylaxis (PEP), pre-exposure prophylaxis (PrEP), and treatment of HIV infection. We reviewed research evidence and current normative guidelines to identify best practices for integrating these high-impact prevention strategies. More sensitive HIV tests used for screening enable earlier diagnosis and treatment of HIV infection, more appropriate counseling, and help limit drug resistance. A fully suppressive PEP regimen should be initiated based on exposure history or physical findings when sensitive diagnostic testing is delayed or not available and antibody tests are negative. Transitions from PEP to PrEP are often warranted because HIV exposure events may continue to occur. This algorithmic approach to integrating PEP, PrEP, and early treatment decisions may increase the uptake of these interventions by a greater number and diversity of knowledgeable healthcare providers. © The Author 2015. Article	2015	Grov, Christian; Whitfield, Thomas H; F; Rendina, H Jonathon; Ventuneac, Ana; Parsons, Jeffrey T	Willingness to Take PrEP and Potential for Risk Compensation Among Highly Sexually Active Gay and Bisexual Men	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-015-1030-1	https://www.proquest.com/scholarly-journals/willingness-take-prep-potential-risk-compensation/docview/1722696012/se-2?accountid=8113	Once-daily Truvada (Emtricitabine/Tenofovir) as a method of pre-exposure prophylaxis (PrEP) is one of the most promising biomedical interventions to eliminate new HIV infections; however, uptake among gay, bisexual, and other men who have sex with men has been slow amidst growing concern in popular/social media that PrEP use will result in reduced condom use (i.e., risk compensation). We investigated demographic, behavioral, and psychosocial differences in willingness to use PrEP as well as the perceived impact of PrEP on participants' condom use in a sample of 206 highly sexually active HIV-negative gay and bisexual men. Nearly half (46.1 %) said they would be willing to take PrEP if it were provided at no cost. Although men willing to take PrEP (vs. others) reported similar numbers of recent casual male partners (<6 weeks), they had higher odds of recent receptive condomless anal sex (CAS)--i.e., those already at high risk of contracting HIV were more willing to take PrEP. Neither age, race/ethnicity, nor income were associated with willingness to take PrEP, suggesting equal acceptability among subpopulations that are experiencing disparities in HIV incidence. There was limited evidence to suggest men would risk compensate. Only 10 % of men who had not engaged in recent CAS felt that PrEP would result in them starting to have CAS. Men who had not tested for HIV recently were also significantly more likely than others to indicate willingness to take PrEP. Offering PrEP to men who test infrequently may serve to engage them more in routine HIV/STI testing and create a continued dialogue around sexual health between patient and provider in order to prevent HIV infection. Article	2015	Guanira J.V.; Leigler T.; Kallas E.; Schechter M.; Sharma U.; Glidden D.; Grant R.M.	Streamlining HIV Testing for HIV Preexposure Prophylaxis	Journal of Clinical Microbiology	-	-	-	951137	10.1128/JCM.01540-14	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84919495524&doi=10.1128%2fJCM.01540-14&partnerID=40&md5=0ae6a52279a3af488f0e085e7d781ffa	HIV-testing algorithms for preexposure prophylaxis (PrEP) should be optimized to minimize the risk of drug resistance, the time off PrEP required to evaluate false-positive screening results, and costs and to expedite the start of therapy for those confirmed to be infected. HIV rapid tests (RTs) for anti-HIV antibodies provide results in less than 1 h and can be conducted by nonlicensed staff at the point of care. In many regions, Western blot (WB) testing is required to confirm reactive RT results.WBtesting, however, causes delays in diagnosis and adds expense. The iPrEx study evaluated the safety and efficacy of daily oral emtricitabine-tenofovir disoproxil fumarate among HIV-seronegative men and transgender women who have sex with men: HIV infection was assessed with two RTs plusWB confirmation, followed by HIV-1 plasma viral load testing. During the iPrEx study, there were 51,260 HIV status evaluations among 2,499 volunteers using RTs: 142 (0.28%) had concordant positive results (100% were eventually confirmed) and 19 (0.04%) had discordant results among 14 participants; 11 were eventually determined to be HIV infected. A streamlined approach using only one RT to screen and a second RT to confirm (without WB) would have had nearly the same accuracy. Discrepant RT results are best evaluated with nucleic acid testing, which would also increase sensitivity. Copyright © 2015, American Society for Microbiology. All Rights Reserved. Article	2015	Guédou, FA; Béhanzin, L; Geraldo, N; Mastétsé, EG; Singbo, N; Sossa, JC; Zannou, MD; Alary, M	EARLY ANTIRETROVIRAL THERAPY AND PRE-EXPOSURE PROPHYLAXIS FOR HIV PREVENTION AMONG FEMALE SEX WORKERS IN COTONOU, BENIN: EARLY FOLLOW-UP AND ADHERENCE DATA	Sexually Transmitted Infections	-	-	-	1368-4973	10.1136/sextrans-2015-052270.629	https://www.researchgate.net/publication/305225586_P1806_Early_antiretroviral_therapy_and_pre-exposure_prophylaxis_for_hiv_prevention_among_female_sex_workers_in_cotonou_benin_early_follow-up_and_adherence_data	Introduction To assess the feasibility and usefulness of integrating treatment as prevention (TasP) and pre-exposure prophylaxis (PrEP) with Truvada® to the combination prevention package offered to female sex workers (FSWs) in Cotonou, we are currently carrying out a demonstration project on these two HIV preventive strategies among FSWs. Methods We are currently recruiting 100 HIV-infected FSWs for TasP and 250 HIV-negative FSWs for PrEP (one-year recruitment period, followed by an additional one year of follow-up). The actual recruitment visit is preceded by a screening visit two weeks earlier in order to determine the HIV status and assess other eligibility criteria. Through follow-up visits at day 14 and then quarterly, we closely monitor treatment adherence, using various tools including a pill count strategy. For the latter, we ask participants to bring in their bottles of medication at each visit. We report here on the first five months of the clinical phase of the study. Results From 18th september 2014 to 28th February 2015, we screened 154 FSWs and out of them, 85 and 34 were recruited in the PrEP and TasP arms, respectively. Median age of the participants was 34 years and 38% were from Benin, whereas the other were from surrounding countries. To 28th February, the overall retention rate in the study was 100% for TasP and 85% for PrEP. Most drop-outs were due to mobility and leaving the sex trade. Adherence to PrEP was 84% according to pill count. Conclusion The retention rate in the study is encouraging so far. Adherence levels, although estimated through a simple method that could lead to overestimation, could be improved and a multi-faceted adherence-to-education program is now implemented. The availability of Truvada® blood levels will allow an objective assessment of adherence, a highly crucial parameter for the success of eventual PrEP programs. Disclosure of interest statement This study is funded by the Bill and Melinda Gates Foundation, and Truvada® for pre-exposure prophylaxis is provided free of charge by Gilead Sciences, Inc. Article	2015	Gunawardana, Manjula; Remedios-Chan, Mariana; Miller, Christine S.; Fanter, Rob; Yang, Flora; Marzinke, Mark A.; Hendrix, Craig W.; Beliveau, Martin; Moss, John A.; Smith, Thomas J.; Baum, Marc M.	Pharmacokinetics of long-acting tenofovir alafenamide (GS-7340) subdermal implant for HIV prophylaxis.	Antimicrobial Agents and Chemotherapy	-	-	-	1098-6596 0066-4804	10.1128/AAC.00656-15	https://pubmed.ncbi.nlm.nih.gov/25896688/	Oral or topical daily administration of antiretroviral (ARV) drugs to HIV-1-negative individuals in vulnerable populations is a promising strategy for HIV-1 prevention. Adherence to the dosing regimen has emerged as a critical factor determining efficacy outcomes of clinical trials. Because adherence to therapy is inversely related to the dosing period, sustained-release or long-acting ARV formulations hold significant promise for increasing the effectiveness of HIV-1 preexposure prophylaxis (PrEP) by reducing dosing frequency. A novel, subdermal implant delivering the potent prodrug tenofovir alafenamide (TAF) with controlled, sustained, zero-order (linear) release characteristics is described. A candidate device delivering TAF at 0.92 mg day(-1) in vitro was evaluated in beagle dogs over 40 days for pharmacokinetics and preliminary safety. No adverse events related to treatment with the test article were noted during the course of the study, and no significant, unusual abnormalities were observed. The implant maintained a low systemic exposure to TAF (median, 0.85 ng ml(-1); interquartile range IQR, 0.60 to 1.50 ng ml(-1)) and tenofovir (TFV; median, 15.0 ng ml(-1); IQR, 8.8 to 23.3 ng ml(-1)), the product of in vivo TAF hydrolysis. High concentrations (median, 512 fmol/10(6) cells over the first 35 days) of the pharmacologically active metabolite, TFV diphosphate, were observed in peripheral blood mononuclear cells at levels over 30 times higher than those associated with HIV-1 PrEP efficacy in humans. Our report on the first sustained-release nucleoside reverse transcriptase inhibitor (NRTI) for systemic delivery demonstrates a successful proof of principle and holds significant promise as a candidate for HIV-1 prophylaxis in vulnerable populations. Essay	2015	Haberer, Jessica E; Bangsberg, David R; Baeten, Jared M; Curran, Kathryn; Koechlin, Florence; Amico, K Rivet; Anderson, Peter; Mugo, Nelly; Venter, Francois; Goicochea, Pedro; Caceres, Carlos; O'Reilly, Kevin	Defining success with HIV pre-exposure prophylaxis: a prevention-effective adherence paradigm.	AIDS	-	-	-	1473-5571	10.1097/QAD.0000000000000647	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4480436	Clinical trial data have shown that oral pre-exposure prophylaxis (PrEP) is efficacious when taken as prescribed; however, PrEP adherence is complex and must be understood within the context of variable risk for HIV infection and use of other HIV prevention methods. Different levels of adherence may be needed in different populations to achieve HIV prevention, and the optimal methods for achieving the necessary adherence for both individual and public health benefits are unknown. Guidance for PrEP use must consider these questions to determine the success of PrEP-based HIV prevention programs. In this article, we propose a new paradigm for understanding and measuring PrEP adherence, termed prevention-effective adherence, which incorporates dynamic HIV acquisition risk behaviors and the use of HIV alternative prevention strategies. We discuss the need for daily PrEP use only during periods of risk for HIV exposure, describe key issues for measuring and understanding relevant behaviors, review lessons from another health prevention field (i.e., family planning), and provide guidance for prevention-effective PrEP use. Moreover, we challenge emerging calls for sustained, near perfect PrEP adherence regardless of risk exposure and offer a more practical and public health-focused vision for this prevention intervention.	pre-exposure prophylaxis, PrEP, adherence	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Other
Article	2015	Haire, Bridget	It's Time: The Case for PrEP as an Active Comparator in HIV Biomedical Prevention Trials	Journal of Bioethical Inquiry	-	-	-	11767529	10.1007/s11673-014-9565-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84930081890&doi=10.1007%2fs11673-014-9565-9&partnerID=40&md5=366bbca69f016d33c3e6740000a71b4a	In July 2012, based on evidence from two major trials, the United States Food and Drug Administration approved the use of combined oral tenofovir/emtricitabine as pre-exposure prophylaxis (PrEP) for people at high risk of HIV acquisition. PrEP effectiveness is marred by poor adherence, however, even in trial populations, thus it is not a magic bullet for HIV prevention. It is, however, the most effective biomedical HIV prevention intervention available for people at high risk of HIV, particularly those who have receptive sex and lack the power to negotiate condom use. Accordingly, there are compelling reasons to compare future experimental HIV prevention interventions against PrEP. The interests both of trial participants and of science are served by using PrEP as comparator: Not only would HIV incidence be reduced, but also the question of whether new interventions were superior to best proven interventions, in a given setting, would be answered comprehensively. © 2014, Journal of Bioethical Inquiry Pty Ltd. Article	2015	Haire, Bridget G	Preexposure prophylaxis-related stigma: Strategies to improve uptake and adherence –a narrative review	HIV/AIDS - Research and Palliative Care	-	-	-	11791373	10.2147/HIV.S72419	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84944446908&doi=10.2147%2fHIV.S72419&partnerID=40&md5=24955666653051d357f1ae6e939b24da	Despite high levels of efficacy, the implementation of preexposure prophylaxis (PrEP) as a strategy to prevent new HIV infection has been slow. Studies show that PrEP works so long as it is taken, making adherence one of the great challenges of effective PrEP implementation alongside issues of access and uptake. Given that effective PrEP use requires ongoing self-administration of pills by people at high risk of HIV acquisition, it is a strategy best understood not as simply biomedical, but as biobehavioral or biopsychosocial, meaning that that social, psychological, cultural, and structural factors all contribute to the success or failure of the intervention. The willingness of people at risk of HIV to take up and adhere to PrEP depends greatly upon social understandings – whether it is seen as effective, as a healthy option, and a socially acceptable strategy for preventing HIV. Stigma – unfavorable associations – can negatively influence the implementation of PrEP. Because it is associated with high-risk sexual activity, PrEP risks multiple stigmas that can differ according to specific cultural conditions. This includes the stigma of being related to HIV (which may also relate to other stigmas, such as homosexuality, sex work, and/or drug use) and the stigma of PrEP being an alternative to condoms (as condom use is associated with responsible sexual activity). PrEP-related stigma has emerged as a significant social harm that can arise from PrEP research participation, reported by trial participants from a range of different trial sites, different trial populations, and spanning different continents. Social marketing needs to redress PrEP-related stigmas through health promotion campaigns aimed at clinicians, HIV-affected communities, and people at high risk of HIV who might benefit from PrEP access. PrEP access needs to be reframed as a positive and responsible option to help people remain HIV-negative. © 2015 Haire. Theses and Dissertations	2015	Hale, Stephanne P.; Parker, Kimberly	Examining psychosocial factors and intent to use prep as an HIV prevention strategy among African American women in the southern United States	-	-	TEXAS WOMAN'S UNIVERSITY	-	NA	NA	https://www.proquest.com/dissertations-theses/examining-psychosocial-factors-intent-use-prep-as/docview/1762584401/se-2?accountid=8113	HIV/AIDS rates continue to be worst among African Americans (AA) compared to other racial and ethnic groups. In particular, African American women are more impacted than any other group. The primary mode of transmission among AA women is high risk heterosexual contact. In 2010, AA women accounted for 87 percent of new HIV infections from heterosexual sex (Centers for Disease Control and Prevention CDC, 2012). Since the discovery of the epidemic in the United States, HIV prevention strategies have been implemented with documented success. Programs such as increasing awareness about HIV/AIDS, proper and consistent condom use, and decreasing high risk sexual behaviors have all been proven effective in decreasing HIV transmission. However, that success has not been realized among AA women. Literature suggests that a major reason for increased HIV rates within the AA female population is the impact of psychosocial factors and low HIV risk perception. AA women do not perceive themselves to be at increased risk for contracting HIV. This low perception of risk can lead to a false sense of security and a decreased belief that protection from HIV is required. Therefore, in an effort to develop future HIV prevention programs that would be effective among AA females, it is critical that psychosocial factors, such as perceived risks, and the impact they have on sexual health and sexual decision making are understood. Article	2015	Hallal R.C.; Raxach J.C.; Barcellos N.T.; Maksud I.	Strategies to prevent HIV transmission to serodiscordant couples; Estratégias de prevenção da transmissão do HIV para casais sorodiscordantes	Revista Brasileira de Epidemiologia	-	-	-	1415790X	10.1590/1809-4503201500050013	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946826851&doi=10.1590%2f1809-4503201500050013&partnerID=40&md5=17cb487749e6deba6b154767aeb6b2bf	Introduction: The use antiretroviral reduces the sexual transmission of HIV, expanding interventions for serodiscordant couples. Objective: This article aims to review the use of antiretroviral and other prevention interventions among serodiscordant couples and to analyze its use in Brazil. Methods: A retrospective review was performed through the MEDLINE database and bases included in the Biblioteca Virtual em Saúde. Results: The articles recovered exhibit four main strategies: (1) condom; (2) reduction of risks in sexual practices; (3) use of antiretrovirals, particularly early initiation of antiretroviral therapy (TASP) and pre-exposure prophylaxis (PrEP); (4) risk reduction in reproduction. Discussion: TASP is highly effective in reducing sexual transmission, PrEP was tested in serodiscordant couples and both reduce the sexual transmission risk in different sexual practices, enabling individualized prevention strategies. Conclusions: When used correctly, antiretroviral and sexual practices with condoms offer greater efficacy than any single strategy. The combined use of new and old strategies allows us to build a prevention policy for all. © 2015, Assocaicao Brasileira de Pos, Gradacao em Saude Coletiva. All rights reserved. Article	2015	Hankins, Catherine; Macklin, Ruth; Warren, Mitchell	Translating PrEP effectiveness into public health impact: Key considerations for decision-makers on cost-effectiveness, price, regulatory issues, distributive justice and advocacy for access	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.18.4.19973	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84938222060&doi=10.7448%2fIAS.18.4.19973&partnerID=40&md5=02d1b208c70621b7f001a186bd0819ed	Introduction: The extraordinary feat of proving the effectiveness of oral pre-exposure prophylaxis (PrEP) in clinical trials in different populations in a variety of settings may prove to have been easier than ensuring it is used well. Decision-makers must make difficult choices to realize the promise of antiretroviral prophylaxis for their countries. This paper outlines key economic, regulatory and distributive justice issues that must be addressed for effective and acceptable PrEP implementation. Discussion: In considering the role that PrEP can play in combination prevention programmes, decision-makers must determine who can benefit most from PrEP, how PrEP can be provided safely and efficiently, and what kind of health system support will ensure successful implementation. To do this, they need contextualized information on disease burden by population, analyses of how PrEP services might best be delivered, and projections of the human resource and infrastructure requirements for each potential delivery model. There are cost considerations, varying cost-effectiveness results and regulatory challenges. The principles of ethics can inform thorny discussions about who should be prioritized for oral PrEP and how best to introduce it fairly. We describe the cost-effectiveness of PrEP in different populations at higher risk of HIV exposure, its price in low- and middle-income countries, and the current regulatory situation. We explore the principles of ethics that can inform resource allocation decision-making about PrEP anchored in distributive justice, at a time when universal access to antiretroviral treatment remains to be assured. We then highlight the role of advocacy in moving the PrEP agenda forward. Conclusions: The time is ripe now for decisions about whether, how and for whom PrEP should be introduced into a country's HIV response. It has the potential to contribute significantly to high impact HIV prevention if it is tailored to those who can most benefit from it and if current regulatory and pricing barriers can be overcome. Advocacy at all levels can help inform decisionmaking and push the access agenda to avert HIV infections among those at highest risk of HIV exposure. The benefits will accrue beyond the individual level to slow HIV transmission at the population level. © 2015 Hankins C et al; licensee International AIDS Society. Article	2015	Harrison, Abigail; Colvin, Christopher J.; Kuo, Caroline; Swartz, Alison; Lurie, Mark	Sustained High HIV Incidence in Young Women in Southern Africa: Social, Behavioral, and Structural Factors and Emerging Intervention Approaches.	Current HIV/AIDS Reports	-	-	-	1548-3576	10.1007/s11904-015-0261-0	https://pubmed.ncbi.nlm.nih.gov/25855338/	Young women in southern Africa experience some of the highest incidence rates of HIV infection in the world. Across southern Africa, HIV prevalence among women increases rapidly between the teenage years and young adulthood. Adult HIV prevalence is 16.8 % in South Africa, 23 % in Botswana, 23 % in Lesotho, and 26.5 % in Swaziland. Existing research has illuminated some of the key social, behavioral, and structural factors associated with young women's disproportionate HIV risk, including gendered social norms that advantage male power in sexual relationships and age disparities in relationships between younger women and older male partners. Important structural factors include the region's history of labor migration and legacy of family disruption, and entrenched social and economic inequalities. New interventions are emerging to address these high levels of HIV risk in the key population of young women, including structural interventions, biomedical prevention such as PrEP, and combined HIV prevention approaches. Article	2015	Hartmann M.; Montgomery E.; Stadler J.; Laborde N.; Magazi B.; Mathebula F.; van der Straten A.	Negotiating the use of female-initiated HIV prevention methods in a context of gender-based violence: The narrative of rape	Culture, Health & Sexuality	-	-	-	-	13691058	10.1080/13691058.2015.1101786	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946601234&doi=10.1080%2f13691058.2015.1101786&partnerID=40&md5=04b002e350255d513b9a6187636a782c	Female-initiated methods of HIV prevention are needed to address barriers to HIV prevention rooted in gender inequalities. Understanding the sociocultural context of pre-exposure prophylaxis (PrEP) trials, including gender-based violence, is thus critical. MTN- 003C (VOICE-C), a qualitative sub-study of the larger MTN-003 (VOICE) trial, examined sociocultural barriers and facilitators to PrEP amongst women in Johannesburg. We conducted focus-group discussions, in-depth interviews and ethnographic interviews with 102 trial participants, 22 male partners, 17 community advisory board members and 23 community stakeholders. We analysed how discussions of rape are emblematic of the gendered context in which HIV risk occurs. Rape emerged spontaneously in half of discussions with community advisory board members, two-thirds with stakeholders and among one-fifth of interviews/discussions with trial participants. Rape was used to reframe HIV risk as external to women's or partner's behaviour and to justify the importance of PrEP. Our research illustrates how women, in contexts of high levels of sexual violence, may use existing gender inequalities to negotiate PrEP use. This suggests that future interventions should simultaneously address harmful gender attitudes, as well as equip women with alternative means to negotiate product use, in order to more effectively empower women to protect themselves from HIV. © 2015 Taylor & Francis. Theses and Dissertations	2015	Hiruy, Hiwot	Utility of Quantitative Analysis in Drug Development and Optimization of Anti-Infective Therapy	-	-	-	Johns Hopkins University	-	NA	NA	http://jhir.library.jhu.edu/handle/1774.2/39654	The cornerstone of anti-infective therapy is attainment of the effective target concentration of the drug at the site of infection; achieving this goal requires integration of the pharmacokinetic and pharmacodynamics properties of the anti-infective drug. In this interplay, systemic and local quantitative analysis of the drug plays an integral part in providing information about the pharmacokinetic and pharmacodynamic properties of the anti-infective; this information is critical for drug development as well as evaluation of adequacy of established therapies. In this thesis, we will demonstrate the role of systemic and local quantitative analysis in the development of preventative strategies for HIV and also, the role of quantitative analysis in assessing adequacy of therapy in pediatric tuberculosis (TB). The projects in this thesis highlight the various points that are key for successful use of anti-infective drugs. The first two projects, CHARM-01 and CHARM-02, focus on use of anti-infectives for prophylaxis; specifically the development of tenofovir (TFV)-containing gels as locally applied (rectal) microbicides. Since these gels are locally-dosed, there are several factors that have to be considered such as the mucosal safety of the formulations, the ability of the formulations to cover all potentially HIV-exposed mucosa, and the ability to reach the optimal concentration of the active drug, TFV diphosphate (TDF-DP) to prevent HIV infection. In contrast, the PHATISA project looks at systemic (oral) dosing of anti-TB drugs in children for treatment. Children are a unique population in that optimal therapy has to account for the differences in absorption, distribution, metabolism and excretion of xenobiotic in the growing, ever-changing child. For instance, children have a less acidic gastric environment and their gastric motility is slow, which may affect the absorption of drugs. Children, mainly neonates and infants, have different water body composition as compared to older children and adults, which may affect the volume of distribution of drugs. The ontogeny of metabolic enzymes may affect the degree of metabolism that goes on at a specific age, and immaturity of the kidneys will affect the excretion of drugs. Unfortunately, most drug regimens used in children are extrapolated from adult dosing, which does not consider the abovementioned factors that are unique to children9. In the PHATISA study, we sought to evaluate whether a revised WHO-recommendation for TB drugs is able to achieve the presumed optimal concentrations for treatment of TB in children. Because this is a new prevention strategy, we broadly assessed its effects on the mucosa. In MTN-007, a phase-1, randomized, double-blinded rectal microbicide trial, we used systems genomics/proteomics to determine the effect of tenofovir 1% gel, nonoxynol-9 2% gel, placebo gel or no treatment on rectal biopsies (15 subjects/arm). We also treated primary vaginal epithelial cells from four healthy women with tenofovir in vitro. After seven days of administration, tenofovir 1% gel had broad-ranging effects on the rectal mucosa, which were more pronounced than, but different from, those of the detergent nonoxynol-9. Tenofovir suppressed anti-inflammatory mediators, increased T cell densities, caused mitochondrial dysfunction, altered regulatory pathways of cell differentiation and survival, and stimulated epithelial cell proliferation. The breadth of mucosal changes induced by tenofovir indicates that its safety over longer-term topical use should be carefully monitored. Theses and Dissertations	2015	Hoenigl, Martin; Anderson, Christy M; Green, Nella; Mehta, Sanjay R; Smith, Davey M	Repeat HIV-testing is associated with an increase in behavioral risk among men who have sex with men: a cohort study	-	-	-	University of California	-	1741-7015	https://doi.org/10.1186/s12916-015-0458-5	https://escholarship.org/uc/item/4gf1c6c0	BackgroundThe Center for Disease Control and Prevention recommends that high-risk groups, like sexually active men who have sex with men (MSM), receive HIV testing and counseling at least annually. The objective of this study was to investigate the relationship between voluntary repeat HIV testing and sexual risk behavior in MSM receiving rapid serologic and nucleic acid amplification testing.MethodsWe performed a cohort study to analyze reported risk behavior among MSM receiving the "Early Test", a community-based, confidential acute and early HIV infection screening program in San Diego, California, between April 2008 and July 2014. The study included 8,935 MSM receiving 17,333 "Early Tests". A previously published risk behavior score for HIV acquisition in MSM (i.e. Menza score) was chosen as an outcome to assess associations between risk behaviors and number of repeated tests.ResultsAt baseline, repeat-testers (n = 3,202) reported more male partners and more condomless receptive anal intercourse (CRAI) when compared to single-testers (n = 5,405, all P <0.001). In 2,457 repeat testers there was a strong association observed between repeated HIV tests obtained and increased risk behavior, with number of male partners, CRAI with high risk persons, non-injection stimulant drug use, and sexually transmitted infections all increasing between the first and last test. There was also a linear increase of risk (i.e. high Menza scores) with number of tests up to the 17th test. In the multivariable mixed effects model, more HIV tests (OR = 1.18 for each doubling of the number of tests, P <0.001) and younger age (OR = 0.95 per 5-year increase, P = 0.006) had significant associations with high Menza scores.ConclusionsThis study found that the highest risk individuals for acquiring HIV (e.g. candidates for antiretroviral pre-exposure prophylaxis) can be identified by their testing patterns. Future studies should delineate causation versus association to improve prevention messages delivered to repeat testers during HIV testing and counseling sessions. Article	2015	Hoff, Colleen C.; Chakravarty, Deepalika; Bircher, Anja E.; Campbell, Chadwick K.; Grisham, Kirk; Neilands, Torsten B.; Wilson, Patrick A.; Dworkin, Shari	Attitudes Towards PrEP and Anticipated Condom Use Among Concordant HIV-Negative and HIV-Discordant Male Couples.	AIDS Patient Care and STDs	-	-	-	-	1557-7449 1087-2914	10.1089/apc.2014.0315	https://pubmed.ncbi.nlm.nih.gov/26057304/	Since the July 2012 approval by the FDA of emtricitabine/ tenofovir disoproxil fumarate (Truvada) for use as pre-exposure prophylaxis (PrEP) against HIV, its feasibility and acceptability has been under study. HIV-discordant couples are likely targets for PrEP but little is known about how this new prevention tool impacts relationships. We examined, among gay male couples, the acceptability of individual and partner use of PrEP and intentions to use condoms with primary and outside partners in the context of PrEP use. Data are from two independent samples of couples recruited in the San Francisco bay area and New York City-a qualitative one (N=48 couples) between March and November, 2011, and a quantitative one (N=171 couples) between June, 2012 and May, 2013. Data were categorized by couple HIV status and general linear models; chi-square tests of independence were used to examine condom-use intentions with primary and outside partners, by sexual risk profile, and race. Almost half of the HIV-negative couples felt PrEP was a good HIV prevention strategy for themselves and their partner. Over half reported that they would not change their current condom use if they or their partner were taking PrEP. However, approximately 30% of HIV-negative couples reported that they would stop using condoms or use them less with primary and outside partners if they were on PrEP or if their partner was on PrEP. A large percentage of couples view PrEP positively. However, to ensure safety for both partners, future programing must consider those who intend not to use condoms while on PrEP.	*Homosexuality, Male; Adult; Humans; Male; Middle Aged; Risk-Taking; Interviews as Topic; Anti-HIV Agents/administration & dosage; HIV Seropositivity; HIV Seronegativity; Family Characteristics; New York City; *Health Knowledge, Attitudes, Practice; Condoms/*statistics & numerical data; *Pre-Exposure Prophylaxis; Health Surveys; San Francisco; Qualitative Research; Intention; Sexual Partners/*psychology; HIV Infections/ethnology/*prevention & control/psychology; Patient Acceptance of Health Care/ethnology/*psychology; Sexual Behavior/psychology/statistics & numerical data	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Mixed methods
Article	2015	Hoffman R.M.; Jaycocks A.; Vardavas R.; Wagner G.; Lake J.E.; Mindry D.; Currier J.S.; Landovitz R.J.	Benefits of PrEP as an adjunctive method of HIV prevention during attempted conception between HIV-uninfected women and hivinfected male partners	Journal of Infectious Diseases	-	-	-	-	221899	10.1093/infdis/jiv305	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84966315780&doi=10.1093%2finfdis%2fjiv305&partnerID=40&md5=05c8dab03b394982903bdae647f83f0d	Background. Data on effectiveness of preexposure prophylaxis (PrEP) for human immunodeficiency virus (HIV)- uninfected women attempting conception with HIV-infected male partners are limited to observational studies. Methods. To explore the benefits of PrEP for conception, we developed a model to estimate the average annual probability of a woman remaining HIV-uninfected and having a child ("successful" outcome) via condomless sex with an HIV-infected male. The outcome likelihood is dependent upon parameters defining HIV-1 infectivity. We simulated 2 scenarios: optimal (condomless sex acts limited to the ovulation window), and suboptimal (acts not limited to ovulation). Results. In the optimal scenario when the male is on antiretroviral therapy (ART), the average annual probability of the successful outcome is 29.1%, increasing to 29.2%with the addition of PrEP (P = .45). In the suboptimal scenario, the probability is 26.8% with ART alone versus 27.3% with ART/PrEP (P > .0001). Older maternal age reduces the probability of success in both scenarios, particularly after age 30. Conclusions. In our model, PrEP provides little added benefit when the HIV-infected male partner is on ART, condomless sex is limited to the ovulation window, and othermodifiable transmission risks are optimized. Older female age decreases the probability of success by increasing the number of condomless sex acts required for conception. © The Author 2015. Article	2015	Holt M.	Configuring the users of new HIV-prevention technologies: the case of HIV pre-exposure prophylaxis	Culture, Health & Sexuality	-	-	-	-	13691058	10.1080/13691058.2014.960003	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84924497181&doi=10.1080%2f13691058.2014.960003&partnerID=40&md5=09e32069d6042075288b9b7367c6fe03	HIV pre-exposure prophylaxis (PrEP) is a prevention technology that involves prescribing antiretroviral drugs to HIV-negative people to protect them from infection. This paper considers how the development of the technology has necessitated the parallel configuration of its users, and how this process has affected the perception and uptake of the technology. In designing a technology, potential users are typically defined, enabled and constrained, partly to create a target population (or market) for the technology, but also to reassure people that it can be used safely and effectively. This process may or may not be helpful for the uptake and use of the technology. Published research on PrEP indicates that while the technology was under trial, the primary focus was on the 'at-risk' subject in need of PrEP, with little or no consideration of the other qualities necessary for successful use. Post-trial accounts of PrEP have begun to outline desirable qualities of successful PrEP use, such as caution, compliance and being organised. It appears that the PrEP user was only partially configured during the technology's development, and the initial focus on risk has done little to counter fears of the technology, which may partially account for its slow uptake. © 2014, © 2014 Taylor & Francis.	gay and bisexual men; HIV prevention; pre-exposure prophylaxis; users	English	United Kingdom	Western and Central Europe and North America	Australia	Asia and the Pacific	Australia	Asia and the Pacific	Review
Article	2015	Hong, Jennifer N.; Farel, Claire E.; Rahangdale, Lisa	Pharmacologic prevention of human immunodeficiency virus in women: practical approaches for the obstetrician and gynecologist.	Obstetrical & Gynecological Survey	-	-	-	-	1533-9866 0029-7828	10.1097/OGX.0000000000000170	https://journals.lww.com/obgynsurvey/fulltext/2015/04000/pharmacologic_prevention_of_human_immunodeficiency.20.aspx	IMPORTANCE: Obstetricians and gynecologists (Ob-Gyns) play a crucial role in efforts to detect and prevent human immunodeficiency virus (HIV) infection in women. Multiple strategies can be implemented into general practice as part of a comprehensive primary women's health care agenda. Educational and behavioral strategies to reduce HIV acquisition in women can now be supplemented with pharmacologic measures. OBJECTIVE: This article aimed to review the literature regarding preexposure prophylaxis (PrEP) for HIV prevention in women. After reading this article, readers should be able to describe available methods to prevent HIV acquisition in women, select appropriate candidates for PrEP, and outline the steps necessary for initiation of PrEP. EVIDENCE ACQUISITION: A review of the available literature was obtained by a PubMed search of HIV prevention, women, preexposure prophylaxis, and PrEP. Additional information was obtained from the Centers for Disease Control and Prevention; the American Congress of Obstetricians and Gynecologists; and expert opinion in the fields of obstetrics and gynecology, infectious diseases, and reproductive infectious diseases. RESULTS: This review of the literature summarizes the efficacy of PrEP in HIV prevention and identifies limitations and barriers of PrEP. Women who are at risk for HIV acquisition and candidates for PrEP are clearly defined. Certain populations face unique challenges in HIV prevention and the administration of PrEP, and clinical guidelines and references are provided. This article provides a practical guide for the initiation, maintenance, and discontinuation of PrEP for the general Ob-Gyn. CONCLUSIONS: Preexposure prophylaxis is an effective measure to prevent HIV in women. The Ob-Gyn plays a key role in the identification of at-risk women and the initiation of HIV prevention. RELEVANCE: This information is relevant to general Ob-Gyns and other women's health providers. Article	2015	Hope, Thomas J.; Marrazzo, Jeanne M.	A Shot in the Arm for HIV Prevention? Recent Successes and Critical Thresholds.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/aid.2015.0310	https://pubmed.ncbi.nlm.nih.gov/26486613/	Efforts to decrease the spread of HIV worldwide continue at a rapid pace. With the development of new biomedical interventions and findings from pivotal clinical trials, a new framework for short-term and long-term prevention strategies is emerging. It is clear that biomedical-based approaches targeted at the highest risk populations have the greatest potential to have a short-term impact. Unfortunately, challenges with adherence in healthy populations at risk are now well-recognized, and competing health care priorities in the context of fragile delivery infrastructures pose formidable obstacles to implementation. We need better ways to identify high-risk populations, sophisticated understanding of the behavioral parameters that can ensure adherence, and the development of better strategies to provide sustained delivery of preexposure prophylaxis (PrEP). In the long term, we need an effective vaccine--a path that has proven to be rocky. Research facilitating an increased understanding of immune responses and what represents effective responses to prevent HIV acquisition should facilitate progress. While we wait for that time, PrEP offers the best strategy for short-term impact. Article	2015	Hu, Minlu; Patel, Sravan Kumar; Zhou, Tian; Rohan, Lisa C.	Drug transporters in tissues and cells relevant to sexual transmission of HIV: Implications for drug delivery.	Journal of Controlled Release	-	-	-	-	1873-4995 0168-3659	10.1016/j.jconrel.2015.08.018	https://www.sciencedirect.com/science/article/pii/S016836591530064X?via%3Dihub	Efflux and uptake transporters of drugs are key regulators of the pharmacokinetics of many antiretroviral drugs. A growing body of literature has revealed the expression and functionality of multiple transporters in female genital tract (FGT), colorectal tissue, and immune cells. Drug transporters could play a significant role in the efficacy of preventative strategies for HIV-1 acquisition. Pre-exposure prophylaxis (PrEP) is a promising strategy, which utilizes topically (vaginally or rectally), orally or other systemically administered antiretroviral drugs to prevent the sexual transmission of HIV to receptive partners. The drug concentration in the receptive mucosal tissues and target immune cells for HIV is critical for PrEP effectiveness. Hence, there is an emerging interest in utilizing transporter information to explain tissue disposition patterns of PrEP drugs, to interpret inter-individual variability in PrEP drug pharmacokinetics and effectiveness, and to improve tissue drug exposure through modulation of the cervicovaginal, colorectal, or immune cell transporters. In this review, the existing literature on transporter expression, functionality and regulation in the transmission-related tissues and cells is summarized. In addition, the relevance of transporter function for drug delivery and strategies that could exploit transporters for increased drug concentration at target locales is discussed. The overall goal is to facilitate an understanding of drug transporters for PrEP optimization. Article	2015	Idoko J.; Folayan M.O.; Dadem N.Y.; Kolawole G.O.; Anenih J.; Alhassan E.	Why should i take drugs for your infection?: Outcomes of formative research on the use of HIV pre-exposure prophylaxis in Nigeria	BMC Public Health	-	-	-	-	14712458	10.1186/s12889-015-1690-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84928041190&doi=10.1186%2fs12889-015-1690-9&partnerID=40&md5=93ce0bff53d5603991f193f9826674c1	Background: Nigeria has the second highest number of new HIV infections annually. Therefore, it is important to explore new strategies for preventing new infections. The introduction of pre-exposure prophylaxis (PrEP) for use by persons at high risk of HIV infection has new potential in preventing new HIV infections. The aim of this study is to explore the public opinion, community interest, and perceptions about the use and access to PrEP in Nigeria. Methods: This formative study used a mixed method approach to collect data on public opinions and perceptions on appropriate target groups for PrEP access, community interest, perceptions about the use of PrEP as an HIV-prevention tool, how best to communicate with participants about PrEP, concerns about PrEP use by serodiscordant couples, and suggestions for the design and implementation of a PrEP demonstration project. Telephone and in-depth interviews were conducted, and focus group discussions and consultative meetings were held with critical stakeholders engaged in HIV-prevention, treatment, care, and support programmes in Nigeria. An online survey was also conducted. Results: HIV serodiscordant couples were identified as the appropriate target group for PrEP use. Most respondents felt that PrEP use by key affected populations would help reduce the HIV incidence. Stigma was identified as a major concern and a potential barrier for the acceptance and use of PrEP by HIV serodiscordant couples. Electronic and print media were identified as important means for massive public education to prevent stigma and create awareness about PrEP. In a male dominated society such as Nigeria, HIV-negative male partners in serodiscordant relationships may resist enrolment in PrEP programmes. This may be complicated by the fact that the identified index partner in most serodiscordant relationships in Nigeria is an HIV-positive woman, who is often diagnosed during pregnancy. Conclusions: PrEP uptake and use by HIV serodiscordant couples in Nigeria may face notable but surmountable challenges. Much depends on the appropriateness of actions taken by multiple players. Motivation of HIV-negative male partners to use PrEP and establishment of effective public education programmes in addressing stigma are essential. © 2015 Idoko et al.; licensee BioMed Central. Article	2015	Irvin, Risha; Vallabhaneni, Snigdha; Scott, Hyman; Williams, John K.; Wilton, Leo; Li, Xin; Buchbinder, Susan	Examining levels of risk behaviors among black men who have sex with Men (MSM) and the association with HIV acquisition.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0118281	https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0118281	Seroadaptation is defined as the practice of modifying sexual behavior based on one's own HIV serostatus, the perceived HIV serostatus of sexual partners, and differences in risk of HIV transmission by sexual acts. Because this definition implies intent, we use the term "seroprotection" to describe HIV negative participants reporting condomless anal sex (CAS) either exclusively with seronegative partners, or only as the insertive partner with HIV positive or unknown serostatus partners. Little is known about seroprotection in Black men who have sex with men (MSM). We evaluated the independent association of seroprotection and HIV acquisition among the 1144 HIV-negative Black MSM enrolled in HPTN 061 using Cox models; we stratified by city of enrollment, and controlled for number of partners, age, and drug use. Behaviors reported at 0, 6, and 12 months were assigned to three mutually exclusive categories: (1) No CAS; (2) Seroprotection; and (3) CAS without seroprotection. In 2,861 six-month intervals; 28 HIV seroconversions occurred. No CAS was reported at 33.3% of visits, seroprotection at 46.6% of visits, and CAS without seroprotection at 20.1% of visits. The seroconversion rate per 100 person-years for no CAS was 0.98 (95% CI: 0.27, 2.51), compared with 2.39 (95% CI: 1.03, 4.71) and 13.33 (95% CI: 7.62, 21.66) for seroprotection and CAS without seroprotection, respectively. Compared to CAS without seroprotection, intervals without CAS were associated with an 87% reduction (aHR: 0.13, 95% CI: 0.03-0.46) in HIV acquisition and intervals with seroprotection with a 78% reduction (aHR: 0.22, 95% CI: 0.09-0.57). No CAS is the safest behavior to prevent HIV acquisition. Seroprotective behaviors significantly reduced risk, but HIV incidence was still >2/100 person-years, suggesting that additional strategies, such as pre-exposure prophylaxis, are warranted for this population.	*Homosexuality, Male; Adult; Humans; Male; Middle Aged; Young Adult; Prevalence; *Risk-Taking; Black or African American/statistics & numerical data; HIV Infections/epidemiology/*prevention & control/*transmission	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2015	Iwuji, Collins C.; McGrath, Nuala; de Oliveira, Tulio; Porter, Kholoud; Pillay, Deenan; Fisher, Martin; Newport, Melanie; Newell, Marie-Louise	The Art of HIV Elimination: Past and Present Science.	Journal of AIDS & Clinical Research	-	-	-	-	2155-6113	10.4172/2155-6113.1000525	https://pubmed.ncbi.nlm.nih.gov/27774350/	INTRODUCTION: Remarkable strides have been made in controlling the HIV epidemic, although not enough to achieve epidemic control. More recently, interest in biomedical HIV control approaches has increased, but substantial challenges with the HIV cascade of care hinder successful implementation. We summarise all available HIV prevention methods and make recommendations on how to address current challenges. DISCUSSION: In the early days of the epidemic, behavioural approaches to control the HIV dominated, and the few available evidence-based interventions demonstrated to reduce HIV transmission were applied independently from one another. More recently, it has become clear that combination prevention strategies targeted to high transmission geographies and people at most risk of infections are required to achieve epidemic control. Biomedical strategies such as male medical circumcision and antiretroviral therapy for treatment in HIV-positive individuals and as pre-exposure prophylaxis in HIV-negative individuals provide immense promise for the future of HIV control. In resource-rich settings, the threat of HIV treatment optimism resulting in increased sexual risk taking has been observed and there are concerns that as ART roll-out matures in resource-poor settings and the benefits of ART become clearly visible, behavioural disinhibition may also become a challenge in those settings. Unfortunately, an efficacious vaccine, a strategy which could potentially halt the HIV epidemic, remains elusive. CONCLUSION: Combination HIV prevention offers a logical approach to HIV control, although what and how the available options should be combined is contextual. Therefore, knowledge of the local or national drivers of HIV infection is paramount. Problems with the HIV care continuum remain of concern, hindering progress towards the UNAIDS target of 90-90-90 by 2020. Research is needed on combination interventions that address all the steps of the cascade as the steps are not independent of each other. Until these issues are addressed, HIV elimination may remain an unattainable goal. Article	2015	Jain, Sachin; Krakower, Douglas S; Mayer, Kenneth H	The Transition From Postexposure Prophylaxis to Preexposure Prophylaxis: An Emerging Opportunity for Biobehavioral HIV Prevention.	Clinical Infectious Diseases	-	-	-	-	1537-6591	10.1093/cid/civ094	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4492410	Although some individuals who present for antiretroviral postexposure prophylaxis (PEP) had a 1-time exposure to human immunodeficiency virus (HIV), others may be recurrently risky. Given that preexposure prophylaxis (PrEP) has been shown to be efficacious, identification of those individuals who present for PEP who might benefit from PrEP is important to decrease HIV acquisition in high-risk individuals. While inclusion criteria for PrEP have been developed, there is a paucity of data to help clinicians determine which PEP users are at highest risk for HIV acquisition and therefore should be offered PrEP. We will discuss the rationale for using PrEP after PEP use, and will focus on the assessment of PEP users who may benefit from PrEP. Theses and Dissertations	2015	Jenness, Samuel	Stochastic network models for HIV-1 transmission dynamics	-	-	-	University of Washington	-	NA	NA	http://hdl.handle.net/1773/33161	The studies in this dissertation investigate how the structure of dynamically evolving sexual networks shape the HIV-1 epidemic among heterosexuals in Sub-Saharan Africa (SSA). The aims of this project were to: 1) develop a comprehensive set of demographic, behavioral, and biological parameters characterizing the target population of heterosexuals in SSA for use in network-based mathematical models of HIV transmission dynamics; 2) mathematically model the synergistic effects of network structure and male circumcision on HIV transmission in SSA; and 3) use mathematical modeling to estimate the total, direct, and indirect effects of pre-exposure prophylaxis (PreP) on HIV incidence within a simulated randomized control trial (RCT) environment with counterfactual scenarios for threshold levels of network structures that can bias the estimation of treatment efficacy. The heterosexual spread of HIV-1 infection in SSA depends on the unique configurations of how sexually active persons form and break sexual partnerships over time. For disease transmission, individuals are linked in dyads through partnerships, dyads are connected to other dyads when persons have multiple ongoing partnerships, and this forms the larger sexual network within the population. Effective HIV prevention tools, like male circumcision and PreP, operate within this network context. The studies here ask how these interventions, targeted at individuals, function given dynamic networks. Stochastic network models were developed to test key hypotheses for this interaction, aimed both at the population level and within RCT settings. Parameters for these models were primarily drawn from an original retrospective panel study we conducted in Accra, Ghana specifically for mathematical modeling. The findings from these studies address important empirical questions on the relationship between biomedical prevention tools and socio-behavioral risk, and also provide insight into the design and targeting of single-element and combination prevention packages for HIV in high-incidence settings. The broader mathematical modeling methods in this project have many potential applications for future HIV prevention research. Article	2015	Jewell B.L.; Cremin I.; Pickles M.; Celum C.; Baeten J.M.; Delany-Moretlwe S.; Hallett T.B.	Estimating the cost-effectiveness of pre-exposure prophylaxis to reduce HIV-1 and HSV-2 incidence in HIV-serodiscordant couples in South Africa	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0115511	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84921790656&doi=10.1371%2fjournal.pone.0115511&partnerID=40&md5=337e1567d06a2e537de1071c39c8743a	Objective To estimate the cost-effectiveness of daily oral tenofovir-based PrEP, with a protective effect against HSV-2 as well as HIV-1, among HIV-1 serodiscordant couples in South Africa. Methods We incorporated HSV-2 acquisition, transmission, and interaction with HIV-1 into a microsimulation model of heterosexual HIV-1 serodiscordant couples in South Africa, with use of PrEP for the HIV-1 uninfected partner prior to ART initiation for the HIV-1 1infected partner, and for one year thereafter. Results We estimate the cost per disability-adjusted life-year (DALY) averted for two scenarios, one in which PrEP has no effect on reducing HSV-2 acquisition, and one in which there is a 33% reduction. After a twenty-year intervention, the cost per DALY averted is estimated to be $10,383 and $9,757, respectively - a 6% reduction, given the additional benefit of reduced HSV-2 acquisition. If all couples are discordant for both HIV-1 and HSV-2, the cost per DALY averted falls to $1,445, which shows that the impact is limited by HSV-2 concordance in couples. Conclusion After a 20-year PrEP intervention, the cost per DALY averted with a reduction in HSV-2 is estimated to be modestly lower than without any effect, providing an increase of health benefits in addition to HIV-1 prevention at no extra cost. The small degree of the effect is in part due to a high prevalence of HSV-2 infection in HIV-1 serodiscordant couples in South Africa.. © 2015 Jewell et al. Theses and Dissertations	2015	Jewell, Britta	Understanding and optimising HIV prevention and related outcomes among serodiscordant couples in Africa	-	-	-	Imperial College London	-	NA	NA	https://core.ac.uk/download/pdf/144577168.pdf	Daily oral tenofovir-based pre-exposure prophylaxis (PrEP) has recently been shown to be an efficacious HIV prevention strategy for key populations at high risk of acquiring HIV-1, including serodiscordant couples. This thesis addresses the following research question: what is the projected impact and cost-effectiveness of PrEP for serodiscordant couples in sub-Saharan Africa, and would it be a worthwhile intervention? By using statistical analysis and mathematical modelling, I answer this question and provide recommendations for the optimisation of antiretroviral-based HIV prevention this population. In this thesis, I begin by exploring the effect of the reduced risk of herpes simplex virus type 2 (HSV-2) acquisition by means of PrEP on the outcomes of an intervention, but conclude that the supplementary benefit is unlikely to substantially alter the costeffectiveness. I also perform statistical analysis of adherence by electronic monitoring, from the Partners PrEP Study and the Partners Demonstration Project in Kenya and Uganda and find that adherence was high in both settings. Finally, I adapt a microsimulation model of serodiscordant couples in Africa to include realistic PrEP adherence patterns, HIV-1 transmission, external partnerships, and empirical costs. Using this model, I simulate the likely impact and cost-effectiveness of a PrEP intervention according to characteristics and behaviours of couples in the context of a clinical trial and a demonstration project. Overall, I conclude that a PrEP intervention could be cost-effective or cost-saving when targeted to high-risk couples, but is unlikely to be cost-effective if expected incidence is low. In addition, the utility of PrEP for serodiscordant couples could be compromised if the resources needed to find high-risk couples are expensive or if couples are not found easily. Theses and Dissertations	2015	Jhunjhunwala, Kunal	Design and Evaluation of a Topical Rectal Specific Microbicide for HIV prevention	-	-	-	University of Pittsburgh	-	NA	NA	http://d-scholarship.pitt.edu/25845/	According to the UNAIDS report 2013, there were 2.1 million new HIV infections including adults and children. This indicates that apart from the already existing therapeutic ART (Antiretroviral Therapy), there is a need for development of HIV prevention products which can reduce the risk of HIV transmission from person to person. Such products which are referred to as microbicides could be used as a means of pre exposure prophylaxis (PrEP). A vaginal gel containing 1% tenofovir, a nucleotide reverse transcriptase inhibitor (NtRTI), has been evaluated in clinical trials to be used prior to sexual intercourse for prevention of HIV infection. This vaginal gel was also evaluated for rectal use, where it showed negative side effects. However the same gel with reduced amount of glycerin did not show any side effects rectally. Physiologically, the rectum and vagina are very different. Hence, development of rectal specific microbicide products is needed. In addition to gel formulations, such products may also be in the form of a suppository, enemas, foams etc. 1. The design of rectal specific gel and suppository products for tenofovir and its combination is the focus of this thesis work. In addition to tenofovir, other classes of antiretroviral (ARV) drugs such as reverse transcriptase inhibitors, integrase inhibitors (IIs), entry inhibitors, and fusion inhibitors have been evaluated for the development of HIV prevention products 2, 3. Raltegravir, an II, has shown potential to be a drug candidate for HIV preventative topical product given its anti-HIV activity when challenged post product treatment using a macaque model 4. Elvitegravir is a potent analog of raltegravir, which is currently available on the market in the form of a combination ART. Therefore a combination of the NtRTI (tenofovir) and the II (elvitegravir) in the form of a rectal specific gel and a rectal suppository was evaluated in this body of work. Article	2015	Kebaabetswe P.M.; Stirratt M.J.; McLellan-Lemal E.; Henderson F.L.; Gray S.C.; Rose C.E.; Williams T.; Paxton L.A.	Factors Associated with Adherence and Concordance Between Measurement Strategies in an HIV Daily Oral Tenofovir/Emtricitibine as Pre-exposure Prophylaxis (Prep) Clinical Trial, Botswana, 2007–2010	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-014-0891-z	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84928720597&doi=10.1007%2fs10461-014-0891-z&partnerID=40&md5=a2612ff8776a5cd3e9c27dce596b56fd	This study examined study product adherence and its determinants in the Botswana oral pre-exposure prophylaxis efficacy trial. Among the 1,219 participants, the mean adherence by pill count and 3-day self-report was 94 % for each. In multivariable models, pill count adherence was significantly associated with adverse events (nausea, dizziness, vomiting) (RR 0.98 95 % CI 0.98–1.00; p = 0.03) and side effect concerns (RR 0.98 95 % CI 0.96–0.99; p = 0.01). Self-reported adherence was significantly associated with having an HIV-positive partner (RR 1.02 95 % CI 1.00–1.04; p = 0.02) and Francistown residence (RR 0.98 95 % CI 0.96, 0.99; p = 0.0001). Detectable drug concentrations showed modest associations with self-report and pill count adherence, and drug levels were higher among those self-reporting 100 % adherence than those reporting <100 %. Most common adherence barriers involved refill delays and other logistic challenges; cellphone alarm reminder use was the most common facilitator. © 2014, Springer Science+Business Media New York (outside the USA). Article	2015	Kelley C.F.; Kahle E.; Siegler A.; Sanchez T.; Del Rio C.; Sullivan P.S.; Rosenberg E.S.	Applying a PrEP Continuum of Care for Men Who Have Sex with Men in Atlanta, Georgia	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/civ664	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84947740151&doi=10.1093%2fcid%2fciv664&partnerID=40&md5=195fa06f56806a7728a4e6ba8123274b	Reductions in human immunodeficiency virus (HIV) incidence with pre-exposure prophylaxis (PrEP) for men who have sex with men (MSM) will require significant coverage of those at risk. We propose a simplified framework, similar to the HIV care continuum, to achieve protection with PrEP as follows: 1. At-risk MSM; 2. Awareness of and willingness to take PrEP; 3. Access to healthcare; 4. Receiving a prescription; and 5. Adhering to effective PrEP. We evaluated the PrEP care continuum on an Atlanta cohort of MSM and projected how many MSM might achieve protection from HIV. Even with optimistic estimates, few Atlanta MSM (15%) are projected to achieve protection from HIV with PrEP given the significant barriers described. Each continuum step represents an important point for intervention that could substantially increase the overall effectiveness of PrEP. In addition, novel strategies for PrEP delivery are needed to achieve the necessary effectiveness for Atlanta MSM at risk of HIV. © The Author 2015. Article	2015	Kelley, Colleen F.; Vaughan, Adam S.; Luisi, Nicole; Sanchez, Travis H.; Salazar, Laura F.; Frew, Paula M.; Cooper, Hannah L. F.; Diclemente, Ralph; del Rio, Carlos; Sullivan, Patrick S.; Rosenberg, Eli S.	The Effect of High Rates of Bacterial Sexually Transmitted Infections on HIV Incidence in a Cohort of Black and White Men Who Have Sex with Men in Atlanta, Georgia.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/AID.2015.0013	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4458736/	Data reporting sexually transmitted infection (STI) incidence rates among HIV-negative U.S. men who have sex with men (MSM) are lacking. In addition, it is difficult to analyze the effect of STI on HIV acquisition given that sexual risk behaviors confound the relationship between bacterial STIs and incident HIV. The InvolveMENt study was a longitudinal cohort of black and white HIV-negative, sexually active MSM in Atlanta who underwent routine screening for STI and HIV and completed behavioral questionnaires. Age-adjusted incidence rates were calculated for urethral and rectal Chlamydia (CT), gonorrhea (GC), and syphilis, stratified by race. Propensity-score-weighted Cox proportional hazards models were used to estimate the effect of STI on HIV incidence and calculate the population attributable fraction (PAF) for STI. We included 562 HIV-negative MSM with 843 person-years of follow-up in this analysis. High incidence rates were documented for all STIs, particularly among black MSM. Having a rectal STI was significantly associated with subsequent HIV incidence in adjusted analyses (aHR 2.7; 95% CI 1.2, 6.4) that controlled for behavioral risk factors associated with STI and HIV using propensity score weights. The PAF for rectal STI was 14.6 (95% CI 6.8, 31.4). The high incidence of STIs among Atlanta MSM and the association of rectal STI with HIV acquisition after controlling for behavioral risk underscore the importance of routine screening and treatment for STIs among sexually active MSM. Our data support targeting intensive HIV prevention interventions, such as preexposure chemoprophylaxis (PrEP), for Atlanta MSM diagnosed with rectal STIs. Article	2015	Khawcharoenporn T.; Chunloy K.; Apisarnthanarak A.	HIV knowledge, risk perception and pre-exposure prophylaxis interest among Thai university students	International journal of STD & AIDS	-	-	-	-	9564624	10.1177/0956462414564607	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946546998&doi=10.1177%2f0956462414564607&partnerID=40&md5=56710de8f117a651c805d53435f77de8	To assess HIV risk perception and pre-exposure prophylaxis (PrEP) interest among university students, an anonymous survey was conducted among students from a large public university in Thailand. There were 641 participants; 118 (18%) were categorised into moderate or high-risk group. Of these 118 participants, 111 (94%) perceived themselves as no or low risk. Despite high levels of knowledge about HIV transmission risks, rates of consistent condom use with vaginal, oral and anal sex were all low (43%, 18% and 33%, respectively). The low rates of consistent condom use were significantly associated with false perception of low HIV risk (P0.05). Independent factors associated with the false perception were male gender (P0.001), living with a domestic partner (P = 0.004), being homosexual or bisexual (P = 0.02) and being students from a non-medicine faculty (P = 0.04). Of the 641 participants, 211 (33%) were not interested in PrEP. Consistent condom use with oral sex (P = 0.004), consistent condom use with vaginal sex (P = 0.04) and being heterosexual (P = 0.02) were independently associated with no PrEP interest. Our study suggests the need for enhanced interventions to improve HIV risk perception and safe sex practices among the university students. © 2015, © The Author(s) 2015. Article	2015	Kingori P.	When the science fails and the ethics works: Fail-safe ethics in the FEM-PrEP study	Anthropology and Medicine	-	-	-	-	13648470	10.1080/13648470.2015.1081378	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84954390624&doi=10.1080%2f13648470.2015.1081378&partnerID=40&md5=391f44234b5b23186385cdaf828f591d	This paper will explore the concept of fail safe ethics in the FEM PrEP trial, and the practice of research and ethics on the ground. FEM-PrEP examined the efficacy of PrEP in African women after promising outcomes in research conducted with MSM. This was a hugely optimistic time and FEM-PrEP was mobilised using rights-based ethical arguments that women should have access to PrEP.This paper will present data collected during an ethnographic study of frontline research workers involved in FEM-PrEP. During our discussions, fail-safe ethics emerged as concept that encapsulated their confidence that their ethics could not fail. However, in 2011, FEM-PrEP was halted and deemed a failure. The women involved in the study were held responsible because contrary to researcher's expectations they were not taking the oral PrEP being researched.This examination of FEM-PrEP will show that ethical arguments are increasingly deployed to mobilise, maintain and in some cases stop trials in ways which, at times, are superseded or co-opted by other interests. While promoting the interests of women, rights-based approaches are argued to indirectly justify the continuation of individualised, biomedical interventions which have been problematic in other women-centred trials. In this examination of FEM-PrEP, the rights-based approach obscured: ethical concerns beyond access to PrEP; the complexities of power relationships between donor and host countries; the operations of the HIV industry in research-saturated areas and the cumulative effect of unfilled expectations in HIV research and how this has shaped ideas of research and ethics. © 2015 Photograph taken by Patricia Kingori, May 2009. Sexual relationships outside primary partnerships and abstinence are associated with lower adherence and adherence gaps: Data from the partners PrEP ancillary adherence study	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000000538	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84928406386&doi=10.1097%2fQAI.0000000000000538&partnerID=40&md5=c149edecbb274af7b5eb16724833953	Objective: To assess the role of sexual relationships on levels and patterns of adherence to medication for pre-exposure prophylaxis against HIV. Methods: We enrolled 1147 HIV-negative individuals in long-term serodiscordant relationships at 3 sites in Uganda from the Partners Pre-exposure Prophylaxis Study, a randomized placebo-controlled trial of daily oral tenofovir and emtricitabine/tenofovir. We used generalized estimation equations to assess the effects of sexual relationships on low adherence (<80%) and on gaps in adherence. Results: Fifty-three percent were male, 51% were 18-34 years and 24% were polygamous. Participants who reported sex in the past month with someone other than their primary partner and with <100% condom use were more than twice as likely to have low adherence adjusted odds ratio (aOR) = 2.48, 95% CI: 1.70 to 3.62 compared with those who had sex with only their primary partners and 100% condom use. Using the same reference group, those who abstained from sex in the previous month had 30% increased odds of low adherence (aOR = 1.30, 95% CI: 1.05 to 1.62) and participants in nonpolygamous marriages who reported sex with both their primary and other partners and <100% condom use were almost twice as likely to be low adherers (aOR = 1.76, 95% CI: 1.01 to 3.08). At least one 72-hour gap in adherence was seen in 598 participants (54.7%); 23.2% had at least one 1-week gap. Conclusions: Risk of low overall adherence was higher in participants who reported sex outside primary partnerships and suboptimal condom use, as well as in those who abstained from sex. Adherence gaps were common, potentially creating risk for HIV acquisition. Article	2015	Kinuthia, John; Drake, Alison L.; Matemo, Daniel; Richardson, Barbra A.; Zeh, Clement; Osborn, Lusi; Overbaugh, Julie; McClelland, R. Scott; John-Stewart, Grace	HIV acquisition during pregnancy and postpartum is associated with genital infections and partnership characteristics.	AIDS	-	-	-	-	1473-5571 0269-9370	10.1097/QAD.0000000000000793	https://pubmed.ncbi.nlm.nih.gov/26352880/	OBJECTIVE: The objective of this study is to determine the risk and cofactors for HIV acquisition during pregnancy and postpartum. DESIGN: A prospective cohort study METHODS: : Pregnant women in western Kenya were enrolled if HIV seronegative at that visit or within 3 months. Serial HIV nucleic acid amplification tests (NAATs) were conducted at 1 to 3-month intervals to 9 months postpartum. Genital swabs were collected for detection of chlamydia and gonorrhoea at baseline, and for trichomonas, bacterial vaginosis and yeast at baseline and follow-up. RESULTS: Among 1304 pregnant women, median age was 22 years, 78% were married for a median of 4 years, 66% reported knowing partner HIV status and 8% reported using condoms. Study retention was 98%. During 1235 person-years of follow-up, HIV incidence was 2.31/100 person-years 95% confidence interval (95% CI) 0.71-4.10. Incident HIV was associated with syphilis (hazard ratio 9.18, 95% CI 2.15-39.3), chlamydia (hazard ratio 4.49, 95% CI 1.34-15.0), bacterial vaginosis (hazard ratio 2.91, 95% CI 1.25-6.76), yeast (hazard ratio 3.46, 95% CI 1.46-8.19), sexually transmitted infection (STI) history (hazard ratio 3.48, 95% CI 1.31-9.27), lifetime number of sex partners (hazard ratio 1.19, 95% CI 1.02-1.37), partner age discordance (hazard ratio 1.07 per year, 95% CI 1.02-1.13) and shorter marriage (hazard ratio 1.19 per year, 95% CI 1.03-1.38). No women with incident HIV reported an HIV-infected partner. In multivariate analyses, chlamydia, older partners and yeast infection remained significant; however, power was limited. CONCLUSION: Pregnant and lactating women may not perceive HIV risk and rarely used condoms. Prevention and treatment of genital infections and risk stratification to identify women for pre-exposure prophylaxis (PrEP) could decrease HIV acquisition in pregnant/lactating women. Article	2015	Knight, Daniel A.; Jarrett, Diane	Preventive Health Care for Men Who Have Sex with Men.	American Family Physician	-	-	-	-	1532-0650 0002-838X	NA	https://www.aafp.org/pubs/afp/issues/2015/0615/p844.pdf	Men who have sex with men (MSM) comprise at least 4% of males in the United States. MSM may describe themselves as gay, bisexual, or heterosexual. Because current medical practice does not always facilitate discussion of sexual behaviors, this group of men may face barriers to receiving culturally competent, comprehensive health care, including preventive services. Barriers include a lack of a welcoming clinical environment, lack of adequate health insurance, and sexual minority stress. Health issues that have a disproportionate impact on MSM include mental health and behavioral problems, smoking and illicit substance use, and sexually transmitted infections (STIs). Family physicians must be prepared to ask explicit questions about sexual activities to determine risk levels for STIs. MSM should receive the same immunizations routinely recommended for other patients, as well as for hepatitis A and B viruses. Although anal Papanicolaou testing is available to screen for cytologic abnormalities, there are no consistent guidelines about its effectiveness. Preexposure prophylaxis is an option for MSM who are at very high risk of human immunodeficiency virus (HIV) infection. For MSM who are not taking preexposure prophylaxis and report a recent high-risk exposure to HIV, postexposure prophylaxis should be offered immediately, preferably within 72 hours of exposure. Because STIs are commonly asymptomatic, screening should be based on risk rather than symptoms. Screening for hepatitis C virus infection is recommended for HIV-positive MSM at least annually and more often for high-risk individuals.	*Homosexuality, Male; Humans; Male; Smoking; Post-Exposure Prophylaxis; Substance-Related Disorders/complications; Unsafe Sex; Communication; Vaccination; Referral and Consultation; Pre-Exposure Prophylaxis; Cultural Competency; Prejudice; Health Status Disparities; Physician-Patient Relations; *Preventive Health Services; Depression/complications; Medical History Taking; Medically Uninsured; Rectal Diseases/diagnosis; Sexually Transmitted Diseases/complications/prevention & control; Stress, Psychological/etiology	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2015	Koester K.A.; Liu A.; Eden C.; Amico K.R.; McMahan V.; Goicochea P.; Hosek S.; Mayer K.H.; Grant R.M.	Acceptability of drug detection monitoring among participants in an open-label pre-exposure prophylaxis study	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2015.1039958	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84945478758&doi=10.1080%2f09540121.2015.1039958&partnerID=40&md5=eb570a4b812c167785eb3426f09fccb1	In the world of HIV pre-exposure prophylaxis (PrEP) research, there is emerging interest in providing study participants with pharmacokinetic results from drug level testing to guide adherence counseling. The iPrEx randomized control trial was the first study to produce meaningful results of PrEP in humans. In the iPrEx open-label extension (OLE) study, blood plasma samples collected in the first 12 weeks of study participation were tested for the presence of tenofovir/emtricitabine – the drugs which compromise PrEP. Study clinicians shared results (detectable/undetectable) with participants at their 24-week visit. We evaluated the acceptability of receiving these results among a subset of iPrEx OLE participants. We conducted in-depth interviews (n = 59) with participants (those with and those without drug detected) enrolled in Boston, Chicago, and San Francisco to assess their experiences with receiving drug detection feedback. Incorporating drug detection results into the clinical study visit was well received and no negative reactions were expressed. For about half of participants, receiving their drug detection lab result was useful while for others it was not important. In a few cases, no drug detected results led to increased efforts to take PrEP consistently and in most cases enhanced open discussion of missed doses. Participants reported a desire for greater specificity, particularly quantitative drug levels needed for protection. We recommend exploring strategies to increase the salience of drug level results, including using feedback to target adherence counseling, and reducing the time between specimen collection, testing, and receipt of results. Future studies should evaluate the feasibility and impact of providing more specific quantitative drug levels using biomarkers of longer term PrEP exposure, i.e., hair/dried blood spots. © 2015 Taylor & Francis.	adherence; drug detection monitoring; HIV; pre-exposure prophylaxis; qualitative methods	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative

Article	2015	Krakower D.S.; Mayer K.H.	Pre-Exposure Prophylaxis to Prevent HIV Infection: Current Status, Future Opportunities and Challenges	Drugs	-	-	-	-	126667	10.1007/s40265-015-0355-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84925536173&doi=10.1007%2fs40265-015-0355-4&partnerID=40&md5=549c1049d601f66b4dd50b81ece9bb8e	As the global incidence of HIV exceeds 2 million new infections annually, effective interventions to decrease HIV transmission are needed. Randomized, placebo-controlled studies have demonstrated that daily oral antiretroviral pre-exposure prophylaxis (PrEP) with a fixed-dose combination tablet containing tenofovir disoproxil fumarate and emtricitabine can significantly reduce HIV incidence among diverse at-risk populations. In these studies, the efficacy of PrEP was correlated with levels of adherence. Official guidelines recommend provision of PrEP to people at greatest risk of HIV acquisition, and demonstration projects suggest that high levels of uptake and adherence are possible outside of controlled studies. However, several potential barriers to implementing PrEP remain. These challenges include low awareness and utilization of PrEP by at-risk individuals, uncertainty about adherence in 'real-world' settings, the majority of healthcare providers being untrained in PrEP provision, limited data about potential adverse effects from long-term use of tenofovir-emtricitabine, high costs of PrEP medications, and stigma associated with PrEP use and the behaviors that would warrant PrEP. Innovative pharmacologic chemoprophylactic approaches could provide solutions to some of these challenges. Less-than-daily oral dosing regimens and long-acting injectable medications could reduce pill burdens and facilitate adherence, and local delivery of PrEP medications to genital compartments via gels, rings and films may limit systemic drug exposure and potential toxicities. As the portfolio of chemoprophylactic agents and delivery systems expands to meet the diverse sexual health needs and product preferences of individuals who may benefit from PrEP, it is hoped that antiretroviral chemoprophylaxis could become an acceptable, feasible, and highly effective addition to existing HIV prevention strategies. © 2015 Springer International Publishing Switzerland. Article	2015	Krakower D.S.; Oldenburg C.E.; Mitty J.A.; Wilson I.B.; Kurth A.E.; Maloney K.M.; Gallagher D.; Mayer K.H.	Knowledge, beliefs and practices regarding antiretroviral medications for HIV prevention: Results from a survey of healthcare providers in New England	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0132398	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84940094707&doi=10.1371%2fjournal.pone.0132398&partnerID=40&md5=b6f08b492057f257baef865317af848a	Background: Antiretroviral treatment for HIV-infection before immunologic decline (early ART) and preexposure chemoprophylaxis (PrEP) can prevent HIV transmission, but routine adoption of these practices by clinicians has been limited. Methods: Between September and December 2013, healthcare practitioners affiliated with a regional AIDS Education and Training Center in New England were invited to complete online surveys assessing knowledge, beliefs and practices regarding early ART and PrEP. Multivariable models were utilized to determine characteristics associated with prescribing intentions and practices. Results: Surveys were completed by 184 practitioners. Respondent median age was 44 years, 58% were female, and 82% were white. Among ART-prescribing clinicians (61% of the entire sample), 64% were aware that HIV treatment guidelines from the Department of Health and Human Services recommended early ART, and 69% indicated they would prescribe ART to all HIV-infected patients irrespective of immunologic status. However, 77% of ART-prescribing clinicians would defer ART for patients not ready to initiate treatment. Three-fourths of all respondents were aware of guidance from the U.S. Centers for Disease Control and Prevention recommending PrEP provision, 19% had prescribed PrEP, and 58% of clinicians who had not prescribed PrEP anticipated future prescribing. Practitioners expressed theoretical concerns and perceived practical barriers to prescribing early ART and PrEP. Clinicians with higher percentages of HIV-infected patients (aOR 1.16 per 10% increase in proportion of patients with HIV-infection, 95% CI 1.01-1.34) and infectious diseases specialists (versus primary care physicians; aOR 3.32, 95% CI 0.98-11.2) were more likely to report intentions to prescribe early ART. Higher percentage of HIV-infected patients was also associated with having prescribed PrEP (aOR 1.19, 95% CI 1.06-1.34), whereas female gender (aOR 0.26, 95% CI 0.10-0.71) was associated with having not prescribed PrEP. Conclusions: These findings suggest many clinicians have shifted towards routinely recommending early ART, but not PrEP, so interventions to facilitate PrEP provision are needed. © 2015 Krakower et al. Article	2015	Krakower, Douglas S.; Jain, Sachin; Mayer, Kenneth H.	Antiretrovirals for primary HIV prevention: the current status of pre- and post-exposure prophylaxis.	Current HIV/AIDS Reports	-	-	-	-	1548-3576 1548-3568	10.1007/s11904-014-0253-5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4370784/	In light of the 2 million HIV infections that occur globally each year, there is a need to optimize strategies that integrate biomedical and behavioral approaches to HIV prevention. Post-exposure prophylaxis (PEP) immediately after acute high-risk exposures and pre-exposure prophylaxis (PrEP) for those who engage in recurrent high-risk behaviors are promising bio-behavioral approaches to decreasing HIV transmission. Guidelines have recommended PEP for occupational and non-occupational exposures for over 15 years, but uptake of PEP has been limited, partly as a result of insufficient awareness of this intervention among persons at highest risk for acquiring HIV. However, since the publication of large randomized clinical trials demonstrating the efficacy of PrEP, and the dissemination of guidelines endorsing its use, there is a renewed focus on bio-behavioral prevention. Numerous studies have recently assessed the acceptability of bio-behavioral prevention programs among diverse populations or described experiences implementing these programs in "real-world" settings. As research and clinical data informing optimal utilization of PEP and PrEP are rapidly accumulating, this review provides a timely summary of recent progress in bio-behavioral prevention. By contextualizing the most noteworthy recent findings regarding PEP and PrEP, this review seeks to inform the successful implementation of these promising prevention approaches. Article	2015	Kramer, Sarah C.; Drewes, Jochen; Kruspe, Martin; Marcus, Ulrich	Factors associated with sexual risk behaviors with non-steady partners and lack of recent HIV testing among German men who have sex with men in steady relationships: results from a cross-sectional internet survey.	BMC Public Health	-	-	-	-	1471-2458	10.1186/s12889-015-1987-8	https://bmcpublichealth.biomedcentral.com/articles/10.1186/s12889-015-1987-8	BACKGROUND: Recent evidence suggests that the majority of HIV transmissions among men who have sex with men (MSM) occur between steady partners. We sought to determine factors associated with HIV transmission risks in steady partnerships. METHODS: Data is from the German cross-sectional 2013 Gay Men and AIDS survey. The study population was HIV-negative or untested men reporting a steady partnership and at least one non-steady anal sex partner in the previous year. Bivariate and multivariate logistic regression was used to determine which of several independent variables best predicted both unprotected anal intercourse (UAI) with a non-steady partner and lack of HIV testing in the past year (high-risk outcome group). RESULTS: The study population consisted of 1731 men. Among individuals in the outcome group (n = 271), 67% reported UAI with a non-steady partner of unknown status and 9% reported UAI with a non-steady HIV-positive partner in the past 12 months; 55% considered themselves to be at low risk for HIV acquisition. In multivariate analyses (n = 1304), participants were statistically more likely to belong to the outcome group if they reported UAI with their steady partner in the past year (OR = 2.21), did not know their steady partner's HIV status (OR = 1.98), or agreed that condoms were disruptive during sex (OR = 3.82 (strongly agree), OR = 2.19 (agree)). Participants were less likely to belong to the outcome group if they were out to their primary doctor (OR = 0.54), were well-educated about post-exposure prophylaxis (OR = 0.46), had sought information on HIV in the past year and kept condoms in an accessible place (OR = 0.20), or believed that insisting on condoms would lead partners to assume they were HIV-negative (OR = 0.20). Participants in the outcome group were more likely to say they would use HIV home tests (OR = 1.58) or pre-exposure prophylaxis (OR = 2.11). CONCLUSIONS: Based on our results, we reflect on HIV prevention measures that should be improved in order to better target behaviors that may lead to HIV transmission between MSM in steady relationships. In particular, we highlight the need for multifaceted interventions focusing not only on members of the at-risk community themselves, but on communities as a whole. Article	2015	Kubicek K.; Arauz-Cuadra C.; Kipke M.D.	Attitudes and Perceptions of Biomedical HIV Prevention Methods: Voices from Young Men Who Have Sex with Men	Archives of Sexual Behavior	-	-	-	-	40002	10.1007/s10508-014-0398-8	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84925484070&doi=10.1007%2fs10508-014-0398-8&partnerID=40&md5=d23cd455f1191a8883c86a06c6ed05f	In the third decade of the HIV/AIDS epidemic in the United States, the prevalence rates of new HIV infections among young men who have sex with men (YMSM) continue to increase. As new and emerging HIV prevention methods are developed, it is important to understand the perceptions of this vulnerable population—as they may be an ideal target for these intervention methods. This pilot study provides an overview of YMSM of color's awareness and perceptions of pre-exposure prophylaxis (PrEP) and rectal microbicides (RM). A total of 6 focus groups were convened with 53 YMSM (23 Latino/Hispanic and 30 Black/African American). Findings indicate a lack of knowledge of biomedical interventions and high perceived acceptability. Concerns regarding PrEP included potential side effects, potential for misinterpretation of its use and cost. RMs were perceived to be more acceptable than PrEP, but the limited knowledge about their potential was emphasized by YMSM. Results are discussed in relation to the need for providers to continue to provide general health education about safe sexual practices. As PrEP and other biomedical interventions are introduced into community settings, caution should be taken with regards to determining the appropriate target user and sufficient education. © 2015, Springer Science+Business Media New York. Article	2015	Kuchenbecker, Ricardo	What is the benefit of the biomedical and behavioral interventions in preventing HIV transmission?	Revista Brasileira de Epidemiologia	-	-	-	-	1415-790X	10.1590/1809-4503201500050004	http://www.scielosp.org/scielo.php?script=sci_arttext&pid=S1415-790X2015000500026	ABSTRACT Introduction: Scientific evidence supports the sinergy between biomedical and behavioral interventions aimed at preventing the transmission of HIV as a strategy to eradicate AIDS. Objective: To characterize comparatively the benefits from biomedical and behavioral interventions to prevent HIV transmission. Methods: Narrative review. We performed a comparative analysis of the benefits of studied interventions by means of estimating the number needed to treat (NNT). Evaluated interventions: counseling activities for behavior change to prevent exposure to HIV; antiretroviral pre-exposure prophylaxis (PrEP) and antiretroviral post-exposure prophylaxis (PEP) for HIV and treatment of serodiscordant couples as a strategy for prevention of HIV (TasP). Results: counseling interventions and TasP have smaller NNTs, equal to, respectively, 11 (95%CI 9 - 18) at 12 months and 34 (95%CI 23 - 54) in 42 months comparatively to PrEP interventions, that resulted in 41 (95%CI 28 - 67) individuals receiving antiretrovirals in order to prevent one case of HIV infection at 36 months for men and serodiscordant couples. PEP interventions are associated with protective effects estimated at 81%. Lack of trials evaluating PEP prevents estimate of NNT. Conclusion: The estimate of the NNT can be a helpful parameter in the comparison between the effectiveness of different behavioral and biomedical HIV prevention strategies. Studies evaluating the benefit and safety of combined behavioral and biomedical interventions are needed, especially considering the attributable fraction of each component. Integration of behavioral and biomedical interventions is required to achieve complete suppression of the virus, and thus reducing viral replication, infectivity and the number of cases. Article	2015	Kunkel, Amber; Colijn, Caroline; Lipsitch, Marc; Cohen, Ted	How could preventive therapy affect the prevalence of drug resistance? Causes and consequences.	Philosophical Transactions of the Royal Society B: Biological Sciences	-	-	-	-	1471-2970 0962-8436	10.1098/rstb.2014.0306	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4424428/	Various forms of preventive and prophylactic antimicrobial therapies have been proposed to combat HIV (e.g. pre-exposure prophylaxis), tuberculosis (e.g. isoniazid preventive therapy) and malaria (e.g. intermittent preventive treatment). However, the potential population-level effects of preventative therapy (PT) on the prevalence of drug resistance are not well understood. PT can directly affect the rate at which resistance is acquired among those receiving PT. It can also indirectly affect resistance by altering the rate at which resistance is acquired through treatment for active disease and by modifying the level of competition between transmission of drug-resistant and drug-sensitive pathogens. We propose a general mathematical model to explore the ways in which PT can affect the long-term prevalence of drug resistance. Depending on the relative contributions of these three mechanisms, we find that increasing the level of coverage of PT may result in increases, decreases or non-monotonic changes in the overall prevalence of drug resistance. These results demonstrate the complexity of the relationship between PT and drug resistance in the population. Care should be taken when predicting population-level changes in drug resistance from small pilot studies of PT or estimates based solely on its direct effects. Article	2015	Laeyendecker O.; Redd A.D.; Nason M.; Longosz A.F.; Karim Q.A.; Naranbhai V.; Garrett N.; Eshleman S.H.; Abdool Karim S.S.; Quinn T.C.	Antibody maturation in women who acquire HIV infection while using antiretroviral preexposure prophylaxis	Journal of Infectious Diseases	-	-	-	-	221899	10.1093/infdis/jiv110	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84943327425&doi=10.1093%2finfdis%2fjiv110&partnerID=40&md5=b7be79276ea57603b4c7394adebed99a	The CAPRISA 004 preexposure prophylaxis (PrEP) randomized trial demonstrated that women who used a vaginal gel containing the antiretroviral drug tenofovir (TFV) had a 39% lower risk of acquiring human immunodeficiency virus (HIV). It is not known whether topical TFV alters the antibody response to breakthrough HIV infection. In this study, antibody maturation was evaluated using 3 serologic assays: the BED capture enzyme immunoassay (CEIA), the Bio-Plex (Luminex) assay, and the Bio-Rad avidity assay. Tests were performed using serum samples collected 3, 6, 9, 12, 24, 36, 48, and >48 months after seroconversion from 95 women in the CAPRISA 004 trial (35 in the TFV gel arm and 60 in the placebo arm). For the BED CEIA and Luminex assays, linear mixed effects models were used to examine test results by study arm. Cox proportional hazard analysis was used to examine time to avidity cutoff. Anti-HIV antibody titers did not differ between study arms. Women assigned to TFV gel demonstrated slower antibody avidity maturation, as determined by the Bio-Rad (P = .04) and gp120 Bio-Plex (P = .028) assays. Women who were assigned to receive topical TFV but became infected had slower antibody avidity maturation, with potential implications for diagnosis and antibody-based incidence assays as access to antiretroviral therapy-based PrEP is increased. © The Author 2015. Article	2015	Laeyendecker, OB; Redd, AD; Nason, M; Longosz, A; Karim, QA; Naranbhai, V; Garrett, N; Karim, SSA; Quinn, TC	The impact of preexposure prophylaxis on antibody maturation in HIV-infected women	Topics in Antiviral Medicine	-	-	-	-	NA	NA	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01198328/full	Background: The CAPRISA 004 pre-exposure prophylaxis (PrEP) randomized trial demonstrated that women who used a vaginal gel containing the antiretroviral drug Tenofovir (TFV) had a 39% lower chance of acquiring HIV. It is not known if topical TFV alters the antibody response to breakthrough HIV infection, although a previous study of TFV PrEP treated rhesus macaques demonstrated a delay in antibody avidity maturation but not in titer. Methods: Using the BED capture enzyme immune and Bio-Plex assays, anti-HIV antibody titers were measured in stored serum samples collected at 3, 6, 9, 12, 24, 36, 48, and >48 months post-infection from 35 women assigned to TFV gel and 60 assigned to placebo gel, who acquired HIV during the trial. Additionally, anti-HIV antibody avidity maturation was assessed by the Bio-Rad avidity, and Bio-Plex assays. Kaplan Meier survival analysis and log rank test was used to determine differences between treatment arms. The slope and intercepts of the increase of antibody avidity or titer, as determined by the Bio-Plex assay, was compared. A linear mixed effects model was used to examine antibody titer and avidity by treatment group. Cox proportional hazard analysis examined time to avidity cut-off. Results: Anti-HIV antibody titers, by both BED-CEIA and BioPlex assays did not differ between women assigned to TFV gel compared to those assigned to placebo gel. However, women assigned to TFV gel demonstrated slower antibody avidity maturation as determined by the Bio-Rad assay (p=0.04). In the Cox proportional hazard model, after adjustment for CD4 count and viral load, there was a significant reduction in the time to high avidity (HR=0.52, CI=0.32-0.84; p=0.008). For the Bio-Plex assay, there was a statistically significant slower increase in antibody avidity to gp120 (p=0.03) and a trend in gp160 (p=0.06) using a linear mixed effects model. Conclusions: Women assigned to topical TFV had slower antibody avidity maturation, similar to effects previously seen in TFV PrEP treated rhesus macaques. These results may have substantial public health implications for antibody-based incidence measurement as PrEP use increases globally.	*Human immunodeficiency virus; *Retroviridae; *female; *human; *maturation; *opportunistic infection; *prophylaxis; Antibody response; Antibody titer; Arm; Assay; Human immunodeficiency virus infection; Infection; Log rank test; Model; Pre-exposure prophylaxis; Proportional hazards model; Public health; Rhesus monkey; Serum; Survival; Virus load	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	NA	NA	Clinical

Journal of Chromatography B, Analytical Technologies in the Biomedical and Life Sciences	-	-	-	-	1873-376X 1570-0232	10.1016/j.jchromb.2015.08.039	https://www.sciencedirect.com/science/article/abs/pii/S1570023215301677	A specific and reliable HPLC-MS/MS method was developed and validated for the simultaneous determination of 2',3'-dideoxyinosine (ddI) and the active metabolites, 2',3'-dideoxyadenosine-5'-triphosphate (ddA-TP) in human peripheral-blood mononuclear cell for the first time. The analytes were separated on a HILIC column (100mm×2.1mm, 1.7μm) and a triple-quadrupole mass spectrometry equipped with an electrospray ionization (ESI) source was used for detection. The cell homogenates sample was prepared by the solid phase extraction. The calibration curves were linear over a concentration range of 0.5-200.0ng/mL for ddI and 0.25-100.0ng/mL for ddA-TP. The intra-day and inter-day precision was less than 15% and the relative error (RE) were all within ±15%. The validated method was successfully applied to assess the disposition characteristics of ddI and support cell pharmacokinetics after the patients with AIDS were orally administrated with ddI and tenofovir disoproxyl fumarate (TDF). Article	2015	Landovitz R.J.	Preexposure prophylaxis for hiv prevention: What we know and what we still need to know for implementation	Topics in Antiviral Medicine	-	-	-	-	21615861	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84948748021&partnerID=40&md5=36027442386f140de61dd3207c5ea233	Preexposure prophylaxis (PrEP) with tenofovir and emtricitabine has been shown to be effective and cost-effective in preventing acquisition of HIV infection. However, PrEP has not yet been widely adopted in the clinical practice setting. Data thus far, although imperfect, do not indicate an increase in risk behaviors in the setting of PrEP, although potential risk compensation outside of the clinical trial setting should be further examined. Substantial work remains to implement and support PrEP use, including identification of optimal settings for providing and managing PrEP, identification of methods to ensure optimal adherence to treatment, and employment of strategies to deliver PrEP to populations at greatest risk., This article summarizes a presentation made by Raphael J. Landovitz, MD, MSc, at the 2015 Conference on Retroviruses and Opportunistic Infections held from February 23 to February 26 in Seattle, Washington. © 2015, IAS-USA. All rights reserved. Article	2015	Laufer F.N.; O'Connell D.A.; Feldman I.; Zucker H.A.	Vital signs: Increased medicaid prescriptions for preexposure prophylaxis against HIV infection — New York, 2012–2015	MMWR Recommendations and Reports	-	-	-	-	1492195	10.15585/mmwr.mm6446a5	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84951277110&doi=10.15585%2fmmwr.mm6446a5&partnerID=40&md5=968fb6ae4cdd1d5382dd32b4a61efb	Background: Approximately 3,000 incident cases of human immunodeficiency virus (HIV) infection occur in New York state each year. Daily HIV preexposure prophylaxis (PrEP) with the oral antiretroviral medication Truvada is a key component of New York's plan to end HIV/acquired immunodeficiency syndrome (AIDS) as an epidemic in the state by 2020. Methods: Prescription data from the New York state Medicaid program from July 2012 through June 2015 were analyzed with an algorithm using medication and diagnosis codes to identify continuous use of Truvada for > 30 days, after excluding use for postexposure prophylaxis or treatment of HIV or chronic hepatitis B infection. Results: During July 2012–June 2013, a total of 259 persons filled prescriptions for PrEP in the Medicaid program. During July 2013–June 2014, a total of 303 persons filled prescriptions for PrEP. During July 2014–June 2015, a total of 1,330 persons filled prescriptions for PrEP, a substantial increase over the previous 12 months. Across all periods studied, 1,708 Medicaid recipients filled at least one prescription for PrEP, most of whom were New York City (NYC) residents, male, aged < 50 years, and, for those with available data on race, white. Conclusions: PrEP use by Medicaid-insured persons increased substantially in the years following statewide efforts to increase knowledge of PrEP among potential prescribers and candidates for PrEP. Other jurisdictions can follow New York state's example by taking similar steps to remove the financial and knowledge barriers experienced by both potential users and prescribers of PrEP. Implications for Public Health Practice: Although both state and local health department efforts contribute to the availability and use of PrEP, their collaboration enhances the successful implementation of strategies to increase PrEP use. In addition, the decision by the state Medicaid agency to cover PrEP recognizes the long-term benefits of preventing HIV infections. © 2015, Department of Health and Human Services. Article	2015	Lehman, DA; Baeten, JM; McCoy, CO; Weis, JF; Peterson, D; Mbara, G; Donnell, D; Thomas, KK; Hendrix, CW; Marzinke, MA; Frenkel, L; Ndase, P; Mugo, NR; Celum, C; Overbaugh, J; Matsen, FA	Risk of drug resistance among persons acquiring HIV within a randomized clinical trial of single- or dual-agent preexposure prophylaxis	Journal of Infectious Diseases	-	-	-	-	NA	10.1093/infdis/jiu677	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01111098/full	BACKGROUND: Preexposure prophylaxis (PrEP) with emtricitabine plus tenofovir disoproxil fumarate (FTC/TDF) or TDF alone reduces the risk of human immunodeficiency virus (HIV) acquisition. Understanding the risk of antiretroviral resistance selected by PrEP during breakthrough infections is important because of the risk of treatment failure during subsequent antiretroviral use. METHODS: Within the largest randomized trial of FTC/TDF versus TDF as PrEP, plasma samples were tested for HIV with resistance mutations associated with FTC (K65R and M184IV) and TDF (K65R and K70E), using 454 sequencing. RESULTS: Of 121 HIV seroconverters, 25 received FTC/TDF, 38 received TDF, and 58 received placebo. Plasma drug levels in 26 individuals indicated PrEP use during or after HIV acquisition, of which 5 had virus with resistance mutations associated with their PrEP regimen. Among those with PrEP drug detected during infection, resistance was more frequent in the FTC/TDF arm (4 of 7 57%), compared with the TDF arm (1 of 19 5.3%; P = .01), owing to the FTC-associated mutation M184IV. Of these cases, 3 had unrecognized acute infection at PrEP randomization, and 2 were HIV negative at enrollment. CONCLUSIONS: These results suggest that resistance selected by PrEP is rare but can occur both with PrEP initiation during acute seronegative HIV infection and in PrEP breakthrough infections and that FTC is associated with a greater frequency of resistance mutations than TDF. Article	2015	Lépine, Aurélia; Terris-Prestholt, Fern; Vickerman, Peter	Determinants of HIV testing among Nigerian couples: a multilevel modelling approach.	Health Policy and Planning	-	-	-	-	1460-2237 0268-1080	10.1093/heapol/czu036	https://pubmed.ncbi.nlm.nih.gov/24906362/	In this article we analyse the determinants of HIV testing among Nigerian couples using Demographic and Health Survey data set (2008). This study is motivated by the fact that although there is a strong willingness from the Nigerian Government to examine new HIV preventions approaches such as Pre-Exposure Prophylaxis for HIV (PrEP) and Treatment as Prevention (TasP) for HIV serodiscordant couples, the implementation of such policies would require the HIV status of each partner in the couple to be known. This is far to be achieved in the Nigerian context since in Nigeria only 6% of couples know their HIV status. In order to identify potential policies that are needed to increase HIV testing uptake, we use a three-level random intercept logistic model to separately explore the determinants of knowing HIV status among female and male partners. The use of the multilevel modelling allows including the unobserved heterogeneity at the village and state level that may affect HIV testing behaviours. Our results indicate that education, wealth, stigma, HIV knowledge and perceived risk are predictors of HIV testing among both partners while routine provider initiated testing appears to be very effective to increase HIV testing among women. The introduction of financial incentives as well as an increase in routine testing and home-based testing may be needed for large scale increase in HIV testing prior to the implementation of new HIV prevention technologies among discordant couples. Article	2015	Letchumanan M.; Coyte P.C.; Loutfy M.	An economic evaluation of conception strategies for heterosexual serodiscordant couples where the male partner is HIV-positive	Antiviral Therapy	-	-	-	-	13596535	10.3851/IMP2956	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84983380018&doi=10.3851%2fIMP2956&partnerID=40&md5=3be2cc2a6688e2f24612860c5d2411db	Background: To conduct an economic evaluation of the three commonly used interventions that reduce sexual HIV transmission when an HIV-negative female aims to conceive with an HIV-positive male on combination antiretroviral therapy (condomless sex restricted to timed ovulation CS, sperm washing with intrauterine insemination SW and condomless sex restricted to timed ovulation with pre-exposure prophylaxis CS-PrEP). As SW and CS-PrEP are only privately available for pregnancy planning for this population in Canada, this study was conducted to inform policy decisions concerning potential public health insurance coverage, as well as to inform fertility counselling in settings with adequate combination antiretroviral therapy access globally. Methods: We developed a cohort Markov model with a lifetime horizon and used the perspective of Ontario's Ministry of Health (MOH). Input parameters were drawn from literature, the MOH's Schedule of Benefits and a time trade-off questionnaire designed for this study. Outcome measures included quality-adjusted life-years and incremental cost-effectiveness. Costs and benefits were discounted at annual rates of 3%. Costs were reported in Canadian 2013 dollars and an exchange rate of 1 USD to 1.066 CND was applied where necessary. Sensitivity analysis assessed the uncertainty of model parameters. Results: The base case analysis found that CS-PrEP and SW were each more costly and less effective at conception than CS. The results were robust in the sensitivity analysis and suggest that CS is the dominant conception strategy in this population. Conclusions: Neither CS-PrEP nor SW represent better value for money relative to CS as a conception option for HIV-discordant couples with positive male partners. Based on these findings, CS-PrEP and SW cannot be recommended for public-funding in developed countries. © 2015 International Medical Press. Simultaneous Evaluation of Safety, Acceptability, Pericoital Kinetics, and Ex Vivo Pharmacodynamics Comparing Four Rectal Microbicide Vehicle Candidates	AIDS Research and Human Retroviruses	-	-	-	-	8892229	10.1089/aid.2015.0086	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946709487&doi=10.1089%2faid.2015.0086&partnerID=40&md5=dc962334eb5aba23938442b173b719c5	Preexposure prophylaxis (PrEP) of HIV infection with tenofovir-containing regimens is effective, but plagued by poor adherence in some studies. Options for safe, effective, and acceptable PrEP products, especially for men and women at risk of HIV via receptive anal intercourse (RAI), are needed. We performed a randomized, partially blinded, first-in-human evaluation of four candidate rectal microbicide vehicles - aqueous gel, aqueous fluid, lipid gel, and lipid fluid - to select a prototype for further clinical development. Eight seronegative participants received three doses of each product with each dose separated by at least 2 weeks: one dose was given alone without simulated RAI in clinic, another dose was followed by simulated RAI in clinic, and another dose was self-administered at home in the context of RAI with a partner. Assessments included safety, acceptability, colon histology, ex vivo HIV infectivity of colon tissue explants, and colonic luminal distribution of vehicle and HIV surrogates. Adverse events were all mild and mainly sigmoidoscopy associated. There were minor differences in colon distribution of products and little effect of RAI. Vehicle distribution covered 95% (±7% standard deviation) of the distribution of an HIV surrogate in the colonic lumen. The lipid fluid vehicle increased HIV colon tissue infectability 5-fold log10 p24 0.68 (95% confidence interval 0.08, 1.28) and aqueous gel provided 6-fold protection log10 p24 0.80 (95% confidence interval 0.20, 1.41) compared to no product baseline. Colon permeability of lipid vehicles was more than 10-fold greater than aqueous vehicles. All products received similar acceptability ratings, though trends favored the gel products. Intensive simultaneous assessment of safety and toxicity, luminal and tissue distribution, ex vivo HIV infectivity, and product acceptability in relevant sexual contexts provided clear differentiation among candidate gels very early in product development. We selected the aqueous gel for further development as a rectal microbicide vehicle. © Copyright 2015, Mary Ann Liebert, Inc. 2015. Theses and Dissertations	2015	Lippman, Sheri A; Koester, Kimberly A; Amico, K Rivet; Lama, Javier R; Fernandes, Nilo Martinez; Gonzales, Pedro; Grinsztejn, Beatriz; Liu, Al; Buchbinder, Susan	Client and Provider Perspectives on New HIV Prevention Tools for MSM in the Americas	-	-	University of California	University of California	-	1932-6203	https://doi.org/10.1371/journal.pone.0121044	https://escholarship.org/uc/item/6c72r1ng	Men who have sex with men (MSM) in the Americas require targeted, combination HIV prevention approaches. We solicited client and provider perspectives on emerging prevention interventions including HIV pre-exposure prophylaxis (PrEP) and HIV self-tests through focus groups and in-depth interviews with 130 MSM and 41 providers across four sites: New York, San Francisco, Lima, and Rio de Janeiro. Among the MSM participants, we identified three prevention typologies: non-condom users, inconsistent condom users, and consistent condom users. Northern and Southern MSM differed in the variety of harm reduction strategies utilized: where U.S. MSM relied on condom use as well as disclosure and seroadaptive behaviors for prevention, condom use without disclosure or serostatus discussions was the norm in South America. Interest in new prevention technologies was shaped by the social context. U.S. MSM preferences differed by typology, such that non-condom users were interested in taking PrEP and using home HIV tests. MSM in Brazil, regardless of typology, were excited about exploring new prevention options. MSM in Peru demonstrated moderate interest but were less comfortable with adopting new strategies. MSM and providers' opinions differed substantially with respect to new prevention options. Across sites, most providers were reticent to engage with new prevention options, though some NGO-based providers were more supportive of exploring new prevention tools. Both clients and providers will need to be engaged in developing integrated prevention strategies for MSM. Article	2015	Lo Y.-R.; Chu C.; Ananworanich J.; Excler J.-L.; Tucker J.D.	Stakeholder Engagement in HIV Cure Research: Lessons Learned from Other HIV Interventions and the Way Forward	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2014.0348	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84934285482&doi=10.1089%2fapc.2014.0348&partnerID=40&md5=742172bf66508fb49a4b6b0f9abc6c21	Clinical and basic science advances have raised considerable hope for achieving an HIV cure by accelerating research. This research is dominated primarily by issues about the nature and design of current and future clinical trials. Stakeholder engagement for HIV cure remains in its early stages. Our analysis examines timing and mechanisms of historical stakeholder engagement in other HIV research areas for HIV-uninfected individuals vaccine development and pre-exposure prophylaxis (PrEP), and HIV-infected individuals (treatment as prevention, prevention of mother-to-child transmission, and treatment of acute HIV infection) and articulate a plan for HIV cure stakeholder engagement. The experience from HIV vaccine development shows that early engagement of stakeholders helped manage expectations, mitigating the failure of several vaccine trials, while paving the way for subsequent trials. The relatively late engagement of HIV stakeholders in PrEP research may partly explain some of the implementation challenges. The treatment-related stakeholder engagement was strong and community-led from the onset and helped translation from research to implementation. We outline five steps to initiate and sustain stakeholder engagement in HIV cure research and conclude that stakeholder engagement represents a key investment in which stakeholders mutually agree to share knowledge, benefits, and risk of failure. Effective stakeholder engagement prevents misconceptions. As HIV cure research advances from early trials involving subjects with generally favorable prognosis to studies involving greater risk and uncertainty, success may depend on early and deliberate engagement of stakeholders. © Copyright 2015, Mary Ann Liebert, Inc. Article	2015	Looney, David; Ma, Ariel; Johns, Scott	HIV therapy-the state of art.	Current Topics in Microbiology and Immunology	-	-	-	-	0070-217X	10.1007/82_2015_440	https://link.springer.com/chapter/10.1007/82_2015_440	HIV Attachment. In this cross section, HIV is shown at the top and a target cell is shown at the bottom in blues. HIV envelope protein (A) has bound to the receptor CD4 (B) and then to coreceptor CCR5 (C), causing a change in conformation that inserts fusion peptides into the cellular membrane Antiretroviral therapy changed the face of HIV/AIDS from that of soon and certain death to that of a chronic disease in the years following introduction of highly active antiretroviral therapy in 1995-1996 (initially termed HAART, but now most often abbreviated to ART since not all combinations of regimens are equally active). Since then, many new agents have been developed and introduced in response to problems of resistance, toxicity, and tolerability, and great advances have been achieved in accessibility of HIV drugs in resource-poor global regions. Potential challenges that providers of HIV therapy will face in the coming decade include continuing problems with resistance, especially where access to drugs is inconsistent, determining how best to combine new and existing agents, defining the role of preventive treatment (pre-exposure prophylaxis or PrEP), and evaluating the potential of strategies for cure in some populations. Article	2015	Mabileau, Guillaume; Schwarzinger, Michael; Flores, Juan; Patrat, Catherine; Luton, Dominique; Epelboin, Sylvie; Mandelbrot, Laurent; Matheron, Sophie; Yazdanpanah, Yazdan	HIV-serodiscordant couples desiring a child: 'treatment as prevention,' preexposure prophylaxis, or medically assisted procreation?	American Journal of Obstetrics and Gynecology	-	-	-	-	1097-6868	10.1016/j.ajog.2015.05.010	https://dx.doi.org/10.1016/j.ajog.2015.05.010	OBJECTIVE: We sought to assess the residual risk of HIV transmission, cost, and cost-effectiveness of various strategies that can help fertile HIV-uninfected female/HIV-1-infected male on combination antiretroviral therapy with plasma HIV RNA <50 copies/mL couples to have a child: (1) unprotected sexual intercourse (treatment as prevention); (2) treatment as prevention limited to fertile days (targeting fertile days); (3) treatment as prevention with preexposure prophylaxis (tenofovir/emtricitabine); (4) treatment as prevention and preexposure prophylaxis limited to fertile days; or (5) medically assisted procreation (MAP). STUDY DESIGN: This was a model-based, cost-effectiveness analysis performed from a French societal perspective. Input parameters derived from international literature included: 85% probability of live births in different strategies, 0.0083%/mo HIV transmission risk with unprotected vaginal intercourse, 1% HIV mother-to-child transmission rate, and 4.4% birth defect risk related to combination antiretroviral therapy when the mother is infected at conception. Targeting fertile days and preexposure prophylaxis were estimated to decrease the risk of HIV transmission by 80% and 67%, respectively, and by 93.4% for preexposure prophylaxis limited to fertile days assuming to be (1-80%)*(1-67%) = 16.6% in basecase). Tenofovir/emtricitabine monthly cost was set at 540. RESULTS: The HIV transmission risk was highest with treatment as prevention and lowest for MAP (5.4 and 0.0 HIV-infected women/10,000 pregnancies, respectively). Targeting fertile days was more effective than preexposure prophylaxis (0.9 vs 1.8) and associated with lowest costs. Preexposure prophylaxis limited to fertile days was more effective than targeting fertile days (0.3 vs 0.9) with a cost-effectiveness ratio of 1,130,000/life year saved; MAP cost-effectiveness ratio when compared with preexposure prophylaxis limited to fertile days was 3,600,000/life year saved. Results were robust to multiple sensitivity analyses. CONCLUSION: Targeting fertile days is associated with a low risk of HIV transmission in fertile HIV-uninfected female/male with controlled HIV-1 infection couples. The risk is lower with preexposure prophylaxis limited to fertile days, or MAP, but these strategies are associated with unfavorable cost-effectiveness ratios under their current costs.	cost-effectiveness HIV postexposure prophylaxis pregnancy reproductive techniques transmission	English	United States	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Quantitative
Article	2015	Mack N.; Wong C.; McKenna K.; Lemons A.; Odhiambo J.; Agot K.	Human resource challenges to integrating HIV pre-exposure prophylaxis (PrEP) into the public health system in Kenya: A qualitative study	African Journal of Reproductive Health	-	-	-	-	11184841	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84938691811&partnerID=40&md5=9b8aa88582fb3ed257d29611fb5c6cb4	Extensive planning will be necessary to integrate HIV pre-exposure prophylaxis (PrEP) into public health systems. In Bondo and Kisumu, Kenya, we conducted interviews with 16 district and provincial public health stakeholders and held consultations with 18 provincial and 23 national public health stakeholders on topics related to PrEP rollout. We coded interview transcripts and created memos summarizing responses. We documented consultation discussions through note taking. Human resource challenges identified included increased workload and insufficient personnel, the need for task shifting/sharing, training needs, infrastructural requirements, discrimination and stigma by staff towards at-risk clients, and providers' personal priorities about offering PrEP. These challenges paralleled current challenges related to integration of antiretroviral therapy (ART) and could be partially addressed prior to PrEP rollout. The recommendations for training staff are likewise grounded in lessons from ART and have practical application for program planners developing training curricula for PrEP delivery. © 2015, Women's Health and Action Research Centre. Article	2015	Maksud, Ivia; Fernandes, Nilo Martinez; Filgueiras, Sandra Lucia	Technologies for HIV prevention and care: challenges for health services	Revista Brasileira de Epidemiologia	-	-	-	-	1415-790X	10.1590/1809-4503201500050008	http://www.scielosp.org/scielo.php?script=sci_arttext&pid=S1415-790X2015000500104&lang=pt	ABSTRACT This article aims to consider some relevant challenges to the provision of "new prevention technologies" in health services in a scenario where the "advances" in the global response to AIDS control are visible. We take as material for analysis the information currently available on the HIV post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP), treatment as prevention (TASP) and over the counter. The methodology consisted of the survey and analysis of the Biblioteca Virtual em Saúde (BVS: MEDLINE, LILACS, WHOLIS, PAHO, SciELO) articles that addressed the issue of HIV prevention and care in the context of so-called new prevention technologies. The results of the studies show that there is assistance on the ground of clinics for the treatment of disease responses, but there are several challenges related to the sphere of prevention. The articles list some challenges regarding to management, organization of services and the attention given by health professionals to users. The current context shows evidence of the effectiveness of antiretroviral therapy in reducing the risk of HIV transmission, but the challenges for the provision of preventive technologies in health services permeate health professionals and users in their individual dimensions and health services in organizational and structural dimension. Interventions should be made available in a context of community mobilization; there should be no pressure on people to make HIV testing, antiretroviral treatment or for prevention. In the management is responsible for the training of health professionals to inform, clarify and make available to users, partners and family information about the new antiretroviral use strategies. Article	2015	Malahleha M.; Ahmed K.; Deese J.; Nanda K.; Van Damme L.; De Baetselier I.; Burnett R.J.	Hepatitis B virus reactivation or reinfection in a FEM-PrEP participant: A case report	Journal of Medical Case Reports	-	-	-	-	17521947	10.1186/s13256-015-0679-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84942414320&doi=10.1186%2fs13256-015-0679-4&partnerID=40&md5=686b2426b285700d018e8f926a16c48f	Introduction: The FEM-PrEP trial was a pre-exposure prophylaxis clinical trial to test the safety and efficacy of Truvada (tenofovir disoproxil fumarate and emtricitabine) in the prevention of human immunodeficiency virus infection. Because Truvada can suppress hepatitis B virus replication, and withdrawal of Truvada can cause hepatic flares in patients with chronic hepatitis B, pre-enrollment screening included serological screening for hepatitis B virus markers. Women with chronic infections were not enrolled in the trial. Women found to be unprotected against hepatitis B were enrolled and offered three doses of hepatitis B vaccine. Reinfection and reactivation of previously resolved hepatitis B virus infections have been documented in immunosuppressed individuals but not in healthy individuals. We present the case of a participant enrolled in the FEM-PrEP clinical trial with baseline evidence of immunity against hepatitis B virus who subsequently developed acute hepatitis B. Case presentation: A 21-year-old Black non-pregnant woman was enrolled in the FEM-PrEP trial. She was human immunodeficiency virus-negative and a serological test for hepatitis B virus was negative. She had evidence of low levels of protection against hepatitis B virus and normal liver function. She had no hepatitis B vaccination history, thus it was concluded that she had post-infection immunity. At week 36 she presented with severely elevated liver enzyme levels that, upon further investigation, were a result of acute hepatitis B virus infection. The infection followed an asymptomatic course until full recovery of her liver enzymes a few weeks later. At study unblinding, the participant was found to be on the Truvada arm. Retrospective plasma drug level testing found low levels of study drugs from week 4. The participant remained human immunodeficiency virus-negative throughout the study. Conclusion: Hepatitis B virus infection reactivation or reinfection is a rare phenomenon in healthy individuals. However, reactivations have been reported in patients being treated for chronic hepatitis B with the drugs contained in Truvada, after treatment had been withdrawn. This participant may have reactivated after stopping Truvada, or she may have reactivated spontaneously owing to relatively low levels of protective antibodies against hepatitis B. Alternatively, she may have been reinfected. Clinicians should be aware that hepatitis B virus reactivation or reinfection may cause elevated transaminases even in the presence of low baseline immunity. © 2015 Malahleha et al. Article	2015	Marra E.; Hankins C.A.	Perceptions among Dutch men who have sex with men and their willingness to use rectal microbicides and oral pre-exposure prophylaxis to reduce HIV risk - A preliminary study	AIDS Care	-	-	-	-	9540121	10.1080/09540121.2015.1069785	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84951817467&doi=10.1080%2f09540121.2015.1069785&partnerID=40&md5=e33d673558b5ec004d7310898439cd93	Oral pre-exposure prophylaxis (PrEP) with antiretroviral (ARV) tablets and topical PrEP or microbicides containing ARV drugs could help to reduce HIV incidence. These methods hold promise for men who have sex with men (MSM) who are at higher risk of acquiring HIV. This mixed-methods study in the Netherlands explored perceptions of MSM and their willingness to use oral PrEP and rectal microbicides (RM) if made available. Recruited through social media (Facebook and Twitter), 108 MSM completed online questionnaires. Seven of them consented to discuss the survey results in semi-structured interviews. Survey participants preferred a RM that could be applied before and after anal intercourse (60.8%) to daily oral PrEP (20.3%). This preference was based on anticipated user friendliness, hypothetically fewer expected adverse events, and perceptions that RM would be less likely to be confused with ARVs for treatment. Those who preferred oral PrEP had stronger beliefs in the effectiveness of pills, perceived its use as easy, and viewed not requiring sexual partner awareness as advantages. No predictive factors were found for the choice of one prevention method over the other. Although Dutch MSM perceive both oral and topical PrEP positively, many barriers exist to the introduction of these products in the Netherlands. These include lack of regulatory approval of oral PrEP, no proven efficacy as yet for RM, and strong HIV stigma within the MSM population. In-depth qualitative research is needed to further explore the perceptions of MSM to inform implementation of programmes should these HIV prevention methods become available. © 2015 Taylor & Francis. Tenofovir-based preexposure prophylaxis for HIV infection among African women	New England Journal of Medicine	-	-	-	-	284793	10.1056/NEJMoa1402269	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84922287392&doi=10.1056%2fNEJMoa1402269&partnerID=40&md5=e5fc8768b42ddfaa33e5ae51ae40a1f8	BACKGROUND: Reproductive-age women need effective interventions to prevent the acquisition of human immunodeficiency virus type 1 (HIV-1) infection. METHODS: We conducted a randomized, placebo-controlled trial to assess daily treatment with oral tenofovir disoproxil fumarate (TDF), oral tenofovir-emtricitabine (TDF-FTC), or 1% tenofovir (TFV) vaginal gel as preexposure prophylaxis against HIV-1 infection in women in South Africa, Uganda, and Zimbabwe. HIV-1 testing was performed monthly, and plasma TFV levels were assessed quarterly. RESULTS: Of 12,320 women who were screened, 5029 were enrolled in the study. The rate of retention in the study was 91% during 5509 person-years of follow-up. A total of 312 HIV-1 infections occurred; the incidence of HIV-1 infection was 5.7 per 100 personyears. In the modified intention-to-treat analysis, the effectiveness was-49.0% with TDF (hazard ratio for infection, 1.49; 95% confidence interval CI, 0.97 to 2.29),-4.4% with TDF-FTC (hazard ratio, 1.04; 95% CI, 0.73 to 1.49), and 14.5% with TFV gel (hazard ratio, 0.85; 95% CI, 0.61 to 1.21). In a random sample, TFV was detected in 30%, 29%, and 25% of available plasma samples from participants randomly assigned to receive TDF, TDF-FTC, and TFV gel, respectively. Independent predictors of TFV detection included being married, being older than 25 years of age, and being multiparous. Detection of TFV in plasma was negatively associated with characteristics predictive of HIV-1 acquisition. Elevations of serum creatinine levels were seen more frequently among participants randomly assigned to receive oral TDF-FTC than among those assigned to receive oral placebo (1.3% vs. 0.2%, P = 0.004). We observed no significant differences in the frequencies of other adverse events. CONCLUSIONS: None of the drug regimens we evaluated reduced the rates of HIV-1 acquisition in an intention-to-treat analysis. Adherence to study drugs was low. Article	2015	Martin, M; Vanichseni, S; Suntharasamai, P; Sangkum, U; Mock, PA; Leethochawalit, M; Chiamwongpaet, S; Curlin, ME; Na-Pompet, S; Warapronmongkholkul, A; Kittimunkong, S; Gvetadze, RJ; McNicholl, JM; Paxton, LA; Choopanya, K	The impact of adherence to preexposure prophylaxis on the risk of HIV infection among people who inject drugs	AIDS	-	-	-	-	NA	10.1097/QAD.0000000000000613	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01258143/full	OBJECTIVE: To describe participant adherence to daily oral tenofovir in an HIV preexposure prophylaxis (PrEP) trial, examine factors associated with adherence, and assess the impact of adherence on the risk of HIV infection. DESIGN: The Bangkok Tenofovir Study was a randomized, double-blind, placebo-controlled trial conducted among people who inject drugs, 2005-2012. METHODS: Participants chose daily visits or monthly visits. Study nurses observed participants swallow study drug and both initialed a diary. We assessed adherence using the diary. We examined adherence by age group and sex and used logistic regression to evaluate demographics and risk behaviors as predictors of adherence and Cox regression to assess the impact of adherence on the risk of HIV infection. RESULTS: A total of 2413 people enrolled and contributed 9665 person-years of follow-up (mean 4.0 years, maximum 6.9 years). The risk of HIV infection decreased as adherence improved, from 48.9% overall to 83.5% for those with at least 97.5% adherence. In multivariable analysis, men were less adherent than women (P=0.006) and participants 20-29 years old (P<0.001) and 30-39 years old (P=0.01) were less adherent than older participants. Other factors associated with poor adherence included incarceration (P=0.02) and injecting methamphetamine (P=0.04). CONCLUSION: In this HIV PrEP trial among people who inject drugs, improved adherence to daily tenofovir was associated with a lower risk of HIV infection. This is consistent with trials among MSM and HIV-discordant heterosexual couples and suggests that HIV PrEP can provide a high level of protection from HIV infection. Article	2015	Martínez E.; Ribera E.; Clotet B.; Estrada V.; Sanz J.; Berenguer J.; Rubio R.; Pulido F.; Larrousse M.; Curran A.; Negredo E.; Arterburn S.; Ferrer P.; Álvarez M.L.	Switching from zidovudine/lamivudine to tenofovir/emtricitabine improves fat distribution as measured by fat mass ratio	HIV Medicine	-	-	-	-	14642662	10.1111/hiv.12210	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84931566034&doi=10.1111%2fhiv.12210&partnerID=40&md5=d07ac4398070aff1e1513bdccc7f2483	Objectives: Fat mass ratio (FMR) has been suggested as an objective indicator of abnormal body fat distribution in HIV infection. Although it could provide more comprehensive information on body fat changes than limb fat mass, FMR has scarcely been used in clinical trials examining body fat distribution in HIV-infected patients. Methods: A subanalysis of a controlled, randomized clinical trial in virologically suppressed HIV-1-infected men switching from zidovudine (ZDV)/lamivudine (3TC) to emtricitabine (FTC)/tenofovir (TDF) versus continuing on ZDV/3TC was carried out. FMR was assessed by dual X-ray absorptiometry (DEXA) for a period of 72 weeks. Lipoatrophy was defined as FMR≥1.5. Multivariate linear regression models for the change in FMR from baseline were fitted. Results: Sixty-five men were randomized and treated (28 in the FTC/TDF arm and 37 in the ZDV/3TC arm), and 57 completed the study (25 and 32 in each arm, respectively). In the FTC/TDF arm, adjusted mean FMR decreased by 0.52 at week 72 (P=0.014), and in the ZDV/3TC arm it increased by 0.13 (P=0.491; P between arms=0.023). Among subjects with lipoatrophy (baseline FMR≥1.5), adjusted FMR decreased by 0.76 (P=0.003) in the FTC/TDF arm and increased by 0.21 (P=0.411; P between arms=0.009) in the ZDV/3TC arm. Baseline FMR and treatment group were significant predictors (P<0.05) of post-baseline changes in FMR. Conclusions: Switching from ZDV/3TC to FTC/TDF led to an improvement in FMR, compared with progressive worsening of FMR in subjects receiving ZDV/3TC, showing that fat mass not only increased but was also distributed in a healthier way after the switch. © 2014 British HIV Association. Article	2015	Mayer K.H.; Hosek S.; Cohen S.; Liu A.; Pickett J.; Warren M.; Krakower D.; Grant R.	Antiretroviral pre-exposure prophylaxis implementation in the United States: A work in progress	Journal of the International AIDS Society	-	-	-	-	17582652	10.7448/IAS.18.4.19980	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84938274721&doi=10.7448%2fIAS.18.4.19980&partnerID=40&md5=170ef4609256e58b5341263545a8303e	Introduction: After the initial approval of the use of tenofovir disoproxil fumarate-emtricitabine (TDF/FTC) by the US Food and Drug Administration in 2012 for anti-HIV pre-exposure prophylaxis (PrEP), uptake was initially limited, but more recent community surveys and expert opinion suggest wider acceptance in some key populations. Discussion: Demonstration projects are underway to determine the best practices in the United States to identify at-risk individuals in primary care and sexually transmitted disease clinics who could benefit from PrEP. Studies of PrEP in combination with behavioural interventions are being evaluated. Studies to evaluate the use of PrEP by HIV-uninfected women in HIV-discordant couples interested in safe conception are also getting underway. The optimal deployment of PrEP as part of a comprehensive national HIV/AIDS strategy in the United States has been limited by lack of knowledge among some at-risk people and by some medical providers indicating that they do not feel sufficiently knowledgeable and comfortable in prescribing PrEP. Studies are underway to determine how to assist busy clinicians to determine which of their patients could benefit from PrEP. Although most federal health insurance programmes will cover most of the costs associated with PrEP, underinsured patients in states that have not enacted health reform face additional challenges in paying for PrEP medication and appropriate clinical monitoring. Conclusions: PrEP implementation in the United States is a work in progress, with increasing awareness and uptake among some individuals in key populations. Article	2015	Mayer, Kenneth H.; Ramjee, Gita	The current status of the use of oral medication to prevent HIV transmission.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318 1746-630X	10.1097/COH.0000000000000170	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5002947/	PURPOSE OF REVIEW: This review was designed to evaluate the progress in studies of the use of oral and topical antiretroviral (ARV) medication for primary HIV prevention. RECENT FINDINGS: Nonhuman primate data have suggested that the administration of ARV medication before or after retroviral exposure can protect against the establishment of chronic infection. Over the past two decades, observational studies have demonstrated the safety of ARV agents for postexposure prophylaxis and more recent efficacy studies have demonstrated that tenofovir with or without emtricitabine can protect against HIV when used as preexposure prophylaxis (PrEP). Efficacy studies have been conducted in diverse populations, including men and transgender women who have sex with men, young African heterosexuals, and injection drug users. Three studies in African women evaluating oral and topical tenofovir-based regimens did not demonstrate efficacy, in large part because of suboptimal medication adherence. Further research is underway to determine the optimal ways to provide chemoprophylaxis, the optimal medications, and dosing regimens. SUMMARY: PrEP can be effective in decreasing HIV transmission to at-risk uninfected persons, but further research is needed to determine the optimal modes of delivery. Article	2015	McMahon, James M.; Pouget, Enrique R.; Tortu, Stephanie; Volpe, Ellen M.; Torres, Leilani; Rodriguez, William	Couple-based HIV counseling and testing: a risk reduction intervention for US drug-involved women and their primary male partners.	Prevention Science	-	-	-	-	1573-6695 1389-4986	10.1007/s11121-014-0540-9	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4310810/	To help reduce the elevated risk of acquiring HIV for African-American and Latina women drug users in primary heterosexual relationships, we developed a brief couple-based HIV counseling and testing prevention intervention. The intervention was based on an integrated HIV risk behavior theory that incorporated elements of social exchange theory, the theory of gender and power, the stages-of-change model, and the information-motivation-behavior skills model. In this article, we describe the development, content, and format of the couple-based HIV testing and counseling intervention, and its delivery to 110 couples (220 individuals) in a randomized effectiveness trial, the Harlem River Couples Project, conducted in New York City from 2005 to 2007. Components of the couple-based intervention included a personalized dyadic action plan based on the couple's risk profile and interactive exercises designed to help build interpersonal communication skills, and facilitated discussion of social norms regarding gender roles. The couple-based HIV testing and counseling intervention significantly reduced women's overall HIV risk compared to a standard-of-care individual HIV testing and counseling intervention. Experiences and perceptions of the intervention were positive among both clients and interventionists. The study was the first to demonstrate the effectiveness and feasibility of delivering a brief couple-based HIV counseling and testing intervention to reduce risk among drug-using heterosexual couples in high HIV prevalent urban communities in the USA. The intervention can be expanded to include new HIV prevention strategies, such as pre-exposure prophylaxis. Further research is needed to evaluate cost-effectiveness and implementation of the intervention in clinical settings. Article	2015	Melody K.; McBeth S.; Kline C.; Kashuba A.D.M.; Mellors J.W.; Ambrose Z.	Low frequency of drug-resistant variants selected by long-acting rilpivirine in macaques infected with simian immunodeficiency virus containing HIV-1 reverse transcriptase	Antimicrobial Agents and Chemotherapy	-	-	-	-	664804	10.1128/AAC.01937-15	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84954495868&doi=10.1128%2fAAC.01937-15&partnerID=40&md5=bfbefe81b782d7d13675dede84887955	Preexposure prophylaxis (PrEP) using antiretroviral drugs is effective in reducing the risk of human immunodeficiency virus type 1 (HIV-1) infection, but adherence to the PrEP regimen is needed. To improve adherence, a long-acting injectable formulation of the nonnucleoside reverse transcriptase (RT) inhibitor rilpivirine (RPV LA) has been developed. However, there are concerns that PrEP may select for drug-resistant mutations during preexisting or breakthrough infections, which could promote the spread of drug resistance and limit options for antiretroviral therapy. To address this concern, we administered RPV LA to macaques infected with simian immunodeficiency virus containing HIV-1 RT (RT-SHIV). Peak plasma RPV levels were equivalent to those reported in human trials and waned over time after dosing. RPV LA resulted in a 2-log decrease in plasma viremia, and the therapeutic effect was maintained for 15 weeks, until plasma drug concentrations dropped below 25 ng/ml. RT mutations E138G and E138Q were detected in single clones from plasma virus in separate animals only at one time point, and no resistance mutations were detected in viral RNA isolated from tissues. Wild-type and E138Q RT-SHIV displayed similar RPV susceptibilities in vitro, whereas E138G conferred 2-fold resistance to RPV. Overall, selection of RPV-resistant variants was rare in an RTSHIV macaque model despite prolonged exposure to slowly decreasing RPV concentrations following injection of RPV LA. Article	2015	Meyers, Kathrine; Golub, Sarit A	Planning ahead for implementation of long-acting HIV prevention: challenges and opportunities.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0000000000000159	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4620059/	PURPOSE OF REVIEW: Broad-based access, uptake, and dissemination of daily oral HIV preexposure prophylaxis (PrEP) have been slow, despite strong evidence for efficacy. Effective and efficient implementation of long-acting HIV prevention products will require both analysis of the dynamics and determinants of daily oral PrEP implementation and identification of the distinct challenges and opportunities inherent in emerging technologies. RECENT FINDINGS: Evidence suggests the importance of addressing implementation issues at three levels: patient, provider, and system. Patient-level factors include targeted education and messaging, tailored supports to enhance acceptability and uptake, and effective strategies for promoting adherence/persistence and retention in care. Provider-level factors include engaging a broad mix of providers, while ensuring adequate training and support for patient assessment, counseling, and follow-up. Systems-level factors include optimal delivery modalities, resource allocation, and ensuring access to populations most in need of new prevention options. SUMMARY: Formative social/behavioral research must be undertaken proactively to prepare for and address future implementation challenges and reduce the gap between proving efficacy in clinical trials and assuring real-world effectiveness. Conceptualizing new HIV prevention technologies as behavioral interventions at the level of the patient, provider, and system will be paramount to effective and efficient implementation. Article	2015	Mitchell J.W.; Stephenson R.	HIV-negative partnered men's willingness to use pre-exposure prophylaxis and associated factors among an internet sample of U.S. HIV-negative and HIV-discordant male couples	LGBT Health	-	-	-	-	23258292	10.1089/lgbt.2014.0092	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84969213618&doi=10.1089%2flgbt.2014.0092&partnerID=40&md5=b8013a6234a57ade21fe27035f704696	Purpose: Research on male couples' willingness to use pre-exposure prophylaxis (PrEP) is critically lacking. Methods: A cross-sectional 2011 Internet survey collected dyadic data from 275 HIV-negative and 58 HIV-discordant male couples to describe 631 HIV-negative partnered mens' willingness to use PrEP and associated couple-level demographic and behavioral factors with multivariate multilevel modeling. Results: Fifty-three percent were very to extremely likely to use PrEP. Willingness was positively associated with being in a mixed race and behaviorally non-monogamous relationship, and with amyl nitrate use with sex outside the relationship. Willingness was negatively associated with having a college education. Conclusion: Prevention efforts should educate male couples about the potential benefits of PrEP. © Mary Ann Liebert, Inc. 2015. Article	2015	Mitchell, KM; Lépine, A; Terris-Prestholt, F; Torpey, K; Khamofu, H; Folayan, MO; Musa, J; Anenih, J; Sagay, AS; Alhassan, E; Idoko, J; Vickerman, P	Modelling the impact and cost-effectiveness of combination prevention amongst HIV serodiscordant couples in Nigeria	AIDS	-	-	-	-	0269-9370	10.1097/QAD.0000000000000798	https://pubmed.ncbi.nlm.nih.gov/26355574/	Objective:To estimate the impact and cost-effectiveness of treatment as prevention (TasP), pre-exposure prophylaxis (PrEP) and condom promotion for serodiscordant couples in Nigeria.Design:Mathematical and cost modelling.Methods:A deterministic model of HIV-1 transmission within a cohort of serodiscordant couples and to/from external partners was parameterized using data from Nigeria and other African settings. The impact and cost-effectiveness were estimated for condom promotion, PrEP and/or TasP, compared with a baseline where antiretroviral therapy (ART) was offered according to 2010 national guidelines (CD4(+) <350cells/l) to all HIV-positive partners. The impact was additionally compared with a baseline of current ART coverage (35% of those with CD4(+) <350cells/l). Full costs (in US $2012) of programme introduction and implementation were estimated from a provider perspective.Results:Substantial benefits came from scaling up ART to all HIV-positive partners according to 2010 national guidelines, with additional smaller benefits of providing TasP, PrEP or condom promotion. Compared with a baseline of offering ART to all HIV-positive partners at the 2010 national guidelines, condom promotion was the most cost-effective strategy US $1206/disability-adjusted-life-year (DALY), the next most cost-effective intervention was to additionally give TasP to HIV-positive partners (incremental cost-effectiveness ratio US $1607/DALY), followed by additionally giving PrEP to HIV-negative partners until their HIV-positive partners initiate ART (US $7870/DALY). When impact was measured in terms of infections averted, PrEP with condom promotion prevented double the number of infections as condom promotion alone.Conclusions:The first priority intervention for serodiscordant couples in Nigeria should be scaled up ART access for HIV-positive partners. Subsequent incremental benefits are greatest with condom promotion and TasP, followed by PrEP. Copyright (C) 2015 Wolters Kluwer Health, Inc. Article	2015	Molina, Jean-Michel; Capitant, Catherine; Spire, Bruno; Pialoux, Gilles; Cotte, Laurent; Charreau, Isabelle; Tremblay, Cecile; Le Gall, Jean-Marie; Cua, Eric; Pasquet, Armelle; Raffi, François; Pintado, Claire; Chidiac, Christian; Chas, Julie; Charbonneau, Pierre; Delaugerre, Constance; Suzan-Monti, Marie; Loze, Benedicte; Fonsart, Julien; Peytavin, Gilles; Cheret, Antoine; Timsit, Julie; Girard, Gabriel; Lorente, Nicolas; Préau, Marie; Rooney, James F; Wainberg, Mark A; Thompson, David; Rozenbaum, Willy; Doré, Veronique; Marchand, Lucie; Simon, Marie-Christine; Etien, Nicolas; Aboulker, Jean-Pierre; Meyer, Laurence; Delfraissy, Jean-François	On-Demand Preexposure Prophylaxis in Men at High Risk for HIV-1 Infection.	New England Journal of Medicine	-	-	-	-	1533-4406	10.1056/NEJMoa1506273	https://dx.doi.org/10.1056/NEJMoa1506273	BACKGROUND: Antiretroviral preexposure prophylaxis has been shown to reduce the risk of human immunodeficiency virus type 1 (HIV-1) infection in some studies, but conflicting results have been reported among studies, probably due to challenges of adherence to a daily regimen. METHODS: We conducted a double-blind, randomized trial of antiretroviral therapy for preexposure HIV-1 prophylaxis among men who have unprotected anal sex with men. Participants were randomly assigned to take a combination of tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) or placebo before and after sexual activity. All participants received risk-reduction counseling and condoms and were regularly tested for HIV-1 and HIV-2 and other sexually transmitted infections. RESULTS: Of the 414 participants who underwent randomization, 400 who did not have HIV infection were enrolled (199 in the TDF-FTC group and 201 in the placebo group). All participants were followed for a median of 9.3 months (interquartile range, 4.9 to 20.6). A total of 16 HIV-1 infections occurred during follow-up, 2 in the TDF-FTC group (incidence, 0.91 per 100 person-years) and 14 in the placebo group (incidence, 6.60 per 100 person-years), a relative reduction in the TDF-FTC group of 86% (95% confidence interval, 40 to 98; P=0.002). Participants took a median of 15 pills of TDF-FTC or placebo per month (P=0.57). The rates of serious adverse events were similar in the two study groups. In the TDF-FTC group, as compared with the placebo group, there were higher rates of gastrointestinal adverse events (14% vs. 5%, P=0.002) and renal adverse events (18% vs. 10%, P=0.03). CONCLUSIONS: The use of TDF-FTC before and after sexual activity provided protection against HIV-1 infection in men who have sex with men. The treatment was associated with increased rates of gastrointestinal and renal adverse events. (Funded by the National Agency of Research on AIDS and Viral Hepatitis ANRS and others; ClinicalTrials.gov number, NCT01473472.). Article	2015	Montgomery, Elizabeth T; van der Straten, Ariane; Stadler, Jonathan; Hartmann, Miriam; Magazi, Busisiwe; Mathebula, Florence; Laborde, Nicole; Soto-Torres, Lydia	Male Partner Influence on Women's HIV Prevention Trial Participation and Use of Pre-exposure Prophylaxis: the Importance of "Understanding".	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-014-0950-5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4416996/	There is widespread evidence that male partners influence women's ability and willingness to join HIV prevention trials and to use female-controlled prevention strategies such as microbicide gels. VOICE-C was an ancillary study to the Microbicide Trials Network's VOICE trial at the Johannesburg site that explored social and structural factors influencing women's use of study tablets and vaginal gel. Qualitative data were analyzed from 102 randomly-selected VOICE participants interviewed through in-depth interviews (IDI, n = 41); ethnographic interviews (n = 21) or focus group discussions (FGD, n = 40) and 22 male partners interviewed in 14 IDI and 2 FGD. Male partners' "understanding" pervaded as a central explanation for how male partners directly and indirectly influenced their female partners' trial participation and product use, irrespective of assignment to the gel or tablet study groups. The meaning behind "understanding" in this context was described by both men and women in two important and complementary ways: (1) "comprehension" of the study purpose including biological properties or effects of the products, and (2) "support/agreeability" for female partners being study participants or using products. During analysis a third dimension of "understanding" emerged as men's acceptance of larger shifts in gender roles and relationship power, and the potential implications of women's increased access to biomedical knowledge, services and prevention methods. Despite displays of some female agency to negotiate and use HIV prevention methods, male partners still have a critical influence on women's ability and willingness to do so. Efforts to increase their understanding of research goals, study design and products' mechanisms of action could ameliorate distrust, empower men to serve as product advocates, adherence buddies, and foster greater adherence support for women in situations where it is needed. Strategies to address gender norms and the broader implications these have for female-initiated HIV prevention should likewise be integrated into future research and program activities. Article	2015	Mugo, Peter Mwangi; Sanders, Eduard J; Mutua, Gaudensia; van der Elst, Elisabeth; Anzala, Omu; Barin, Burc; Bangsberg, David R; Priddy, Frances H; Haberer, Jessica E	Understanding Adherence to Daily and Intermittent Regimens of Oral HIV Pre-exposure Prophylaxis Among Men Who Have Sex with Men in Kenya.	AIDS and Behavior	-	-	-	-	1573-3254	10.1007/s10461-014-0958-x	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4415948/	A qualitative assessment of Kenyan men who have sex with men taking daily and intermittent oral HIV pre-exposure prophylaxis (PrEP) found stigma, sex work, mobility, and alcohol impacted adherence. We analyzed quantitative data from the same cohort to explore different definitions of intermittent adherence. Volunteers were randomized to daily emtricitabine/tenofovir or placebo, or intermittent (prescription: Mondays/Fridays/after sex, maximum 1 dose/day) emtricitabine/tenofovir or placebo (2:1:2:1), and followed for 4 months. By electronic monitoring, median adherence for daily dosing was 80 %. Median adherence for intermittent dosing was 71 % per a "relaxed" definition (accounting for off-prescription dosing) and 40 % per a "strict" definition (limited to the prescription). Factors associated with lower adherence included travel, transactional sex, and longer follow-up; higher adherence was associated with daily dosing and an income. The definition of intermittent dosing strongly affects interpretation of adherence. These findings suggest interventions should address challenges of mobility, sex work, and long-term PrEP. Article	2015	Mugwanya, Kenneth K; Wyatt, Christina; Celum, Connie; Donnell, Deborah; Mugo, Nelly R; Tappero, Jordan; Kiarie, James; Ronald, Allan; Baeten, Jared M	Changes in glomerular kidney function among HIV-1-uninfected men and women receiving emtricitabine-tenofovir disoproxil fumarate preexposure prophylaxis: a randomized clinical trial.	JAMA Internal Medicine	-	-	-	-	2168-6114	10.1001/jamainternmed.2014.6786	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4354899/	IMPORTANCE: Tenofovir disoproxil fumarate (TDF) use has been associated with declines in the estimated glomerular filtration rate (eGFR) when used as part of antiretroviral treatment by persons with human immunodeficiency virus (HIV) type 1, but limited data are available for risk when used as preexposure prophylaxis (PrEP) for HIV-1 prevention. OBJECTIVE: To determine whether TDF-based PrEP causes eGFR decline in HIV-1-uninfected adults. DESIGN, SETTING, AND PARTICIPANTS: A per-protocol safety analysis of changes in eGFR in the Partners PrEP Study, a randomized, placebo-controlled trial of daily oral TDF and emtricitabine (FTC)-TDF PrEP among heterosexual HIV-1-uninfected members of serodiscordant couples in Kenya and Uganda. The trial was conducted from 2008 to 2012. MAIN OUTCOMES AND MEASURES: Predefined outcomes of this analysis were mean eGFR change and a 25% or greater eGFR decline from baseline. The eGFR was calculated using the Chronic Kidney Disease Epidemiology Collaboration equation. RESULTS: Of 4640 participants in the once-daily TDF (n = 1548), FTC-TDF (n = 1545), or placebo (n = 1547) groups, 63% were men. At enrollment, median age was 35 years (range, 18-64 years), and mean eGFR was 130 mL/min/1.73 m². During a median follow-up of 18 months (interquartile range 12-27 months), mean within-group eGFR change from baseline was +0.14 mL/min/1.73 m² for TDF, -0.22 mL/min/1.73 m² for FTC-TDF, and +1.37 mL/min/1.73 m² for placebo, translating into average declines in eGFR attributable to PrEP vs placebo of -1.23 mL/min/1.73 m² (95% CI, -2.06 to -0.40; P = .004) for TDF and -1.59 mL/min/1.73 m² (95% CI, -2.44 to -0.74; P < .001) for FTC-TDF. The difference in mean eGFR between PrEP and placebo appeared by 1 month after randomization, was stable through 12 months, and then appeared to wane thereafter. The respective proportions of persons who developed a confirmed 25% or greater eGFR decline from baseline by 12 and 24 months was 1.3% and 1.8% for TDF and 1.2% and 2.5% for FTC-TDF, and these frequencies were not statistically different from the confirmed decline in the placebo group (0.9% and 1.3% by 12 and 24 months, respectively). CONCLUSIONS AND RELEVANCE: In this large randomized, placebo-controlled trial among heterosexual persons, with median follow-up of 18 months and maximum follow-up of 36 months, daily oral TDF-based PrEP resulted in a small but nonprogressive decline in eGFR that was not accompanied by a substantial increase in the risk of clinically relevant (≥25%) eGFR decline. Effects of Emtricitabine/Tenofovir on Bone Mineral Density in HIV-Negative Persons in a Randomized, Double-Blind, Placebo-Controlled Trial	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/civ324	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84938598621&doi=10.1093%2fcid%2fciv324&partnerID=40&md5=18537e603b13007c7ed026391ae0c0fb	Background. Daily preexposure prophylaxis (PrEP) with oral emtricitabine and tenofovir disoproxil fumarate (FTC/TDF) decreases the risk of human immunodeficiency virus (HIV) acquisition. Initiation of TDF decreases bone mineral density (BMD) in HIV-infected people. We report the effect of FTC/TDF on BMD in HIV-seronegative men who have sex with men and in transgender women. Methods. Dual-energy X-ray absorptiometry was performed at baseline and 24-week intervals in a substudy of iPrEx, a randomized, double-blind, placebo-controlled trial of FTC/TDF PrEP. Plasma and intracellular tenofovir concentrations were measured in participants randomized to FTC/TDF. Results. In 498 participants (247 FTC/TDF, 251 placebo), BMD in those randomized to FTC/TDF decreased modestly but statistically significantly by 24 weeks in the spine (net difference, -0.91% 95% confidence interval [CI], -1.44% to -.38%; P =. 001) and hip (-0.61% 95% CI, -.96% to -.27%, P =. 001). Changes within each subsequent 24-week interval were not statistically significant. Changes in BMD by week 24 correlated inversely with intracellular tenofovir diphosphate (TFV-DP), which was detected in 53% of those randomized to FTC/TDF. Net BMD loss by week 24 in participants with TFV-DP levels indicative of consistent dosing averaged -1.42% ± 29% and -0.85% ± 19% in the spine and hip, respectively (P <. 001 vs placebo). Spine BMD tended to rebound following discontinuation of FTC/TDF. There were no differences in fractures (P =. 62) or incidence of low BMD. Conclusions. In HIV-uninfected persons, FTC/TDF PrEP was associated with small but statistically significant decreases in BMD by week 24 that inversely correlated with TFV-DP, with more stable BMD thereafter. © 2015 The Author 2015.	bone; DXA; emtricitabine; PrEP; tenofovir	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2015	Mullins, TLK; Lally, M; Zimet, G; Kahn, JA; Adolescent Med Trials Network HIV	Clinician Attitudes Toward CDC Interim Pre-Exposure Prophylaxis (PrEP) Guidance and Operationalizing PrEP for Adolescents	AIDS Patient Care and STDs	-	-	-	-	1087-2914	10.1089/apc.2014.0273	https://psycnet.apa.org/record/2015-13986-003	Prior to issuing formal HIV pre-exposure prophylaxis (PrEP) clinical practice guidelines in 2014, the US Centers for Disease Control and Prevention (CDC) had released interim guidance for oral PrEP use among adults. Because oral PrEP may be used off-label for youth and may soon be indicated for minor adolescents, we examined the potential adoption of the interim guidance among clinicians who care for HIV-infected and at-risk youth. Individual, semi-structured interviews were conducted with 15 US clinicians who were recruited through an adolescent HIV research network. The theory-driven interview guide, consisting primarily of open-ended questions, assessed demographics, familiarity with the guidance, attitudes toward the guidance, and attitudes toward the use of the guidance for adult and adolescent patients. Transcripts were analyzed using framework analysis. Most clinicians (11/15) reported that the guidance was compatible with their practice, although several reported that some aspects, particularly frequency of follow-up visits, needed to be tailored to meet their patients' needs. We found variability in clinician reported characteristics of appropriate PrEP candidates (e.g., youth with substance use and mental health issues were noted to be both suitable and unsuitable PrEP candidates) and PrEP use in serodiscordant couples (e.g., whether PrEP would be recommended to a patient whose HIV-infected partner is virally suppressed). Clinician reported steps for initiation, monitoring, and discontinuing PrEP were largely consistent with the guidance. The observed variability in clinician practice with regard to oral PrEP may be reduced through interventions to educate clinicians about the content and rationale for guideline recommendations. Article	2015	Murnane P.M.; Brown E.R.; Donnell D.; Coley R.Y.; Mugo N.; Mujugira A.; Celum C.; Baeten J.M.	Estimating Efficacy in a Randomized Trial With Product Nonadherence: Application of Multiple Methods to a Trial of Preexposure Prophylaxis for HIV Prevention	American Journal of Epidemiology	-	-	-	-	29262	10.1093/aje/kwv202	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84947580609&doi=10.1093%2faje%2fkwv202&partnerID=40&md5=39225faf7a9ea558458f8c404ae3405f	Antiretroviral preexposure prophylaxis (PrEP) for persons at high risk of human immunodeficiency virus infection is a promising new prevention strategy. Six randomized trials of oral PrEP were recently conducted and demonstrated efficacy estimates ranging from 75% to no effect, with nonadherence likely resulting in attenuated estimates of the protective effect of PrEP. In 1 of these trials, the Partners PrEP Study (Kenya and Uganda, 2008-2011), participants (4,747 serodiscordant couples) were randomized to receipt of tenofovir (TDF), coformulated TDF/emtricitabine (FTC), or placebo. Intention-to-treat analyses found efficacy estimates of 67% for TDF and 75% for TDF/FTC. We applied multiple methods to data from that trial to estimate the efficacy of PrEP with high adherence, including principal stratification and inverse-probability-of-censoring (IPC) weights. Results were further from the null when correcting for nonadherence: 1) among the strata with an estimated 100% probability of high adherence (TDF hazard ratio (HR) = 0.19, 95% confidence interval (CI): 0.07, 0.56; TDF/FTC HR = 0.12, 95% CI: 0.03, 0.52); 2) with IPC weights used to approximate a continuously adherent population (TDF HR = 0.18, 95% CI: 0.06, 0.53; TDF/FTC HR = 0.15, 95% CI: 0.04, 0.52); and 3) in per-protocol analysis (TDF HR = 0.18, 95% CI: 0.06, 0.53; TDF/FTC HR = 0.16, 95% CI: 0.05, 0.53). Our results suggest that the efficacy of PrEP with high adherence is over 80%. © The Author 2015. Article	2015	Murphy, Dean A.	Processing, selecting and ritualizing: ambivalent relationships to semen.	Reproductive Biomedicine Online	-	-	-	-	1472-6491 1472-6483	10.1016/j.rbmo.2015.01.014	https://pubmed.ncbi.nlm.nih.gov/25773527/	Two articles on human immunodeficiency virus (HIV) and reproduction have recently been published in Reproductive BioMedicine Online, both describing developments that increase reproductive options for HIV-positive men. A study of a semen-processing technique used at a South African hospital found that two out of 103 processed samples tested positive for HIV DNA and none for RNA, indicating 98.1% and 100% effectiveness, respectively. The authors recommend semen processing followed by viral validation of processed sperm samples when providing assisted reproduction treatment to couples with an HIV-positive male partner. The other article reviews developments such as semen processing, antiretroviral (ARV) therapy and pre-exposure prophylaxis (PrEP), which have all reduced the risk of HIV transmission in the context of reproduction. The author also notes, however, that research on fertility in the context of HIV focuses almost exclusively on heterosexual couples, and has overlooked the links between reproduction, HIV and homosexuality. This article analyses the ambivalent role of semen - associated with both reproduction and infection - and how reproductive medicine and health care in different ways seek to 'get hold' of sperm. By taking this analytic approach, sex and parenthood can be thought of as two different but related kinds of intimacy and kinship. Article	2015	Mutchler M.G.; McDavitt B.; Ghani M.A.; Nogg K.; Winder T.J.A.; Soto J.K.	Getting PrEPared for HIV Prevention Navigation: Young Black Gay Men Talk about HIV Prevention in the Biomedical Era	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2015.0002	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84940047660&doi=10.1089%2fapc.2015.0002&partnerID=40&md5=b1a114125a7c421d55d37f71eb9ef3ce	Biomedical HIV prevention strategies, such as pre-exposure prophylaxis (PrEP) and post-exposure prophylaxis (PEP), represent new opportunities to reduce critically high HIV infection rates among young black men who have sex with men (YBMSM). We report results of 24 dyadic qualitative interviews (N=48), conducted in Los Angeles, CA, exploring how YBMSM and their friends view PrEP and PEP. Interviews were analyzed using a grounded theory approach. Participants had widely divergent levels of knowledge about these prevention methods. Misconceptions and mistrust regarding PrEP were common, and concerns were expressed about PrEP-related stigma and the potential for gossip among peers who might assume a person on PrEP was HIV-positive. Yet participants also framed PrEP and PEP as valuable new options within an expanded "tool kit" of HIV prevention strategies that created possibilities for preventing new HIV infections, dating men with a different HIV status, and decreased anxiety about exposure to HIV. We organized themes around four main areas: (1) information and misinformation about biomedical HIV prevention; (2) expectations about PrEP, sexual behavior, and stigma; (3) gossip, disclosure, and "spreading the word" about PrEP and PEP; and (4) the roles of PrEP and PEP in an expanded HIV prevention tool kit. The findings suggest a need for guidance in navigating the increasingly complex array of HIV-prevention options available to YBMSM. Such "prevention navigation" could counter misconceptions and address barriers, such as stigma and mistrust, while helping YBMSM make informed selections from among expanded HIV prevention options. © Copyright 2015, Mary Ann Liebert, Inc. 2015. Article	2015	Myers J.E.; Ellman T.M.; Westhoff C.	Injectable agents for pre-exposure prophylaxis: Lessons learned from contraception to inform HIV prevention	Current Opinion in HIV and AIDS	-	-	-	-	1746630X	10.1097/COH.0000000000000166	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84943182665&doi=10.1097%2fCOH.0000000000000166&partnerID=40&md5=bb2fe32048175b332c5a38c19bb7840f	Purpose of review Long-acting injectable (LAI) forms of preexposure prophylaxis (PrEP) are in clinical trials, generating much hope for HIV prevention. But this is not the first time that an injectable form of preventive medication has emerged: the contraceptive agent depomedroxyprogesterone acetate (DMPA) has an important precedent. DMPA's long journey, its initial reception, and ongoing implementation challenges can help inform the field of HIV prevention as we plan for approval, acceptance, and scale-up of LAI-PrEP. Recent findings DMPA faced a long regulatory journey in the USA, with a lag of 25 years from initial application (1967) to approval (1992). Acceptance after introduction was rapid, but challenges hampered scale-up. Specific lessons learned include that extensive acceptability work is needed in parallel to product development. Also, low continuation rates, challenges with timing of initiation, and difficulty ensuring access for the most vulnerable populations have limited DMPA's impact. A new subcutaneous formulation presents opportunities for administration outside of clinical settings and for self-administration. Summary Those involved in LAI-PrEP development and those who plan to be involved in its future implementation must consider these lessons and possible solutions from DMPA to ensure a successful future for this new HIV prevention modality. © 2015 Wolters Kluwer Health, Inc. Article	2015	Ndase, Patrick; Celum, Connie; Kidoguchi, Lara; Ronald, Allan; Fife, Kenneth H; Bukusi, Elizabeth; Donnell, Deborah; Baeten, Jared M	Frequency of false positive rapid HIV serologic tests in African men and women receiving PrEP for HIV prevention: implications for programmatic roll-out of biomedical interventions.	PLOS One	-	-	-	-	1932-6203	10.1371/journal.pone.0123005	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4401675/	BACKGROUND: Rapid HIV assays are the mainstay of HIV testing globally. Delivery of effective biomedical HIV prevention strategies such as antiretroviral pre-exposure prophylaxis (PrEP) requires periodic HIV testing. Because rapid tests have high (>95%) but imperfect specificity, they are expected to generate some false positive results. METHODS: We assessed the frequency of true and false positive rapid results in the Partners PrEP Study, a randomized, placebo-controlled trial of PrEP. HIV testing was performed monthly using 2 rapid tests done in parallel with HIV enzyme immunoassay (EIA) confirmation following all positive rapid tests. RESULTS: A total of 99,009 monthly HIV tests were performed; 98,743 (99.7%) were dual-rapid HIV negative. Of the 266 visits with ≥1 positive rapid result, 99 (37.2%) had confirmatory positive EIA results (true positives), 155 (58.3%) had negative EIA results (false positives), and 12 (4.5%) had discordant EIA results. In the active PrEP arms, over two-thirds of visits with positive rapid test results were false positive results (69.2%, 110 of 159), although false positive results occurred at <1% (110/65,945) of total visits. CONCLUSIONS: When HIV prevalence or incidence is low due to effective HIV prevention interventions, rapid HIV tests result in a high number of false relative to true positive results, although the absolute number of false results will be low. Program roll-out for effective interventions should plan for quality assurance of HIV testing, mechanisms for confirmatory HIV testing, and counseling strategies for persons with positive rapid test results. Article	2015	Nelson, Antoinette G; Zhang, Xiaoping; Ganapathi, Usha; Szekely, Zoltan; Flexner, Charles W; Owen, Andrew; Sinko, Patrick J	Drug delivery strategies and systems for HIV/AIDS pre-exposure prophylaxis and treatment.	Journal of Controlled Release	-	-	-	-	1873-4995	10.1016/j.jconrel.2015.08.042	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4879940/	The year 2016 will mark an important milestone - the 35th anniversary of the first reported cases of HIV/AIDS. Antiretroviral Therapy (ART) including Highly Active Antiretroviral Therapy (HAART) drug regimens is widely considered to be one of the greatest achievements in therapeutic drug research having transformed HIV infection into a chronically managed disease. Unfortunately, the lack of widespread preventive measures and the inability to eradicate HIV from infected cells highlight the significant challenges remaining today. Moving forward there are at least three high priority goals for anti-HIV drug delivery (DD) research: (1) to prevent new HIV infections from occurring, (2) to facilitate a functional cure, i.e., when HIV is present but the body controls it without drugs and (3) to eradicate established infection. Pre-exposure Prophylaxis (PrEP) represents a significant step forward in preventing the establishment of chronic HIV infection. However, the ultimate success of PrEP will depend on achieving sustained antiretroviral (ARV) tissue concentrations and will require strict patient adherence to the regimen. While first generation long acting/extended release (LA/ER) DD Systems (DDS) currently in development show considerable promise, significant DD treatment and prevention challenges persist. First, there is a critical need to improve cell specificity through targeting in order to selectively achieve efficacious drug concentrations in HIV reservoir sites to control/eradicate HIV as well as mitigate systemic side effects. In addition, approaches for reducing cellular efflux and metabolism of ARV drugs to prolong effective concentrations in target cells need to be developed. Finally, given the current understanding of HIV pathogenesis, next generation anti-HIV DDS need to address selective DD to the gut mucosa and lymph nodes. The current review focuses on the DDS technologies, critical challenges, opportunities, strategies, and approaches by which novel delivery systems will help iterate towards prevention, functional cure and eventually the eradication of HIV infection. Article	2015	Ong, Koh Jun; Desai, Sarika; Desai, Monica; Nardone, Anthony; Hoek, Albert Jan van; Gill, O Noel	Cost and cost-effectiveness of an HIV pre-exposure prophylaxis (PrEP) programme for high-risk men who have sex with men in England: results of a static decision analytical model	The Lancet	-	-	-	-	01406736	10.1016/S0140-6736(15)00854-5	https://www.proquest.com/scholarly-journals/cost-effectiveness-hiv-pre-exposure-prophylaxis/docview/1732854827/se-2?accountid=8113	Background The efficacy and effectiveness of pre-exposure prophylaxis (PrEP) for preventing HIV infection acquisition by high-risk men who have sex with men (MSM) is established. We estimated the cost and cost-effectiveness of a proposed daily oral PrEP programme covering 10 000 high-risk MSM attending genitourinary medicine clinics in England. Methods From the perspective of public providers, a static decision analytical model was used to investigate lifetime HIV infections, treatment costs, and quality-adjusted-life-year (QALY) losses associated with daily PrEP given for 1 year, beginning in 2016, compared with no intervention. A cohort of MSM who were not known to be HIV positive at their first attendance in 2012 and had tested HIV negative between 42 and 365 days previously was identified. These men were followed up from the date of their earliest negative HIV test in 2012 for up to 1 year either until they seroconverted or until their last attendance. HIV incidence was calculated as the number of seroconversions (new HIV diagnoses) per 100 person-years. Data sources including genitourinary medicine clinic activity data were used to estimate HIV incidence in year 1 and thereafter. Costs were updated to 2013-14 values and both future costs and QALYs were discounted at 3·5%. Budgetary impact was undiscounted. Findings At 86% effectiveness, delivery of PrEP to 10 000 high-risk MSM in the first year (target population with an HIV incidence of 2·4 per 100 person-years in year 1) resulted in 178 fewer lifetime HIV infections, 28 delayed infections, and an incremental cost-effectiveness ratio (ICER) of £26 300, compared with no PrEP. More conservative assumptions of 64% PrEP effectiveness gave an ICER of £54 500, compared with no PrEP. ICER was highly sensitive to year 1 HIV incidence (eg, with HIV incidence of 3·3 per 100 person-years and at 86% PrEP effectiveness, ICER was £4170), PrEP effectiveness, PrEP drug costs, and potential changes in antiretroviral treatment cost upon patent expiry. An investment of £54 million in year 1 breaks even anywhere from year 42 (86% PrEP effectiveness) to beyond year 61 (64% PrEP effectiveness). Interpretation The model shows that the estimated cost-effectiveness of PrEP is very sensitive to key variables (eg, year 1 HIV incidence and patient adherence), about which there is much uncertainty, especially if programme scale-up occurs. A substantial reduction in the price of antiretroviral drugs, when used for PrEP, is needed to give the necessary assurance of cost-effectiveness, and for an affordable public health programme of sufficient size. Funding None. Article	2015	Ouellet E.; Durand M.; Guertin J.R.; LeLorier J.; Tremblay C.L.	Cost effectiveness of 'on demand' Hiv pre-exposure prophylaxis for non-injection drug-using men who have sex with men in Canada	Canadian Journal of Infectious Diseases and Medical Microbiology	-	-	-	-	17129532	10.1155/2015/964512	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84923286264&doi=10.1155%2f2015%2f964512&partnerID=40&md5=a06b9928bb8f99a24d7bdce196650a09	BACKGROUND: Recent trials report the efficacy of continuous tenofovir-based pre-exposure prophylaxis (PrEP) for prevention of HIV infection. The cost effectiveness of 'on demand' PrEP for non-injection drug-using men who have sex with men at high risk of HIV acquisition has not been evaluated. OBJECTIVE: To conduct an economic evaluation of the societal costs of HIV in Canada and evaluate the potential benefits of this PrEP strategy. METHODS: Direct HIV costs comprised outpatient, inpatient and emergency department costs, psychosocial costs and antiretroviral costs. Resource consumption estimates were derived from the Centre Hospitalier de l'Université de Montréal HIV cohort. Estimates of indirect costs included employment rate and work absenteeism. Costs for 'on demand' PrEP were modelled after an ongoing clinical trial. Cost-effectiveness analysis compared costs of 'on demand' PrEP to prevent one infection with lifetime costs of one HIV infection. Benefits were presented in terms of life-years and quality-adjusted life-years. RESULTS: The average annual direct cost of one HIV infection was $16,109 in the least expensive antiretroviral regimen scenario and $24,056 in the most expensive scenario. The total indirect cost was $11,550 per year. Total costs for the first year of HIV infection ranged from $27,410 to $35,358. Undiscounted lifetime costs ranged from $1,439,984 ($662,295 discounted at 3% and $448,901 at 5%) to $1,482,502 ($690,075 at 3% and $485,806 at 5%). The annual cost of PrEP was $12,001 per participant, and $621,390 per infection prevented. The PrEP strategy was cost-saving in all scenarios for undis-counted and 3% discounting rates. At 5% discounting rates, the strategy is largely cost-effective: according to least and most expensive scenarios, incremental cost-effectiveness ratios ranged from $60,311 to $47,407 per quality-adjusted life-year. CONCLUSION: This 'on demand' PrEP strategy ranges from cost-saving to largely cost-effective. The authors believe it represents an important public health strategy for the prevention of HIV transmission. © 2015 Canadian Pediatric Society. All rights reserved. Article	2015	Page K.; Tsui J.; Maher L.; Choopanya K.; Vanichseni S.; Philip Mock M.; Celum C.; Martin M.	Biomedical HIV prevention including pre-exposure prophylaxis and opiate agonist therapy for women who inject drugs: State of research and future directions	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000000641	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946956621&doi=10.1097%2fQAI.0000000000000641&partnerID=40&md5=127fbfb324a7f19649766eac20acd0c8	Women who inject drugs (WWID) are at higher risk of HIV compared with their male counterparts as a result of multiple factors, including biological, behavioral, and sociostructural factors, yet comparatively little effort has been invested in testing and delivering prevention methods that directly target this group. In this article, we discuss the need for expanded prevention interventions for WWID, focusing on 2 safe, effective, and approved, yet underutilized biomedical prevention methods: opiate agonist therapy (OAT) and oral pre-exposure prophylaxis (PrEP). Although both interventions are well researched, they have not been well examined in the context of gender. We discuss the drivers of women injectors' higher HIV risk, review the effectiveness of OAT and PrEP interventions among women, and explain why these new HIV prevention tools should be prioritized for WWID. There is substantial potential for impact of OAT and PrEP programs for WWID in the context of broader gender-responsive HIV prevention initiatives. Although awaiting efficacy data on other biomedical approaches in the HIV prevention research "pipeline," we propose that the scale-up and implementation of these proven, safe, and effective interventions are needed now. Article	2015	Parsons, Jeffrey T; Rendina, H Jonathon; Grov, Christian; Ventuneac, Ana; Mustanski, Brian	Accuracy of highly sexually active gay and bisexual men's predictions of their daily likelihood of anal sex and its relevance for intermittent event-driven HIV pre-exposure prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000000507	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4334732/	OBJECTIVE: We sought to examine highly sexually active gay and bisexual men's accuracy in predicting their sexual behavior for the purposes of informing future research on intermittent event-driven HIV Pre-Exposure Prophylaxis. DESIGN: For 30 days, 92 HIV-negative men completed a daily survey about their sexual behavior (n = 1688 days of data) and indicated their likelihood of having anal sex with a casual male partner next day. METHOD: We used multilevel modeling to analyze the association between self-reported likelihood of and subsequent engagement in anal sex. RESULTS: We found a linear association between men's reported likelihood of anal sex with casual partners and the actual probability of engaging in sex, although men overestimated the likelihood of sex. Overall, we found that men were better at predicting when they would not have sex than when they would, particularly if any likelihood value greater than 0% was treated as indicative that sex might occur. We found no evidence that men's accuracy of prediction was affected by whether it was a weekend or whether they were using substances, although both did increase the probability of sex. DISCUSSION: These results suggested that, men taking event-driven intermittent Pre-Exposure Prophylaxis, 14% of doses could have been safely skipped with a minimal rate of false negatives using guidelines of taking a dose unless there was no chance (ie, 0% likelihood) of sex on next day. This would result in savings of over US $1300 per year in medication costs per participant. Article	2015	Pathela, Preeti; Braunstein, Sarah L.; Blank, Susan; Shepard, Colin; Schillinger, Julia A.	The high risk of an HIV diagnosis following a diagnosis of syphilis: a population-level analysis of New York City men.	Clinical Infectious Diseases	-	-	-	-	1537-6591 1058-4838	10.1093/cid/civ289	https://pubmed.ncbi.nlm.nih.gov/25870333/	BACKGROUND: Epidemiologic studies have shown that syphilis is associated with risk for human immunodeficiency virus (HIV) infection. We used population-level syphilis and HIV data to quantify HIV incidence among men following primary or secondary (P&S) syphilis diagnoses and identify the highest-risk subgroups for intensified prevention, such as pre-exposure prophylaxis with antiretroviral medications. METHODS: Male cases reported to the New York City HIV/AIDS and Sexually Transmitted Disease (STD) surveillance registries were matched using a deterministic algorithm. We measured HIV incidence following P&S syphilis diagnosed between 2000 and June 2010 and identified risk factors for HIV infection using Cox proportional hazards models. RESULTS: Of 2805 men with syphilis contributing 11 714 person-years of follow-up, 423 (15.1%) acquired HIV; annual incidence was 3.61% (95% confidence interval CI, 3.27%, 3.97%). HIV incidence was high among men who have sex with men (MSM) (5.56%, 95% CI, 5.02%-6.13%); males with secondary compared with primary syphilis (4.10% vs 2.64%, P < .0001); and males diagnosed with another bacterial STD after syphilis (7.89%, 95% CI, 6.62%-9.24%). CONCLUSIONS: HIV incidence among men diagnosed with syphilis is high; one in 20 MSM were diagnosed with HIV within a year. Our data have implications for syphilis and HIV screening and may be useful for further targeting HIV-negative populations for pre-exposure prophylaxis. Antiretroviral pre-exposure prophylaxis does not enhance immune responses to HIV in exposed but uninfected persons	Journal of Infectious Diseases	-	-	-	-	221899	10.1093/infdis/jiu815	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84930332067&doi=10.1093%2finfdis%2fjiu815&partnerID=40&md5=921310182abf8669da346ee0af13acae	Background. Antiretroviral preexposure prophylaxis (PrEP), using daily oral combination tenofovir disoproxil fumarate plus emtricitabine, is an effective human immunodeficiency virus (HIV) prevention strategy for populations at high risk of HIV acquisition. Although the primary mode of action for the protective effect of PrEP is probably direct antiviral activity, nonhuman primate studies suggest that PrEP may also allow for development of HIV-specific immune responses, hypothesized to result from aborted HIV infections providing a source of immunologic priming. We sought to evaluate whether PrEP affects the development of HIV-specific immune response in humans. Methods and Results. Within a PrEP clinical trial among high-risk heterosexual African men and women, we detected HIV-specific CD4+ and CD8+ peripheral blood T-cell responses in 10%-20% of 247 subjects evaluated. The response rate and magnitude of T-cell responses did not vary significantly between those assigned PrEP versus placebo, and no significant difference between those assigned PrEP and placebo was observed in measures of innate immune function. Conclusions. We found no evidence to support the hypothesis that PrEP alters either the frequency or magnitude of HIV-specific immune responses in HIV-1-exposed seronegative individuals. These results suggest that PrEP is unlikely to serve as an immunologic prime to aid protection by a putative HIV vaccine. © 2014 The Author.	cellular immunity; HIV-1; prevention of sexual transmission; T-lymphocyte	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2015	Pérez-Figueroa R.E.; Kapadia F.; Barton S.C.; Eddy J.A.; Halkitis P.N.	Acceptability of prep uptake among racially/ethnically diverse young men who have sex with men: The p18 study	AIDS Education and Prevention	-	-	-	-	8999546	10.1521/aeap.2015.27.2.112	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84939214113&doi=10.1521%2faeap.2015.27.2.112&partnerID=40&md5=d39a7930cf2ef6fdd1b7078dd2dc1f69	Pre-exposure prophylaxis (PrEP) is considered an effective biomedical approach for HIV prevention. However, there is limited understanding of PrEP uptake among racially/ethnically and socioeconomically diverse young men who have sex with men (YMSM). This study examined attitudes and perceptions toward PrEP uptake among YMSM by conducting semistructured interviews with a sample (N 100) of YMSM in New York City. Thematic analysis was employed to explore key issues related to attitudes and perceptions toward PrEP utilization. Findings suggest that self-perceived risk for HIV transmission, enjoying unprotected sex, and being in a romantic relationship were associated with PrEP uptake. The most prominent barriers to PrEP uptake included costs, adherence regimen, and access. In summary, these findings underscore the importance of addressing behavioral and structural factors in maximizing the effectiveness of PrEP. In addition, PrEP implementation programs ought to consider the role of social and structural challenges to PrEP uptake and adherence among YMSM. © 2015 The Guilford Press. Article	2015	Peterson K.; Folayan M.O.; Chigwedere E.; Nthete E.	Saying No to PrEP research in Malawi: What constitutes failure in offshored HIV prevention research?	Anthropology and Medicine	-	-	-	-	13648470	10.1080/13648470.2015.1081377	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84954377321&doi=10.1080%2f13648470.2015.1081377&partnerID=40&md5=54f6664a02d51d84c5de7ebc87181f41	Between 2004 and 2005, the first multi-sited clinical trial tested whether an existing, marketed antiretroviral drug, Tenofovir (TDF), could prevent HIV transmission. Referred to as pre-exposure prophylaxis (PrEP), most of these trial sites prematurely closed down. Two sites located in Cambodia and Cameroon received international media attention. But little attention was drawn to sites in Malawi and Nigeria, where university ethicists and research scientists extensively debated PrEP. This article focuses on events that took place in Malawi where there was a prolonged dispute over the scientific rationales of PrEP and not trial specific ethics referred to as bioethics. Specifically, the article discusses debates pertaining to three PrEP trial protocols that were refused ethics approval in Malawi between 2004 and 2009. It is argued that HIV science debates in Malawi are embedded in postcolonial politics - geopolitical histories and state and household economic dispossessions that have created the structural possibilities for Malawi to become an offshore destination for HIV clinical research. As such, ethics in this case does not pertain to trial or bioethical failures. Rather, ethics is located at the scale of imperial relations that give rise to multiple, often invisible, research concerns and constraints. © 2015 Taylor & Francis. Article	2015	Pettifor A.; Nguyen N.L.; Celum C.; Cowan F.M.; Go V.; Hightow-Weidman L.	Tailored combination prevention packages and PrEP for young key populations	Journal of the International AIDS Society	-	-	-	-	17582652	10.7448/IAS.18.2.19434	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84924337183&doi=10.7448%2fIAS.18.2.19434&partnerID=40&md5=91e24722ef3a3f85eb0fb5390b2fd6f1	Young key populations, defined in this article as men who have sex with men, transgender persons, people who sell sex and people who inject drugs, are at particularly high risk for HIV. Due to the often marginalized and sometimes criminalized status of young people who identify as members of key populations, there is a need for HIV prevention packages that account for the unique and challenging circumstances they face. Pre-exposure prophylaxis (PrEP) is likely to become an important element of combination prevention for many young key populations. Objective: In this paper, we discuss important challenges to HIV prevention among young key populations, identify key components of a tailored combination prevention package for this population and examine the role of PrEP in these prevention packages. Methods: We conducted a comprehensive review of the evidence to date on prevention strategies, challenges to prevention and combination prevention packages for young key populations. We focused specifically on the role of PrEP in these prevention packages and on young people under the age of 24, and 18 in particular. Results and discussion: Combination prevention packages that include effective, acceptable and scalable behavioural, structural and biologic interventions are needed for all key populations to prevent new HIV infections. Interventions in these packages should meaningfully involve beneficiaries in the design and implementation of the intervention, and take into account the context in which the intervention is being delivered to thoughtfully address issues of stigma and discrimination. These interventions will likely be most effective if implemented in conjunction with strategies to facilitate an enabling environment, including increasing access to HIV testing and health services for PrEP and other prevention strategies, decriminalizing key populations' practices, increasing access to prevention and care, reducing stigma and discrimination, and fostering community empowerment. PrEP could offer a highly effective, time-limited primary prevention for young key populations if it is implemented in combination with other programs to increase access to health services and encourage the reliable use of PrEP while at risk of HIV exposure. Conclusions: Reductions in HIV incidence will only be achieved through the implementation of combinations of interventions that include biomedical and behavioural interventions, as well as components that address social, economic and other structural factors that influence HIV prevention and transmission. ©2015 Pettifor A et al;. Article	2015	Phanuphak, Nittaya; Lo, Ying-Ru; Shao, Yiming; Solomon, Sunil Suhas; O'Connell, Robert J.; Tovanabutra, Sodsai; Chang, David; Kim, Jerome H.; Excler, Jean Louis	HIV Epidemic in Asia: Implications for HIV Vaccine and Other Prevention Trials.	AIDS Research and Human Retroviruses	-	-	-	-	1931-8405 0889-2229	10.1089/aid.2015.0049	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4651036/	An overall decrease of HIV prevalence is now observed in several key Asian countries due to effective prevention programs. The decrease in HIV prevalence and incidence may further improve with the scale-up of combination prevention interventions. The implementation of future prevention trials then faces important challenges. The opportunity to identify heterosexual populations at high risk such as female sex workers may rapidly wane. With unabating HIV epidemics among men who have sex with men (MSM) and transgender (TG) populations, an effective vaccine would likely be the only option to turn the epidemic. It is more likely that efficacy trials will occur among MSM and TG because their higher HIV incidence permits smaller and less costly trials. The constantly evolving patterns of HIV-1 diversity in the region suggest close monitoring of the molecular HIV epidemic in potential target populations for HIV vaccine efficacy trials. CRF01_AE remains predominant in southeast Asian countries and MSM populations in China. This relatively steady pattern is conducive to regional efficacy trials, and as efficacy warrants, to regional licensure. While vaccines inducing nonneutralizing antibodies have promise against HIV acquisition, vaccines designed to induce broadly neutralizing antibodies and cell-mediated immune responses of greater breadth and depth in the mucosal compartments should be considered for testing in MSM and TG. The rationale and design of efficacy trials of combination prevention modalities such as HIV vaccine and preexposure prophylaxis (PrEP) remain hypothetical, require high adherence to PrEP, are more costly, and present new regulatory challenges. The prioritization of prevention interventions should be driven by the HIV epidemic and decided by the country-specific health and regulatory authorities. Modeling the impact and cost-benefit may help this decision process. Article	2015	Pokharkar, Varsha B.; Jolly, Mallika R.; Kumbhar, Dipak D.	Engineering of a hybrid polymer-lipid nanocarrier for the nasal delivery of tenofovir disoproxil fumarate: physicochemical, molecular, microstructural, and stability evaluation.	European Journal of Pharmaceutical Sciences	-	-	-	-	1879-0720 0928-0987	10.1016/j.ejps.2015.02.009	https://pubmed.ncbi.nlm.nih.gov/25708940/	PURPOSE: To engineer a hybrid nanocarrier system based on lipid and polymer for the nasal delivery of tenofovir disoproxil fumarate (TDF), and further to investigate its physicochemical, molecular, microstructural, and stability aspects. METHODS: Nanoparticles were prepared by melt emulsification-probe sonication technique. A 3(2) factorial design was used to identify key formulation variables influencing the characteristics of drug-loaded carrier. FT-IR, mass spectroscopy (MS) and (1)H NMR was used to probe molecular interactions among the components of the system, while the surface morphology was imagined through electron microscopy (TEM and SEM). Thermal analysis and powder X-ray diffraction (PXRD) was used to explore melting and crystallization behavior of drug and the carrier lipid. PLN-9 GEL was studied for its rheology, drug release, ex-vivo permeation, histopathology, and stability. RESULTS: Batch PLN-9 had size of 239 nm, drug encapsulation of 87.14% and revealed spherical morphology. MS, FT-IR and (1)H NMR established compatibility between the drug (TDF) and the carrier lipid (Lauric acid), while, a strong H-bonding was identified between the amino (-NH2) group of drug and the carboxyl (-COOH) group of pemulen polymer. Thermal analysis confirmed an amorphous TDF within the carrier matrix. PXRD analysis indicated substantial change in the molecular packing and subcell structure of carrier lipid during the PLN processing. PLN-9 GEL had shear thinning rheology, an anomalous type (n>0.5) of drug release and possessed potential to transport TDF across the nasal mucosa with an average flux of 135.36 μg/cm(2)/h. CONCLUSION: The designed carrier can encapsulate TDF and accentuates its transnasal flux, thus could be used as a carrier for an effective nasal delivery of TDF. Article	2015	Radzio J.; Spreen W.; Yueh Y.L.; Mitchell J.; Jenkins L.; García-Lerma J.G.; Heneine W.	The long-acting integrase inhibitor GSK744 protects macaques from repeated intravaginal SHIV challenge	Science Translational Medicine	-	-	-	-	19466234	10.1126/scitranslmed.3010297	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84921044609&doi=10.1126%2fscitranslmed.3010297&partnerID=40&md5=3a3a7e6adc72cad254c234bd11595ff0	Daily preexposure prophylaxis (PrEP) with Truvada is a proven HIV prevention strategy; however, its effectiveness is limited by low adherence. Antiretroviral drug formulations that require infrequent dosing may increase adherence and thus PrEP effectiveness. We investigated whether monthly injections of a long-acting formulation of the HIV integrase inhibitor GSK1265744 (GSK744 LA) prevented simian/human immunodeficiency virus (SHIV) infection by vaginal challenge inmacaques. Female pigtailmacaques (n = 12) were exposed to intravaginal inoculations of SHIV twice a week for up to 11 weeks. Half of the animals received a GSK744 LA injection every 4 weeks, and half received placebo. GSK744 LA, at plasma concentrations achievablewith quarterly injections in humans, protected all six macaques from infection. Placebo controls were all infected after a median of 4 (range, 2 to 20) vaginal challenges with SHIV. Efficacy was related to high and sustained vaginal and plasma drug concentrations that remained above the protein-adjusted 90% inhibitory concentration during the dosing cycles. These data support advancement of GSK744 LA as a potential PrEP candidate for women. © 2015, American Association for the Advancement of Science. All rights reserved. Article	2015	Raffi, F; Rachlis, A; Brinson, C; Arasteh, K; Gorgolas, M; Brennan, C; Pappa, K; Almond, S; Granier, C; Nichols, WG; Cuffe, RL; Eron, J; Walmsley, S	Dolutegravir efficacy at 48 weeks in key subgroups of treatment-naive HIV-infected individuals in three randomized trials	AIDS	-	-	-	-	NA	10.1097/QAD.0000000000000519	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01040219/full	Objectives: Dolutegravir (DTG) has been studied in three trials in HIV treatment-naive participants, showing noninferiority compared with raltegravir (RAL), and superiority compared with efavirenz and ritonavir-boosted darunavir. We explored factors that predicted treatment success, the consistency of observed treatment differences across subgroups and the impact of NRTI backbone on treatment outcome. Design: Retrospective exploratory analyses of data from three large, randomized, international comparative trials: SPRING-2, SINGLE, and FLAMINGO. Methods: We examined the efficacy of DTG in HIV-infected participants with respect to relevant demographic and HIV-1-related baseline characteristics using the primary efficacy endpoint from the studies (FDA snapshot) and secondary endpoints that examine specific elements of treatment response. Regression models were used to analyze pooled data from all three studies. Results: Snapshot response was affected by age, hepatitis co-infection, HIV risk factor, baseline CD4+ cell count, and HIV-1 RNA by third agent. Differences between DTG and other third agents were generally consistent across these subgroups. There was no evidence of a difference in snapshot response between abacavir/lamivudine (ABC/3TC) and tenofovir/emtricitabine (TDF/FTC) overall ABC/3TC 86%, TDF/FTC 85%, difference 1.1%, confidence interval (CI) -1.8, 4.0 percentage points, P = 0.61 or at high viral loads (difference -2.5, 95% CI -8.9, 3.8 percentage points, P = 0.42). Conclusions: DTG is a once-daily, unboosted integrase inhibitor that is effective in combination with either ABC/3TC or TDF/FTC for first-line antiretroviral therapy in HIV-positive individuals with a variety of baseline characteristics.	*Human immunodeficiency virus infection /drug therapy /drug therapy; *drug efficacy; Adenine analogs & derivatives, therapeutic use; Adult; Antiretroviral Therapy, Highly Active methods; Anti-HIV Agents *therapeutic use; Article; CD4 Lymphocyte Count; CD4 lymphocyte count; Clinical Trials, Phase III as Topic; Coinfection; Comparative study; Controlled study; Demography; Deoxycytidine analogs & derivatives, therapeutic use; Dideoxynucleosides *therapeutic use; Double blind procedure; Drug Combinations; Emtricitabine; Exploratory research; Female; HIV Infections *drug therapy; HIV Integrase Inhibitors therapeutic use; HIV Protease Inhibitors therapeutic use; HIV-1; Hepatitis; Heterocyclic Compounds, 3-Ring *therapeutic use; Human; Human immunodeficiency virus infected patient; Humans; Lamivudine *therapeutic use; Major clinical study; Male; Mixed infection; Organophosphonates therapeutic use; Oxazines; Phase 3 clinical trial; Piperazines; Pyridones; Pyrrolidinones therapeutic use; Raltegravir Potassium; Randomized Controlled Trials as Topic; Randomized controlled trial; Regression Analysis; Retrospective Studies; Retrospective study; Ritonavir therapeutic use; Tenofovir; Treatment Outcome; Treatment outcome; Treatment response; Viral Load; Virus load	English	United Kingdom	Western and Central Europe and North America	France	Western and Central Europe and North America	France	Western and Central Europe and North America	Clinical
Article	2015	Ramezani, Ali; Dubrovsky, Larisa; Pushkarsky, Tatiana; Sviridov, Dmitri; Karandish, Sara; Raj, Dominic S.; Fitzgerald, Michael L.; Bukrinsky, Michael	Stimulation of Liver X Receptor Has Potent Anti-HIV Effects in a Humanized Mouse Model of HIV Infection.	The Journal of Pharmacology and Experimental Therapeutics	-	-	-	-	1521-0103 0022-3565	10.1124/jpet.115.224485	https://pubmed.ncbi.nlm.nih.gov/26126533/	Previous studies demonstrated that liver X receptor (LXR) agonists inhibit human immunodeficiency virus (HIV) replication by upregulating cholesterol transporter ATP-binding cassette A1 (ABCA1), suppressing HIV production, and reducing infectivity of produced virions. In this study, we extended these observations by analyzing the effect of the LXR agonist T0901317 N-4-(1,1,1,3,3,3-hexafluoro-2-hydroxypropan-2-yl)phenyl-N-(2,2,2-trifluoroethyl)benzenesulfonamide on the ongoing HIV infection and investigating the possibility of using LXR agonist for pre-exposure prophylaxis of HIV infection in a humanized mouse model. Pre-exposure of monocyte-derived macrophages to T0901317 reduced susceptibility of these cells to HIV infection in vitro. This protective effect lasted for up to 4 days after treatment termination and correlated with upregulated expression of ABCA1, reduced abundance of lipid rafts, and reduced fusion of the cells with HIV. Pre-exposure of peripheral blood leukocytes to T0901317 provided only a short-term protection against HIV infection. Treatment of HIV-exposed humanized mice with LXR agonist starting 2 weeks postinfection substantially reduced viral load. When eight humanized mice were pretreated with LXR agonist prior to HIV infection, five animals were protected from infection, two had viral load at the limit of detection, and one had viral load significantly reduced relative to mock-treated controls. T0901317 pretreatment also reduced HIV-induced dyslipidemia in infected mice. In conclusion, these results reveal a novel link between LXR stimulation and cell resistance to HIV infection and suggest that LXR agonists may be good candidates for development as anti-HIV agents, in particular for pre-exposure prophylaxis of HIV infection. Article	2015	Reddy, Ambavaram Vijaya Bhaskar; Jaafar, Jafariah; Aris, Azmi Bin; Majid, Zaiton Abdul; Umar, Khalid; Talib, Juhaizah; Madhavi, Gajulapalle	Development and validation of a rapid ultra high performance liquid chromatography with tandem mass spectrometry method for the simultaneous determination of darunavir, ritonavir, and tenofovir in human plasma: Application to human pharmacokinetics.	Journal of Separation Science	-	-	-	-	1615-9314 1615-9306	10.1002/jssc.201500250	https://pubmed.ncbi.nlm.nih.gov/25989063/	A sensitive ultra high performance liquid chromatography with tandem mass spectrometry method was developed for the simultaneous determination of darunavir, ritonavir and tenofovir in human plasma. Sample preparation involved a simple liquid-liquid extraction using 200 μL of human plasma extracted with methyl tert-butyl ether for three analytes and internal standard. The separation was accomplished on an Acquity UPLC BEH C18 (50 mm × 2.1 mm, 1.7 μm) analytical column using gradient elution of acetonitrile/methanol (80:20, v/v) and 5.0 mM ammonium acetate containing 0.01% formic acid at a flow rate of 0.4 mL/min. The linearity of the method ranged between 20.0 and 12 000 ng/mL for darunavir, 2.0 and 2280 ng/mL for ritonavir, and 14.0 and 1600 ng/mL for tenofovir using 200 μL of plasma. The method was completely validated for its selectivity, sensitivity, linearity, precision and accuracy, recovery, matrix effect, stability, and dilution integrity. The extraction recoveries were consistent and ranged between 79.91 and 90.04% for all three analytes and internal standard. The method exhibited good intra-day and inter-day precision between 1.78 and 6.27%. Finally the method was successfully applied for human pharmacokinetic study in eight healthy male volunteers after the oral administration of 600 mg darunavir along with 100 mg ritonavir and 100 mg tenofovir as boosters. Article	2015	Reynolds E.E.; Libman H.; Mayer K.H.	Preexposure prophylaxis for HIV prevention: Grand rounds discussion from beth Israel deaconess medical center	Annals of Internal Medicine	-	-	-	-	34819	10.7326/M15-1993	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84950318996&doi=10.7326%2fM15-1993&partnerID=40&md5=3fb5960198d29cab0a807fadcfb26f7b	The U.S. Public Health Service recently issued guidelines about the daily use of medication as preexposure prophylaxis (PrEP) to prevent HIV infection. The guidelines, based on randomized trials showing substantial reduction in HIV transmission among those receiving a daily combination of tenofovir and emtricitabine, suggest physicians offer PrEP to patients at high risk, including nonmonogamous men who have sex with men, serodiscordant couples (in both male-male and male-female relationships), heterosexual men and women in other risk groups (such as sex workers or those with recent sexually transmitted infection), and injection drug users. Here, 2 prominent HIV experts debate the use of PrEP in a 45-year-old man whose husband has HIV infection with an undetectable viral load on treatment. They discuss the patient's risk for HIV transmission from his husband and from other partners, the magnitude of the risk reduction he would gain with PrEP, and nonpharmacologic alternatives to reduce his likelihood of contracting HIV infection. © 2015 American College of Physicians. Article	2015	Rowniak, Stefan	PrEP: A case study.	Journal of the American Association of Nurse Practitioners	-	-	-	-	2327-6924	10.1002/2327-6924.12240	https://dx.doi.org/10.1002/2327-6924.12240	PURPOSE: The purpose of this case study is to present information and raise awareness about the provision of pre-exposure prophylaxis (PrEP) to those individuals who are at risk for HIV infection. DATA SOURCES: PubMed, CINAHL, government websites, press releases, and the author's clinical experiences. CONCLUSIONS: PrEP is the latest tool available for HIV prevention that has been approved by the FDA. It involves taking the HIV medication TDF/FTC on a daily basis. Documented side effects are minimal but renal monitoring is recommended because of possible kidney damage. PrEP may provide as much as 90% protection against HIV infection, but this is dependent upon patient compliance. IMPLICATIONS FOR PRACTICE: Nurse practitioners are in an ideal position to be the gatekeepers for information and access to PrEP. However, this requires that they engage in thorough risk assessments with their patients. This includes both a comprehensive sexual history and drug use history. The case study demonstrates the importance of intervention in and recognition of high-risk stigmatized populations such as transgender individuals and that prompt action may prevent future HIV infections. Article	2015	Santos, José R.; Saumoy, María; Curran, Adrian; Bravo, Isabel; Llibre, Josep M.; Navarro, Jordi; Estany, Carla; Podzamczer, Daniel; Ribera, Esteban; Negredo, Eugènia; Clotet, Bonaventura; Paredes, Roger	The lipid-lowering effect of tenofovir/emtricitabine: a randomized, crossover, double-blind, placebo-controlled trial.	Clinical Infectious Diseases	-	-	-	-	1537-6591 1058-4838	10.1093/cid/civ296	https://academic.oup.com/cid/article/61/3/403/490899	BACKGROUND: It is unknown if tenofovir disoproxil fumarate (TDF), which is often coformulated with the lipid-neutral emtricitabine (FTC), has a lipid-lowering effect. METHODS: We performed a randomized, crossover, double-blind, placebo-controlled clinical trial on human immunodeficiency virus type 1 (HIV-1)-infected subjects with HIV-1 RNA < 50 copies/mL during ≥6 months on stable darunavir/ritonavir (800/100 mg once daily) or lopinavir/ritonavir (400/100 mg twice daily) monotherapy, fasting total cholesterol (TC) ≥200 mg/dL or low-density lipoprotein cholesterol (LDL-c) ≥130 mg/dL, and no lipid-lowering drugs. In arm 1, TDF/FTC was added for 12 weeks, followed by 12 weeks of placebo (washout) and 12 additional weeks of placebo (placebo period). Subjects in arm 2 added placebo for 12 weeks (placebo period) followed by TDF/FTC for 12 weeks and placebo for 12 additional weeks (washout). The primary endpoint was change in median fasting TC levels. RESULTS: Of 46 subjects enrolled, 56% received darunavir/ritonavir and 44% lopinavir/ritonavir. Exposure to TDF/FTC reduced TC from 234 to 205 mg/dL (P < .001), LDL-c from 155 to 128 mg/dL (P < .001), and high-density lipoprotein cholesterol (HDL-c) from 50.3 to 44.5 mg/dL (P < .001). It also decreased the proportion of subjects with fasting TC ≥200 mg/dL from 86.7% to 56.8% (P = .001), and LDL-c ≥130 mg/dL from 87.8% to 43.9% (P < .001). After 12 weeks, TDF/FTC exposure was associated with lower TC and LDL-c levels than placebo (P = .001 and P = .002, respectively). The TC/HDL-c ratio and triglyceride levels did not change with TDF/FTC exposure. CONCLUSIONS: Coformulated TDF/FTC has an intrinsic lipid-lowering effect, likely attributable to TDF. Article	2015	Schneider, John A.; Zhou, A. Ning; Laumann, Edward O.	A new HIV prevention network approach: sociometric peer change agent selection.	Social Science & Medicine	-	-	-	-	1873-5347 0277-9536	10.1016/j.socscimed.2013.12.034	https://pubmed.ncbi.nlm.nih.gov/24518188/	Internationally, the Peer Change Agent (PCA) model is the most frequently used conceptual framework for HIV prevention. Change agents themselves can be more important than the messages they convey. PCA selection is operationalized via heterogeneous methods based upon individual-level attributes. A sociometric position selection strategy, however, could increase peer influence potency and halt transmission at key network locations. In this study, we selected candidate PCAs based upon relative sociometric bridging and centrality scores and assessed their attributes in comparison to one another and to existing peer educators. We focused upon an emerging HIV epidemic among men who have sex with men in Southern India in 2011. PCAs selected based on their bridging score were more likely to be innovators when compared to other centrally-located PCAs, to PCAs located on the periphery, and to existing peer educators. We also found that sociodemographic attributes and risk behaviors were similar across all candidate PCAs, but risk behaviors of existing peer educators differed. Existing peer educators were more likely to engage in higher risk behavior such as receiving money for sex when compared to sociometrically selected peer changes agents. These existing peer educators were also more likely to exhibit leadership qualities within the overall network; they were, however, just as likely as other non-trained candidate peer change agents to report important HIV intravention behavior (encouraging condoms within their network). The importance of identifying bridges who may be able to diffuse innovation more effectively within high risk HIV networks is especially critical given recent efficacy data from novel HIV prevention interventions such as pre-exposure prophylaxis. Moreover, while existing peer educators were more likely to be leaders in our analysis, using peer educators with high risk behavior may have limited utility in enacting behavior change among sex worker peers or male clients in the network. Article	2015	Seay, Kieran; Khajoueinejad, Nazanin; Zheng, Jian Hua; Kiser, Patrick; Ochsenbauer, Christina; Kappes, John C.; Herold, Betsy; Goldstein, Harris	The Vaginal Acquisition and Dissemination of HIV-1 Infection in a Novel Transgenic Mouse Model Is Facilitated by Coinfection with Herpes Simplex Virus 2 and Is Inhibited by Microbicide Treatment.	Journal of Virology	-	-	-	-	1098-5514 0022-538X	10.1128/JVI.01326-15	https://pubmed.ncbi.nlm.nih.gov/26157126/	Epidemiological studies have demonstrated that herpes simplex virus 2 (HSV-2) infection significantly increases the risk of HIV-1 acquisition, thereby contributing to the expanding HIV-1 epidemic. To investigate whether HSV-2 infection directly facilitates mucosal HIV-1 acquisition, we used our transgenic hCD4/R5/cT1 mouse model which circumvents major entry and transcription blocks preventing murine HIV-1 infection by targeting transgenic expression of human CD4, CCR5, and cyclin T1 genes to CD4(+) T cells and myeloid-committed cells. Productive infection of mucosal leukocytes, predominantly CD4(+) T cells, was detected in all hCD4/R5/cT1 mice intravaginally challenged with an HIV-1 infectious molecular clone, HIV-Du151.2env-NLuc, which expresses an env gene (C.Du151.2) cloned from an acute heterosexually infected woman and a NanoLuc luciferase reporter gene. Lower genital tract HIV-1 infection after HIV-Du151.2env-NLuc intravaginal challenge was increased ~4-fold in hCD4/R5/cT1 mice coinfected with HSV-2. Furthermore, HIV-1 dissemination to draining lymph nodes was detected only in HSV-2-coinfected mice. HSV-2 infection stimulated local infiltration and activation of CD4(+) T cells and dendritic cells, likely contributing to the enhanced HIV-1 infection in HSV-2-coinfected mice. We then used this model to demonstrate that a novel gel containing tenofovir disoproxil fumarate (TDF), the more potent prodrug of tenofovir (TFV), but not the TFV microbicide gel utilized in the recent CAPRISA 004, VOICE (Vaginal and Oral Interventions to Control the Epidemic), and FACTS 001 clinical trials, was effective as preexposure prophylaxis (PrEP) to completely prevent vaginal HIV-1 infection in almost half of HSV-2-coinfected mice. These results also support utilization of hCD4/R5/cT1 mice as a highly reproducible immunocompetent preclinical model to evaluate HIV-1 acquisition across the female genital tract. IMPORTANCE: Multiple epidemiological studies have reported that genital herpes simplex virus 2 (HSV-2) infection increases the risk of HIV-1 sexual acquisition by severalfold. Understanding the underlying mechanisms by which HSV-2 facilitates HIV-1 infection and optimizing the efficacy of therapies to inhibit HIV-1 infection during HSV-2 coinfection should contribute to reducing HIV-1 transmission. Using our novel transgenic hCD4/R5/cT1 mouse model infectible with HIV-1, we demonstrated that HSV-2 infection enhances vaginal transmission and dissemination of HIV-1 infection while stimulating recruitment and activation of CD4(+) T cells and dendritic cells in the lower genital tract. HIV acquisition by hCD4/R5/cT1 mice vaginally coinfected with HSV-2 could be completely prevented in almost half the mice by preexposure prophylaxis (PrEP) with a novel gel containing tenofovir disoproxil fumarate (TDF), the tenofovir prodrug, but not with the tenofovir microbicide gel utilized in CAPRISA-004, VOICE, and FACTS-001 clinical trials. The hCD4/R5/cT1 mice represent a new preclinical mouse model to evaluate vaginal HIV-1 acquisition. Article	2015	Seifert S.M.; Glidden D.V.; Meditz A.L.; Castillo-Mancilla J.R.; Gardner E.M.; Predhomme J.A.; Rower C.; Klein B.; Kerr B.J.; Guida L.A.; Zheng J.-H.; Bushman L.R.; Anderson P.L.	Dose response for starting and stopping HIV preexposure prophylaxis for men who have sex with men	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciu916	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84935513976&doi=10.1093%2fcid%2fciu916&partnerID=40&md5=63262d408a1e5739ff5f1d4a2f51490b	Background. This study estimated the number of daily tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) doses required to achieve and maintain (after discontinuation) intracellular drug concentrations that protect against human immunodeficiency virus (HIV) infection for men who have sex with men (MSM). Methods. Tenofovir diphosphate (TFV-DP) concentrations in peripheral blood mononuclear cells (PBMCs) and rectal mononuclear cells from an intensive pharmacokinetic study ("Cell-PrEP" preexposure prophylaxis) of 30 days of daily TDF/FTC followed by 30 days off drug were evaluated. A regression formula for HIV risk reduction derived from PBMCs collected in the preexposure prophylaxis initiative study was used to calculate inferred HIV risk reduction. Time required to reach steady state for TFV-DP in rectal mononuclear cells was also determined. Results. Twenty-one HIV-uninfected adults participated in Cell-PrEP. The inferred HIV risk reduction, based on PBMC TFV-DP concentration, reached 99% (95% confidence interval CI, 69%-100%) after 5 daily doses, and remained <90% for 7 days after stopping drug from steady-state conditions. The proportion of participants reaching the 90% effective concentration (EC90) was 77% after 5 doses and 89% after 7 doses. The percentage of steady state for natural log TFV-DP in rectal mononuclear cells was 88% (95% CI, 66%-94%) after 5 doses and 94% (95% CI, 78%-98%) after 7 doses. Conclusions. High PrEP activity for MSM was achieved by approximately 1 week of daily dosing. Although effective intracellular drug concentrations persist for several days after stopping PrEP, a reasonable recommendation is to continue PrEP dosing for 4 weeks after the last potential HIV exposure, similar to recommendations for postexposure prophylaxis. © The Author 2014. Article	2015	Shey, Muki S.; Garrett, Nigel J.; McKinnon, Lyle R.; Passmore, Jo-Ann S.	The role of dendritic cells in driving genital tract inflammation and HIV transmission risk: are there opportunities to intervene?	Innate Immunity	-	-	-	-	1753-4267 1753-4259	10.1177/1753425913513815	https://pubmed.ncbi.nlm.nih.gov/24282122/	Effective prevention of new HIV infections will require an understanding of the mechanisms involved in HIV acquisition. HIV transmission across the female genital tract is the major mode of new HIV infections in sub-Saharan Africa and involves complex processes, including cell activation, inflammation and recruitment of HIV target cells. Activated CD4(+) T-cells, dendritic cells (DC) and macrophages have been described as targets for HIV at the genital mucosa. Activation of these cells may occur in the presence of sexually-transmitted infections, disturbances of commensal flora and other inflammatory processes. In this review, we discuss causes and consequences of inflammation in the female genital tract, with a focus on DC. We describe the central role these cells may play in facilitating or preventing HIV transmission across the genital mucosa, and in the initial recognition of HIV and other pathogens, allowing activation of an adaptive immune response to infection. We discuss studies that investigate interventions to limit DC activation, inflammation and HIV transmission. This knowledge is essential in the development of novel strategies for effective HIV control, including microbicides and pre-exposure prophylaxis. Article	2015	Siegfried, Nandi; Beanland, Rachel L; Ford, Nathan; Mayer, Kenneth H	Formulating the Future Research Agenda for Postexposure Prophylaxis for HIV: Methodological Challenges and Potential Approaches	Clinical Infectious Diseases	-	-	-	-	10584838	NA	https://www.proquest.com/scholarly-journals/formulating-future-research-agenda-postexposure/docview/1684374797/se-2?accountid=8113	During a World Health Organization-convened Guideline Development Group meeting, recommendations for postexposure prophylaxis (PEP) for human immunodeficiency virus were made and research gaps identified. We used the PEP clinical management pathway and the Grading of Evidence, Assessment, Development and Evaluation (GRADE) system as a framework to formulate future research questions, describe the most feasible study design, and identify potential biases. Three key study design formats were identified to address 12 research questions: (1) survey- and interview-driven research to identify barriers to access to PEP and related clinical care; (2) establishment of a global PEP registry to generate data to inform the choice of an optimal PEP drug regimen, record drug toxicities arising from specific PEP regimens, and track follow-up and linkage to care (including transition from PEP to preexposure prophylaxis); and (3) randomized controlled trials to determine the optimal adherence promotion strategies necessary for successful outcomes following PEP. Positioning key clinical and programmatic research questions within the GRADE framework facilitates the formulation of an evidence-based research agenda and future revisions of guidelines. Article	2015	Siemieniuk R.A.C.; Sivachandran N.; Murphy P.; Sharp A.; Walach C.; Placido T.; Bogoch I.I.	Transitioning to HIV Pre-Exposure Prophylaxis (PrEP) from Non-Occupational Post-Exposure Prophylaxis (nPEP) in a comprehensive HIV prevention clinic: A prospective cohort study	AIDS Patient Care and STDs	-	-	-	-	10872914	10.1089/apc.2015.0014	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84938366314&doi=10.1089%2fapc.2015.0014&partnerID=40&md5=2aa2277aa5d2113a355c79fce105299d	The uptake of pre-exposure prophylaxis (PrEP) for HIV prevention remains low. We hypothesized that a high proportion of patients presenting for HIV non-occupational post-exposure prophylaxis (nPEP) would be candidates for PrEP based on current CDC guidelines. Outcomes from a comprehensive HIV Prevention Clinic are described. We evaluated all patients who attended the HIV Prevention Clinic for nPEP between January 1, 2013 and September 30, 2014. Each patient was evaluated for PrEP candidacy based on current CDC-guidelines and subjectively based on physician opinion. Patients were then evaluated for initiation of PrEP if they met guideline suggestions. Demographic, social, and behavioral factors were then analyzed with logistic regression for associations with PrEP candidacy and initiation. 99 individuals who attended the nPEP clinic were evaluated for PrEP. The average age was 32 years (range, 18-62), 83 (84%) were male, of whom 46 (55%) men who had have sex with men (MSM). 31 (31%) met CDC guidelines for PrEP initiation, which had very good agreement with physician recommendation (kappa=0.88, 0.78-0.98). Factors associated with PrEP candidacy included sexual exposure to HIV, prior nPEP use, and lack of drug insurance (p<0.05 for all comparisons). Combining nPEP and PrEP services in a dedicated clinic can lead to identification of PrEP candidates and may facilitate PrEP uptake. Strategies to ensure equitable access of PrEP should be explored such that those without drug coverage may also benefit from this effective HIV prevention modality. © Mary Ann Liebert, Inc. 2015. Article	2015	Siemieniuk, Reed A; Bogoch, Isaac I	Preexposure prophylaxis for HIV infection.	New England Journal of Medicine	-	-	-	-	1533-4406	10.1056/NEJMc1502749	https://www.nejm.org/doi/full/10.1056/NEJMc1502749	TO THE EDITOR: The study by Marrazzo et al. (Feb. 5 issue)1 highlights the need for cautious monitoring during the rollout of preexposure prophylaxis against human immunodeficiency virus (HIV) infection. In keeping with the maxim "first, do no harm," the burden of proof against potential harm needs to be high, because people who qualify for preexposure prophylaxis are generally young and healthy. Tenofovir disoproxil fumarate (TDF) may reduce bone mineral density2 and is associated with proximal renal tubulopathy, phosphate wasting, and resultant osteomalacia.3 TDF may also have an effect on osteoblast function.4 It is unclear whether TDF-related loss of bone density is cumulatively dose-dependent, reversible, or more severe in geographic areas in which vitamin D deficiency is prevalent — all of which are factors that have long-term implications for young patients. Although clinical trials have not identified any clear signal of harm, intention-to-treat analyses underestimate the incidence of adverse effects, especially events with a long lead time. This underestimation is greater when compliance with a study-drug regimen is low, as it was in the study by Marrazzo et al. and in other trials.5 As the role of preexposure prophylaxis in the fight to end HIV infection appropriately expands, scientific vigilance is required for the early identification of any adverse consequences. Article	2015	Smith D.K.; Herbst J.H.; Rose C.E.	Estimating HIV protective effects of method adherence with combinations of preexposure prophylaxis and condom use among African American men who have sex with men	Sexually Transmitted Diseases	-	-	-	-	1485717	10.1097/OLQ.0000000000000238	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84921905379&doi=10.1097%2fOLQ.0000000000000238&partnerID=40&md5=1220d7bd28a241421b015291b7d11319	Prevention of sexually acquired HIV infection now includes both consistent condom use and daily use of oral antiretroviral preexposure prophylaxis (PrEP). Persons at substantial HIV risk can now use one or both prevention methods, but a combined HIV protective effect has not been assessed. METHODS: We use deterministic models to examine the impact of method adherence and rates of PrEP and male condom use on number of anticipated HIV infections. Analyses were based on hypothetical cohorts of 10,000 African American men who have sex with men (AAMSM), a population with the highest HIV incidence in the United States. Parameters used in the model (condom effectiveness, PrEP effectiveness, HIV incidence) were based on published findings. RESULTS: Among AAMSM who never use PrEP, an estimated 323 annual HIV infections would occur among those who always use condoms, 1007 among sometimes condom users, and 1094 among never condom users. Among AAMSM who never (or inconsistently) use condoms, 295 (272) infections would occur among those who report at least 90% PrEP adherence and 744 (684) infection occur with less than 50% adherence. Among AAMSM who are consistently (or sometimes) taking PrEP, the highest protection is seen with consistent condom use, 87 (220) HIV infections and 92.0% (79.9%) prevention effectiveness. DISCUSSION: Among AAMSM with inconsistent or never condom use, the addition of PrEP at either modest or high adherence can increase HIV protection. For consistent condom users, any PrEP use can increase HIV protection. These analyses provide an approach for rethinking HIV risk management by calculating combined HIV protective effects of using one or more effective prevention methods. Article	2015	Smith, Dawn K; Van Handel, Michelle; Wolitski, Richard J; Stryker, Jo Ellen; Hall, H Irene; Prejean, Joseph; Koenig, Linda J; Valleroy, Linda A	Vital signs: Estimated percentages and numbers of adults with indications for preexposure prophylaxis to prevent HIV acquisition — United States, 2015	MMWR Recommendations and Reports	-	-	-	-	1492195	10.15585/mmwr.mm6446a4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84951294025&doi=10.15585%2fmmwr.mm6446a4&partnerID=40&md5=4ef953a667e756e85602d5a8393152d5	Background: In 2014, approximately 40,000 persons in the United States received a diagnosis of human immunodeficiency virus (HIV) infection. Preexposure prophylaxis (PrEP) with daily oral antiretroviral medication is a new, highly effective intervention that could reduce the number of new HIV infections. Methods: CDC analyzed nationally representative data to estimate the percentages and numbers of persons in the United States, by transmission risk group, with indications for PrEP consistent with the 2014 U.S. Public Health Service's PrEP clinical practice guideline. Results: Approximately 24.7% of sexually active adult men who have sex with men (MSM) (492,000 95% confidence interval {CI} = 212,000-772,000), 18.5% of persons who inject drugs (115,000 CI = 45,000-185,000), and 0.4% of heterosexually active adults (624,000 CI = 404,000-846,000), had substantial risks for acquiring HIV consistent with PrEP indications. Conclusions: Based on current guidelines, many MSM, persons who inject drugs, and heterosexually active adults have indications for PrEP. A higher percentage of MSM and persons who inject drugs have indications for PrEP than heterosexually active adults, consistent with distribution of new HIV diagnoses across these populations. Implications for Public Health Practice: Clinical organizations, health departments, and community-based organizations should raise awareness of PrEP among persons with substantial risk for acquiring HIV infection and their health care providers. These data can be used to inform scale-up and evaluation of PrEP coverage. Increasing delivery of PrEP and other highly effective HIV prevention services could lower the number of new HIV infections occurring in the United States each year. © 2015, Department of Health and Human Services. Article	2015	Solomon, Marc M.; Nureña, César R.; Tanur, Judith M.; Montoya, Orlando; Grant, Robert M.; McConnell, J. Jeff	Transactional sex and prevalence of STIs: a cross-sectional study of MSM and transwomen screened for an HIV prevention trial.	International journal of STD & AIDS	-	-	-	-	1758-1052 0956-4624	10.1177/0956462414562049	https://journals.sagepub.com/doi/10.1177/0956462414562049	Few studies have characterised the degree of engagement in transactional sex among men and transgender women who have sex with men and explored its association with sexually transmitted infections and human immunodeficiency virus in Ecuador. We screened 642 men who have sex with men and transgender women for a pre-exposure prophylaxis clinical trial (iPrEx) in Guayaquil, Ecuador, 2007-2009. We analysed the association of degree of engagement in transactional sex and prevalence of sexually transmitted infections including human immunodeficiency virus using chi-square and analysis of variance tests. Although just 6.2% of those who screened self-identified as sex workers, 52.1% reported having engaged in transactional sex. Compared to those who had never been paid for sex, those who had been paid were more likely to have a sexually transmitted infection (56.6% vs. 45.0%, p = 0.007) and trended towards a higher human immunodeficiency virus prevalence (16.6% vs. 10.4%, p = 0.082) at screening. Transgender women compared to other men who have sex with men were more likely to have sexually transmitted infections diagnosed at screening (75.6% vs. 50.0%, p = 0.001). Transactional sex is practiced widely but occasionally among the men who have sex with men and transgender women in Guayaquil who screened for the iPrEx study; however, engaging in transactional sex may not lead to a sex worker self-identification. Both transactional sex and being a transgender woman are associated with sexually transmitted infections prevalence. Article	2015	Spector A.Y.; Remien R.H.; Tross S.	PrEP in substance abuse treatment: A qualitative study of treatment provider perspectives	Substance Abuse: Treatment, Prevention, and Policy	-	-	-	-	1747597X	10.1186/1747-597X-10-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84924245513&doi=10.1186%2f1747-597X-10-1&partnerID=40&md5=633eecb9f9544e0fbabd6775d3f97e56	Objectives: To examine substance abuse treatment providers' views on engaging clients in Pre-exposure Prophylaxis (PrEP) care and research trials. Methods: Thirty-six medical and counseling service providers in six New York City outpatient substance abuse treatment programs participated in semi-structured qualitative interviews. Thematic content analysis was conducted by three coders, independently. Results: Providers' perspectives toward PrEP were characterized by six salient themes: 1) Limited PrEP awareness. 2) Ambivalence about PrEP; 3) Perception of multiple challenges to delivery; 4) Uncertainty about clients' ability to be adherent to medication; 5) Concerns about medication safety/side effects; and 6) Perception of multiple barriers to conducting clinical trials. Conclusions: Despite anticipated challenges, providers supported the introduction of PrEP in outpatient substance abuse treatment. Comprehensive training for providers is needed and should include PrEP eligibility criteria, strategies to support adherence and medication monitoring guidelines. Linkages between substance abuse treatment and primary care and/or enhancement of capacity within clinics to offer PrEP may help facilitate PrEP delivery. When conducting research in outpatient clinics, it is particularly important to protect client confidentiality. © Spector et al. Article	2015	Sun L.; Wang F.; Liu A.; Xin R.; Zhu Y.; Li J.; Shao Y.; Ye J.; Chen D.; Li Z.	Natural conception may be an acceptable option in HIV-serodiscordant couples in resource limited settings	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0142085	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84951281482&doi=10.1371%2fjournal.pone.0142085&partnerID=40&md5=aa2edf8fb4b4f49b472efdaf811d3765	Many HIV serodiscordant couples have a strong desire to have their own biological children. Natural conception may be the only choice in some resource limited settings but data about natural conception is limited. Here, we reported our findings of natural conception in HIV serodiscordant couples. Between January 2008 and June 2014, we retrospectively collected data on 91 HIV serodiscordant couples presenting to Beijing Youan Hospital with childbearing desires. HIV counseling, effective ART on HIV infected partners, pre-exposure prophylaxis (PrEP) and post-exposure prophylaxis (PEP) in negative female partners and timed intercourse were used to maximally reduce the risk of HIV transmission. Of the 91 HIV serodiscordant couples, 43 were positive in male partners and 48 were positive in female partners. There were 196 unprotected vaginal intercourses, 100 natural conception and 97 newborns. There were no cases of HIV seroconversion in uninfected sexual partners. Natural conception may be an acceptable option in HIV-serodiscordant couples in resource limited settings if HIV-positive individuals have undetectable viremia on HAART, combined with HIV counseling, PrEP, PEP and timed intercourse. © 2015 Sun et al.This is an open access article distributed under the terms of the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original author and source are credited. Article	2015	Suntharasamai, Pravan; Martin, Michael; Choopanya, Kachit; Vanichseni, Suphak; Sangkum, Udomsak; Tararut, Pairote; Leelawiwat, Wanna; Anekvorapong, Rapeepan; Mock, Philip A; Cherdtrakulkiat, Thitima; Leethochawalit, Manoj; Chiamwongpaet, Sithisat; Gvetadze, Roman J; McNicholl, Janet M; Paxton, Lynn A; Kittimunkong, Somyot; Curlin, Marcel E	Assessment of Oral Fluid HIV Test Performance in an HIV Pre-Exposure Prophylaxis Trial in Bangkok, Thailand.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0145859	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4696659	BACKGROUND: Rapid easy-to-use HIV tests offer opportunities to increase HIV testing among populations at risk of infection. We used the OraQuick Rapid HIV-1/2 antibody test (OraQuick) in the Bangkok Tenofovir Study, an HIV pre-exposure prophylaxis trial among people who inject drugs. METHODS: The Bangkok Tenofovir Study was a randomized, double-blind, placebo-controlled trial. We tested participants' oral fluid for HIV using OraQuick monthly and blood using a nucleic-acid amplification test (NAAT) every 3 months. We used Kaplan-Meier methods to estimate the duration from a positive HIV NAAT until the mid-point between the last non-reactive and first reactive oral fluid test and proportional hazards to examine factors associated with the time until the test was reactive. RESULTS: We screened 3678 people for HIV using OraQuick. Among 447 with reactive results, 436 (97.5%) were confirmed HIV-infected, 10 (2.2%) HIV-uninfected, and one (0.2%) had indeterminate results. Two participants with non-reactive OraQuick results were, in fact, HIV-infected at screening yielding 99.5% sensitivity, 99.7% specificity, a 97.8% positive predictive value, and a 99.9% negative predictive value. Participants receiving tenofovir took longer to develop a reactive OraQuick (191.8 days) than participants receiving placebo (16.8 days) (p = 0.02) and participants infected with HIV CRF01_AE developed a reactive OraQuick earlier than participants infected with other subtypes (p = 0.04). DISCUSSION: The oral fluid HIV test performed well at screening, suggesting it can be used when rapid results and non-invasive tools are preferred. However, participants receiving tenofovir took longer to develop a reactive oral fluid test result than those receiving placebo. Thus, among people using pre-exposure prophylaxis, a blood-based HIV test may be an appropriate choice. TRIAL REGISTRATION: ClinicalTrials.gov NCT00119106. Article	2015	Tatham, Lee M.; Rannard, Steven P.; Owen, Andrew	Nanoformulation strategies for the enhanced oral bioavailability of antiretroviral therapeutics.	Therapeutic Delivery	-	-	-	2041-6008 2041-5990	10.4155/tde.15.4	https://pubmed.ncbi.nlm.nih.gov/25996045/	The oral delivery of drugs with poor aqueous solubility is challenging and often results in poor bioavailability. Various nanoformulation platforms have demonstrated improved oral bioavailability of a range of drugs for different indications. The focus of this review is to provide an overview of the application of nanomedicine to oral antiretroviral therapy and outline how the current short-falls of this life-long therapy may be resolved using nanotechnology. As well as highlighting the rationale for a nanomedicine-based approach, the review focuses on the various strategies used to enhance oral bioavailability and describes the mechanisms of particle absorption across the GI tract. The recent advances in the development of long-acting formulations for both HIV treatment and pre-exposure prophylaxis are also discussed. Theses and Dissertations	2015	Teller, Ryan Stevenson	Engineering antiretroviral eluting intravaginal rings for human immunodeficiency virus prevention	-	-	University of Utah	-	NA	NA	http://content.lib.utah.edu/cdm/singleitem/collection/etd3/id/3907/rec/873	Over three decades have passed since the discovery of human immunodeficiency virus (HIV), and with no viable vaccine, new technologies to prevent the spread of the virus are urgently needed. Pre-exposure prophylaxis, the concept of chemically interrupting HIV transmission, effectively reduced HIV incidence in a number of clinical trials. However, it has been difficult to achieve high and consistent effectiveness in clinical trials due to variable adherence to the dosing regimens requiring frequent administration. This, along with the disproportionate burden of the HIV/AIDS pandemic in young women in sub- Saharan Africa, has catalyzed the research into long-acting, antiretroviral eluting drug delivery systems like intravaginal rings (IVR) in an attempt to increase adherence over dosage forms that require frequent administration, and provide a more consistent drug concentration where transmission occurs. However, IVR technology is generally limited to releasing small quantities of hydrophobic, low molecular weight species that can diffuse through the IVR elastomer. This dissertation describes two adaptable drug delivery platforms that increased the diversity of the drugs that can be delivered from IVRs. Polyether urethane reservoir IVRs were engineered for the delivery of the thermally and hydrolytically unstable prodrug tenofovir disoproxil fumarate. This drug presents a unique design challenge to minimize the hydrolytic drug degradation in the IVR core while also promoting hydration to solubilize and release the drug. This design delivered mg/day quantities of drug and conferred complete protection in macaques from multiple vaginal viral exposures. Next, we engineered a system that uncouples the mechanism of drug release from the interaction of the drug with the elastomer and provides nearly constant release of any stable molecule. In this system, orifices control the hydration rate of the hydrophilic matrix contained within the core of the IVR, and release of the drug-containing gel. We evaluated the utility of this system for the topical delivery of macromolecules, and multiple different small molecule antiretrovirals, specifically for the delivery of drug microparticles. This work describes the design and evaluation of antiretroviral eluting IVR systems that provide adaptable platforms for vaginal drug delivery. Article	2015	Toledo, Lauren; McLellan-Lemal, Eleanor; Henderson, Faith L; Kebaabetswe, Poloko M	Knowledge, Attitudes, and Experiences of HIV Pre-Exposure Prophylaxis (PrEP) Trial Participants in Botswana.	World Journal of AIDS	-	-	-	2160-8814	10.4236/wja.2015.51002	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4708891	Recent clinical trials have shown that a daily dose of oral TDF/FTC pre-exposure prophylaxis (PrEP) is effective in reducing human immunodeficiency (HIV) risk. Understanding trial participants' perspectives about retention and PrEP adherence is critical to inform future PrEP trials and the scale-up and implementation of PrEP programs. We analyzed 53 in-depth interviews conducted in April 2010 with participants in the TDF2 study, a Phase 3, randomized, double-blind, placebo-controlled clinical trial of daily oral TDF/FTC with heterosexual men and women in Francistown and Gaborone, Botswana. We examined participants' knowledge, attitudes, and experiences of the trial, identified facilitators and barriers to enrollment and retention, and compared participant responses by study site, sex, and study drug adherence. Our findings point to several factors to consider for participant retention and adherence in PrEP trials and programs, including conducting pre-enrollment education and myth reduction counseling, providing accurate estimates of participant obligations and side effect symptoms, ensuring participant understanding of the effects of non-adherence, gauging personal commitment and interest in study outcomes, and developing a strong external social support network for participants. Article	2015	Tsegaye, Theodros S; Butler, Katherine; Luo, Wei; Radzio, Jessica; Srinivasan, Priya; Sharma, Sunita; Aubert, Rachael D; Hanson, Debra L; Dobard, Charles; Garcia-Lerma, Jose Gerardo; Heneine, Walid; McNicholl, Janet M; Kersh, Ellen N	Repeated Vaginal SHIV Challenges in Macaques Receiving Oral or Topical Preexposure Prophylaxis Induce Virus-Specific T-Cell Responses.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000000642	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4485592	BACKGROUND: Preexposure prophylaxis (PrEP) for HIV prevention is a novel biomedical prevention method. We have previously modeled PrEP during rectal SHIV exposures in macaques and identified that Simian/Human Immunodeficiency Virus chimera (SHIV)-specific T-cell responses were induced in the presence of antiretroviral drugs, an observation previously termed T-cell chemo-vaccination. This report expands those initial findings by examining a larger group of macaques that were given oral or topical PrEP during repeated vaginal virus exposure. METHODS: Thirty-six female pigtail macaques received up to 20 repeat low-dose vaginal inoculations with wild-type (WT) SHIVSF162P3 (n = 24) or a clonal derivative with the tenofovir (TFV) K65R drug-resistant mutation (n = 12). PrEP consisted of oral Truvada (n = 6, WT), TFV vaginal gel (n = 6, K65R), or TFV intravaginal ring (n = 6, WT). The remaining animals were PrEP-inexperienced controls (n = 12, WT; n = 6, K65R). SHIV-specific T cells were identified and characterized using interferon Î³ Enzyme-Linked ImmunoSpot (ELISPOT) and multiparameter flow cytometry. RESULTS: Of 9 animals that were on PrEP and remained uninfected during WT SHIV vaginal challenges, 8 (88.9%) developed virus-specific T-cell responses. T cells were in CD4 and CD8 compartments, reached up to 4900 interferon Î³-producing cells per million peripheral blood mononuclear cells, and primarily pol directed. In contrast, the replication-impaired K65R virus did not induce detectable T-cell responses, likely reflecting the need for adequate replication. CONCLUSIONS: Virus-specific T-cell responses occur frequently in oral or topical PrEP-protected pigtail macaques after vaginal exposure to WT SHIV virus. The contribution of such immune responses to protection from infection during and after PrEP warrants further investigation. Article	2015	Underhill K.; Morrow K.M.; Colleran C.; Holcomb R.; Calabrese S.K.; Operario D.; Galárraga O.; Mayer K.H.	A Qualitative Study of Medical Mistrust, Perceived Discrimination, and Risk Behavior Disclosure to Clinicians by U.S. Male Sex Workers and Other Men Who Have Sex with Men: Implications for Biomedical HIV Prevention	Journal of Urban Health	-	-	-	10993460	10.1007/s11524-015-9961-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84938744037&doi=10.1007%2fs11524-015-9961-4&partnerID=40&md5=b272dcb694182224c52e61ec7387d121	Access to biomedical HIV prevention technologies such as pre-exposure prophylaxis (PrEP) requires individuals to disclose risk behavior to clinicians, but experiences of discrimination and medical mistrust may limit disclosure among male sex workers and other MSM. We explored experiences of perceived discrimination, medical mistrust, and behavior disclosure among male sex workers compared to other men who have sex with men (MSM). We conducted 56 interviews with MSM and compared findings about medical mistrust, discrimination, and disclosure for 31 men who engaged in sex work vs. 25 men who did not. MSM who engaged in sex work reported more medical mistrust and healthcare discrimination due to issues beyond MSM behavior/identity (e.g., homelessness, substance use, poverty). MSM who did not report sex work described disclosing sex with men to clinicians more often. Both subgroups reported low PrEP awareness, but willingness to disclose behavior to obtain PrEP. Medical mistrust and perceived discrimination create barriers for sexual behavior disclosure to clinicians, potentially impeding access to PrEP and other forms of biomedical HIV prevention. These barriers may be higher among male sex workers compared to other MSM, given overlapping stigmas including sex work, substance use, homelessness, and poverty. An intersectionality framework for understanding multiple stigmas can help to identify how these dynamics may limit access to biomedical HIV prevention among male sex workers, as well as suggesting strategies for addressing stigmas to improve the delivery of PrEP and other HIV prevention approaches in this population. © 2015, The New York Academy of Medicine. Theses and Dissertations	2015	Valade, Elodie	Traitement et prévention de la transmission de l'infection à VIH : analyse pharmacocinétique de l'emtricitabine par approche de population / Treatment and prevention of the transmission of HIV infection : pharmacokinetic analysis of emtricitabine by a population approach	-	-	Sorbonne Paris Cité, Urien, Saïk	-	NA	NA	http://www.theses.fr/2015USPCB150	L'emtricitabine est une molécule centrale dans la stratégie de lutte contre l'infection à VIH. En effet, elle est recommandée en première intention pour le traitement de l'infection chez l'adulte, ainsi que pour la prévention de la transmission de l'infection. Bien que l'emtricitabine soit une molécule clé, elle reste jusqu'à présent peu étudiée. Il est donc primordial d'analyser et de caractériser la pharmacocinétique de l'emtricitabine dans les différentes populations susceptibles d'être exposées à cette molécule. Une approche de population a été utilisée pour réaliser les analyses pharmacocinétiques, nous permettant de décrire la pharmacocinétique avec peu de prélèvements par individu (contraintes éthiques, difficulté de recueil des prélèvements…) et nous permettant d'expliquer la variabilité observée. L'étude rapportant la pharmacocinétique de l'emtricitabine chez l'adulte a mis en évidence une modification du profil cinétique selon l'état de la fonction rénale. Le modèle développé nous a permis d'évaluer les recommandations posologiques actuelles. Afin d'optimiser l'efficacité, la simulation de schémas thérapeutiques alternatifs chez les patients avec une insuffisance rénale modérée a été réalisée. Dans le cadre de la prévention de la transmission mère-enfant, l'étude décrivant la pharmacocinétique de l'emtricitabine chez les femmes enceintes a mis en évidence une modification de la pharmacocinétique au cours de la période gestationnelle. Toutefois, il ne semblait pas nécessaire d'adapter la posologie au cours de la grossesse. La dernière étude a permis d'étudier la pharmacocinétique de l'emtricitabine dans le tractus génital masculin. L'étude de la pénétration dans le compartiment génital est d'un intérêt capital pour le traitement mais aussi pour la prévention de la transmission de l'infection à VIH dans le cadre de la prophylaxie pré-exposition. Notre étude a rapporté une distribution importante de l'emtricitabine dans le tractus génital, avec des concentrations séminales supérieures aux concentrations plasmatiques. / Emtricitabine is a key antiretroviral drug in the strategy to fight against HIV infection. Indeed, emtricitabine is recommended in first-line treatment for HIV infection in adults, as well as for the prevention of HIV transmission. Although emtricitabine is a key molecule, it remains poorly studied until now. It is therefore essential to analyze and characterize the pharmacokinetics of emtricitabine in the different populations that may be exposed to this drug. A population approach was used to perform pharmacokinetic analyses, allowing us to describe the pharmacokinetics with few samples per individual (ethical constraints, difficulty of samples collection...) and allowing us to explain the observed variability. The study reporting emtricitabine pharmacokinetics in adults highlighted a change in emtricitabine kinetic profile depending on the state of renal function. The developed model allowed us to evaluate the current dosing recommendations. To optimize efficiency, simulations of alternative regimens in patients with moderate renal impairment were performed. As part of the prevention of mother to child transmission, the study describing emtricitabine pharmacokinetics in pregnant women showed a change in pharmacokinetics during the gestational period. However, it did not seem necessary to adjust the dosage during pregnancy. The latest work focused on emtricitabine pharmacokinetics in the male genital tract. Studying the penetration in the genital tract is of major interest for treatment but also for prevention of HIV transmission in the context of pre-exposure prophylaxis. Our study reported a significant distribution of emtricitabine in the genital compartment, with concentrations in seminal plasma higher than concentrations in blood plasma. Theses and Dissertations	2015	van der Elst, E. M.	Strengthening HIV health care services for men who have sex with men in coastal Kenya	-	-	Universiteit van Amsterdam	-	na	NA	http://hdl.handle.net/11245/1.495741	This thesis describes work with Kenyan men who have sex with men (MSM) who are highly stigmatized and discriminated against in society, and have not been targeted in HIV prevention programming until recently. Initial work included a size estimation of MSM who sell sex in coastal Kenya in 2006, and a comparison of two methods of risk behaviour assessment (Audio computer-assisted self-interview and face-to-face interview) at cohort enrolment. Subsequent studies included pre- and 3-month post-assessments of MSM-knowledge and homophobic attitudes among 74 health care providers from 49 ART-proving health facilities from four districts in coastal Kenya who had undergone an 8-modular computer-facilitated MSM-sensitivity training, which is also provided freely online (www.marps-africa.org). The MSM-sensitivity training included modules on practical knowledge of the burden of HIV among MSM, sexual behaviour, stigma, and mental health challenges among other topics. Learning was complimented by group discussions, facilitated by MSM. Three months after training, more health care providers had adequate knowledge compared to baseline (49% versus 13%, p<0.001), and homophobic attitudes had decreased significantly, particularly among health care providers with high homophobia scores at baseline. Qualitative assessments among MSM participants in a four-month oral pre-exposure prophylaxis (PrEP) phase I trial underscored the major role health care providers will play in future PrEP implementation. In conclusion, sensitized health care providers in rights constrained environments can strengthen HIV health care services for MSM and have the potential to become 'agents of change', striving for and enhancing health equity for MSM and other sexual minorities in sub-Saharan Africa. Article	2015	van der Straten A.; Mayo A.; Brown E.R.; Amico K.R.; Cheng H.; Laborde N.; Marrazzo J.; Torjesen K.	Perceptions and Experiences with the VOICE Adherence Strengthening Program (VASP) in the MTN-003 Trial	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-014-0945-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84939957849&doi=10.1007%2fs10461-014-0945-2&partnerID=40&md5=c2d607fa07f2387229411f965c9e50f5	The VOICE Adherence Strengthening Program (VASP) was implemented in May 2011 to improve adherence counseling in VOICE (MTN-003), a multisite placebo-controlled trial of daily oral or vaginal tenofovir-based Pre-Exposure Prophylaxis (PrEP). Anonymous baseline (N = 82) and final follow-up (N = 75) surveys were administered to counselors and pharmacists at 15 VOICE sites, and baseline (N = 18) and final (N = 26) qualitative in-depth interviews were conducted with purposively selected counseling staff at 13 VOICE sites. Qualitative interviews with VOICE participants (N = 38) were also analyzed for segments related to counseling. Behavioral and biological measures of product use collected in the 6 months prior to VASP implementation were compared to those collected during the 6 months following implementation. Results show that the majority of staff preferred VASP and thought that participants preferred VASP over the previous education and counseling strategy, although there was no evidence to suggest that participants noticed modifications in the counseling approach. No meaningful changes were observed in pre/post levels of reported use or drug detection. Interpretation of results is complicated by mid-trial implementation of VASP and its proximity to early closure of oral and vaginal tenofovir study arms because of futility. © 2014, Springer Science+Business Media New York. Article	2015	Vanichseni, Suphak; Martin, Michael; Suntharasamai, Pravan; Sangkum, Udomsak; Mock, Philip A; Gvetadze, Roman J; Curlin, Marcel E; Leethochawalit, Manoj; Chiamwongpaet, Sithisat; Chaipung, Benjamaporn; McNicholl, Janet M; Paxton, Lynn A; Kittimunkong, Somyot; Choopanya, Kachit	High Mortality Among Non-HIV-Infected People Who Inject Drugs in Bangkok, Thailand, 2005-2012.	American Journal of Public Health	-	-	-	1541-0048	10.2105/AJPH.2014.302473	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4431084	OBJECTIVES: We examined the causes of hospitalization and death of people who inject drugs participating in the Bangkok Tenofovir Study, an HIV preexposure prophylaxis trial. METHODS: The Bangkok Tenofovir Study was a randomized, double-blind, placebo-controlled trial conducted during 2005 to 2012 among 2413 people who inject drugs. We reviewed medical records to define the causes of hospitalization and death, examined participant characteristics and risk behaviors to determine predictors of death, and compared the participant mortality rate with the rate of the general population of Bangkok, Thailand. RESULTS: Participants were followed an average of 4 years; 107 died: 22 (20.6%) from overdose, 13 (12.2%) from traffic accidents, and 12 (11.2%) from sepsis. In multivariable analysis, older age (40-59 years; P = .001), injecting drugs (P = .03), and injecting midazolam (P < .001) were associated with death. The standardized mortality ratio was 2.9. CONCLUSIONS: People who injected drugs were nearly 3 times as likely to die as were those in the general population of Bangkok and injecting midazolam was independently associated with death. Drug overdose and traffic accidents were the most common causes of death, and their prevention should be public health priorities. Article	2015	Veloso, Valdilea G; Mesquita, Fabio; Grinsztejn, Beatriz	Pre-exposure prophylaxis for men and transgender women who have sex with men in Brazil: opportunities and challenges.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.18.4.20010	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4509891	INTRODUCTION: The World Health Organization recently released guidelines on the use of pre-exposure prophylaxis (PrEP) for prevention of HIV infection among men and transgender women (TGW) who have sex with men based on results of randomized clinical trials. The aim of this commentary is to discuss the opportunities and challenges of incorporating PrEP into the Brazilian continuum of HIV care and prevention for men who have sex with men (MSM) and TGW. DISCUSSION: Key aspects of the AIDS epidemic among MSM and TGW in Brazil and the comprehensive Brazilian response to the epidemic are presented. The universal access to health care provided through the Brazilian Unified Health System (SUS) and the range of prevention and care services already available countrywide to HIV-positive individuals and at-risk MSM and TGW are identified as the main facilitators for the implementation of PrEP. Limited PrEP awareness among MSM, TGW and health care providers, low HIV testing frequency and low HIV risk perception among MSM and TGW represent the core challenges to be addressed. Data generated by demonstration projects in Brazil will provide an important contribution to PrEP rollout in Brazil. CONCLUSIONS: The implementation of PrEP in Brazil is feasible. A synergistic rollout of treatment as prevention and PrEP will maximize public health and individual benefits of the country's comprehensive response to the AIDS epidemic.	pre-exposure prophylaxis, MSM, TGW, prevention, Brazil, resource-limited setting, health system	English	United States	Western and Central Europe and North America	Brazil	Latin America and the Caribbean	Brazil	Latin America and the Caribbean	Clinical
Article	2015	Venter, Willem Daniel François; Cowan, Frances; Black, Vivian; Rebe, Kevin; Bekker, Linda-Gail	Pre-exposure prophylaxis in Southern Africa: feasible or not?	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.18.4.19979	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4509894	INTRODUCTION: Southern and Eastern Africa bear the brunt of the AIDS epidemic, and current prevention interventions remain inadequate. Antiretroviral-based pre-exposure prophylaxis (PrEP) is gaining momentum as an effective prevention intervention. DISCUSSION: Discussions have been started on how this strategy could be employed in Africa such that the populations most in need can be reached urgently for the greatest impact. This requires the selection of specific risk groups and service environments in which PrEP can be distributed safely and cost effectively while being mindful of any ethical issues. CONCLUSIONS: Given the need for an integrated public health approach to this, a number of potential populations and opportunities for PrEP distribution exist and are discussed in this commentary. Correlates of Use of Timed Unprotected Intercourse to Reduce Horizontal Transmission Among Ugandan HIV Clients with Fertility Intentions.	AIDS and Behavior	-	-	-	1573-3254 1090-7165	10.1007/s10461-014-0906-9	https://link.springer.com/article/10.1007/s10461-014-0906-9	We examined the correlates of use of safer conception methods (SCM) in a sample of 400 Ugandan HIV clients (75 % female; 61 % on antiretroviral therapy; 61 % with HIV-negative or unknown status partners) in heterosexual relationships with fertility intentions. SCM assessed included timed unprotected intercourse, manual self-insemination, sperm washing, and pre-exposure prophylaxis (PrEP). In the 6 months prior to baseline, 47 (12 %) reported using timed unprotected intercourse to reduce risk of HIV infection (or re-infection), none had used manual self-insemination or sperm washing, and two had used PrEP. In multiple regression analysis, correlates of use of timed unprotected intercourse included greater perceptions of partner's willingness to use SCM and providers' stigma of childbearing among people living with HIV, higher SCM knowledge, and desire for a child within the next 6 months. These findings highlight the need for policy and provider training regarding integration of couples' safer conception counselling into HIV care. Article	2015	Wall, Kristin M.; Kilembe, William; Vwalika, Bellington; Htee Khu, Naw; Brill, Ilene; Chomba, Elwyn; Johnson, Brent A.; Haddad, Lisa; Tichacek, Amanda; Allen, Susan	Hormonal contraception does not increase women's HIV acquisition risk in Zambian discordant couples, 1994-2012.	Contraception	-	-	-	1879-0518 0010-7824	10.1016/j.contraception.2015.02.004	https://pubmed.ncbi.nlm.nih.gov/25708502/	OBJECTIVE: To determine the impact of hormonal contraceptive methods on risk of HIV acquisition among HIV-negative women cohabiting with HIV-positive male partners. STUDY DESIGN: From 1994-2012, HIV discordant couples recruited from a couples' voluntary HIV counseling and testing center in Lusaka, Zambia were followed longitudinally. HIV-negative partners were tested quarterly. This analysis is restricted to couples in which the man was HIV-positive and the woman was HIV-negative at enrollment and the man was not on antiretroviral treatment. Multivariate Cox models evaluated associations between time-varying contraceptive methods and HIV acquisition among women. Sensitivity analyses explored exposure misclassification and time-varying confounder mediation. RESULTS: Among 1393 couples, 252 incident infections occurred in women over 2842 couple-years (8.9 infections per 100 couple-years; 95% CI, 7.8-10.0). Multivariate Cox models indicated that neither injectable adjusted hazard ratio (aHR)=1.2; 95% CI, 0.8-1.7, oral contraceptive pill (OCP, aHR=1.3; 95% CI, 0.9-1.8), or implant (aHR=1.1; 95% CI, 0.5-2.2) use was significantly associated with HIV acquisition relative to non-hormonal contraception controlling for woman's age, literacy and time-varying measures of genital ulceration/inflammation. This remained true when only looking at the subset of infections acquired from the spouse (82% of infections) and additionally controlling for baseline HIV viral load of the male partner, pregnancy status, and time-varying measures of sperm on a vaginal swab wet prep and self-reported unprotected sex. OCP and injectable users reported more unprotected sex (p<.001), and OCP users were more likely to have sperm on vaginal swab (p=.1) than nonhormonal method users. CONCLUSIONS: We found no association between hormonal contraception and HIV acquisition risk in women. Condom use and reinforced condom counseling should always be recommended for HIV discordant couples. HIV testing of sex partners together is critical to establish HIV risk, ascertain couple fertility intentions and counsel appropriately. IMPLICATIONS: These findings add to a controversial literature and uniquely address several common design and analytic challenges faced by previous studies. After controlling for confounders, we found no association between hormonal contraception and HIV acquisition risk in women. We support promoting condoms for HIV prevention and increasing the contraceptive method mix to decrease unintended pregnancy. Lay Social Resources for Support of Adherence to Antiretroviral Prophylaxis for HIV Prevention Among Serodiscordant Couples in sub-Saharan Africa: A Qualitative Study	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-014-0899-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84939883702&doi=10.1007%2fs10461-014-0899-4&partnerID=40&md5=97246dc39b0b8ceda9ef9819f752f342	Effectiveness of antiretroviral pre-exposure prophylaxis (PrEP) for HIV prevention will require high adherence. Using qualitative data, this paper identifies potential lay social resources for support of PrEP adherence by HIV serodiscordant couples in Uganda, laying the groundwork for incorporation of these resources into adherence support initiatives as part of implementation. The qualitative analysis characterizes support for PrEP adherence provided by HIV-infected spouses, children, extended family members, and the larger community. Results suggest social resources for support of PrEP adherence in Africa are plentiful outside formal health care settings and health systems and that couples will readily use them. The same shortage of health professionals that impeded scale-up of antiretroviral treatment for HIV/AIDS in Africa promises to challenge delivery of PrEP. Building on the treatment scale-up experience, implementers can address this challenge by examining the value of lay social resources for adherence support in developing strategies for delivery of PrEP. © 2014, The Author(s). Article	2015	Washington, Thomas Alex; D'Anna, Laura; Meyer-Adams, Nancy; Malotte, C. Kevin	From Their Voices: Barriers to HIV Testing among Black Men Who Have Sex with Men Remain.	Healthcare	-	-	-	2227-9032	10.3390/healthcare3040933	https://www.mdpi.com/2227-9032/3/4/933	BACKGROUND: HIV testing continues to be a major priority for addressing the epidemic among young Black men who have sex with men (BMSM). METHODS: This study explored barriers to HIV testing uptake, and recommendations for motivating HIV testing uptake among Black men who have sex with men (BMSM) aged 18 to 30. BMSM (N = 36) were recruited through flyers and social media for six focus groups. RESULTS: From the perspectives and experiences of young BMSM, participants recommended that information be included in HIV testing messages that would help young BMSM do self HIV-risk appraisals. Particularly, participants recommended that more knowledge about Pre-Exposure Prophylaxis (PrEP) and the role of PrEP in safer-sex practices be provided. This information is important to help those untested, or who infrequently test, better understand their risk and need for testing. Likewise, participants recommended that more information about a person being undetectable and the risk of condomless sex with an HIV negative sex partner; this information will be helpful for both the HIV negative and HIV positive sex partner for making safer sex decisions. Participants also recommended that interventions should focus on more than drug use as risk; the risk posed by the use of alcohol before and during sex deserves attention among young BMSM. CONCLUSIONS: These findings may inform new HIV testing interventions being tailored for young BMSM. The interventions should also consider revisiting street-based peer-outreach approaches for those young BMSM with limited access to social media campaigns due to limited access or infrequent use of social media. Article	2015	Westreich, Daniel; Edwards, Jessie K.	Invited commentary: every good randomization deserves observation.	American Journal of Epidemiology	-	-	-	1476-6256 0002-9262	10.1093/aje/kwv200	https://academic.oup.com/aje/article/182/10/857/92985	Preexposure prophylaxis (PrEP) is a promising approach to prevention of human immunodeficiency virus (HIV) transmission, in which an HIV-negative individual takes a single daily dose of an antiretroviral drug so that, if exposed to HIV, an active antiretroviral drug is already present in his or her system. In this issue of the Journal, Murnane et al. (Am J Epidemiol. 2015;182(10):848-856) use data from the Partners PrEP Study (Kenya and Uganda, 2008-2011) to estimate the efficacy of PrEP under perfect adherence. We discuss Murnane et al.'s work and then examine the larger issues of generalizability or transportability of findings from a randomized trial to a new setting when adherence to an intervention determines its effectiveness. We discuss sufficient conditions for generalizability and use causal directed acyclic graphs to show how these assumptions might play out when trials are used to make inferences about the effect of PrEP in current and future real-world target populations. Article	2015	Wilson, Erin C; Jin, Harry; Liu, Albert; H Fisher Raymond	Knowledge, Indications and Willingness to Take Pre-Exposure Prophylaxis among Transwomen in San Francisco, 2013	PLOS One	-	-	-	NA	10.1371/journal.pone.0128971	https://www.proquest.com/scholarly-journals/knowledge-indications-willingness-take-pre/docview/1685759086/se-2?accountid=8113	Safe and effective HIV prevention strategies are needed for transwomen. Transwomen in the US have a 34 times greater odds of being infected with HIV than all adults age 15-49, and in San Francisco, California 42.4% of transwomen are estimated to be infected with HIV. Pre-exposure prophylaxis (PrEP) is the first biomedical intervention with promise for reducing HIV acquisition in transwomen. However, little is known about whether transwomen know about PrEP, are taking PrEP and would be good candidates for PrEP based on their risk profile and behaviors. A population-based dataset was analyzed to determine how many transwomen in San Francisco knew about PrEP by the end of 2013 – more than a year after iPrex results demonstrated efficacy of PrEP in preventing HIV. We found that of 233 transwomen, only 13.7% had heard of PrEP. Transwomen who were living with HIV compared to those who were HIV-negative, and those who recently injected drugs compared to non-injection drug users were more likely to have heard of PrEP. Based on CDC guidelines for PrEP among MSM and IDU, 45 (30.2%) transwomen of the 149 HIV-negative transwomen in the sample were candidates for PrEP. This estimate based on CDC criteria is arguably low. Given that almost half of transwomen in San Francisco are living with HIV, this findings points to a need for further consideration of PrEP criteria that are specific and tailored to the risks for HIV faced by transwomen that are different from MSM and injection drug users. Research to scale up access and test the effectiveness of PrEP for transwomen is also urgently needed. Article	2015	Wilton, James; Senn, Heather; Sharma, Malika; Tan, Darrell HS	Pre-exposure prophylaxis for sexually-acquired HIV risk management: a review	HIV/AIDS - Research and Palliative Care	-	-	-	10410236	10.2147/HIV.S50025	https://www.proquest.com/scholarly-journals/pre-exposure-prophylaxis-sexually-acquired-hiv/docview/2229431428/se-2?accountid=8113	Despite significant efforts, the rate of new HIV infections worldwide remains unacceptably high, highlighting the need for new HIV prevention strategies. HIV pre-exposure prophylaxis (PrEP) is a new approach that involves the ongoing use of antiretroviral medications by HIV-negative individuals to reduce the risk of HIV infection. The use of daily tenofovir/emtricitabine as oral PrEP was found to be effective in multiple placebo-controlled clinical trials and approved by the United States Food and Drug Administration. In addition, the Centers for Disease Control and Prevention in the United States and the World Health Organization have both released guidelines recommending the offer of oral PrEP to high-risk populations. The scale-up of PrEP is underway, but several implementation questions remain unanswered. Demonstration projects and open-label extensions of placebo-controlled trials are ongoing and hope to contribute to our understanding of PrEP use and delivery outside the randomized controlled trial setting. Evidence is beginning to emerge from these open-label studies and will be critical for guiding PrEP scale-up. Outside of such studies, PrEP uptake has been slow and several client- and provider-related barriers are limiting uptake. Maximizing the public health impact of PrEP will require rollout to be combined with interventions to promote uptake, support adherence, and prevent increases in risk behavior. Additional PrEP strategies are currently under investigation in placebo-controlled clinical trials and may be available in the future.	tenofovir; Thailand; emtricitabine; HIV prevention; Pre-exposure prophylaxis; Antiretroviral drugs; Prevention; Drug resistance; Treatment; Risk management; Disease prevention; biomedical intervention; Human immunodeficiency virus--HIV; Womens health; United States--US; Acquired immune deficiency syndrome--AIDS; Medical Sciences--Allergology And Immunology; Health risk assessment; Bangkok Thailand	English	New Zealand	Asia and the Pacific	Canada	Western and Central Europe and North America	Canada	Western and Central Europe and North America	Review
Theses and Dissertations	2015	Winfield, Paul T. (author), Bertrand, William (Thesis advisor), School of Law International Development (Degree granting institution)	The Effectiveness Of Us Federal Hiv/aids Policy On Black Men Who Have Sex With Men: An Intersectionality Based Analysis & Evaluation	-	-	Tulane University	-	NA	NA	http://search.ndltd.org/show.php?id=oai%3Aunion.ndltd.org%3ATULANE%2Foai%3Ahttp%3A%2F%2Fdigitallibrary.tulane.edu%2F%3Atulane_45928&back=http%3A%2F%2Fsearch.ndltd.org%2Fsearch.php%3Fq%3D%2522pre-exposure%2Bprophylaxis%2522%26start%3D60#:~:text=Links%20%26%20Downloads-,tulane%3A45928,-local%3A%C2%A0td005582	By the age of 35, Black Men who have Sex with Men (MSM's) have a one in two chance of HIV infection. Black MSM's, which represent less than one percent of the US population, is home to nearly a quarter of existing HIV cases, AIDS deaths as well as new HIV diagnosis. As early as 1987 studies were published revealing a paradoxical reality, that although Black MSM's had no significant difference in risk behavior, there is a much larger HIV Prevalence among this group as nearly one in three Black MSM's are HIV positive. Consistently and repeatedly, studies have shown Black MSM's have fewer sexual partners than their White counterparts, and fewer occurrences of unprotected anal intercourse, yet significantly higher rates of HIV Incidence. The theoretical basis for this analysis is the concept Intersectionality, originated by Kimberlé Crenshaw, which states that cohorts comprised of multiple statuses of historic discrimination are qualitatively different from individual cohorts of component status. This qualitative difference requires the analysis of the composite cohort as an independent and unique entity as opposed to only looking at the components that it is made of. Therefore, Black MSM's are a unique group and cannot be fully understood by looking at Black Men or MSM separately. This is particularly applicable for Black MSM's because of the: history of oppression as Black Men, history of marginalization as MSM, isolation of Blacks within MSM community, isolation of MSM within the Black community and the history of HIV among Black MSM's which dates back at least to 1969 (predating the publicly acknowledged epidemic in the White MSM community by 12 years) . This traditional policy analysis evaluated the 2010 National HIV/AIDS Strategy for its effectiveness in addressing HIV/AIDS among Black MSM's. To accomplish this, a convergence of evidence approach was implemented, utilizing a key document review, qualitative interviews with key stakeholders, as well as quantitative surveys of 300 Black MSM's. These methods were then applied to each of the four stages of Policy Analysis: agenda setting, formulation, implementation and evaluation. This analysis revealed a landmark policy that has comprehensively improved the Federal response to HIV in the US. Innovations developed and instituted because of this policy included the Community Listening Sessions of the formulation stage, and even more importantly the new metrics that better equip agencies to understand the nature of the epidemic. Further, the results of this study were compared with the August 2014 Kaiser Family Foundation study, which produced a nationally representative survey of Gay and Bisexual men (sampling error ±7%). The findings of this study paralleled and/or magnified those of Kaiser in several key areas. Kaiser found that Men of Color were more likely to know someone with HIV/AIDS and those that do are more likely to say it is a significant personal issue. The results of this study of Black MSM's expose a sample where 97% knew someone who has/had HIV/AIDS and almost all considered this to be a significant personal issue. Both studies also confirmed the continuing presence of stigma and perceived discrimination by the general public. In both studies, evidence also indicates the opportunity for increasing frequency of HIV testing and the widespread lack of knowledge of PrEP (Pre-Exposure Prophylaxis). Several key recommendations should also be taken from this analysis to improve the policy moving forward. The first is that Black MSM's should be an independent category for policy targeting. The next is that as Black MSM's are the only group that is at high risk of infection and also makes up a large portion of the disease, Black MSM's are a significant hotspot that should be a primary focus of the intervention. Finally, the greatest advances in fighting HIV have come through biomedical progress. Therefore, educating and implementing biomedical innovations such as PrEP should compliment behavioral change as intervention objectives. Institutional	2015	World Health Organization	Guideline on when to start antiretroviral therapy and on pre-exposure prophylaxis for HIV	-	-	-	-	978-92-4-150956-5	NA	http://apps.who.int/iris/bitstream/10665/186275/1/9789241509565_eng.pdf?ua=1	This early-release guideline makes available two key recommendations that were developed during the revision process in 2015. First, antiretroviral therapy (ART) should be initiated in everyone living with HIV at any CD4 cell count. Second, the use of daily oral pre-exposure prophylaxis (PrEP) is recommended as a prevention choice for people at substantial risk of HIV infection as part of combination prevention approaches. The first of these recommendations is based on evidence from clinical trials and observational studies released since 2013 showing that earlier use of ART results in better clinical outcomes for people living with HIV compared with delayed treatment. The second recommendation is based on clinical trial results confirming the efficacy of the ARV drug tenofovir for use as PrEP to prevent people from acquiring HIV in a wide variety of settings and populations. The recommendations in this guideline will form part of the revised consolidated guidelines on the use of ARV drugs for treating and preventing HIV infection to be published by WHO in 2016. The full update of the guidelines will consist of comprehensive clinical recommendations together with revised operational and service delivery guidance to support implementation. Article	2015	Wu, Hsiu; Hightow-Weidman, Lisa B.; Gay, Cynthia L.; Zhang, Xinjian; Beagle, Steve; Hall, Laura; Jackson, Tonyka; Marmorino, Jenni; Do, Ann N.; Peters, Philip J.	Unreported Male Sex Partners Among Men with Newly Diagnosed HIV Infection - North Carolina, 2011-2013.	MMWR Recommendations and Reports	-	-	-	1545-861X 0149-2195	10.15585/mmwr.mm6437a2	https://pubmed.ncbi.nlm.nih.gov/26401589/	Human immunodeficiency virus (HIV) prevention interventions, such as preexposure prophylaxis (PrEP), are often targeted to men who have sex with men (MSM) who self-report high-risk behaviors. Data from a prospective study evaluating methods to detect acute HIV infection among a primarily young (aged <25 years) and black or African American (African American) population from North Carolina were analyzed. In the study, participants were asked about risk behaviors during pretest counseling (at the time of testing) and then during a partner services interview (at HIV diagnosis). Participants whose disclosure of sexual risk behaviors during pretest counseling was different from their disclosure of sexual risk behaviors during their partner services interview were identified, and factors associated with these discordant responses were examined. Among 113 HIV-infected men, 26 (23.0%) did not disclose male sex partners at pretest counseling, but subsequently did disclose this information during their partner services interview. When compared with men who disclosed having male partners at pretest counseling, these 26 MSM who did not disclose male partners during pretest counseling were found to have a similar number of male partners during contact tracing, but were more likely to have a female partner (30.8% versus 6.9%). In addition, the proportions of MSM found to have at least one HIV-infected partner were similar for both groups (MSM who disclosed having male partners during pretest counseling and those who did not). To better customize HIV prevention interventions for MSM, HIV prevention programs might consider using novel strategies to accurately assess risk in this population. Article	2015	Xue H.; Liu H.; Cai L.	Analysis of willingness and influencing factors for usage of pre-exposure prophylaxis among men who have sex with men	Zhonghua Yu Fang Yi Xue Za Zhi (Chinese Journal of Preventive Medicine)	-	-	-	2539624	NA	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84966340058&partnerID=40&md5=1b0a26803a4efc56bf914623e862209c	OBJECTIVE: To analyze willingness and influencing factors for usage of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM).; METHODS: 887 men who were older than 18 years old and used to have sex with men were recruited through internet between November 27 and December 17, 2013. Data were collected through self designed questionnaire, which was designed to collect information including demography features, willingness of usage of PrEP and associated factors.; RESULTS: Totally 760 qualified questionnaires were collected. The ages of surveyed MSM were between 18 and 60, 58.2% (442) were single, 78.9% (600) of them have received college education, 60.4% (459) received annual income less than 60 000 yuan, 73.3% (557) only had sex with men and 77.2% (587) self reported being gay. 32.1% (243/758) of the respondent MSM said they would like to use PrEP. 61.0% (305/500) would like or possibly to take PrEP orally each day. 70.9% (354/499) would keep the same condom using frequency as current situation after using PrEP. In the univariate analysis, the willingness of taking PrEP was (?2) = 27.61, P < 0.001) lower among those annual income less than 60 000 yuan (27.7% (127/458)) than those annual income higher (44.7% (116/260)); the willingness was significantly (?2) = 10.99, P = 0.001) higher among those understanding PrEP (35.4% (196/554)) than those not understanding (22.8% (44/206)). In multivariate logistic regression analysis, it suggested that annual income under 60 000 yuan (OR = 0.64 (95% CI: 0.45-0.92)) and understanding PrEP (OR = 1.98 (95% CI: 1.36-2.88)) were influencing factors for usage of PrEP among MSM.; CONCLUSION: MSM didn't understand the PrEP sufficiently currently, economic consideration and worries about the side effects will affect their willingness of using PrEP. Theses and Dissertations	2015	Yamada, Eiko	Relationship between concentrations of antiretroviral drugs in plasma and saliva of HIV-1 infected individuals : HIV-1患者における血中と唾液の抗HIV薬濃度の関係	-	-	Niigata University / 新潟大学	-	NA	NA	http://hdl.handle.net/10191/32174	Therapeutic drug monitoring (TDM) is valuable to evaluate the efficacy of a regimen or monitor the compliance of patients treated with a drug. However, TDM requires frequent blood sampling, which carries a risk of viral transmission to medical staff and causes pain to patients. In contrast, saliva sampling is safe and easily performed, so the possibility of using saliva for TDM as an alternative body fluid was examined. Firstly, a liquid chromatography-tandem mass spectrometry (LC-MS/MS) assay for the determination of abacavir (ABC), tenofovir (TFV), darunavir (DRV), and raltegravir (RAL) in human plasma and saliva was developed and validated. Analytes were detected using LC-MS/MS, and the linearity of the assay was assessed in the range 1–10,000 ng/mL for all four drugs. Within-run and between-run mean accuracy, precision, and the extraction recovery for all drugs were−14.5 to 18.1%, 1.2 to 13.1%, and 86.0 to 111.1%, respectively. The proposed assay is sufficiently sensitive and accurate to quantify these drugs in plasma and saliva. Secondly, the drug concentrations in plasma, plasma ultrafiltrate, and saliva of 30 human immunodeficiency virus (HIV)-1 infected outpatients who had been treated with these drugs for > 1 month were measured. Ratios of concentrations in saliva to plasma were 62.3% for ABC, 2.4% for TFV, 6.5% for DRV, and 13.5% for RAL. Significant correlations were evident between drug concentrations in saliva and those in plasma or plasma ultrafiltrate for ABC, DRV, and RAL, therefore the possibility of using saliva for TDM was suggested for these three drugs. Moreover, ABC, DRV, and RAL concentrations in saliva correlated more strongly with those in plasma ultrafiltrate than in plasma, suggesting that non-protein-bound drug may be secreted more easily to saliva. In contrast, saliva cannot be used for this purpose with TFV, which exhibited a very low saliva concentration and no correlation between concentrations in saliva and plasma. ABC was the most abundant in saliva, and those of ABC were above IC_<50> for half of patients. An ABC-containing regimen may be a candidate for pre-exposure prophylaxis against oral HIV transmission. In conclusion, this study facilitates the use of saliva as an alternative body fluid of blood for TDM of ART of HIV infection by developing the innovative method. Article	2015	Ying R.; Sharma M.; Heffron R.; Celum C.L.; Baeten J.M.; Katabira E.; Bulya N.; Barnabas R.V.	Cost-effectiveness of pre-exposure prophylaxis targeted to high-risk serodiscordant couples as a bridge to sustained ART use in Kampala, Uganda	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.18.4.20013	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84938217939&doi=10.7448%2fIAS.18.4.20013&partnerID=40&md5=17b442b611dc2decc6ff3d1850b6a63b	Introduction: Despite scale-up of antiretroviral therapy (ART) for treating HIV-positive persons, HIV incidence remains elevated among those at high risk such as persons in serodiscordant partnerships. Antiretrovirals taken by HIV-negative persons as preexposure prophylaxis (PrEP) has the potential to avert infections in individuals in serodiscordant partnerships. Evaluating the cost-effectiveness of implementing time-limited PrEP as a short-Term bridge during the first six months of ART for the HIVpositive partner to prevent HIV transmission compared to increasing ART coverage is crucial to informing policy-makers considering PrEP implementation. Methods: To estimate the real world delivery costs of PrEP, we conducted micro-costing and time and motion analyses in an open-label prospective study of PrEP and ART delivery targeted to high-risk serodiscordant couples in Uganda (the Partners Demonstration Project). The cost (in USD, in 2012) of PrEP and ART for serodiscordant couples was assessed, with and without research components, in the study setting. Using Ministry of Health costs, the cost of PrEP and ART provision within a government programme was estimated, as was the cost of providing PrEP in addition to ART. We parameterized an HIV transmission model to estimate the health and economic impacts of 1) PrEP and ART targeted to high-risk serodiscordant couples in the context of current ART use and 2) increasing ART coverage to 55% of HIV-positive persons with CD4 5500 cells/mL without PrEP. The incremental cost-effectiveness ratios (ICERs) per HIV infection and disability-adjusted life year (DALY) averted were calculated over 10 years. Results: The annual cost of PrEP and ART delivery for serodiscordant couples was 1058 per couple in the study setting and 453 in the government setting. The portion of the programme cost due to PrEP was 408 and 92 per couple per year in the study and government settings, respectively. Over 10 years, a programme of PrEP and ART for high-risk serodiscordant couples was projected to avert 43% of HIV infections compared to current practice with an ICER of 1340 per infection averted. This was comparable to ART expansion alone, which would avert 37% of infections with an ICER of 1452. Conclusions: Using Uganda's gross domestic product per capita of 1681 as a threshold, PrEP and ART for high-risk persons have the potential for synergistic action and are cost-effective in preventing HIV infections in high prevalence settings. The annual cost of PrEP in this programme is less than 100 per serodiscordant couple if implemented in public clinics. Article	2015	Zablotska, I; Prestage, G; Grulich, AE	PREEXPOSURE PROPHYLAXIS OF HIV (PrEP): UTILISATION ESTIMATES IN AUSTRALIA	Sexually Transmitted Infections	-	-	-	1368-4973	10.1136/sextrans-2015-052270.182	https://sti.bmj.com/content/91/Suppl_2/A67.2	Background Preexposure prophylaxis (PrEP) with daily oral Truvada® is recommended for people at high risk for HIV infection. The population-level benefit of PrEP requires higher levels of use than is currently observed. In Australia, homosexually active men (HM), particularly those who identify as gay or homosexual, contribute most to HIV transmission. We estimated how many HM are eligible for and likely to request PrEP. Method Using data from the Australian Bureau of Statistics (2013) and the second Australian Study of Health and Relationships (ASHR2, 2013), we estimated the number of HHMM nationally. PrEP eligibility was defined by the national PrEP guidelines. Input indicators from the 2013 Gay Community Periodic Surveys (GCPS) were applied to estimate the numbers of men eligible for PrEP based on each individual and any behavioural eligibility criteria. Using data from Treatment Options to Reduce Chances of HIV (TORCH) study, we estimated how many eligible HM are likely to request Truvada® for PrEP. Results We estimated 143,000 Australian men would identify as 'gay/homosexual' plus 95,000 as 'other' HAM. In GCPS, 15.7% of the HIV non-positive respondents reported sustained risk behaviour (≥6 sex partners in previous 6 months). Overall, 5.7% of HIV non-positive respondents satisfied behavioural eligibility criteria for PrEP, while having at least one episode of receptive condomless anal intercourse in the previous 6 months appeared the most common criterion (5%). Based on national eligibility criteria, 8,300 'gay/homosexual' and 5,300 'other' HM can be considered eligible for daily PrEP in Australia, and 44.9% of those are likely to uptake PrEP. Conclusions Our estimate of the number of HM eligible for PrEP in Australia is based on the current PrEP eligibility criteria, which target individuals at the highest risk for HIV infection. This estimation helps to predict service needed for PrEP prescribing nationally.Disclosure of interest statement Input indicators for these analyses were obtained from Australian Bureau of Statistics, Australian Study of Health and Relationships and Gay Community Periodic Surveys (all funded by the Australian state and federal governments) and from Treatment Options to Reduce Chances of HIV (TORCH) study funded by Gilead Sciences. Funding sources were not involved in research conducted.	NA	English	United Kingdom	Western and Central Europe and North America	Australia	Asia and the Pacific	NA	NA	Quantitative
Article	2015	Zablotska, I; Vaccher, S; Gianacas, C; Prestage, G; McNulty, A; Holden, J; Schmidt, H; Templeton, DJ; Poynten, IM; Grulich, A; PRELUDE Study Team	STI RATES AMONG GAY MEN TAKING DAILY ANTIRETROVIRALS FOR PRE-EXPOSURE PROPHYLAXIS OF HIV: THE NSW DEMONSTRATION PROJECT PRELUDE	Sexually Transmitted Infections	-	-	-	1368-4973	NA	https://sti.bmj.com/content/91/Suppl_2/A78.2	Introduction Pre-exposure prophylaxis (PrEP) prevents HIV infections but not other STIs. We assessed prevalence and incidence of STIs among PrEP users in the NSW demonstration study, PRELUDE. Methods By 14 July 2015, 268 gay and homosexually-identified men (GHM) were enrolled and started taking PrEP; 98 (36.6%) and 27 (10.1%) had reached three and six-month follow-up respectively. STI testing was conducted at baseline and quarterly follow-up visits. We calculated the baseline prevalence and incidence of STIs. The sample STI incidence will be compared with the population incidence in NSW. Results At enrolment, 17.2% of participants were diagnosed with ≥1 STI, including 10.8% with rectal gonorrhoea, rectal chlamydia and/or syphilis. The latter three STIs were diagnosed in 2.6%, 7.8%, and 1.1% of men, respectively. Among 98 men at 3-month follow-up, 17.3% were diagnosed with any of these STIs (3.1% had rectal gonorrhoea, 11.2% rectal chlamydia and 4.1% syphilis). At three months of follow-up, the incidence of these STIs was 18.4, 67.4 and 24.5 per 100 person-years (PY), respectively. By 14 July 2015, 27 PrEP users reached six months of follow-up. In this group, the incidence of rectal gonorrhoea was 29.6 per 100 PY (11.2% increase from month three follow-up, p < 0.04). No HIV infections were observed in the cohort. Conclusion Among PrEP users in PRELUDE, the baseline prevalence and incidence of STIs were high and remained high in the early follow-up (indeed, the incidence of gonorrhoea has increased). Despite enrolment in a clinical study, with frequent follow-up, STI testing and treatment, PrEP users remain at very high risk of STIs. Longer follow-up is necessary to assess whether STI trends among PrEP users will change. The investigation of prophylaxis against other STIs and other methods of testing and treating STIs among these high-risk men appears to be warranted. Disclosure of interest statement The PRELUDE study is funded by the NSW Ministry of Health, with Gilead Sciences providing the study medication (Truvada). Article	2015	Zhang, Xing-quan	The newest developments of the study on anti-HIV drugs.	Yao Xue Xue Bao = Acta Pharmaceutica Sinica	-	-	-	0513-4870	NA	https://pubmed.ncbi.nlm.nih.gov/26234128/	Besides 36 (28 single-tablets and 8 fixed-dose combinations) used antiretroviral drugs clinically, there are a number of investigational antiretroviral agents currently in phase 2-3 clinical trial. Tenofoviralafenamidefumarate (TAF) is a novel nucleoside analogue reverse transcriptase inhibitor that is potent and less toxicity than tenofovir (TDF). Doravirine is a non-nucleoside analogue reverse transcriptase inhibitor that demonstrates activity against NNRTI-resistant viral strains. GSK744 is an integrase inhibitor with a long acting preparation. In addition, several drugs with new mechanisms are also noted, for example, BMS-663 068 is a small molecule CD4 attachment inhibitors and cenicriviroc is a novel CCR5/CCR2 antagonist with antiretroviral activity and anti-inflammatory effects. Several drug classes that target known pathways in HIV latency have being developed, and leading the list are histone deacetylase inhibitors. Other agents include protein kinase C activators, positive transcription elongation factor activators, DNA methyl-transferase inhibitors and histone methyl-transferase inhibitors and so on. This review is focused on the above-mentioned drug candidates that may be used in clinical in next couple of years and those compounds that can reverse latent HIV infections. Article	2015	Zhao, Jian-yuan; Ding, Ji-wei; Mi, Ze-yun; Wei, Tao; Cen, Shan	Identification and characterization of HIV-1 transmitted /founder viruses.	Yi Chuan = Hereditas	-	-	-	0253-9772	10.16288/j.yczz.14-452	https://pubmed.ncbi.nlm.nih.gov/25998429/	During the spread of human immunodeficiency virus type 1 (HIV-1) in the mucosa, the entire genetic diversity of the viruses is significantly reduced. The vast majority of HIV-1 mucosal infections are established by one or a few viruses and ultimately develop into systemic infections, thus the initial virus is called transmitted/founder virus (T/F virus). The study of T/F virus will benefit understanding its key characteristics resulting in successful viral replication in the new host body, which may provide novel strategies for the development of AIDS vaccines, pre-exposure prophylaxis and other therapeutic interventions. In this review, we summarize the discovery and evolutionary characteristics of T/F virus as well as early immune response after HIV-1 infection, which will establish the basis to explore the features of T/F viruses. Article	2016	Adams L.M.; Balderson B.H.	HIV providers' likelihood to prescribe pre-exposure prophylaxis (PrEP) for HIV prevention differs by patient type: a short report	AIDS Care	-	-	-	9540121	10.1080/09540121.2016.1153595	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84959242880&doi=10.1080%2f09540121.2016.1153595&partnerID=40&md5=9508437399459872b55cbb46fccde83a	ABSTRACT: Pre-exposure prophylaxis (PrEP), the antiretroviral treatment regimen for HIV-negative people at high risk of acquiring HIV, has demonstrated efficacy across clinical trials in several patient populations. The Centers for Disease Control (CDC) have released detailed guidelines to aid providers in prescribing PrEP for their high-risk patients, including men who have sex with men (MSM), high-risk heterosexuals, and injection drug users (IDUs). Given that much attention in PrEP has focused on MSM patients, the present study used an online survey to assess factors involved in HIV care providers' (n = 363) decisions about prescribing PrEP, along with their willingness to prescribe PrEP to patients from various risk populations (e.g., MSM, heterosexuals, IDUs). The efficacy of PrEP was an important factor in providers' decisions about prescribing PrEP, as were considerations about patients' adherence to the regimen, regular follow-up for care, and medication costs. This survey's findings also suggest that providers' willingness to prescribe PrEP varies by patient group, with providers most willing to prescribe to patients with MSM who have an HIV-positive partner, and least willing to prescribe to high-risk heterosexuals or IDUs. In the context of the current CDC recommendations for PrEP that include MSM, heterosexuals, and IDUs, examining providers' rationales for and barriers against supporting this HIV prevention strategy across patient groups merits further attention. © 2016 Informa UK Limited, trading as Taylor & Francis Group. Theses and Dissertations	2016	Afassinou, Komi.	Analysis of multiple control strategies for pre-exposure prophylaxis and post-infection interventions on HIV infection.	-	-	University of KwaZulu-Natal	-	-	NA	http://hdl.handle.net/10413/15048	HIV pre-exposure prophylaxis (PrEP) of which advocates the use of antiretroviral (ARV) agents by uninfected individuals at high risk infection, has recently become a promising preventive measure against sexual HIV transmission. While results from clinical trials undertaken in different parts of the world hold the promise that PrEP intervention could significantly stem the risk of new sexual HIV transmission, very little attention has so far been given to the analysis of the impact of PrEP strategy in mathematical modelling to explore the processes that inform the current trends and other possible feedback mechanisms that can not be captured by the clinical trials. In this research study, we develop mathematical HIV models to investigate the impact of PrEP use as a single intervention and PrEP intervention in combination with other strategies such as ARV therapy (ART) and post-infection educational support services, on HIV incidence and prevalence. Thus, throughout the models analysis, PrEP awareness level, PrEP efficacy level, and ARV treatment rate are considered as key aspects of HIV control. PrEP drug resistance is also considered in our model analysis to examine its contribution to the HIV infection spread. PrEP as a control strategy, is first considered as a single intervention to examine different PrEP intervention scenarios where PrEP use and PrEP efficacy are implemented at high/low levels	Spacetimes.; Rotation and twist. Theses and Dissertations	2016	Akudibillah, Gordon Amed	Optimizing HIV Treatment in Resource-Limited Settings	-	-	Oregon State University	-	-	NA	http://hdl.handle.net/1957/58560	Apart from the traditional role of preventing progression from HIV to AIDS, antiretroviral drug therapy (ART) has an additional benefit of substantially reducing infectiousness, making them potentially an important strategy in the fight against HIV. Recent advances in drug therapy have also seen the use of antiretroviral drugs as a prophylaxis, administered either as post-exposure prophylaxis (PEP) after high-risk exposure or as pre-exposure prophylaxis (PrEP) in those with ongoing HIV exposure. In this dissertation I developed two models for HIV transmission and parameterized them with data from South Africa to study governmental-level intervention programs in which antiretroviral drugs are given as treatment and prophylaxis. The first model is based on the dynamics of HIV in heterosexual population in Sub-Saharan Africa. The model classifies the male and female adult populations by HIV risk into three categories (low, medium and high) according to their sexual preferences. I used a non-linear optimization method to determine the optimal population-level allocation of ART and PrEP allocations required to minimize four objectives: new infections, infection-years, deaths and cost. I considered several strategies for allocating ART and PrEP. I found that generally for low treatment availability, prevention through PrEP to the general population or PrEP and ART to high-risk females is key to optimize all objectives, while for higher drug availability, an all-ART treatment is optimal. At South Africa's current level of treatment availability, using prevention is most effective at reducing new infections, infection-years, and cost, while using the treatment as ART to the general population best reduces deaths. At treatment levels that meet the UNAIDS's ambitious new 90-90-90 target in South Africa, using all or almost all treatment as ART to the general population best reduces all four objectives considered. The second model is based on the WHO's five-stage classification of HIV/AIDS disease progression. This models stratified the population by disease status, whether diagnosed and whether on treatment. I used optimal control methods to determine the best time-dependent treatment allocation required to minimize new infections, infection-years, deaths and cost. My results indicated that the treatment strategy to minimize infection-years and new infections is to place emphasis on early treatment (i.e. treatment in Stage II & III) while to minimize cost and death, the emphasis should be on late treatment (i.e. Stage III & IV). Applying the optimal treatment strategy also leads to a substantial reduction in disease incidence and prevalence. The results of this study will hopefully provides some guidance for policymakers in determining how to allocate antiretroviral drugs in order to maximize the benefit of treatment. Article	2016	Amico K.R.; Mehrotra M.; Avelino-Silva V.I.; McMahan V.; Veloso V.G.; Anderson P.; Guanira J.; Grant R.	Self-reported Recent PrEP Dosing and Drug Detection in an Open Label PrEP Study	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1360-7	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961203398&doi=10.1007%2fs10461-016-1360-7&partnerID=40&md5=048d77cfe6cac0687d0be7868795a1ca	Monitoring adherence to pre-exposure prophylaxis (PrEP) is part of the recommended package for PrEP prescribing, yet ongoing concerns about how to do so confidently are exacerbated by gross discrepancies in reported and actual use in clinical trials. We evaluated concordance between reports of recent PrEP dosing collected via neutral interviewing and drug quantitation in the iPrEx open-label extension, where participants (n = 1172) had the choice to receive or not receive PrEP. Self-report of recent dosing (at least one PrEP dose in the past 3-day) was the most common report (84 % of participants), and among these 83 % did have quantifiable levels of drug. The vast majority of those reporting no doses in the past 3-day (16 % of the sample) did not have quantifiable levels of drug (82 %). Predictors of over-report of dosing included younger age and lower educational attainment. Monitoring recent PrEP use through neutral interviewing may be a productive approach for clinicians to consider in implementation of real-world PrEP. Strategies to capture longer term or prevention-effective PrEP use, particularly for younger cohorts, are needed. © 2016, The Author(s). Article	2016	Andany, Nisha; Walmsley, Sharon L	What's new for antiretroviral treatment in women with HIV.	Journal of Virus Eradication	-	-	-	2055-6640	NA	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4965248	Currently, women represent 52% of persons infected with HIV worldwide and 23% of those in the United States. Combination antiretroviral therapy (cART) has resulted in remarkable reductions in HIV-associated morbidity and mortality, and has dramatically improved life expectancy. Treatment guidelines do not differ for HIV-infected men and non-pregnant women. However, clinical trials of antiretroviral agents have limited female enrolment, and results from these predominantly male studies are extrapolated to the female population. Furthermore, many of these studies do not report gender subgroup analyses, and those that do are underpowered to detect differences between men and women, limiting the ability to assess if results are equally applicable to both sexes. Women may have differential responses to and adverse events from cART. A limited number of female-only clinical trials have demonstrated that female recruitment and retention in these studies is feasible. Therefore, urgent attention is required to improve the body of knowledge regarding clinical efficacy, safety and tolerability of cART in women. In particular, women living with HIV are faced with various sexual and reproductive health concerns that may influence choice of cART. These include potential interactions with hormonal contraception, safety in pregnancy, and the impact of the transition through menopause and development of age-related comorbidities. Finally, the ongoing advances in biomedical HIV prevention, particularly pre-exposure prophylaxis (PrEP), provide an enormous opportunity to enhance HIV prevention in high-risk women, in efforts to further reduce global burden of the pandemic. Article	2016	Anderson P.L.; Garcia-Lerma J.G.; Heneine W.	Nondaily preexposure prophylaxis for HIV prevention	Current Opinion in HIV and AIDS	-	-	-	1746630X	10.1097/COH.0000000000000213	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84950298922&doi=10.1097%2fCOH.0000000000000213&partnerID=40&md5=883403ad5404c14986012da724cdd380	Purpose of review To discuss nondaily preexposure prophylaxis (PrEP) modalities that may provide advantages compared with daily PrEP in cost and cumulative toxicity, but may have lower adherence forgiveness. Recent findings Animal models have informed our understanding of early viral transmission events, which help guide eventdriven PrEP dosing strategies. These models indicate early establishment of viral replication in rectal or cervicovaginal tissues, so event-driven PrEP should rapidly deliver high mucosal drug concentrations within hours of the potential exposure event. Macaque models have demonstrated the high biological efficacy for event-driven dosing of oral tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) against both vaginal and rectal virus transmission. In humans, the IPERGAY study demonstrated 86% efficacy for event-driven oral TDF/FTC dosing among men who have sex with men (MSM), while no similar efficacy data are available on women or heterosexual men. The HPTN 067 study showed that certain MSM populations adhere well to nondaily PrEP, whereas other populations of women adhere more poorly to nondaily versus daily regimens. Pharmacokinetic studies following oral TDF/FTC dosing in humans indicate that TFVdiphosphate (the active form of TFV) accumulates to higher concentrations in rectal versus cervicovaginal tissue, but nonadherence in trials complicates the interpretation of differential mucosal drug concentrations. Summary Event-driven dosing for TFV-based PrEP has promise for HIV prevention in MSM. Future research of eventdriven PrEP in women and heterosexual men should be guided by a better understanding of the importance of mucosal drug concentrations for PrEP efficacy and its sensitivity to adherence. Article	2016	Anderson, Peter L; Reirden, Daniel; Castillo-Mancilla, Jose	Pharmacologic Considerations for Preexposure Prophylaxis in Transgender Women.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001105	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4955879	Studies of tenofovir disoproxil fumarate (TDF)-emtricitabine (FTC)-based preexposure prophylaxis (PrEP) have not focused on transgendered women who are at disproportionate risk of HIV acquisition. Concerns exist for drug interactions between cross-sex therapy (estradiol, progestins, and spironolactone) with tenofovir disoproxil fumarate-emtricitabine. This review assessed the experimental and theoretical risk for such drug interactions. It was found that none of these medications are implicated as major perpetrators of drug interactions, and the classes use different metabolic pathways for clearance, suggesting a low likelihood for interactions in either direction. Subanalyses of transgender women in Preexposure Prophylaxis Initiative suggested PrEP efficacy if adherence was high. Nevertheless, several research gaps were identified, particularly the need for controlled interaction studies in transgendered women, including effects on renal clearance, intracellular tenofovir diphosphate and emtricitabine triphosphate in target cells, as well as hormone effects on HIV susceptibility and immunity. PrEP should continue to be offered to transgender women while additional research is planned or pending.	pharmacology, PrEP, transgender	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review

Preexposure prophylaxis (PrEP) is an effective strategy that can avert new HIV infections in YBMSM. Barriers exist for YBMSM to access PrEP. Methods We sought to determine factors associated with awareness of and willingness to take PrEP in a sample of YBMSM. Results Only 8% were currently on PrEP despite many (66%) reporting condomless anal sex, a recent provider visit (54%), disclosing their sexual orientation to their regular medical provider (62%), or a willingness to take PrEP (62%). In bivariate analysis, increased number of lifetime partners, current PrEP use, and disclosure of sexual orientation to a doctor were associated with awareness of PrEP, while condomless anal sex and higher perceived risk was associated with willingness to take PrEP. Sex with females was associated with lower willingness. Conclusions Providers may be missing key opportunities to educate YBMSM about PrEP and incorporate PrEP into comprehensive sexual health care. © 2016 Society for Adolescent Health and Medicine	Preexposure prophylaxis; PrEP; Young black men who have sex with men (YBMSM)	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2016	Baeten, Jared M; Heffron, Renee; Kidoguchi, Lara; Mugo, Nelly R; Katabira, Elly; Bukusi, Elizabeth A; Asiimwe, Stephen; Haberer, Jessica E; Morton, Jennifer; Ngure, Kenneth; Bulya, Nulu; Odoyo, Josephine; Tindimwebwa, Edna; Hendrix, Craig; Marzinke, Mark A; Ware, Norma C; Wyatt, Monique A; Morrison, Susan; Haugen, Harald; Mujugira, Andrew; Donnell, Deborah; Celum, Connie	Integrated Delivery of Antiretroviral Treatment and Pre-exposure Prophylaxis to HIV-1-Serodiscordant Couples: A Prospective Implementation Study in Kenya and Uganda.	PLOS Medicine	-	-	-	1549-1676	10.1371/journal.pmed.1002099	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4995047	BACKGROUND: Antiretroviral-based interventions for HIV-1 prevention, including antiretroviral therapy (ART) to reduce the infectiousness of HIV-1 infected persons and pre-exposure prophylaxis (PrEP) to reduce the susceptibility of HIV-1 uninfected persons, showed high efficacy for HIV-1 protection in randomized clinical trials. We conducted a prospective implementation study to understand the feasibility and effectiveness of these interventions in delivery settings. METHODS AND FINDINGS: Between November 5, 2012, and January 5, 2015, we enrolled and followed 1,013 heterosexual HIV-1-serodiscordant couples in Kenya and Uganda in a prospective implementation study. ART and PrEP were offered through a pragmatic strategy, with ART promoted for all couples and PrEP offered until 6 mo after ART initiation by the HIV-1 infected partner, permitting time to achieve virologic suppression. One thousand thirteen couples were enrolled, 78% of partnerships initiated ART, and 97% used PrEP, during a median follow-up of 0.9 years. Objective measures of adherence to both prevention strategies demonstrated high use (≥85%). Given the low HIV-1 incidence observed in the study, an additional analysis was added to compare observed incidence to incidence estimated under a simulated counterfactual model constructed using data from a prior prospective study of HIV-1-serodiscordant couples. Counterfactual simulations predicted 39.7 HIV-1 infections would be expected in the population at an incidence of 5.2 per 100 person-years (95% CI 3.7-6.9). However, only two incident HIV-1 infections were observed, at an incidence of 0.2 per 100 person-years (95% CI 0.0-0.9, p < 0.0001 versus predicted). The use of a non-concurrent comparison of HIV-1 incidence is a potential limitation of this approach; however, it would not have been ethical to enroll a contemporaneous population not provided access to ART and PrEP. CONCLUSIONS: Integrated delivery of time-limited PrEP until sustained ART use in African HIV-1-serodiscordant couples was feasible, demonstrated high uptake and adherence, and resulted in near elimination of HIV-1 transmission, with an observed HIV incidence of <0.5% per year compared to an expected incidence of >5% per year. Article	2016	Baggaley, Rachel; Dalal, Shona; Johnson, Cheryl; Macdonald, Virginia; Mameletzis, Ioannis; Rodolph, Michelle; Figueroa, Carmen; Samuelson, Julia; Verster, Annette; Doherty, Meg; Hirnschall, Gottfried	Beyond the 90-90-90: refocusing HIV prevention as part of the global HIV response.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.19.1.21348	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5165083/	INTRODUCTION: The remarkable expansion in availability of antiretroviral therapy (ART) over the past two decades has transformed HIV infection into a manageable chronic condition. People with HIV infection now live long and healthy lives on treatment that is simpler, safer and cheaper. According to UNAIDS estimates, the global coverage of ART reached 46% in 2015, resulting in a 26% decrease in annual HIV-related deaths since 2010. Such success has positioned treatment access at the centre of the global HIV response as a way to prevent mortality, morbidity and HIV transmission through a "Treat All" approach. Continuing expansion of treatment is needed to further reduce HIV-related mortality. This progress with treatment, however, masks a stagnation in the estimated annual number of new HIV infections. Continuing levels of HIV incidence despite treatment scale-up stem from several factors, which should be addressed in order to prevent new infections and decrease the numbers of people requiring treatment in the future. DISCUSSION: ART can only reach those already diagnosed, and although it is unclear what proportion of new infections occur during acute and early infection prior to treatment initiation, phylogenetic studies suggest that it might be substantial. Thus, better testing approaches to reach the 40% of people with undiagnosed HIV infection as early as possible are critical. New approaches to reach men, young people and key populations, where HIV risk is highest and HIV prevention, testing and treatment coverage is lowest, are also needed. Overall coverage of effective prevention interventions remains low, enabling HIV transmission to occur, or time is required to show population-level effects. For example, the full impact of the medical male circumcision intervention will be seen once a larger proportion of men in age cohorts with high incidence are circumcised. Finally, strategically focused pre-exposure prophylaxis interventions have the potential to prevent HIV acquisition among populations at substantial risk, averting treatment costs in coming years. CONCLUSIONS: The United Nations (UN) targets to end AIDS include the "90-90-90" targets for HIV diagnosis, treatment and viral suppression. While 90-90-90 has been widely emphasized and adopted by countries and international funders, the focus thus far has largely been on increasing access to ART - the second "90." A similar emphasis on achieving UN HIV prevention targets and adequate funding for meeting these is essential, alongside treatment, in order to reduce population-level incidence and change the trajectory of the HIV epidemic over the long term. Article	2016	Balkus J.E.; Brown E.; Palanee T.; Nair G.; Gafoor Z.; Zhang J.; Richardson B.A.; Chirenje Z.M.; Marrazzo J.M.; Baeten J.M.	An Empiric HIV Risk Scoring Tool to Predict HIV-1 Acquisition in African Women	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000000974	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84959218183&doi=10.1097%2fQAI.0000000000000974&partnerID=40&md5=d806ec89c05c5f8e549bdbc7225f314b	Objective: To develop and validate an HIV risk assessment tool to predict HIV acquisition among African women. Design: Data were analyzed from 3 randomized trials of biomedical HIV prevention interventions among African women (VOICE, HPTN 035, and FEM-PrEP). Methods: We implemented standard methods for the development of clinical prediction rules to generate a risk-scoring tool to predict HIV acquisition over the course of 1 year. Performance of the score was assessed through internal and external validations. Results: The final risk score resulting from multivariable modeling included age, married/living with a partner, partner provides financial or material support, partner has other partners, alcohol use, detection of a curable sexually transmitted infection, and herpes simplex virus 2 serostatus. Point values for each factor ranged from 0 to 2, with a maximum possible total score of 11. Scores ≥5 were associated with HIV incidence >5 per 100 person-years and identified 91% of incident HIV infections from among only 64% of women. The area under the curve (AUC) for predictive ability of the score was 0.71 (95% confidence interval CI: 0.68 to 0.74), indicating good predictive ability. Risk score performance was generally similar with internal cross-validation (AUC 0.69; 95% CI: 0.66 to 0.73) and external validation in HPTN 035 (AUC 0.70; 95% CI: 0.65 to 0.75) and FEM-PrEP (AUC 0.58; 95% CI: 0.51 to 0.65). Conclusions: A discrete set of characteristics that can be easily assessed in clinical and research settings was predictive of HIV acquisition over 1 year. The use of a validated risk score could improve efficiency of recruitment into HIV prevention research and inform scale-up of HIV prevention strategies in women at highest risk. © Copyright 2016 Wolters Kluwer Health, Inc. Article	2016	Béhanzin, L; Guédou, FA; Géraldo, N; Matsètsé, EG; Aza-Gnandji, M; Chabi, AIB; Zannou, DM; Alary, M	PrEP and Early Antiretroviral Therapy Demonstration Project: Challenges to Ensure Follow-up and Adherence among Female Sex Workers in Cotonou, Benin	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1002/jia2.25208	https://onlinelibrary.wiley.com/doi/10.1002/jia2.25208	Introduction In sub-Saharan Africa, HIV prevalence remains high, especially among key populations. In such situations, combination prevention including clinical, behavioural, structural and biological components, as well as adequate treatment are important. We conducted a demonstration project at the Dispensaire IST, a clinic dedicated to female sex workers (FSWs) in Cotonou, on early antiretroviral therapy (E-ART, or immediate "test-and-treat") and pre-exposure prophylaxis (PrEP). We present key indicators such as uptake, retention and adherence. Methods In this prospective observational study, we recruited FSWs from October 4th 2014 to December 31st 2015 and followed them until December 31st 2016. FSWs were provided with daily tenofovir disoproxil fumarate/emtricitabine (Truvada®) for PrEP or received a first-line antiretroviral regimen as per Benin guidelines. We used generalized estimating equations to assess trends in adherence and sexual behaviour. Results Among FSWs in the catchment area, HIV testing coverage within the study framework was 95.5% (422/442). At baseline, HIV prevalence was 26.3% (111/422). Among eligible FSWs, 95.5% (105/110) were recruited for E-ART and 88.3% (256/290) for PrEP. Overall retention at the end of the study was 59.0% (62/105) for E-ART and 47.3% (121/256) for PrEP. Mean (±SD) duration of follow-up was 13.4 (±7.9) months for E-ART and 11.8 (±7.9) months for PrEP. Self-reported adherence was over 90% among most E-ART participants. For PrEP, adherence was lower and the proportion with 100% adherence decreased over time from 78.4% to 56.7% (p-trend < 0.0001). During the 250.1 person-years of follow-up among PrEP initiators, two seroconversions occurred (incidence 0.8/100 person-years (95% confidence interval: 0.3 to 1.9/100 person-years)). The two seroconverters had stopped using PrEP for at least six months before being found HIV-infected. In both groups, there was no evidence of reduced condom use. Conclusions This study provides data on key indicators for the integration of E-ART and PrEP into the HIV prevention combination package already offered to FSWs in Benin. PrEP may be more useful as an individual intervention for adherent FSWs rather than a specific public health intervention. E-ART was a more successful intervention in terms of retention and adherence and is now offered to all key populations in Benin. Article	2016	Bekker, Linda-Gail; Rebe, Kevin; Venter, Francois; Maartens, Gary; Moorhouse, Michelle; Conradie, Francesca; Wallis, Carole; Black, Vivian; Harley, Beth; Eakles, Robyn	Southern African guidelines on the safe use of pre-exposure prophylaxis in persons at risk of acquiring HIV-1 infection	Southern African Journal of HIV Medicine	-	-	-	2078-6751	10.4102/sajhivmed.v17i1.455	http://www.scielo.org.za/scielo.php?script=sci_arttext&pid=S2078-67512016000100016&lang=pt	The Southern African HIV Clinicians Society published its first set of oral pre-exposure prophylaxis (PrEP) guidelines in June 2012 for men who have sex with men (MSM) who are at risk of HIV infection. With the flurry of data that has been generated in PrEP clinical research since the first guideline, it became evident that there was a need to revise and expand the PrEP guidelines with new evidence of safety and efficacy of PrEP in several populations, including MSM, transgender persons, heterosexual men and women, HIV-serodiscordant couples and people who inject drugs. This need is particularly relevant following the World Health Organization (WHO) Consolidated Treatment Guidelines released in September 2015. These guidelines advise that PrEP is a highly effective, safe, biomedical option for HIV prevention that can be incorporated with other combination prevention strategies in Southern Africa, given the high prevalence of HIV in the region. PrEP should be tailored to populations at highest risk of HIV acquisition, whilst further data from studies in the region accrue to guide optimal deployment to realise the greatest impact regionally. PrEP may be used intermittently during periods of perceived HIV acquisition risk, rather than continually and lifelong, as is the case with antiretroviral treatment. Recognition and accurate measurement of potential risk in individuals and populations also warrants discussion, but are not extensively covered in these guidelines. Article	2016	Bernard C.L.; Brandeau M.L.; Humphreys K.; Bendavid E.; Holodniy M.; Weyant C.; Owens D.K.; Goldhaber-Fiebert J.D.	Cost-effectiveness of HIV preexposure prophylaxis for people who inject drugs in the United States	Annals of Internal Medicine	-	-	-	34819	10.7326/M15-2634	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84978141614&doi=10.7326%2fM15-2634&partnerID=40&md5=09c798a3a12e0fb717010221a02165ca	Background: The total population health benefits and costs of HIV preexposure prophylaxis (PrEP) for people who inject drugs (PWID) in the United States are unclear. Objective: To evaluate the cost-effectiveness and optimal delivery conditions of PrEP for PWID. Design: Empirically calibrated dynamic compartmental model. Data Sources: Published literature and expert opinion. Target Population: Adult U.S. PWID. Time Horizon: 20 years and lifetime. Intervention: PrEP alone, PrEP with frequent screening (PrEP+screen), and PrEP+screen with enhanced provision of antiretroviral therapy (ART) for individuals who become infected (PrEP+screen+ART). All scenarios are considered at 25% coverage. Outcome Measures: Infections averted, deaths averted, change in HIV prevalence, discounted costs (in 2015 U.S. dollars), discounted quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratios. Results of Base-Case Analysis: PrEP+screen+ART dominates other strategies, averting 26 700 infections and reducing HIV prevalence among PWID by 14% compared with the status quo. Achieving these benefits costs $253 000 per QALY gained. At current drug prices, total expenditures for PrEP+screen+ART could be as high as $44 billion over 20 years. Results of Sensitivity Analysis: Cost-effectiveness of the intervention is linear in the annual cost of PrEP and is dependent on PrEP drug adherence, individual transmission risks, and community HIV prevalence. Limitation: Data on risk stratification and achievable PrEP efficacy levels for U.S. PWID are limited. Conclusion: PrEP with frequent screening and prompt treatment for those who become infected can reduce HIV burden among PWID and provide health benefits for the entire U.S. population, but, at current drug prices, it remains an expensive intervention both in absolute terms and in cost per QALY gained. Article	2016	Bil, Janneke P; van der Veldt, Wendy M; Prins, Maria; Stolte, Ineke G; Davidovich, Udi	Motives of Dutch men who have sex with men for daily and intermittent HIV pre-exposure prophylaxis usage and preferences for implementation A qualitative study	Medicine (United States)	-	-	-	257974	10.1097/MD.0000000000004910	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85013127758&doi=10.1097%2fMD.0000000000004910&partnerID=40&md5=fb14431092a5d58ffb6cb595353e76c3	Although PrEP is not yet registered in Europe, including the Netherlands, its approval and implementation are expected in the near future. To inform future pre-exposure prophylaxis (PrEP) implementation, this study aimed to gain insight into motives and preferences for daily or intermittent PrEP use among Dutch HIV-negative men having sex with men (MSM). Between February and December 2013, semistructured interviews were conducted until data saturation was reached (N=20). Interviews were analyzed using the Grounded Theory approach. Motives for (not) using daily PrEP were based on beliefs about PrEP efficacy and side effects, preferences for other prevention strategies, self-perceived HIV risk, self-perceived efficacy of PrEP adherence, beliefs about possible benefits (e.g., anxiety reduction, sex life improvement), and barriers of PrEP use (e.g., costs, monitoring procedures). The perceived benefits of intermittent versus daily PrEP use were the lower costs and side effects and the lower threshold to decision to start using intermittent PrEP. Barriers of intermittent PrEP versus daily PrEP use were the perceived need to plan their sex life and adhere to multiple prevention strategies. Although some perceived PrEP as a condom substitute, others were likely to combine PrEP and condoms for sexually transmitted infections (STI) prevention and increased HIV protection. Participants preferred PrEP service locations to have specialized knowledge of HIV, antiretroviral therapy, sexual behavior, STIs, patients' medical background, be easily approachable, be able to perform PrEP follow-up monitoring, and provide support. To maximize the public health impact of PrEP, ensuring high uptake among MSM at highest risk is important. Therefore, targeted information about PrEP efficacy and side effects need to be developed, barriers for accessing PrEP services should be minimized, and perceived self-efficacy to use PrEP should be addressed and improved. To prevent increases in STIs, condom use should be monitored and PrEP should be integrated into routine STI screening and counseling. Copyright © 2016 the Author(s). Article	2016	Blackstock, OJ; Moore, BA; Berkenblit, G; Calabrese, SK; Cunningham, C; Fiellin, DA; Patel, VV; Phillips, KA; Shah, M; Tetrault, J; Edelman, EJ	PRIMARY CARE PROVIDER AND PRACTICE CHARACTERISTICS ASSOCIATED WITH HIV PRE-EXPOSURE PROPHYLAXIS (PREP) UPTAKE	Journal of General Internal Medicine	-	-	-	0884-8734	10.1521/aeap.2021.33.4.325	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8559721/	Increasing access to pre-exposure prophylaxis (PrEP) in primary care settings for patients who may be at risk for HIV could help increase PrEP uptake, which has remained low among certain key risk populations. Previous work suggests a high degree of variability among primary care providers regarding attitudes, knowledge, and prescriptive practices related to PrEP. The current study sought to better understand factors contributing to variation in PrEP prescribing and assess potential interventions. Primary care providers identified from national claims data as having either high- or low-likelihood of having PrEP-eligible patients based on their prescribing practices for other sexually transmitted infections were interviewed by telephone. The study yielded important information about primary care providers' knowledge, attitudes, and beliefs about PrEP, as well as barriers and facilitators to prescribing PrEP. Key recommendations that can inform provider-focused, network-based interventions to increase PrEP-prescribing include increasing patient education to increase demand from providers, and enhancing provider education and connections with other local providers. Other recommendations include leveraging technology (e.g., dashboards illustrating prescription rates as compared to peers), providing prescribing cheat sheets, and instituting standardized sexual health screenings. Article	2016	Blaizot, Stéphanie; Maman, David; Riche, Benjamin; Mukui, Irene; Kirubi, Beatrice; Ecochard, René; Etard, Jean-François	Potential impact of multiple interventions on HIV incidence in a hyperendemic region in Western Kenya: a modelling study.	BMC Infectious Diseases	-	-	-	1471-2334	10.1186/s12879-016-1520-4	https://bmcinfectdis.biomedcentral.com/articles/10.1186/s12879-016-1520-4	BACKGROUND: Multiple prevention interventions, including early antiretroviral therapy initiation, may reduce HIV incidence in hyperendemic settings. Our aim was to predict the short-term impact of various single and combined interventions on HIV spreading in the adult population of Ndhiwa subcounty (Nyanza Province, Kenya). METHODS: A mathematical model was used with data on adults (15-59 years) from the Ndhiwa HIV Impact in Population Survey to compare the impacts on HIV prevalence, HIV incidence rate, and population viral load suppression of various interventions. These interventions included: improving the cascade of care (use of three guidelines), increasing voluntary medical male circumcision (VMMC), and implementing pre-exposure prophylaxis (PrEP) use among HIV-uninfected women. RESULTS: After four years, improving separately the cascade of care under the WHO 2013 guidelines and under the treat-all strategy would reduce the overall HIV incidence rate by 46 and 58 %, respectively, vs. the baseline rate, and by 35 and 49 %, respectively, vs. the implementation of the current Kenyan guidelines. With conservative and optimistic scenarios, VMMC and PrEP would reduce the HIV incidence rate by 15-25 % and 22-28 % vs. the baseline, respectively. Combining the WHO 2013 guidelines with VMMC would reduce the HIV incidence rate by 35-56 % and combining the treat-all strategy with VMMC would reduce it by 49-65 %. Combining the WHO 2013 guidelines, VMMC, and PrEP would reduce the HIV incidence rate by 46-67 %. CONCLUSIONS: The impacts of the WHO 2013 guidelines and the treat-all strategy were relatively close; their implementation is desirable to reduce HIV spread. Combining several strategies is promising in adult populations of hyperendemic areas but requires regular, reliable, and costly monitoring. Article	2016	Bond, Keosha T; Gunn, Alana J	Perceived Advantages and Disadvantages of Using Pre-Exposure Prophylaxis (PrEP) among Sexually Active Black Women: An Exploratory Study.	Journal of Black Sexuality and Relationships	-	-	-	2334-2668	10.1353/bsr.2016.0019	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5512598	Knowledge of pre-exposure prophylaxis (PrEP) continues to remain scarce among Black women who are disproportionally affected by HIV in the United States. A thematic analysis of open-ended questions from a sample of Black women (n=119) who completed a mix-methods, online, e-health study was conducted to examine the perceived advantages and disadvantages of using PrEP. Being a female controlled method, empowerment, option for women with risky sex partners, and serodiscordant couples were advantages described. Disadvantages of PrEP were identified as the complexity of the choice, encouragement of sex with risky partners, increased burden, promotion of unprotected sex, and newness of the drug. Article	2016	Braksmajer, Amy; Senn, Theresa E; McMahon, James	The Potential of Pre-Exposure Prophylaxis for Women in Violent Relationships.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2016.0098	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4913495	HIV and intimate partner violence (IPV) are significant intersecting threats to women's health. Women in violent relationships have few feasible HIV risk reduction options as traditional prevention methods are largely dependent on a partner's cooperation. The purpose of this review is to explore potential benefits and drawbacks of pre-exposure prophylaxis (PrEP) use among women in the United States experiencing IPV. Advantages of PrEP use in this population include the potential for covert or autonomous use, coital independence, dual protection against sexual and injection risk, and facilitated connections to social services. A number of barriers, however, may interfere with the effective use of PrEP, including partner resistance, cost, frequent medical visits, gendered norms regarding sexuality, and stigma. To realize its potential for women in violent relationships, it will be necessary to incorporate PrEP into behavioral and structural interventions that encourage uptake, facilitate adherence, ensure women's safety, and challenge existing gender norms. Risk mitigation of HIV infection for travelers	Tropical Diseases, Travel Medicine and Vaccines	-	-	-	20550936	10.1186/s40794-016-0042-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85069238555&doi=10.1186%2fs40794-016-0042-9&partnerID=40&md5=5db03127cfbf5d6847593f642a619ba8	The HIV pandemic persists globally and travelers are at risk for infection by the Human Immunodeficiency Virus (HIV). While HIV-focused guidelines delineate risk stratification and mitigation strategies for people in their home communities, travel issues are not addressed. In this review, direct and indirect evidence on HIV risk among travelers is explored. The burgeoning practice of employing pre-exposure prophylaxis (PrEP) with anti-retroviral therapy in the non-travel setting is introduced, as well as the more established use of post-exposure prophylaxis (PEP). Challenges in applying these lessons to travelers are discussed, and a new guidelines process is scoped and recommended. © 2016 The Author(s). Article	2016	Brydon C.	PrEP should be a key component of a comprehensive HIV prevention package fully funded on the NHS	Clinical Pharmacist	-	-	-	17589061	10.1211/CP.2016.20201939	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85057720554&doi=10.1211%2fCP.2016.20201939&partnerID=40&md5=1eadb621d7468fe478136e25f6567986	Pre-exposure prophylaxis (PrEP) is the medication taken by HIV-negative individuals to reduce their risk of contracting HIV infection. The large evidence base for the use of PrEP has been reviewed and recommended by the World Health Organization (WHO), a specialised agency of the United Nations that is concerned with international public health, the Joint United Nations Programme on HIV and AIDS (UNAIDS) and the National Institute for Health and Care Excellence (NICE), England's health technology assessment body. NHS England, the body that sets the priorities and direction of the NHS and commissions healthcare services in England, does not currently fund PrEP despite the increasing numbers of HIV infections in the UK. This article aims to review why PrEP should be fully funded through the NHS and the issues that need to be considered, primarily its efficacy and cost as well as risk of side effects, changes in condom use, rates of sexually transmitted infections and drug resistance. It will outline the arguments supporting the use of PrEP as part of a comprehensive HIV prevention package on the NHS. © 2016 Royal Pharmaceutical Society. All rights reserved. Article	2016	Cáceres C.F.; Borquez A.; Klausner J.D.; Baggaley R.; Beyrer C.	Implementation of pre-exposure prophylaxis for human immunodeficiency virus infection: Progress and emerging issues in research and policy	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.19.7.2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84995595304&doi=10.7448%2fIAS.19.7.2&partnerID=40&md5=d8c461bbac300a53e92a7623eb3e7a5f	Background: In this article, we present recent evidence from studies focused on the implementation, effectiveness and costeffectiveness of pre-exposure prophylaxis (PrEP) for HIV infection; discuss PrEP scale-up to date, including the observed levels of access and policy development; and elaborate on key emerging policy and research issues to consider for further scale-up, with a special focus on lower-middle income countries. Discussion: The 2015 WHO Early Release Guidelines for HIV Treatment and Prevention reflect both scientific evidence and new policy perspectives. Those guidelines present a timely challenge to health systems for the scaling up of not only treatment for every person living with HIV infection but also the offer of PrEP to those at substantial risk. Delivery and uptake of both universal antiretroviral therapy (ART) and PrEP will require nation-wide commitment and could reinvigorate health systems to develop more comprehensive "combination prevention" programmes and support wider testing linked to both treatments and other prevention options for populations at highest risk who are currently not accessing services. Various gaps in current health systems will need to be addressed to achieve strategic scale-up of PrEP, including developing prioritization strategies, strengthening drug regulations, determining cost and funding sources, training health providers, supporting user adherence and creating demand. Conclusions: The initial steps in the scale-up of PrEP globally suggest feasibility, acceptability and likely impact. However, to prevent setbacks in less well-resourced settings, countries will need to anticipate and address challenges such as operational and health systems barriers, drug cost and regulatory policies, health providers' openness to prescribing PrEP to populations at substantial risk, demand and legal and human rights issues. Emerging problems will require creative solutions and will continue to illustrate the complexity of PrEP implementation. © 2016 Cáceres CF et al; licensee International AIDS Society. Editorial	2016	Cáceres, Carlos F; Bekker, Linda-Gail; Godfrey-Faussett, Peter	Global implementation of PrEP as part of combination HIV prevention – Unsolved challenges	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.19.7.21479	https://onlinelibrary.wiley.com/doi/full/10.7448/IAS.19.7.21479	The 2015 World Health Organization (WHO) Guidelines on when to start antiretroviral (ARV) therapy and on pre-exposure prophylaxis (PrEP) for HIV (1) made two landmark recommendations: 1) the offer of ARV treatment to anybody diagnosed with HIV infection, regardless of CD4 levels (i.e. "test and offer"); and 2) the offer of oral HIV PrEP with a tenofovir-containing scheme to any person at substantial risk. As of mid-2016, many of the concerns about potential roll-out that emerged from clinical trials are quickly fading: real-life effectiveness has been demonstrated in 2015/2016 and qualified the role of some of the important undesired occurrences that had been anticipated such as low adherence and "risk compensation" leading to viral resistance and new infections (2). Studies such as PROUD (3) have shown that at least men who have sex with men (MSM) who use PrEP are at significant risk (due to frequent condomless anal intercourse with casual partners of unknown serostatus), are highly adherent, and can benefit from PrEP effectiveness. PrEP uptake with high adherence in certain communities (e.g. the gay community in San Francisco) (4) is contributing to significant reductions in HIV infections in that city. In addition, studies assessing intermittent PrEP (e.g. the on-demand PrEP scheme used in Ipergay (5), and alternative schemes for MSM included in a Thai study) have also contributed exciting results (6). On 8 June 2016, the UN General Assembly signed the political declaration on HIV and AIDS: on the fast-track to accelerate the fight against HIV and to end the AIDS epidemic by 2030 (7). To fulfill the aspirations of the political declaration, UNAIDS has established a 2016–2021 strategy (8) with targets set in HIV prevention and care at the local and regional levels: an ambitious target of ensuring access to PrEP for three million people at substantial risk by 2020. This is based on reaching an overall estimate of 10% of populations at increased risk, namely key populations including MSM, transgender people, and sex workers as well as young women of reproductive age living in the most highly affected communities and people in serodiscordant partnerships where the viral load of the positive partner is not known to be reliably suppressed.Despite recent progress and these aspirational goals, actual roll-out at a global scale is just beginning, and considerable challenges remain unmet. The planning and organization of demonstration studies beyond MSM in the United States and the UK has been slow, and implementation-relevant information for both the general population and specific key populations (e.g. female sex workers in generalized epidemic contexts, and MSM and transwomen in Asia and Latin America) is still lacking. While concerns about adherence and effectiveness (particularly among MSM) have abated, some other issues have emerged, including 1) the preferred ARV agent, although tenofovir–emtricitabine is the only licensed agent at present; 2) potential of less frequent dosing, and cost and sustainability (as much in lower-middle income as in higher-income countries); and 3) a long list of implementation questions that vary by setting and target population. The latter may make monitoring of impact and outcome more complex.NEMUS, in collaboration with UNAIDS, has followed its first supplement on PrEP beyond clinical trials (9) with this new collection of papers focused on PrEP roll-out, identifying barriers and solutions, again with a focus on regions and populations not considered before. In this editorial, we highlight the main messages of the papers included in this new series. Together with other tools that will be published soon, such as the upcoming WHO implementation guidelines, this publication will help to document progress and guide implementers through a rapidly changing field.	basic medicine; clinical medicine; general & internal medicine; medical and health sciences; virology; Family medicine; Human immunodeficiency virus (HIV); Bioinformatics	English	United States	Western and Central Europe and North America	Peru	Latin America and the Caribbean	Peru	Latin America and the Caribbean	Other
Editorial	2016	Cáceres, Carlos F; Linda-Gail Bekker; Peter Godfrey-Faussett	No one left behind: how are we doing in the roll-out of PrEP as part of combination HIV prevention?	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.19.7.21364	https://www.proquest.com/scholarly-journals/no-one-left-behind-how-are-we-doing-roll-out-prep/docview/2290093740/se-2?accountid=8113	The 2015 World Health Organization (WHO) Guidelines on when to start antiretroviral (ARV) therapy and on pre-exposure prophylaxis (PrEP) for HIV 1 made two landmark recommendations: 1) the offer of ARV treatment to anybody diagnosed with HIV infection, regardless of CD4 levels (i.e. "test and offer"); and 2) the offer of oral HIV PrEP with a tenofovir-containing scheme to any person at substantial risk. While feasibility, acceptability and potential impact have been demonstrated, creative solutions will be needed to overcome challenges, which include operational and health systems barriers, drug cost and regulatory policies, health providers' openness to prescribing PrEP to populations at substantial risk, demand creation and legal and human rights issues. Some key action areas identified included the normalization of HIV prevention to help demand creation; community level interventions involving opinion leaders as well as empowerment interventions for those at highest risk; access to quality services for all, including for stigmatized populations; and provision of adherence support that recognizes social and structural factors. ...Cairns and Race 18 present a community viewpoint, which reminds the readers that PrEP has been and continues to be an intervention causing controversy and debate between providers, advocates and potential users. Article	2016	Cairns, Gus P; Race, Kane; Goicochea, Pedro	PrEP: controversy, agency and ownership.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.19.7.21120	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5071749	Pre-exposure prophylaxis (PrEP) has been and continues to be an intervention that causes controversy and debate between stakeholders involved in providing or advocating for it, and within communities in need of it. These controversies extend beyond the intrinsically complex issues of making it available. In this commentary, some of the possible roots of the air of dissent and drama that accompanies PrEP are explored. The similarities between the controversies that dogged the earliest human trials of PrEP and the ones we see today in the era of licensing and implementation are explored. We outline five mediating principles or cultural norms that may influence arguments about PrEP differently. Three areas of specific concern are identified: medical risk versus benefit, distrust and fear of healthcare interventions, and fears for individual responsibility and community cohesion. The fear that PrEP may somehow represent a loss of control over one or more of these domains is suggested as an underlying factor. The development of countervailing measures, to institute greater community "ownership" of PrEP, and concomitant improvements in the sense of individual agency over sexual risk are outlined and recommended. Article	2016	Cairns, Gus; McCormack, Sheena; Molina, Jean-Michel	The European preexposure prophylaxis revolution.	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0000000000000223	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4888928	PURPOSE OF REVIEW: The review describes the European epidemic and the challenges in moving from clinical trials of preexposure prophylaxis (PrEP) to routine practice. RECENT FINDINGS: Two European trials conducted in gay and other MSM and transgender women reported a high and consistent reduction in HIV incidence using oral PrEP with tenofovir/emtricitabine (TDF/FTC). The incidence of HIV infection in the control group was much higher than anticipated, based on routine surveillance data in MSM, in spite of the highest standard of HIV prevention available. SUMMARY: Recent results have highlighted the urgent need to make PrEP available to key populations in Europe as an additional prevention tool. Gilead has not yet submitted an application to use TDF/FTC as PrEP in Europe. Although regulatory approval would accelerate implementation, countries are already dispensing TDF/FTC as postexposure prophylaxis without this. Services for prevention are diverse across countries ranging from free, walk-in services for the diagnosis and treatment of HIV and other sexually transmitted infections, to insurance-dependent reimbursement of private clinical services. Momentum is gathering in Europe with PrEP demonstration projects in MSM and a growing demand from community organizations. Each Member State urgently needs to identify their key populations and determine the service best placed to provide this new prevention strategy within a comprehensive prevention package. Article	2016	Calabrese S.K.; Magnus M.; Mayer K.H.; Krakower D.S.; Eldahan A.I.; Gaston Hawkins L.A.; Hansen N.B.; Kershaw T.S.; Underhill K.; Betancourt J.R.; Dovidio J.F.	Putting PrEP into practice: Lessons learned from early-adopting U.S. providers' firsthand experiences providing HIV pre-exposure prophylaxis and associated care	PLOS One	-	-	-	19326203	10.1371/journal.pone.0157324	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84975882061&doi=10.1371%2fjournal.pone.0157324&partnerID=40&md5=69786a6696948c0dbafcbe651d7af0a5	Optimizing access to HIV pre-exposure prophylaxis (PrEP), an evidence-based HIV prevention resource, requires expanding healthcare providers' adoption of PrEP into clinical practice. This qualitative study explored PrEP providers' firsthand experiences relative to six commonly-cited barriers to prescription - financial coverage, implementation logistics, eligibility determination, adherence concerns, side effects, and anticipated behavior change (risk compensation) - as well as their recommendations for training PrEP-inexperienced providers. U.S.-based PrEP providers were recruited via direct outreach and referral from colleagues and other participants (2014-2015). One-one interviews were conducted in person or by phone, transcribed, and analyzed. The sample (n = 18) primarily practiced in the Northeastern (67%) or Southern (22%) U.S. Nearly all (94%) were medical doctors (MDs), most of whom self-identified as infectious disease specialists. Prior experience prescribing PrEP ranged from 2 to 325 patients. Overall, providers reported favorable experiences with PrEP implementation and indicated that commonly anticipated problems were minimal or manageable. PrEP was covered via insurance or other programs for most patients; however, pre-authorization requirements, laboratory/service provision costs, and high deductibles sometimes presented challenges. Various models of PrEP care and coordination with other providers were utilized, with several providers highlighting the value of clinical staff support. Eligibility was determined through joint decision-making with patients; CDC guidelines were commonly referenced but not considered absolute. Patient adherence was variable, with particularly strong adherence noted among patients who had actively sought PrEP (self-referred). Providers observed minimal adverse effects or increases in risk behavior. However, they identified several barriers with respect to accessing and engaging PrEP candidates. Providers offered a wide range of suggestions regarding content, strategy, and logistics surrounding PrEP training, highlighting sexual history-taking and sexual minority competence as areas to prioritize. These insights from early-adopting PrEP providers may facilitate adoption of PrEP into clinical practice by PrEP-inexperienced providers, thereby improving access for individuals at risk for HIV. © 2016 Calabrese et al. Framing HIV Pre-Exposure Prophylaxis (PrEP) for the General Public: How Inclusive Messaging May Prevent Prejudice from Diminishing Public Support	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1318-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84975755411&doi=10.1007%2fs10461-016-1318-9&partnerID=40&md5=a46cefb2b0ace10fb22ca008a822cc2f	Strategic framing of public messages about HIV pre-exposure prophylaxis (PrEP) may influence public support for policies and programs affecting access. This survey study examined how public attitudes toward PrEP differed based on the social group PrEP was described as benefiting ("beneficiary") and the moderating effect of prejudice. Members of the general public (n = 154) recruited online were randomly assigned to three beneficiary conditions: general population, gay men, or Black gay men. All participants received identical PrEP background information before completing measures of PrEP attitudes (specifying beneficiary), racism, and heterosexism. Despite anticipating greater PrEP adherence among gay men and Black gay men and perceiving PrEP as especially beneficial to the latter, participants expressed lower support for policies/programs making PrEP affordable for these groups vs. the general population. This disparity in support was stronger among participants reporting greater prejudice. Inclusive framing of PrEP in public discourse may prevent prejudice from undermining implementation efforts. © 2016, Springer Science+Business Media New York. Article	2016	Cambiano, Valentina; Miners, Alec; Phillips, Andrew	What do we know about the cost-effectiveness of HIV preexposure prophylaxis, and is it affordable?	Current Opinion in HIV and AIDS	-	-	-	1746-6318	10.1097/COH.0000000000000217	https://dx.doi.org/10.1097/COH.0000000000000217	PURPOSE OF REVIEW: The WHO recommends preexposure prophylaxis (PrEP) in populations at substantial risk of HIV. Despite a number of randomized controlled trials demonstrating its efficacy, and several ongoing implementation projects, PrEP is currently only available in a few countries. Modelling studies can provide useful insights into the long-term impact of introducing PrEP in different subgroups of the population. The review summarizes studies that either evaluated the cost-effectiveness or the cost of introducing PrEP, focusing on seven published in the last year. RECENT FINDINGS: These studies used a number of different types of models and investigated the introduction of PrEP in different settings. Among men having sex with men (MSM) in North America, PrEP ranged from being cost-saving (while benefiting population health) to costing US $160,000/quality-adjusted life-year gained. Among heterosexual sero-different couples, it varied from around US $5000 to US $10,000/disability-adjusted life-year averted, when PrEP was used until 6 or 12 months after the HIV-positive partner had initiated antiretroviral therapy (ART) in, respectively, Uganda and South Africa. SUMMARY: Future cost-effectiveness studies of PrEP should consider the HIV incidence, the level of uptake, the effect of its introduction on alternative prevention approaches, and the budget impact of rolling it out. Article	2016	Carlo Hojilla, J; Koester, Kimberly A; Cohen, Stephanie E; Buchbinder, Susan; Ladzekpo, Deawodi; Matheson, Tim; Liu, Albert Y	Sexual Behavior, Risk Compensation, and HIV Prevention Strategies Among Participants in the San Francisco PrEP Demonstration Project: A Qualitative Analysis of Counseling Notes.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-015-1055-5	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4592687	Pre-exposure prophylaxis (PrEP) is a viable HIV prevention strategy but risk compensation could undermine potential benefits. There are limited data that examine this phenomenon outside of clinical trials. We conducted a qualitative analysis of counseling notes from the San Francisco site of the US PrEP demonstration project to assess how men who have sex with men used PrEP as a prevention strategy and its impact on their sexual practices. Four major themes emerged from our analysis of 130 distinct notes associated with 26 participants. Prevention strategy decision-making was dynamic, often influenced by the context and perceived risk of a sexual encounter. Counselors noted that participants used PrEP in conjunction with other health promotion strategies like condoms, asking about HIV status of their sex partners, and seroadaptation. With few exceptions, existing risk reduction strategies were not abandoned upon initiation of PrEP. Risk-taking behavior was 'seasonal' and fluctuations were influenced by various personal, psychosocial, and health-related factors. PrEP also helped relieve anxiety regarding sex and HIV, particularly among serodiscordant partners. Understanding sexual decision-making and how PrEP is incorporated into existing prevention strategies can help inform future PrEP implementation efforts. Article	2016	Carrico, Adam W.; Zepf, Roland; Meanley, Steven; Batchelder, Abigail; Stall, Ronald	Critical Review: When the Party is Over: A Systematic Review of Behavioral Interventions for Substance-Using Men Who Have Sex with Men.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884 1525-4135	10.1097/QAI.0000000000001102	https://pubmed.ncbi.nlm.nih.gov/27258233/	Because problematic patterns of alcohol and other substance use are prevalent drivers of the HIV/AIDS epidemic, comprehensive interventions are needed for substance-using men who have sex with men (SUMSM). We conducted a systematic review of 12 randomized controlled trials (RCTs) of behavioral interventions for reducing condomless anal intercourse (CAI) in SUMSM. Three RCTs observed that cognitive behavioral or motivational interviewing interventions achieved a 24% to 40% decrease in CAI. Interventions also tended to demonstrate greater efficacy for reducing CAI and substance use among those who had lower severity of substance use disorder symptoms. Although behavioral interventions for SUMSM are one potentially important component of biobehavioral HIV/AIDS prevention, further research is needed to examine whether integrative approaches that cultivate resilience and target co-occurring syndemic conditions demonstrate greater efficacy. Multilevel intervention approaches are also needed to optimize the effectiveness of pre-exposure prophylaxis and HIV treatment as prevention with SUMSM. Article	2016	Carroll J.J.; Heffron R.; Mugo N.; Ngure K.; Ndase P.; Asiimwe S.; Celum C.; Baeten J.M.	Perceived Risk among Human Immunodeficiency Virus Serodiscordant Couples in East Africa Taking Oral Pre-Exposure Prophylaxis	Sexually Transmitted Diseases	-	-	-	1485717	10.1097/OLQ.0000000000000472	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84976548764&doi=10.1097%2fOLQ.0000000000000472&partnerID=40&md5=75d69e1107f316be33ac5498ddafa6e8	Objectives Perceived risk of human immunodeficiency virus (HIV) infection is thought to drive low adherence in pre-exposure prophylaxis (PrEP) trials. We explored the level of perceived risk of incident HIV infection in the Partners PrEP Study, in which adherence was generally high. Methods A cross-sectional questionnaire assessed perceived risk of HIV at 12 months after enrollment. Logistic regression was used to analyze the relationship between perceived risk and other demographic and behavioral variables. Results Three thousand two hundred twenty-six couples from the Partners PrEP Study were included in this analysis. Only 15.4% of participants reported high or moderate perceived risk. Participants at high risk of acquiring HIV were slightly more likely to report high perceived risk (odds ratio, 1.60; 95% confidence interval, 1.30-1.95; P < 0.001); nevertheless, only 20% of participants with high-risk reported high perceived risk. Conclusions Participants reported low perceived risk of HIV but were adherent to PrEP. Perceptions of risk are likely socially determined and more complex than Likert scale questionnaires capture. © 2016 American Sexually Transmitted Diseases Association All rights reserved. Article	2016	Carroll J.J.; Ngure K.; Heffron R.; Curran K.; Mugo N.R.; Baeten J.M.	Gendered differences in the perceived risks and benefits of oral PrEP among HIV-serodiscordant couples in Kenya	AIDS Care	-	-	-	9540121	10.1080/09540121.2015.1131972	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84954244267&doi=10.1080%2f09540121.2015.1131972&partnerID=40&md5=bf14280dc24d9539bf6ab798802c4adf	Pre-exposure prophylaxis (PrEP) is effective for preventing HIV among HIV-serodiscordant heterosexual couples. Gender roles may influence perceived personal and social risks related to HIV-prevention behaviors and may affect use of PrEP. In this study, interviews and focus groups were conducted with 68 individuals from 34 mutually disclosed serodiscordant heterosexual partnerships in Thika, Kenya. Sociocultural factors that affect adherence to PrEP were explored using grounded analysis. Three factors were identified, which shape perceptions of PrEP: Gendered power dynamics and control over decision-making in the household; conflicts between risk-reduction strategies and male sexual desire; culture-bound definitions of women's work. Adherence to PrEP in the Partners PrEP Study was high; however, participants articulated conflicting interests related to PrEP in connection with traditional gender roles. The successful delivery of PrEP will require understanding of key social factors, particularly related to gender and dyadic dynamics around HIV serostatus. © 2016 Informa UK Limited, trading as Taylor & Francis Group. Article	2016	Castillo-Mancilla, Jose; Seifert, Sharon; Campbell, Kayla; Coleman, Stacey; McAllister, Kevin; Zheng, Jia-Hua; Gardner, Edward M; Liu, Albert; Glidden, David V; Grant, Robert; Hosek, Sybil; Wilson, Craig M; Bushman, Lane R; MaWhinney, Samantha; Anderson, Peter L	Emtricitabine-Triphosphate in Dried Blood Spots as a Marker of Recent Dosing.	Antimicrobial Agents and Chemotherapy	-	-	-	1098-6596	10.1128/AAC.01017-16	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5075074	New objective measures of antiretroviral adherence are needed. We determined if emtricitabine triphosphate (FTC-TP) in dried blood spots (DBS) can be used as a marker of recent dosing with tenofovir disoproxil fumarate-emtricitabine (TDF-FTC). The half-life of FTC-TP was estimated in DBS samples obtained from an intensive pharmacokinetic (PK) study of coformulated TDF-FTC in HIV-negative and HIV-infected participants. The concordance of quantifiable FTC-TP in DBS with tenofovir (TFV)/FTC in plasma was evaluated by utilizing paired plasma-DBS samples from participants enrolled in 2 large preexposure prophylaxis (PrEP) open-label trials. The time to FTC-TP nondetectability after TDF-FTC dosing was evaluated utilizing DBS from HIV-negative participants enrolled in a directly observed therapy study of variable adherence to TDF-FTC. The mean (95% confidence interval CI) terminal half-life of FTC-TP in the PK study was 35 (23 to 47) h. A total of 143/163 (88%) samples obtained 0 to 48 h post-TDF-FTC dose had quantifiable FTC-TP in DBS, compared with 2/93 (2%) and 0/87 (0%) obtained >48 and >96 h postdose. In 746 paired plasma-DBS samples from 445 participants enrolled in PrEP trials, when both TFV/FTC in plasma were below the limit of quantification, FTC-TP was as well in 98.9% of the samples, and when either TFV or FTC in plasma was quantifiable, FTC-TP was as well in 90.5% of the samples. The half-life of FTC-TP in DBS is short relative to that of TFV-diphosphate (TFV-DP), making it a surrogate for TFV-FTC detection in plasma. FTC-TP can be quantified in DBS simultaneously with TFV-DP, which quantifies cumulative adherence to TDF-FTC. (The clinical trials discussed in this article have been registered at ClinicalTrials.gov under identifiers NCT01040091, NCT02022657, NCT00458393, NCT01772823, and NCT02012621.). Article	2016	Cavilla, S	The potential impact of PrEP (pre-exposure prophylaxis) in a single HIV centre	HIV Medicine	-	-	-	1464-2662	10.1371/journal.pmed.1001323	https://pubmed.ncbi.nlm.nih.gov/23055836/	Background: HIV pre-exposure prophylaxis (PrEP), the use of antiretroviral drugs by uninfected individuals to prevent HIV infection, has demonstrated effectiveness in preventing acquisition in a high-risk population of men who have sex with men (MSM). Consequently, there is a need to understand if and how PrEP can be used cost-effectively to prevent HIV infection in such populations. Methods and findings: We developed a mathematical model representing the HIV epidemic among MSM and transwomen (male-to-female transgender individuals) in Lima, Peru, as a test case. PrEP effectiveness in the model is assumed to result from the combination of a "conditional efficacy" parameter and an adherence parameter. Annual operating costs from a health provider perspective were based on the US Centers for Disease Control and Prevention interim guidelines for PrEP use. The model was used to investigate the population-level impact, cost, and cost-effectiveness of PrEP under a range of implementation scenarios. The epidemiological impact of PrEP is largely driven by programme characteristics. For a modest PrEP coverage of 5%, over 8% of infections could be averted in a programme prioritising those at higher risk and attaining the adherence levels of the Pre-Exposure Prophylaxis Initiative study. Across all scenarios, the highest estimated cost per disability-adjusted life year averted (uniform strategy for a coverage level of 20%, US$1,036-US$4,254) is below the World Health Organization recommended threshold for cost-effective interventions, while only certain optimistic scenarios (low coverage of 5% and some or high prioritisation) are likely to be cost-effective using the World Bank threshold. The impact of PrEP is reduced if those on PrEP decrease condom use, but only extreme behaviour changes among non-adherers (over 80% reduction in condom use) and a low PrEP conditional efficacy (40%) would adversely impact the epidemic. However, PrEP will not arrest HIV transmission in isolation because of its incomplete effectiveness and dependence on adherence, and because the high cost of programmes limits the coverage levels that could potentially be attained. Conclusions: A strategic PrEP intervention could be a cost-effective addition to existing HIV prevention strategies for MSM populations. However, despite being cost-effective, a substantial expenditure would be required to generate significant reductions in incidence. Please see later in the article for the Editors' Summary. Article	2016	Celum, C; Morrow, RA; Donnell, D; Hong, T; Hendrix, CW; Thomas, KK	Daily oral tenofovir and emtricitabine-tenofovir pre-exposure prophylaxis reduces herpes simplex virus type 2 acquisition among heterosexual HIV-1-uninfected men and women: a subgroup analysis of a randomized trial	Annals of Internal Medicine	-	-	-	0003-4819	10.7326/L16-0549	https://pubmed.ncbi.nlm.nih.gov/24979446/	Background: Daily oral preexposure prophylaxis (PrEP) using the antiretroviral tenofovir disoproxil fumarate (TDF) alone or in combination with emtricitabine (FTC-TDF) reduces the risk for HIV-1 acquisition. Tenofovir has in vitro activity against herpes simplex virus type 2 (HSV-2). Objective: To assess the efficacy of daily oral PrEP with tenofovir and FTC-TDF in the prevention of HSV-2 acquisition. Design: Subgroup analysis of data from a randomized, placebo-controlled trial with concealed allocation. (ClinicalTrials.gov: NCT00557245). Setting: Multiple sites in Kenya and Uganda. Participants: Heterosexual men and women who were seronegative for HIV-1 and HSV-2 and at high risk for HIV-1 acquisition due to having an HIV-1-infected partner. Intervention: Once-daily oral tenofovir disoproxil fumarate (TDF), alone or combined with emtricitabine (FTC-TDF), compared with placebo. Measurements: HSV-2 seroconversion. Results: A total of 131 participants seroconverted to HSV-2 (79 of 1041 assigned to tenofovir or FTC-TDF PrEP [HSV-2 incidence, 5.6 per 100 person-years] and 52 of 481 assigned to placebo [HSV-2 incidence, 7.7 per 100 person-years]). The hazard ratio (HR) for HSV-2 acquisition with daily oral PrEP was 0.70 (95% CI, 0.49 to 0.99; P = 0.047) compared with placebo, and the absolute risk reduction was 2.1 per 100 person-years. Among the 1044 participants with HSV-2-infected partners, the HR for PrEP was 0.67 (CI, 0.46 to 0.98; P = 0.038) compared with placebo, and the absolute risk reduction was 3.1 per 100 person-years. Limitation: Randomization was not stratified by HSV-2 status, and diagnostic tests to exclude participants with acute HSV-2 at baseline are not available. Conclusion: Daily oral tenofovir-based PrEP significantly reduced the risk for HSV-2 acquisition among heterosexual men and women. Modest protection against HSV-2 is an added benefit of HIV-1 prevention with oral tenofovir-based PrEP. Article	2016	Chaillon A.; Hoenigl M.; Mehta S.R.; Weibel N.; Little S.J.; Smith D.M.	A practical online tool to estimate antiretroviral coverage for HIV infected and susceptible populations needed to reduce local HIV epidemics	Scientific Reports	-	-	-	20452322	10.1038/srep28707	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84975701671&doi=10.1038%2fsrep28707&partnerID=40&md5=bdd48271d141fa1b2a562b15da68b526	It remains unclear what proportions of HIV-infected and uninfected people should receive effective antiretroviral therapy (ART) to control local HIV epidemics. We developed a flexible model to evaluate the impact of treatment as prevention (TasP) and pre-exposure prophylaxis (PrEP) on HIV incidence in local communities. We evaluated this tool for determining what TasP and PrEP targets are needed to substantially reduce the HIV epidemic in San Diego, which is predominately comprised of men who have sex with men. By increasing the proportion of HIV-infected individuals on ART from 30% to 50%, 686 new infections would be prevented over five years in San Diego. By providing PrEP to 30% of MSM to the age group that account for 90% of local HIV incident cases (21-52 years), we could prevent 433 infections over five years. When combining these initiatives, a PrEP coverage rate of 40% and TasP coverage rate of 34% would be expected to decrease the number of new infections by over half in one year. This online tool is designed to help local public health planners and policy makers to estimate program outcomes and costs that may lead to better control of their local HIV epidemics. Article	2016	Chan P.A.; Mena L.; Patel R.; Oldenburg C.E.; Beauchamps L.; Perez-Brumer A.G.; Parker S.; Mayer K.H.; Mimiaga M.J.; Nunn A.	Retention in care outcomes for HIV pre-exposure prophylaxis implementation programmes among men who have sex with men in three US cities	Journal of the International AIDS Society	-	-	-	17582652	10.7448/IAS.19.1.20903	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84976295655&doi=10.7448%2fIAS.19.1.20903&partnerID=40&md5=297a80738018bc083535ce6fdd5a643d	Introduction: Despite the efficacy of pre-exposure prophylaxis (PrEP) in preventing HIV transmission, few studies have evaluated PrEP use and retention in care outcomes in real-world settings outside of clinical trials. Methods: Data were collected from PrEP clinical care programmes in three mid-size US cities: Providence, Rhode Island (RI); Jackson, Mississippi (MS); and St. Louis, Missouri (MO). We assessed the demographic and social characteristics of patients prescribed PrEP and documented their insurance and copayment experiences. We assessed retention in PrEP care at three and six months. Multivariate analyses were used to predict retention in care among men who have sex with men (MSM). HIV acquisition among the cohort was also assessed. Results: A total of 267 (RI: 117; MS: 88; MO: 62) patients were prescribed PrEP; 81% filled prescriptions (RI: 73%; MS: 82%; MO: 94%; p<0.001). Patients in MS and MO were more commonly African American than in RI (72% and 26% vs. 7%, respectively), but less frequently Latino (2% and 3% vs. 24%, respectively). More patients reported living below the federal poverty line in MS (52%) compared to MO (23%) and RI (26%). Most patients were MSM (RI: 92%; MS: 88%; MO: 84%). The majority of MSM reported recent condomless anal sex (RI: 70%; MS: 65%; MO: 75%). Among 171 patients prescribed PrEP at least six months beforehand, 72% were retained in care at three months (RI: 68%; MS: 70%; MO: 87%; p=0.12) and 57% were retained in PrEP care at six months (RI: 53%; MS: 61%; MO: 63%; p=0.51). Insurance status and medication costs were not found to be significant barriers for obtaining PrEP. Three patients became infected with HIV during the six-month period after being prescribed PrEP (1.1%; 3/267), including one in RI (suspected acute HIV infection), one in MO (confirmed poor adherence) and one in MS (seroconverted just prior to initiation). Conclusions: PrEP initiation and retention in care differed across these distinct settings. In contrast, retention in PrEP care was consistently suboptimal across sites. Further research is needed to identify the individual, social and structural factors that may impede or enhance retention in PrEP care. © 2016 Chan PA et al; licensee International AIDS Society. Article	2016	Chan, Philip A; Glynn, Tiffany R; Oldenburg, Catherine E; Montgomery, Madeline C; Robinette, Ashley E; Almonte, Alexi; Raifman, Julia; Mena, Leandro; Patel, Rupa; Mayer, Kenneth H; Beauchamps, Laura S; Nunn, Amy S	Implementation of Preexposure Prophylaxis for Human Immunodeficiency Virus Prevention Among Men Who Have Sex With Men at a New England Sexually Transmitted Diseases Clinic.	Sexually Transmitted Diseases	-	-	-	1537-4521	10.1097/OLQ.0000000000000514	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5129653	BACKGROUND: Preexposure prophylaxis (PrEP) is efficacious in preventing human immunodeficiency virus (HIV) among men who have sex with men (MSM). We assessed PrEP uptake among MSM presenting for services at a sexually transmitted diseases (STD) clinic. METHODS: Men who have sex with men presenting to the Rhode Island STD Clinic between October 2013 and November 2014 were educated about, and offered, PrEP. We categorized PrEP engagement using an implementation cascade to describe gaps in uptake which described MSM who: (1) were educated about PrEP, (2) indicated interest, (3) successfully received follow-up contact, (4) scheduled an appointment, (5) attended an appointment, and (6) initiated PrEP (ie, received a prescription). Bivariate and multivariable logistic regression models were used to examine predictors of PrEP initiation. RESULTS: A total of 234 MSM were educated about PrEP; of these, 56% expressed interest. Common reasons for lack of interest were low HIV risk perception (37%), wanting more time to consider (10%), concern about side effects (7%), and financial barriers (3%). Among those interested, 53% followed up. Of those, 51% scheduled an appointment. The most common reason patients did not schedule an appointment was low HIV risk perception (38%). Seventy-seven percent of those with an appointment attended the appointment; of those, 93% initiated PrEP. Patients with higher HIV-risk perception (adjusted odds ratios, 2.17; 95% confidence interval, 1.29-3.64) and a history of sex with an HIV-positive partner (adjusted odds ratios, 7.08; 95% confidence interval, 2.35-21.34) had significantly higher odds of initiating PrEP. CONCLUSIONS: Low HIV-risk perception was the most significant barrier to PrEP uptake among MSM attending a public STD clinic.	pre-exposure prophylaxis, implementation, men who have sex with men, HIV, sexually transmitted diseases	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative
Article	2016	Chang, Hyeygjeon; Moog, Claude; Astolfi, Alessandro	Occurrence of HIV eradication for preexposure prophylaxis treatment with a deterministic HIV model.	IET Systems Biology	-	-	-	1751-8849	10.1049/iet-syb.2016.0008	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8687162	The authors examine the human immunodeficiency virus (HIV) eradication in this study using a mathematical model and analyse the occurrence of virus eradication during the early stage of infection. To this end they use a deterministic HIV-infection model, modify it to describe the pharmacological dynamics of antiretroviral HIV drugs, and consider the clinical experimental results of preexposure prophylaxis HIV treatment. They also use numerical simulation to model the experimental scenario, thereby supporting the clinical results with a model-based explanation. The study results indicate that the protocol employed in the experiment can eradicate HIV in infected patients at the early stage of the infection. Article	2016	Chen Y.-H.; Snowden J.M.; McFarland W.; Raymond H.F.	Pre-exposure Prophylaxis (PrEP) Use, Seroadaptation, and Sexual Behavior Among Men Who Have Sex with Men, San Francisco, 2004–2014	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1357-2	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961217976&doi=10.1007%2fs10461-016-1357-2&partnerID=40&md5=309fcae2b70ddca3aac7862002fc6403	The Food and Drug Administration approved pre-exposure prophylaxis (PrEP) to prevent HIV infection, and the Centers for Disease Control and Prevention has presented PrEP as a prevention option for groups at high risk such as men who have sex with men (MSM). Intervention data provide some information on how PrEP affects sexual behavior of MSM in trials, open label extensions, or clinics. However, it is unclear whether sexual risk and preventive behavioral patterns are changing in the population as a whole as PrEP becomes more widely available, whether due to PrEP use or other factors. We examined trends in PrEP use, numbers of condomless anal sex partners, consistent condom use, and seroadaptive strategies in San Francisco—a city which has actively promoted PrEP—using data from National HIV Behavioral Surveillance (NHBS). NHBS recruited 1211, 383, 373, and 268 HIV-negative MSM in 2004, 2008, 2011, and 2014, respectively. PrEP use increased from zero in 2004, 2008, and 2011 to 9.6 % in 2014. The proportion of men with no condomless anal sex partners dropped from 60.6 % in 2004, to 58.2 % in 2008, to 54.2 % in 2011, to 40.2 % in 2014. Consistent condom use decreased from 36.8 % in 2004, to 30.5 % in 2008 and 2011, to 18.3 % in 2014. PrEP's introduction and scale-up enters in a pre-existing trend of decreasing condom use and increasing sexually transmitted infections among MSM which may be accelerating in recent years. While PrEP use should be scaled up as a prevention option among those who would benefit most, we believe that public health officials need to be realistic about the possibility that condom use could very well continue to decline as PrEP use increases, and to an extent that may not be directly or indirectly offset by PrEP. © 2016, Springer Science+Business Media New York. Article	2016	Chen, Xinhui; Castillo-Mancilla, Jose R.; Seifert, Sharon M.; McAllister, Kevin B.; Zheng, Jia-Hua; Bushman, Lane R.; MaWhinney, Samantha; Anderson, Peter L.	Analysis of the Endogenous Deoxynucleoside Triphosphate Pool in HIV-Positive and -Negative Individuals Receiving Tenofovir-Emtricitabine.	Antimicrobial Agents and Chemotherapy	-	-	-	1098-6596 0066-4804	10.1128/AAC.01019-16	https://journals.asm.org/doi/10.1128/aac.01019-16	Tenofovir (TFV) disoproxil fumarate (TDF) and emtricitabine (FTC), two nucleos(t)ide analogs (NA), are coformulated as an anti-HIV combination tablet for treatment and preexposure prophylaxis (PrEP). TDF/FTC may have effects on the deoxynucleoside triphosphate (dNTP) pool due to their similar structures and similar metabolic pathways. We carried out a comprehensive clinical study to characterize the effects of TDF/FTC on the endogenous dNTP pool, from baseline to 30 days of TDF/FTC therapy, in both treatment-naive HIV-positive and HIV-negative individuals. dATP, dCTP, dGTP, and TTP were quantified in peripheral blood mononuclear cells (PBMC) with a validated liquid chromatography-tandem mass spectrometry (LC-MS/MS) methodology. Forty individuals (19 HIV-positive) were enrolled and underwent a baseline visit and then received TDF/FTC for at least 30 days. Longitudinal measurements were analyzed using mixed-model segmented linear regression analysis. The dNTPs were reduced by 14% to 37% relative to the baseline level within 3 days in both HIV-negative and HIV-positive individuals (P ≤ 0.003). These reductions persisted to various degrees at day 30. These findings indicate that dNTP pools are influenced by TDF/FTC therapy. This may affect cellular homeostasis and could increase the antiviral effect through a more favorable analog/dNTP ratio. Further work is needed to elucidate mechanisms, to evaluate the clinical significance of these findings, and to further probe differences between HIV-negative and HIV-positive individuals. (This study has been registered at ClinicalTrials.gov under identifier NCT01040091.). Article	2016	Chen, Xinhui; Seifert, Sharon M; Castillo-Mancilla, Jose R; Bushman, Lane R; Zheng, Jia-Hua; Kiser, Jennifer J; MaWhinney, Samantha; Anderson, Peter L	Model Linking Plasma and Intracellular Tenofovir/Emtricitabine with Deoxynucleoside Triphosphates.	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0165505	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5104339	The coformulation of the nucleos(t)ide analogs (NA) tenofovir (TFV) disoproxil fumarate (TDF) and emtricitabine (FTC) is approved for HIV-infection treatment and prevention. Plasma TFV and FTC undergo complicated hybrid processes to form, accumulate, and retain as their active intracellular anabolites: TFV-diphosphate (TFV-DP) and FTC-triphosphate (FTC-TP). Such complexities manifest in nonlinear intracellular pharmacokinetics (PK). In target cells, TFV-DP/FTC-TP compete with endogenous deoxynucleoside triphosphates (dNTP) at the active site of HIV reverse transcriptase, underscoring the importance of analog:dNTP ratios for antiviral efficacy. However, NA such as TFV and FTC have the potential to disturb the dNTP pool, which could augment or reduce their efficacies. We conducted a pharmacokinetics-pharmacodynamics (PKPD) study among forty subjects receiving daily TFV/FTC (300 mg/200 mg) from the first-dose to pharmacological intracellular steady-state (30 days). TFV/FTC in plasma, TFV-DP/FTC-TP and dNTPs in peripheral blood mononuclear cells (PBMC) were quantified using validated LC/MS/MS methodologies. Concentration-time data were analyzed using nonlinear mixed effects modeling (NONMEM). Formations and the accumulation of intracellular TFV-DP/FTC-TP was driven by plasma TFV/FTC, which was described by a hybrid of first-order formation and saturation. An indirect response link model described the interplay between TFV-DP/FTC-TP and the dNTP pool change. The EC50 (interindividual variability, (%CV)) of TFV-DP and FTC-TP on the inhibition of deoxyadenosine triphosphate (dATP) and deoxycytidine triphosphate (dCTP) production were 1020 fmol/106 cells (130%) and 44.4 pmol/106 cells (82.5%), resulting in (90% prediction interval) 11% (0.45%, 53%) and 14% (2.6%, 35%) reductions. Model simulations of analog:dNTP molar ratios using IPERGAY dosing suggested that FTC significantly contributes to the protective effect of preexposure prophylaxis (PrEP). Simulation-based intracellular operational multiple dosing half-lives of TFV-DP and FTC-TP were 6.7 days and 33 hours. This model described the formation of intracellular TFV-DP/FTC-TP and the interaction with dNTPs, and can be used to simulate analog:dNTP time course for various dosing strategies. Theses and Dissertations	2016	Chen, Yea-Hung	HIV Transmission Among Men Who Have Sex With Men: Tools, Risks, and Consequences	-	-	University of California – San Francisco	-	NA	NA	http://www.escholarship.org/uc/item/2c8831rb	The focus of this dissertation is estimating the distribution of behavioral patterns prior to HIV infection – including behaviors such as serosorting and use of pre-exposure prophylaxis – among newly HIV-infected San Francisco MSM. These quantities have been surprisingly elusive, particularly for the complex behavioral patterns considered in our studies. Though officials and researchers have hypothesized – and sometimes assumed – that HIV infection primarily occurs among high-risk MSM, it is alternatively possible that infection mostly occurs among relatively low-risk MSM, since there are more low-risk MSM in San Francisco than high-risk MSM. Understanding of these quantities could help identify what groups of San Francisco MSM should be reached by HIV prevention. The 2nd chapter of this dissertation examines per-act risks for HIV transmission, which are a crucial basis for a mathematical model we developed and used to estimate the distribution of prior behavioral patterns among newly HIV-infected San Francisco MSM. The 3rd chapter presents the model and its findings. Finally, the 4th chapter examines possible barriers to intervening on the risk group identified via the model. Article	2016	Cheung K.T.; Fairley C.K.; Read T.R.H.; Denham I.; Fehler G.; Bradshaw C.S.; Chen M.Y.; Chow E.P.F.	HIV incidence and predictors of incident HIV among men who have sex with men attending a sexual health clinic in Melbourne, Australia	PLOS One	-	-	-	19326203	10.1371/journal.pone.0156160	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84973925892&doi=10.1371%2fjournal.pone.0156160&partnerID=40&md5=5c5ed909b6124eaf3e08e8565f0a58d5	Introduction: The aim of this study was to determine the risk factors for HIV infection and the incidence in men who have sex with men (MSM). It is important to identify subgroups of MSM in which preventive interventions such as pre-exposure prophylaxis (PrEP) offered at the time of their last negative test would be considered cost-effective. Methods: We conducted a retrospective cohort study of MSM attending Melbourne Sexual Health Centre (MSHC) during 2007-2013 with at least two HIV tests within 12 months of each other. Demographic characteristics, sexual and other behaviours, and bacterial sexually transmitted infection (STI) diagnoses were extracted from the date of the last negative HIV test. HIV incidence rate (IR) per 100 person-years for each risk factor was calculated. Results: Of the 13907 MSM who attended MSHC, 5256 MSM had at least two HIV tests and were eligible, contributing 6391 person-years follow-up. 81 new HIV diagnoses were identified within 12 months of an HIV negative test with an incidence of 1.3 (95% CI: 1.0-1.6) per 100 person-years. Significant associations with subsequent HIV infection were: rectal gonorrhea (HIV IR: 3.4 95% CI: 2.1-5.2), rectal chlamydia (HIV IR: 2.6 95% CI: 1.7-3.7), inconsistent condom use (HIV IR: 2.1 95% CI: 1.6-2.7), use of post-exposure prophylaxis (HIV IR: 2.3 95% CI: 1.7-3.1), and injecting drug use (HIV IR: 8.5 95% CI: 3.4-17.5). Conclusion: The incidence of HIV was above 2.0% in subgroups of MSM with specific characteristics at the last HIV negative test. PrEP is considered cost effective at this incidence and could potentially be used along with other preventive interventions for these individuals in more than half of the population. © 2016 Cheung et al. Article	2016	Cong M.-E.; Pau C.-P.; Heneine W.; García-Lerma J.G.	Antiretroviral drug activity in macaques infected during pre-exposure prophylaxis has a transient effect on cell-associated SHIV DNA reservoirs	PLOS One	-	-	-	19326203	10.1371/journal.pone.0164821	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84994682702&doi=10.1371%2fjournal.pone.0164821&partnerID=40&md5=55dca28f14238c643e051b0b9c05d7a3	Background Pre-exposure prophylaxis (PrEP) with emtricitabine and tenofovir disoproxil fumarate (FTC/TDF) is a novel HIV prevention strategy. Suboptimal PrEP adherence and HIV infection creates an opportunity for continued antiretroviral drug activity during undiagnosed infection. We previously showed that macaques infected with SHIV during PrEP with FTC/ TDF display reduced acute plasma viremias and limited virus diversity. We investigated the effect of PrEP on acute SHIV DNA dynamics and on the size of the persistent virus reservoir in lymphoid tissues. Design Cell-associated SHIV DNA levels in PBMCs were measured in 8 macaques infected during PrEP with FTC/TDF or single-agent TAF and was compared to those seen in untreated infections (n = 10). PrEP breakthrough infections continued treatment with 1-2 weekly drug doses to model suboptimal drug exposure during undiagnosed HIV infection in humans. SHIV DNA was also measured in lymphoid tissues collected from FTC/TDF PrEP breakthroughs after 1 year of infection. Results Compared to untreated controls, PrEP infections had reduced plasma RNA viremias both at peak and throughout weeks 1-12 (p<0.005). SHIV DNA levels were also reduced at peak and during the first 12 weeks of infection (p<0.043) but not throughout weeks 12-20. At 1 year, SHIV DNA reservoirs in lymphoid tissues were similar in size among macaques that received PrEP or placebo. Conclusions Antiviral drug activity due to PrEP limits acute SHIV replication but has only a transient effect on cell-associated SHIV DNA levels. Our model suggests that suboptimal drug exposure in persons that are taking PrEP and become infected with HIV may not be sufficient to reduce the pool of HIV-infected cells, and that treatment intensification may be needed to sustain potential virological benefits from the PrEP regimen. © This is an open access article, free of all copyright, and may be freely reproduced, distributed, transmitted, modified, built upon, or otherwise used by anyone for any lawful purpose. Article	2016	Conniff J.; Evensen A.	Preexposure prophylaxis (PrEP) for HIV prevention: The primary care perspective	Journal of the American Board of Family Medicine	-	-	-	15572625	10.3122/jabfm.2016.01.150223	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84958239430&doi=10.3122%2fjabfm.2016.01.150223&partnerID=40&md5=9a5516af0ea883e03d2947142d023113	Until recently there have been few primary care office-based strategies to reduce the transmission of HIV. In May 2014 the Centers for Disease Control and Prevention published updated practice guidelines recommending the use of preexposure prophylaxis (PrEP) with daily oral dosing of tenofovir/emtricitabine to help prevent HIV infection in high-risk individuals (strength of recommendation, A). Knowledge of PrEP among primary care providers is low, however, and this intervention is likely reaching only a small fraction of eligible patients. PrEP is recommended for certain injection drug users, nonmonogamous men who have sex with men, heterosexual women who have sex with men who have sex with men or injection drug users, and those in HIV serodiscordant relationships. Providers should obtain baseline laboratory values and provide initial counseling before prescribing PrEP. Regular office visits are necessary to ensure adherence, provide ongoing counseling, and monitor for side effects, including nausea, abdominal pain, headache, and, less commonly, increased creatinine. Guidelines and toolkits have been developed to assist in incorporating PrEP into primary care practice. PrEP is gaining widespread acceptance and has become a crucial tool in the fight to stop the spread of HIV. Article	2016	Corneli, Amy; Perry, Brian; McKenna, Kevin; Agot, Kawango; Ahmed, Khatija; Taylor, Jamilah; Malamatsho, Fulufhelo; Odhiambo, Jacob; Skhosana, Joseph; Van Damme, Lut	Participants' Explanations for Nonadherence in the FEM-PrEP Clinical Trial.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	1944-7884	10.1097/QAI.0000000000000880	https://dx.doi.org/10.1097/QAI.0000000000000880	BACKGROUND: FEM-PrEP-a clinical trial of daily, oral emtricitabine/tenofovir disoproxil fumarate for HIV prevention among women in sub-Saharan Africa-did not show a reduction in HIV acquisition because of low adherence to the study pill. We conducted a follow-up study to identify reasons for nonadherence. METHODS: Qualitative, semistructured interviews (n = 88) and quantitative, audio computer-assisted self-interviews (n = 224) were conducted with former FEM-PrEP participants in Bondo, Kenya, and Pretoria, South Africa. Thematic analysis was used to analyze the qualitative data, and descriptive statistics were used to describe audio computer-assisted self-interviews responses. Data are presented within the 5 categories of Ickovics' and Meisler's conceptual framework on adherence: (1) the individual, (2) trial characteristics and study pill regimen, (3) patient-provider relationship, (4) clinical setting, and (5) the disease. RESULTS: Participants' explanations for nonadherence were primarily situated within 3 of the framework's 5 categories: (1) the individual, (2) trial characteristics and study pill regimen, and (3) the disease. Concerns about the investigational nature of the drug being tested and side effects were the prominent reasons reported for nonadherence. Participants also described being discouraged from taking the study pill by members of the community, their sexual partners, and other participants, primarily because of these same concerns. Limited acceptability of the pill's attributes influenced nonadherence for some participants as did concerns about HIV-related stigma. In addition, many participants reported that others continued in FEM-PrEP while not taking the study pill because of the trial's ancillary benefits and visit reimbursement-factors related to the clinical setting. Negative patient-provider relationships were infrequently reported as a factor that influenced nonadherence. CONCLUSIONS: Despite substantial study staff engagement with participants and communities, concerns about the study pill and discouragement from others seemed to have influenced nonadherence considerably. Alternative study designs or procedures and enhanced community engagement paradigms may be needed in future studies.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Cottrell, Mackenzie L; Yang, Kuo H; Prince, Heather M A; Sykes, Craig; White, Nicole; Malone, Stephanie; Dellon, Evan S; Madanick, Ryan D; Shaheen, Nicholas J; Hudgens, Michael G; Wulff, Jacob; Patterson, Kristine B; Nelson, Julie A E; Kashuba, Angela D M	A Translational Pharmacology Approach to Predicting Outcomes of Preexposure Prophylaxis Against HIV in Men and Women Using Tenofovir Disoproxil Fumarate With or Without Emtricitabine.	Journal of Infectious Diseases	-	-	-	-	1537-6613	10.1093/infdis/jiw077	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4907409	BACKGROUND: A novel translational pharmacology investigation was conducted by combining an in vitro efficacy target with mucosal tissue pharmacokinetic (PK) data and mathematical modeling to determine the number of doses required for effective human immunodeficiency virus (HIV) preexposure prophylaxis (PrEP). METHODS: A PK/pharmacodynamic (PD) model was developed by measuring mucosal tissue concentrations of tenofovir, emtricitabine, their active metabolites (tenofovir diphosphate TFVdp and emtricitabine triphosphate FTCtp, respectively), and competing endogenous nucleotides (dATP and dCTP) in 47 healthy women. TZM-bl and CD4(+) T cells were used to identify 90% effective concentration (EC90) ratios of TFVdp to dATP and FTCtp to dCTP (alone and in combination) for protection against HIV. Monte-Carlo simulations were then performed to identify minimally effective dosing strategies to protect lower female genital tract and colorectal tissues. RESULTS: The colorectal TFVdp concentration was 10 times higher than that in the lower female genital tract, whereas concentrations of endogenous nucleotides were 7-11 times lower. Our model predicted that ≥98% of the population achieved protective mucosal tissue exposure by the third daily dose of tenofovir disoproxil fumarate plus emtricitabine. However, a minimum adherence to 6 of 7 doses/week (85%) was required to protect lower female genital tract tissue from HIV, while adherence to 2 of 7 doses/week (28%) was required to protect colorectal tissue. CONCLUSIONS: This model is predictive of recent PrEP trial results in which 2-3 doses/week was 75%-90% effective in men but ineffective in women. These data provide a novel approach for future PrEP investigations that can optimize clinical trial dosing strategies. Article	2016	Cowan F.M.; Delany-Moretlwe S.	Promise and pitfalls of pre-exposure prophylaxis for female sex workers	Current Opinion in HIV and AIDS	-	-	-	-	1746630X	10.1097/COH.0000000000000215	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84950258033&doi=10.1097%2fCOH.0000000000000215&partnerID=40&md5=61166a44b8f9a282cdd5dbd0e96df3b7	Purpose of review We explore the potential benefits of integrating preexposure prophylaxis (PrEP) into combination HIV prevention for female sex workers (FSWs) and the likely challenges to implementation. Recent findings Evidence for the biological effectiveness of PrEP in women who can adhere to daily dosing is strong. FSWs in many countries bear the brunt of the HIV epidemic. Current combination prevention approaches enable many FSWs to remain HIV-free, but in some settings FSWs are unable to mitigate their risk. PrEP provides a new prevention tool for these women. To benefit, HIV-negative FSWs need to perceive that they are at risk, be motivated and able to take PrEP daily and to attend health services for prescription refill and clinical monitoring. FSWs face particular structural challenges to PrEP uptake and use, including stigmatizing health services; fear of disclosure to other FSWs and clients; fear of the authorities; lack of social support; substance use; unplanned travel and risk compensation many of which can be addressed through combination prevention approaches. Summary For those FSWs who are unable to mitigate their HIV risk, PrEP, if adequately supported and integrated with combination prevention, may empower them to remain HIV-free. Article	2016	Cowan F.M.; Delany-Moretlwe S.; Sanders E.J.; Mugo N.R.; Guedou F.A.; Alary M.; Behanzin L.; Mugurungi O.; Bekker L.-G.	PrEP implementation research in Africa: What is new?	Journal of the International AIDS Society	-	-	-	-	17582652	10.7448/IAS.19.7.21101	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84995438658&doi=10.7448%2fIAS.19.7.21101&partnerID=40&md5=cbeb7cc1e19274262eb235b7227b4401	Introduction: Of the two million new HIV infections in adults in 2014, 70% occurred in sub-Saharan Africa. Several African countries have already approved guidelines for pre-exposure prophylaxis (PrEP) for individuals at substantial risk of HIV as part of combination HIV prevention but key questions remain about how to identify and deliver PrEP to those at greatest need. Throughout the continent, individuals in sero-discordant relationships, and members of key populations (sex workers, men who have sex with men (MSM), transgender women and injection drug users) are likely to benefit from the availability of PrEP. In addition, adolescent girls and young women (AGYW) are at substantial risk in some parts of the continent. It has been estimated that at least three million individuals in Africa are likely to be eligible for PrEP according to WHO's criteria. Tens of demonstration projects are planned or underway across the continent among a range of countries, populations and delivery settings. Discussion: In each of the target populations, there are overarching issues related to (i) creating demand for PrEP, (ii) addressing supply-side issues and (iii) providing appropriate and tailored adherence support. Critical for creating demand for PrEP is the normalization of HIV prevention. Community-level interventions which engage opinion leaders as well as empowerment interventions for those at highest risk will be key. Critical to supply of PrEP is that services are accessible for all, including for stigmatized populations. Establishing accessible integrated services provides the opportunity to address other public health priorities including the unmet need for HIV testing, contraception and sexually transmitted infections treatment. National policies need to include minimum standards for training and quality assurance for PrEP implementation and to address supply chain issues. Adherence support needs to recognize that social and structural factors are likely to have an important influence. Combining interventions that build self-efficacy, empowerment and social cohesion, with evidence-based individualized adherence support for PrEP, are most likely to be effective. Conclusions: Efficacy of tenofovir-based PrEP is proven but many issues related to implementation remain unclear. Here, we have summarized some of the important implementation questions that need to be assessed as PrEP is rolled out across Africa. © 2016 Cowan FM et al;. Article	2016	Dai, JY; Hendrix, CW; Richardson, BA; Kelly, C; Marzinke, M; Chirenje, ZM; Marrazzo, JM; Brown, ER	Pharmacological measures of treatment adherence and risk of HIV infection in the VOICE study	Journal of Infectious Diseases	-	-	-	-	na	10.1093/infdis/jiv333	https://www.cochranelibrary.com/central/doi/10.1002/central/CN-01142204/full	BACKGROUND: None of the 3 regimens tested in the VOICE study showed protection against human immunodeficiency virus (HIV) infection in intent-to-treat analyses. Plasma tenofovir concentrations demonstrated poor adherence to the study product among study subjects. Statistical analyses to explore the causal treatment effect on the prevention of HIV infection among adherent individuals are needed. METHODS: We developed an analytical strategy to evaluate whether conventional covariate adjustment removes confounding and thereby reveals a prevention effect among adherent individuals. We applied this strategy to the VOICE study, using 2 dichotomized proxy measures of product use: detection of tenofovir in plasma at least once during follow-up and detection of tenofovir in plasma at the 3-month follow-up visit. RESULTS: After adjustment for a set of baseline predictors of the risk of HIV transmission, the confounding associated with comparison of adherent individuals in the tenofovir gel arm to placebo recipients was nearly eliminated. The relative risk for a prevention effect among those ever having tenofovir detected was 0.53 (P = .038); the relative risk among those having tenofovir detected at 3 months was 0.40 (P = .045). CONCLUSIONS: A novel regression approach was proposed for causal as-treated analyses in the VOICE study. While intent-to-treat analyses yield null results, this exploratory approach presented evidence suggesting a prevention effect among gel users. Article	2016	De Baetselier, Irith; Taylor, Douglas; Mandala, Justin; Nanda, Kavita; Van Campenhout, Christel; Agingu, Walter; Madurai, Lorna; Barsch, Eva-Maria; Deese, Jennifer; Van Damme, Lut; Crucitti, Tania	Verification of chemistry reference ranges using a simple method in sub-Saharan Africa.	African Journal of Laboratory Medicine	-	-	-	-	2225-2002 2225-2010	10.4102/ajlm.v5i1.404	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5436402/	BACKGROUND: Chemistry safety assessments are interpreted by using chemistry reference ranges (CRRs). Verification of CRRs is time consuming and often requires a statistical background. OBJECTIVES: We report on an easy and cost-saving method to verify CRRs. METHODS: Using a former method introduced by Sigma Diagnostics, three study sites in sub-Saharan Africa, Bondo, Kenya, and Pretoria and Bloemfontein, South Africa, verified the CRRs for hepatic and renal biochemistry assays performed during a clinical trial of HIV antiretroviral pre-exposure prophylaxis. The aspartate aminotransferase/alanine aminotransferase, creatinine and phosphorus results from 10 clinically-healthy participants at the screening visit were used. In the event the CRRs did not pass the verification, new CRRs had to be calculated based on 40 clinically-healthy participants. RESULTS: Within a few weeks, the study sites accomplished verification of the CRRs without additional costs. The aspartate aminotransferase reference ranges for the Bondo, Kenya site and the alanine aminotransferase reference ranges for the Pretoria, South Africa site required adjustment. The phosphorus CRR passed verification and the creatinine CRR required adjustment at every site. The newly-established CRR intervals were narrower than the CRRs used previously at these study sites due to decreases in the upper limits of the reference ranges. As a result, more toxicities were detected. CONCLUSION: To ensure the safety of clinical trial participants, verification of CRRs should be standard practice in clinical trials conducted in settings where the CRR has not been validated for the local population. This verification method is simple, inexpensive, and can be performed by any medical laboratory. Article	2016	De Clercq, Erik	Tenofovir alafenamide (TAF) as the successor of tenofovir disoproxil fumarate (TDF).	Biochem Pharmacol	-	-	-	-	1873-2968 0006-2952	10.1016/j.bcp.2016.04.015	https://pubmed.ncbi.nlm.nih.gov/27133890/	Tenofovir alafenamide (TAF) can be considered a new prodrug of tenofovir (TFV), as successor of tenofovir disoproxil fumarate (TDF). It is in vivo as potent against human immunodeficiency virus (HIV) at a 30-fold lower dose (10mg) than TDF (300mg). TAF has been approved in November 2015 (in the US and EU), as a single-tablet regimen (STR) containing 150mg elvitegravir (E), 150mg cobicistat (C), 200mg emtricitabine (-)FTC (F) and 10mg TAF, marketed as Genvoya®, on 01 March 2016 in the US as an STR containing 25mg rilpivirine (R), 200mg F and 25mg TAF, marketed as Odefsey®, and on 4 April 2016 in the US, as an STR containing 200mg F and 25mg TAF, marketed as Descovy®, for the treatment of HIV infections. STR combinations containing TAF and emtricitabine could be paired with a range of third agents, for example, darunavir and cobicistat. TAF has a much lower risk of kidney toxicity or bone density changes than TDF, and also offers long-term potential in the pre-exposure prophylaxis (PrEP) of HIV infections. TAF is specifically accumulated in lymphatic tissue, and in the liver, and hence also holds great potential for the treatment of hepatitis B virus (HBV) infections. Akin to TDF, TAF is converted intracellularly to TFV. Its active diphosphate metabolite (TFVpp) is targeted at the RNA-dependent DNA polymerase (reverse transcriptase) of either HIV or HBV. Article	2016	Delany-Moretlwe, Sinéad; Mullick, Saiqa; Eakle, Robyn; Rees, Helen	Planning for HIV preexposure prophylaxis introduction: lessons learned from contraception.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0000000000000221	https://dx.doi.org/10.1097/COH.0000000000000221	PURPOSE OF REVIEW: We summarize key lessons learned from contraceptive development and introduction, and implications for preexposure prophylaxis (PrEP). RECENT FINDINGS: New approaches to HIV prevention are urgently needed. PrEP is a new technology for HIV prevention. Uncertainty remains about its acceptance, use and potential to have an impact on the HIV epidemic. Despite imperfect use and implementation of programs, the use of modern contraception has led to significant reproductive health and social gains, making it one of the public health's major achievements. Guided by the WHO strategic approach to contraception introduction, we identified the following lessons for PrEP introduction from contraception: (1) the importance of a broader focus on the method mix rather than promotion of a single technology, (2) new technologies alone do not increase choice--service delivery systems and providers are equally important to success, and (3) that failure to account for user preferences and social context can undermine the potential of new methods to provide benefit. SUMMARY: Taking a strategic approach to PrEP introduction that includes a broader focus on the technology/user interface, the method mix, delivery strategies, and the context in which methods are introduced will benefit HIV prevention programs, and will ensure greater success. Article	2016	Delaugerre C.; Gatey C.; Chaix M.-L.; Molina J.-M.	Antiretroviral pre-exposure prophylaxis (PrEP) for pre-exposure prevention of HIV-1; La prévention pré-exposition au VIH-1 par les antirétroviraux, la PrEP	Virologie	-	-	-	-	12678694	10.1684/vir.2016.0658	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85010471347&doi=10.1684%2fvir.2016.0658&partnerID=40&md5=6349b1a02f0291ce349859913a4148146	Due to the lack of vaccine, the HIV epidemic is still uncontrolled. Use of antiretrovirals (ARV) for prevention, successfully implemented to prevent mother-to-child transmission of HIV, is a new avenue to control the epidemic. One approach is to treat all patients diagnosed with HIV, and suppress viremia and transmission to their partner. Another strategy is the use of ARV as a preexposition prophylaxis (PrEP) in HIV-negative at risk individuals. Oral tenofovir (TDF)±emtricitabine (FTC) is the elected drug regimen for PrEP, given its safety, its long intracellular half-life and a high diffusion into mucosal entry sites. PrEP was investigated in randomized trials of oral or local gel given daily or at time of sexual intercourse in high-risk populations. PrEP efficacy is strongly correlated to adherence and concentrations of ARV. Adverse events have been infrequent. Selection of FTC-resistant strains has been mainly reported in undiagnosed HIVinfected participants using PrEP. PrEP is now strongly recommended by WHO in prevention programs for HIV in order to control the epidemic by 2030.	na	English	France	Western and Central Europe and North America	France	Western and Central Europe and North America	NA	NA	Clinical

Article	2016	Desai M.; Gafos M.; Dolling D.; Mccormack S.; Nardone A.	Healthcare providers' knowledge of, attitudes to and practice of pre-exposure prophylaxis for HIV infection	HIV Medicine	-	-	-	-	14642662	10.1111/hiv.12285	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84956923069&doi=10.1111%2fhiv.12285&partnerID=40&md5=0202cd91156f9872b71abdd20178de18	Objectives: Pre-exposure prophylaxis (PrEP) has proven biological efficacy in reducing the risk of sexual acquisition of HIV. Healthcare providers' (HCPs) knowledge of and attitudes to PrEP will be key to successful implementation. In England, PrEP is only available to men who have sex with men (MSM) through the open-label randomized PROUD pilot study of immediate or deferred use. Methods: In September 2013, a cross-sectional survey of UK HCPs distributed through sexual health clinics (219) and professional societies' email lists (2599) and at a conference (80) asked about knowledge of, attitudes to and practice of PrEP. Results: Overall, 328 of 2898 (11%) completed the survey, of whom 160 of 328 (49%) were doctors, 51 (16%) sexual health advisers (SHAs), 44 (14%) nurses and 73 (22%) unspecified. Over a quarter (83 of 311; 27%) were involved in PROUD. Most respondents (260 of 326; 80%) rated their knowledge of PrEP as medium or high. Over half of respondents (166 of 307; 54%) thought PrEP should be available outside of a clinical trial. The main barriers to supporting PrEP availability outside a clinical trial were concerns about current evidence (odds ratio OR 0.13), lack of UK-specific guidance (OR 0.35), concerns about adherence (OR 0.38) and risk of sexual or physical coercion for patients to have condomless or higher risk sex (OR 0.42 in multivariate regression). Just over half (147 of 277; 53%) had been asked about PrEP by patients in the past year, including almost half of those working in a clinic not involved in the PROUD study (86 of 202; 43%). Conclusions: There is support for PrEP availability outside a clinical trial, but HCPs have residual concerns about its effectiveness and negative consequences, and the absence of UK-specific implementation guidance. © 2016 British HIV Association. Article	2016	Destache C.J.; Mandal S.; Yuan Z.; Kang G.; Date A.A.; Lu W.; Shibata A.; Pham R.; Bruck P.; Rezich M.; Zhou Y.; Vivekanandan R.; Fletcher C.V.; Li Q.	Topical tenofovir disoproxil fumarate nanoparticles prevent HIV-1 vaginal transmission in a humanized mouse model	Antimicrobial Agents and Chemotherapy	-	-	-	-	664804	10.1128/AAC.00450-16	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84973533382&doi=10.1128%2fAAC.00450-16&partnerID=40&md5=7a2b8a7d6fd79f97414f739b086ffae6	Preexposure prophylaxis (PrEP) with 1% tenofovir (TFV) vaginal gel has failed in clinical trials. To improve TFV efficacy in vaginal gel, we formulated tenofovir disoproxil fumarate nanoparticles in a thermosensitive (TMS) gel (TDF-NP-TMS gel). TDF-NPs were fabricated using poly(lactic-co-glycolic acid) (PLGA) polymer and an ion-pairing agent by oil-in-water emulsification. The efficacy of TDF-NP-TMS gel was tested in humanized bone marrow-liver-thymus (hu-BLT) mice. Hu-BLT mice in the treatment group (Rx; n = 15) were administered TDF-NP-TMS gel intravaginally, having TDF at 0.1%, 0.5%, and 1% (wt/vol) concentrations, whereas the control (Ctr; n = 8) group received a blank TMS gel. All Rx mice (0.1% n = 4, 0.5% n = 6, and 1% n = 5) were vaginally challenged with two transmitted/founder (T/F) HIV-1 strains (2.5 × 105 50% tissue culture infectious doses). Rx mice were challenged at 4 h (0.1%), 24 h (0.5%), and 7 days (1%) posttreatment (p.t.) and Ctr mice were challenged at 4 h p.t. Blood was drawn weekly for 4 weeks postinoculation (p.i.) for plasma viral load (pVL) using reverse transcription-quantitative PCR. Ctr mice had positive pVL within 2 weeks p.i. Rx mice challenged at 4 h and 24 h showed 100% protection and no detectable pVL throughout the 4 weeks of follow-up (P = 0.009; Mantel-Cox test). Mice challenged at 7 days were HIV-1 positive at 14 days p.i. Further, HIV-1 viral RNA (vRNA) in vaginal and spleen tissues of Rx group mice with negative pVL were examined using an in situ hybridization (ISH) technique. The detection of vRNA was negative in all Rx mice studied. The present studies elucidate TDF-NP-TMS gel as a long-acting, coitus-independent HIV-1 vaginal protection modality. Article	2016	Dimitrov D.T.; Boily M.-C.; Hallett T.B.; Albert J.; Boucher C.; Mellors J.W.; Pillay D.; Van De Vijver D.A.M.C.	How much do we know about drug resistance due to PrEP use? Analysis of experts' opinion and its influence on the projected public health impact	PLOS One	-	-	-	-	19326203	10.1371/journal.pone.0158620	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84978870573&doi=10.1371%2fjournal.pone.0158620&partnerID=40&md5=5f604a5106e0fe187b3fcdaf0945cb25	Background: Randomized controlled trials reported that pre-exposure prophylaxis (PrEP) with tenofovir and emtricitabine rarely selects for drug resistance. However, drug resistance due to PrEP is not completely understood. In daily practice, PrEP will not be used under the well-controlled conditions available in the trials, suggesting that widespread use of PrEP can result in increased drug resistance. Methods: We surveyed expert virologists with questions about biological assumptions regarding drug resistance due to PrEP use. The influence of these assumptions on the prevalence of drug resistance and the fraction of HIV transmitted resistance was studied with a mathematical model. For comparability, 50% PrEP-coverage of and 90% per-act efficacy of PrEP in preventing HIV acquisition are assumed in all simulations. Results: Virologists disagreed on the following: the time until resistance emergence (range: 20-180 days) in infected PrEP users with breakthrough HIV infections; the efficacy of PrEP against drug-resistant HIV (25%-90%); and the likelihood of resistance acquisition upon transmission (10%-75%). These differences translate into projections of 0.6%-1% and 3.5%-6% infected individuals with detectable resistance 10 years after introducing PrEP, assuming 100% and 50% adherence, respectively. The rate of resistance emergence following breakthrough HIV infection and the rate of resistance reversion after PrEP use is discontinued, were the factors identified as most influential on the expected resistance associated with PrEP. Importantly, 17-23% infected individuals could virologically fail treatment as a result of past PrEP use or transmitted resistance to PrEP with moderate adherence. Conclusions: There is no broad consensus on quantification of key biological processes that underpin the emergence of PrEP-associated drug resistance. Despite this, the contribution of PrEP use to the prevalence of the detectable drug resistance is expected to be small. However, individuals who become infected despite the use of PrEP should be closely monitored due to higher risk of virological failure when initiating antiretroviral treatment in the future. © 2016 Dimitrov et al. Article	2016	Dimitrov D.T.; Mâsse B.R.; Donnell D.	PrEP adherence patterns strongly affect individual HIV risk and observed efficacy in randomized clinical trials	Journal of Acquired Immune Deficiency Syndromes	-	-	-	-	15254135	10.1097/QAI.0000000000000993	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961219320&doi=10.1097%2fQAI.0000000000000993&partnerID=40&md5=eb452dc87643f9a368644b6cba0650ca	Background: Randomized controlled trials (RCTs) suggest that the efficacy of tenofovir-based preexposure prophylaxis (PrEP) strongly depends on the consistency of PrEP use. We explore how the patterns of pill taking and waning of PrEP protection may affect PrEP efficacy for HIV prevention. Methods: A 2-arm RCT was simulated by mathematical models assuming that the prescribed daily doses were skipped periodically, randomly, or in large blocks. Risk-driven adherence, in which PrEP was taken when sex was expected, was also investigated. Three temporal PrEP protection profiles were explored: long (5 days), intermediate (3 days), and short (24 hours). Modeling results were compared to the efficacy observed in completed RCTs. Results: The expected PrEP efficacy was 60% with periodic, 50% with random, and 34% with block adherence when PrEP had a long protection profile and pills were taken only 50% of the days. Risk-driven pill taking resulted in 29% and 37% daily pills taken and efficacy of 43% and 51%, respectively, for long protection. High PrEP efficacy comparable with that observed in Partners PrEP and Centers for Disease Control and Prevention Botswana trials was simulated under long protection, high overall adherence, and limited block pill taking; the moderate efficacy observed in iPrEx and Bangkok trials was comparable with the 50% adherence scenarios under random pill taking and long protection. Conclusions: Pill-taking patterns may have a substantial impact on the protection provided by PrEP even when the same numbers of pills are taken. When PrEP retains protection for longer than a day, pill-taking patterns can explain a broad range of efficacies observed in PrEP RCTs. © 2016 Wolters Kluwer Health, Inc. Article	2016	Ding Y.; Yan H.; Ning Z.; Cai X.; Yang Y.; Pan R.; Zhou Y.; Zheng H.; Gao M.; Rou K.; Wu Z.; He N.	Low willingness and actual uptake of pre-exposure prophylaxis for HIV-1 prevention among men who have sex with men in Shanghai, China	BioScience Trends	-	-	-	-	18817815	10.5582/bst.2016.01035	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84973380017&doi=10.5582%2fbst.2016.01035&partnerID=40&md5=de38da7ba6d377b2dc5b26cdc36114fc	Little is known about the acceptance and actual uptake of pre-exposure prophylaxis (PrEP) and associated factors in men who have sex with men (MSM) in China. This study is the baseline survey of an intervention study designed to evaluate the effectiveness of tenofovirdisoproxil fumarate (TDF) on a daily use for human immunodeficiency virus (HIV) prevention among MSM in Shanghai, China. From October 2012 to December 2013, a total of 1,033 MSM in Shanghai were recruited by local district Centers for Disease Control and Prevention (CDC) and a MSM community-based non-governmental organization (NGO). Among them, 197 (19.1%) participants expressed willingness to use the TDF group at baseline survey, but only 26 (2.5%) participated in the TDF group and took TDF one tablet a day. Higher willingness to use PrEP was associated with being 45 years or older, non-local residents, having more male sex partners in the past 6 months and not using condom at last anal sex with man. Acutal uptake of PrEP was associated with having ≥ 11 male sex partners in lifetime and reporting no female sex partners in lifetime. Reasons for not participating in TDF group among those who expressed willingness to use PrEP at baseline survey included loss of contact, ineligiblity because of abnormal results for liver or renal function tests, change of mind, and HIV seroconversion before uptake of PrEP. Our findings suggest that promotion of PrEP in MSM remains challenging at current circumstancein China. Future research is needed to solicit effective education and intervention programs to promote acceptance of PrEP among Chinese MSM. Article	2016	Doblecki-Lewis S.; Jones D.	Community Federally Qualified Health Centers as Homes for HIV Preexposure Prophylaxis: Perspectives from South Florida	Journal of the International Association of Physicians in AIDS Care	-	-	-	-	23259574	10.1177/2325957416661422	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84994291691&doi=10.1177%2f2325957416661422&partnerID=40&md5=41a840a38a29454ca91dc60467dab9d4	Preexposure prophylaxis (PrEP) for HIV has the potential to reduce HIV incidence in highly affected areas. The Southeastern United States is disproportionately impacted by HIV, and 3 counties in South Florida have the highest incidence of new HIV infections in the United States. This study explored the feasibility, acceptability, and uptake of PrEP in South Florida. Focus groups consisting of providers, administrators, and case managers at HIV-servicing community health centers and federally qualified health centers in South Florida reported broad support but low implementation of PrEP. Generally, participants indicated that the centers were appropriate locations for implementation. However, practical concerns and perceived limitations due to financial, insurance, and immigration status of those who would potentially benefit from the intervention were widely reported. Addressing provider concerns appears necessary for successful expansion of PrEP implementation in highly impacted areas such as South Florida. © The Author(s) 2015..	community health centers; HIV prevention; medical providers; preexposure prophylaxis	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2016	Doblecki-Lewis, Susanne; Lester, Larissa; Schwartz, Bryanna; Collins, Constance; Johnson, Rai; Kobetz, Erin	HIV risk and awareness and interest in pre-exposure and post-exposure prophylaxis among sheltered women in Miami.	International Journal of STD & AIDS	-	-	-	-	1758-1052	10.1177/0956462415601304	https://dx.doi.org/10.1177/0956462415601304	Pre- and non-occupational post-exposure prophylaxis for the prevention of HIV infection are recommended for adults at substantial risk of HIV. Women experiencing homelessness have increased risk of HIV infection compared with stably-housed women. We conducted a survey of 74 sheltered women at Lotus House Women's Shelter (Lotus House) in Miami to assess risk behaviour as well as knowledge and perception of pre- and non-occupational post-exposure prophylaxis in this population. Of surveyed women, 58.1% engaged in vaginal and/or anal sex while sheltered, and of sexually-active women 55.4% reported inconsistent condom use. 83.8% of women reported no concern regarding HIV acquisition due to their behaviour. Few women surveyed (20.8%) had previously heard of pre- or non-occupational post-exposure prophylaxis. The majority (58.3%) of respondents indicated receptiveness to these prevention methods when introduced. Those indicating that they would consider pre- or non-occupational post-exposure prophylaxis were significantly younger than those indicating that they would not consider these prevention strategies (p = 0.004). Education and referral for pre- and non-occupational post-exposure prophylaxis should be considered for sheltered women at risk of HIV infection. Additional research to optimise implementation of biomedical prevention strategies in this population is needed.	acesso restrito	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Quantitative

An analysis of baseline data from the PROUD study: An open-label randomised trial of pre-exposure prophylaxis	Trials	-	-	-	-	17456215	10.1186/s13063-016-1286-4	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84962009997&doi=10.1186%2fs13063-016-1286-4&partnerID=40&md5=fad922a1a1ad350d2ccdb8def86026b1	Background: Pre-exposure prophylaxis (PrEP) has proven biological efficacy to reduce the sexual acquisition of the human immunodeficiency virus (HIV). The PROUD study found that PrEP conferred higher protection than in placebo-controlled trials, reducing HIV incidence by 86% in a population with seven-fold higher HIV incidence than expected. We present the baseline characteristics of the PROUD study population and place the findings in the context of national sexual health clinic data. Methods: The PROUD study was designed to explore the real-world effectiveness of PrEP (tenofovir-emtricitabine) by randomising HIV-negative gay and other men who have sex with men (GMSM) to receive open-label PrEP immediately or after a deferral period of 12months. At enrolment, participants self-completed two baseline questionnaires collecting information on demographics, sexual behaviour and lifestyle in the last 30 and 90days. These data were compared to data from HIV-negative GMSM attending sexual health clinics in 2013, collated by Public Health England using the genitourinary medicine clinic activity database (GUMCAD). Results: The median age of participants was 35 (IQR: 29-43). Typically participants were white (81%), educated at a university level (61%) and in full-time employment (72%). Of all participants, 217 (40%) were born outside the UK. A sexually transmitted infection (STI) was reported to have been diagnosed in the previous 12months in 330/515 (64%) and 473/544 (87%) participants reported ever having being diagnosed with an STI. At enrolment, 47/280 (17%) participants were diagnosed with an STI. Participants reported a median (IQR) of 10 (5-20) partners in the last 90days, a median (IQR) of 2 (1-5) were condomless sex acts where the participant was receptive and 2 (1-6) were condomless where the participant was insertive. Post-exposure prophylaxis had been prescribed to 184 (34%) participants in the past 12months. The number of STI diagnoses was high compared to those reported in GUMCAD attendees. Conclusions: The PROUD study population are at substantially higher risk of acquiring HIV infection sexually than the overall population of GMSM attending sexual health clinics in England. These findings contribute to explaining the extraordinary HIV incidence rate during follow-up and demonstrate that, despite broad eligibility criteria, the population interested in PrEP was highly selective. Article	2016	Drabo E.F.; Hay J.W.; Vardavas R.; Wagner Z.R.; Sood N.	A cost-effectiveness analysis of preexposure prophylaxis for the prevention of HIV among Los Angeles County men who have sex with men	Clinical Infectious Diseases	-	-	-	-	10584838	10.1093/cid/ciw578	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85014943912&doi=10.1093%2fcid%2fciw578&partnerID=40&md5=6588e38c82a776dcabfddf58f1958fe0	Background. Substantial gaps remain in understanding the trade-offs between the costs and benefits of choosing alternative human immunodeficiency virus (HIV) prevention strategies, including test-and-treat (expanded HIV testing combined with immediate treatment) and PrEP (initiation of preexposure prophylaxis by high-risk uninfected individuals) strategies. Methods. We develop a mathematical epidemiological model to simulate HIV incidence among men residing in Los Angeles County, California, aged 15-65 years, who have sex with men. We combine these incidence data with an economic model to estimate the discounted cost, effectiveness (quality-adjusted life-years QALYs), and incremental cost-effectiveness ratios of various HIV prevention strategies using a societal perspective and a lifetime horizon. Results. PrEP and test-and-treat yield the largest reductions in HIV incidence, and are highly cost-effective ($27 863/QALY and $19 302/QALY, respectively) relative to status quo and at a US willingness-to-pay threshold of $150 000/QALY saved. Status quo and 12 test-and-treat and PrEP strategies determine the frontier for efficient decisions. More aggressive strategies are costlier, but more effective, albeit with diminishing returns. The relative effectiveness of PrEP is sensitive to the initial HIV prevalence rate, PrEP and antiretroviral therapy (ART) adherence and initiation rates, the probabilities of HIV transmission, and the rates of sexual partner mixing. Conclusions. PrEP and test-and-treat offer cost-effective alternatives to the status quo. The success of these strategies depends on ART and PrEP adherence and initiation rates. The lack of evidence on adherence behaviors toward PrEP, therefore, warrants further studies. © The Author 2016. Published by Oxford University Press for the Infectious Diseases Society of America. Article	2016	Dube, MP; Funk, CA; Corado, K; Morris, S	Tenofovir disoproxil fumarate associated Fanconi syndrome in an HIV-uninfected man receiving HIV pre-exposure prophylaxis	Antiviral Therapy	-	-	-	-	1359-6535	10.1093/ofid/ofx149	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6300303/	Tenofovir disoproxil fumarate (TDF) has been used worldwide in antiretroviral regimens of human immunodeficiency virus (HIV)-infected patients since being approved by the US Food and Drug Administration in 2001. Tenofovir disoproxil fumarate can cause renal tubular dysfunction and reduced renal function [1]. In its fully developed form, TDF renal dysfunction is associated with hypophosphatemia, renal phosphate wasting, and other features of Fanconi syndrome [1]. Cases of TDF-associated Fanconi syndrome have been reported predominantly among patients with HIV infection [1]. There has been no excess risk of renal tubular toxicity with TDF-emtricitabine (TDF-FTC) detected in large, placebo-controlled trials of HIV pre-exposure prophylaxis (PrEP) [2, 3]. One other well documented likely Fanconi syndrome has been reported in an online supplement to the latter paper [3]. In this study, we report an additional case of this previously described phenomenon.	1 a 12	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Dunn D.T.; Glidden D.V.	Statistical issues in trials of preexposure prophylaxis	Current Opinion in HIV and AIDS	-	-	-	-	1746630X	10.1097/COH.0000000000000218	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84951908875&doi=10.1097%2fCOH.0000000000000218&partnerID=40&md5=3224f770f81b509496aa5d4343c2aa43	Purpose of review We discuss selected statistical issues in the design and analysis of preexposure prophylaxis (PrEP) trials. The general principles may inform thinking for other interventions in HIV prevention. Recent findings To date, four different designs have been used to determine the effectiveness of PrEP: randomized, doubleblind, placebo-controlled; randomized, open-label, immediate or delayed access; nonrandomized comparison of HIV incidence according to the level of drug detected; comparison of the observed HIV incidence to the expected rate using historical control data. Open-label trials of PrEP, which assess public health effectiveness, complement the placebo-controlled trials which established the biological efficacy of TDF/ FTC. Future trials of PrEP will be highly challenging to design since a no PrEP group is difficult to justify and the natural control regimen, TDF/FTC, is highly efficacious. Summary Standard statistical paradigms for noninferiority trials should be reconsidered for evaluating alternative PrEP regimens. Copyright © 2015 Wolters Kluwer Health, Inc. All rights reserved. Article	2016	Duwal, S.; Sunkara, V.; von Kleist, M.	Multiscale Systems-Pharmacology Pipeline to Assess the Prophylactic Efficacy of NRTIs Against HIV-1.	CPT: Pharmacometrics & Systems Pharmacology	-	-	-	-	2163-8306	10.1002/psp4.12095	https://pubmed.ncbi.nlm.nih.gov/27439573/	While HIV-1 continues to spread, the use of antivirals in preexposure prophylaxis (PrEP) has recently been suggested. Here we present a modular systems pharmacology modeling pipeline, predicting PrEP efficacy of nucleotide reverse transcriptase inhibitors (NRTIs) at the scale of reverse transcription, target-cell, and systemic infection and after repeated viral exposures, akin to clinical trials. We use this pipeline to benchmark the prophylactic efficacy of all currently approved NRTIs in wildtype and mutant viruses. By integrating pharmacokinetic models, we find that intracellular tenofovir-diphosphate builds up too slowly to halt infection when taken "on demand" and that lamivudine may substitute emtricitabine in PrEP combinations. Lastly, we delineate factors confounding clinical PrEP efficacy estimates and provide a method to overcome these. The presented framework is useful to screen and optimize PrEP candidates and strategies and to understand their clinical efficacy by integrating the diverse scales which determine PrEP efficacy. Article	2016	Duwal, Sulav; von Kleist, Max	Top-down and bottom-up modeling in system pharmacology to understand clinical efficacy: An example with NRTIs of HIV-1.	European Journal of Pharmaceutical Sciences	-	-	-	-	1879-0720	10.1016/j.ejps.2016.01.016	https://dx.doi.org/10.1016/j.ejps.2016.01.016	A major aim of Systems Pharmacology is to understand clinically relevant mechanisms of action (MOA) of drugs and to use this knowledge in order to optimize therapy. To enable this mission it is necessary to obtain knowledge on how in vitro testable insights translate into clinical efficacy. Mathematical modeling and data integration are essential components to achieve this goal. Two modeling philosophies are prevalent, each of which in isolation is not sufficient to achieve the above described: In a 'top-down' approach, a minimal pharmacokinetic-pharmacodynamic (PK-PD) model is derived from- and fitted to available clinical data. This model may lack interpretability in terms of mechanisms and may only be predictive for scenarios already covered by the data used to derive it. A 'bottom-up' approach builds on mechanistic insights derived from in vitro/ex vivo experiments, which can be conducted under controlled conditions, but may not be fully representative for the in vivo/clinical situation. In this work, we employ both approaches side-by-side to predict the clinical potency (IC50 values) of the nucleoside reverse transcriptase inhibitors (NRTIs) lamivudine, emtricitabine and tenofovir. In the 'top-down' approach, this requires to establish the dynamic link between the intracellularly active NRTI-triphosphates (which exert the effect) and plasma prodrug PK and to subsequently link this composite PK model to viral kinetics. The 'bottom-up' approach assesses inhibition of reverse transcriptase-mediated viral DNA polymerization by the intracellular, active NRTI-triphosphates, which has to be brought into the context of target cell infection. By using entirely disparate sets of data to derive and parameterize the respective models, our approach serves as a means to assess the clinical relevance of the 'bottom-up' approach. We obtain very good qualitative and quantitative agreement between 'top-down' vs. 'bottom-up' predicted IC50 values, arguing for the validity of the 'bottom-up' approach. We noted, however, that the 'top-down' approach is strongly dependent on the sparse and noisy intracellular pharmacokinetic data. All in all, our work provides confidence that we can translate in vitro parameters into measures of clinical efficacy using the 'bottom-up' approach. This may allow to infer the potency of various NRTIs in inhibiting e.g. mutant viruses, to distinguish sources of interaction of NRTI combinations and to assess the efficacy of different NRTIs for repurposing, e.g. for pre-exposure prophylaxis. Article	2016	Elion, Richard; Coleman, Megan	The preexposure prophylaxis revolution: from clinical trials to routine practice: implementation view from the USA.	Current Opinion in HIV and AIDS	-	-	-	-	1746-6318	10.1097/COH.0000000000000222	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4670271	PURPOSE OF REVIEW: This article describes the use of tenofovir/emtricitabine (Truvada) as prevention for exposure to HIV preexposure prophylaxis (PrEP) infection in the USA. The use of PrEP and the challenges of implementation are very instructive as other countries adopt this intervention and it becomes a fundamental part of worldwide efforts for HIV prevention and much can be learned from the first 3 years in the USA. RECENT FINDINGS: Randomized trials and demonstration projects have shown the benefits of PrEP for men and women who are at risk for HIV. Numerous studies have showed that the level of prevention is excellent when the drug is taken at least four times weekly, once adequate levels are obtained. However, adherence remains a critical issue as well as tailoring delivery models for specific populations. Six recent studies are discussed, that support excellent efficacy and significantly support PrEP as a means of prevention. These projects have shown high acceptance of PrEP with excellent adherence by individuals demonstrated by those at risk remaining free of HIV over extended periods of time. SUMMARY: The USA faces three significant challenges in scaling up PrEP. The first challenge in implementation in the USA is to get individuals to recognize the actual risks that their behaviors represent and to engage with providers to address these issues. The second challenge is getting a population of providers to recognize the exact same issues and offer PrEP in a compassionate, nonjudgmental fashion. The third challenge is identifying the set of providers and locations to scale-up the response in a timely, cost-effective fashion.	na	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Elsesser S.A.; Oldenburg C.E.; Biello K.B.; Mimiaga M.J.; Safren S.A.; Egan J.E.; Novak D.S.; Krakower D.S.; Stall R.; Mayer K.H.	Seasons of Risk: Anticipated Behavior on Vacation and Interest in Episodic Antiretroviral Pre-exposure Prophylaxis (PrEP) Among a Large National Sample of U.S. Men Who have Sex with Men (MSM)	AIDS and Behavior	-	-	-	-	10907165	10.1007/s10461-015-1238-0	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84946114302&doi=10.1007%2fs10461-015-1238-0&partnerID=40&md5=91a3c9f4af6ab01f6cd8a6f410c61d33	The current analysis evaluates interest in and acceptability of daily PrEP during short episodes of anticipated increased risk (i.e. Epi-PrEP). In 2013, U.S. members of an internet-based MSM sexual networking site were invited to complete a survey about HIV prevention practices in the context of vacationing. 7305 MSM responded to the survey. Of respondents who had vacationed in the past year, 25.6 % reported condomless anal sex (CAS) with new male sex partners while vacationing. Most (92.6 %) respondents agreed that having to use PrEP every day was a barrier to PrEP use and 74.3 % indicated they would take PrEP if they knew it would be helpful for short periods of anticipated increased risk. MSM who reported increased CAS while on vacation in the past year were more likely to indicate that they would take PrEP if it were helpful when used for short periods than respondents who did not (aOR = 2.02, 95 % CI 1.59–2.56, p < 0.001). Studies designed to evaluate uptake, adherence, and protective benefit of short PrEP courses are warranted. © 2015, Springer Science+Business Media New York. Article	2016	Falcão J.R.S.P.; Bradshaw C.C.; Garrett C.C.; Bilardi J.E.; Chen M.Y.; Zablotska I.; Fairley C.K.; Williams H.	Views of HIV-negative partners in heterosexual serodiscordant relationships regarding HIV pre-exposure prophylaxis: A qualitative study	Sexual Health	-	-	-	14485028	10.1071/SH15143	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84982841169&doi=10.1071%2fSH15143&partnerID=40&md5=3f2f23de19db5674f10811024b10d670	Background Pre-exposure prophylaxis (PrEP) may be an effective option for HIV prevention among heterosexual serodiscordant couples. However, there are knowledge gaps in social research about PrEP in heterosexual serodiscordant relationships, including motivations and barriers to its use and possible impacts of PrEP uptake on the sexual practices of these couples. The aim of this study was to explore the views of HIV-negative men and women in stable serodiscordant heterosexual relationships about the possible use of PrEP. Methods: Semi-structured interviews were used to understand participants' views on the use of PrEP. Interviews were conducted face-to-face or by telephone and transcribed verbatim for thematic analysis. Results: In total, 13 HIV-negative partners were interviewed; six men and seven women. Participants demonstrated a high interest in the use of PrEP for conception. PrEP was also considered an option for general HIV prevention, although men saw more benefits for this use than women. Participants' main concerns around PrEP usage were about cost, efficacy, daily adherence and side-effects. HIV-positive partner support is likely to play a central role for PrEP uptake and adherence. Conclusions: This study is one of the first studies to explore the views of HIV-negative heterosexual partners in serodiscordant relationships around the use of PrEP while trying to conceive, as well as for general HIV prevention. These study results provide new insights for the further development of guidelines governing the use of PrEP for serodiscordant couples. © 2016 CSIRO. Article	2016	Ferrández J.S.-R.; Sesmero J.M.M.	Pre-exposure prophylaxis for the prevention of HIV infection: A new prevention paradigm?	Farmacia Hospitalaria	-	-	-	11306343	10.7399/fh.2016.40.3.10439	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84966641622&doi=10.7399%2ffh.2016.40.3.10439&partnerID=40&md5=a5a3ea48bbd970da71310fa34e17063e	Pre-exposure prophylaxis" (PrEP) has been recently developed as a prevention strategy which involves the administration of drugs to non-infected individuals who present high exposure or susceptibility to HIV. Although this use is not approved in our country, several guidelines recommend PrEP as a prevention option in adult MSM, heterosexual men and women, and users of parenteral drugs at risk of acquiring the infection. This article presents the characteristics that an ideal agent to be used as PrEP should meet, recent efficacy published data and barriers for the implementation of this new strategy. On the other hand, the role of hospital pharmacists will be discussed. Article	2016	Ferrer L.; Folch C.; Fernandez-Davila P.; Garcia A.; Morales A.; Belda J.; Susperregui A.R.; Casabona J.	Awareness of Pre-exposure Prophylaxis for HIV, Willingness to Use It and Potential Barriers or Facilitators to Uptake Among Men Who Have Sex with Men in Spain	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1379-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84962267570&doi=10.1007%2fs10461-016-1379-9&partnerID=40&md5=81247cfee46c94335de115e0d186b558	There is a lack of data on pre-exposure prophylaxis (PrEP) effectiveness in Spain. We described the awareness of and willingness to use PrEP and examined potential barriers and facilitators to their use among men who have sex with men recruited either online or in voluntary HIV testing centers in Spain. Nearly a third of men (28.7 %) were aware of PrEP and 57.6 % said they would be willing to use it if available, 16.6 % saying they would be unwilling to use PrEP and 25.8 % not being sure. Men who had heard of PrEP were more forceful in their opinions on willingness to use PrEP (willing/not willing: 29.8 %/32.6 % vs. don't know: 21.8 %). The greatest consensus regarding more acceptable PrEP attributes was in the mode of delivery and its cost. Doctors (91 %) or pharmacists (85.3 %) were the preferred providers. The results confirm the need to inform and educate on PrEP and define implementation strategies. © 2016, Springer Science+Business Media New York. Theses and Dissertations	2016	Figueroa, Dominique Beltran	Towards Understanding Tenofovir Disposition: MALDI-Imaging and Pharmacogenetics	-	-	Johns Hopkins University	-	na	NA	http://jhir.library.jhu.edu/handle/1774.2/40818	The emergence of HIV pre-exposure prophylaxis, applying antiretroviral drugs toward prevention of infection by human immunodeficiency virus in uninfected individuals, reveals a promising avenue toward decreasing the number of annual new HIV infections worldwide. The nucleotide reverse transcriptase inhibitor tenofovir, along with the nucleoside reverse transcriptase inhibitor emtricitabine, currently make up the FDA-approved regimen for pre-exposure prophylaxis. Intracellular phosphorylation of both tenofovir and emtricitabine is necessary to generate nucleotide triphosphate analogs that would competitively inhibit HIV reverse transcriptase. Kinases demonstrated to phosphorylate tenofovir to the intermediate tenofovir monophosphate and then to the active anabolite tenofovir monophosphate have been shown to be expressed in HIV-susceptible tissues. Adenylate kinase 2 phosphorylates tenofovir to tenofovir monophosphate in peripheral blood mononuclear cells, vaginal, and colorectal tissues. In colorectal tissues, creatine kinase, muscle was found to phosphorylate tenofovir monophosphate to tenofovir diphosphate. The two kinases pyruvate kinase, muscle and pyruvate kinase, liver and red blood cell were shown to yield tenofovir diphosphate in peripheral blood mononuclear cells and vaginal tissue. These four kinases were sequenced for genetic variants that could affect tenofovir activation. In a clinical study spread across the three geographic regions Bangkok, Thailand, Cape Town, South Africa, and New York City, USA, 103 previously unreported variants across the kinases AK2, CKM, PKM and PKLR were detected. Of 505 individuals, 19 individuals (3.7% frequency) were found to be carrying variants that were predicted to be deleterious and probably damaging. In emtricitabine activation, we put forward four candidate kinases that would yield the nucleotide triphosphate analog emtricitabine triphosphate. Emtricitabine requires three phosphorylation steps to become pharmacologically active. Deoxycytidine kinase and thymidine kinase 1 are proposed to phosphorylate emtricitabine to emtricitabine-monophosphate. To generate emtricitabine-diphosphate, cytidine monophosphate kinase 1 is suggested to phosphorylate emtricitabine-monophosphate. To form the competitive HIV reverse transcriptase inhibitor emtricitabine triphosphate, phosphoglycerate kinase 1 was identified as a candidate kinase. In a clinical study, we identified 17 previously unreported genetic variants of these kinases. Additionally, to further understand tenofovir and emtricitabine disposition in tissue, a matrix-assisted laser desorption/ionization coupled to mass spectrometry method was developed. This method aims to image tenofovir, emtricitabine, and the corresponding phosphorylated anabolites of each drug in an effort to better understand drug distribution in HIV susceptible tissues. Taken together, development of the imaging technology and application of next-generation sequencing to identify variants in kinases proposed to activate nucleos(t)ide reverse…	HIV; prevention; pre-exposure prophylaxis; tenofovir; emtricitabine; mass spectrometry; MALDI; mass spectrometry imaging	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Clinical
Article	2016	Finocchario-Kessler, Sarah; Champassak, Sofie; Hoyt, Mary Jo; Short, William; Chakraborty, Rana; Weber, Shannon; Levison, Judy; Phillips, Joanne; Storm, Deborah; Anderson, Jean	Pre-Exposure Prophylaxis (PrEP) for Safer Conception Among Serodifferent Couples: Findings from Healthcare Providers Serving Patients with HIV in Seven US Cities.	AIDS Patient Care and STDs	-	-	-	1557-7449	10.1089/apc.2015.0268	https://dx.doi.org/10.1089/apc.2015.0268	Pre-exposure prophylaxis (PrEP) can reduce the risk of HIV transmission among serodifferent couples trying to conceive, yet provider knowledge, attitudes, and experience utilizing PrEP for this purpose are largely unexamined. Trained interviewers conducted phone interviews with healthcare providers treating patients with HIV in seven cities (Atlanta, Baltimore, Houston, Kansas City, Newark, Philadelphia, and San Francisco, N = 85 total). Quantitative and qualitative data were analyzed to describe experience, concerns, and perceived barriers to prescribing PrEP for safer conception. Providers (67.1% female, 43 mean years of age, 70.4% white, 10 mean years treating HIV+ patients, 56% in academic vs. community facilities, 62.2% MD) discussed both benefits and concerns of PrEP for safer conception among serodifferent couples. Only 18.8% of providers reported experience prescribing PrEP, 74.2% were willing to prescribe it under ideal circumstances, and 7.0% were not comfortable prescribing PrEP. Benefits included added protection and a greater sense of control for the HIV-negative partner. Concerns were categorized as clinical, system-level, cost, or behavioral. Significant differences in provider characteristics existed across sites, but experience with PrEP for safer conception did not, p = 0.14. Despite limited experience, most providers were open to recommending PrEP for safer conception as long as patients understood the range of concerns and could make informed decisions. Strategies to identify and link serodifferent couples to PrEP services and clinical guidance specific to PrEP for safer conception are needed.	acesso restrito	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Article	2016	Fisher C.B.; Arbeit M.R.; Dumont M.S.; Macapagal K.; Mustanski B.	Self-consent for HIV prevention research involving sexual and gender minority youth: Reducing barriers through evidence-based ethics	Journal of Empirical Research on Human Research Ethics	-	-	-	15562646	10.1177/1556264616633963	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84978676863&doi=10.1177%2f1556264616633963&partnerID=40&md5=30a05c7d3432bafacf61eb2dc0ceff63	This project examined the attitudes of sexual and gender minority youth (SGMY) toward guardian permission for a preexposure prophylaxis (PrEP) adherence trial and their preparedness to provide informed, rational, and voluntary selfconsent. Sixty sexually active SGMY (ages 14-17) participated in online survey and asynchronous focus group questions after watching a video describing a PrEP adherence study. Youth responses highlighted guardian permission as a significant barrier to research participation, especially for those not "out" to families. Youth demonstrated understanding of research benefits, medical side effects, confidentiality risks, and random assignment and felt comfortable asking questions and declining participation. Reasoning about participation indicated consideration of health risks and benefits, personal sexual behavior, ability to take pills every day, logistics, and post-trial access to PrEP. Results demonstrate youth's ability to self-consent to age-and population-appropriate procedures, and underscore the value of empirical studies for informing institutional review board (IRB) protections of SGMY research participants. © The Author(s) 2016. Article	2016	Fleming, Paul J.; Barrington, Clare; Perez, Martha; Donastorg, Yeycy; Kerrigan, Deanna	HIV testing, care, and treatment experiences among the steady male partners of female sex workers living with HIV in the Dominican Republic.	AIDS Care	-	-	-	1360-0451 0954-0121	10.1080/09540121.2016.1160027	https://www.tandfonline.com/doi/full/10.1080/09540121.2016.1160027	Male steady partners of female sex workers (FSW) living with human immunodeficiency virus (HIV) represent a key population for treatment as prevention and/or pre-exposure prophylaxis interventions. This study uses data collected from male steady partners who were referred by FSW living with HIV participating in a multi-level HIV prevention and care intervention in Santo Domingo, Dominican Republic. We conducted a socio-behavioral survey and HIV testing with all men (n = 64) and 16 in-depth interviews with a sub-sample to obtain more depth. Thirty-five of the 64 participants were living with HIV; 27 were previously diagnosed and 8 were diagnosed during our study. As a result, 45% of men were members of sero-concordant sexual partnerships. Of men with no previously HIV diagnosis (n = 37), 15 had never been tested for HIV and nine had not been tested in the past two years. Ninety-three percent of men previously diagnosed with HIV reported receiving HIV care in the past 6 months and 78% were taking anti-retrovirals. Low HIV testing was partly due to men not feeling at risk for HIV, despite having an HIV-infected partner. Additionally, a lack of tailored care inhibited engagement in anti-retroviral treatment for those infected. HIV testing was low, highlighting a need for test-and-treat strategies. Men not living with HIV would benefit from regular testing and would be good candidates for pre-exposure prophylaxis. While almost all men who had been diagnosed with HIV were engaged in care and adherent to anti-retroviral therapy, future research should assess whether they are achieving optimal HIV outcomes for their health and prevention of ongoing transmission. Theses and Dissertations	2016	Fletcher, Kelly	Awareness, Willingness, and Use of Pre-Exposure Prophylaxis (PrEP) Among Hispanic/Latino Men Who Have Sex With Men, The American Men's Internet Survey 2013-2014.	-	-	Emory University	-	na	NA	http://pid.emory.edu/ark:/25593/rkqq0	Pre-exposure prophylaxis (PrEP) is a promising biomedical prevention method aimed at reducing human immunodeficiency virus (HIV) incidence for high risk populations like Hispanic/Latino men who have sex with men (MSM) in the United States. In order to increase uptake of PrEP, a robust understanding of the characteristics of Hispanic/Latino MSM and their awareness of, willingness to use, and use of PrEP is warranted. An annual, cross-sectional survey of MSM was conducted online in 2013 and 2014. Multivariate logistic regression models selected using a backwards elimination procedure were used to assess the characteristics of 1,446 Hispanic/Latino, HIV-negative MSM in relation to their awareness of, willingness to use, and use of PrEP. Awareness, willingness, and use increased with study year. Sexual health and HIV risk behavior including diagnosis of a bacterial STI in the last 12 months and number of sex partners were associated with awareness, willingness, and use of PrEP while sociodemographic characteristics including insurance type and education level were associated with awareness. Although 55.1% of participants were aware of PrEP and 78.5% reported willingness to take PrEP, only 5.5% reported usage. Increasing access to HIV and sexual health services, enhancing health care provider knowledge of PrEP, and encouraging serodiscussion may help facilitate increased uptake to PrEP among Hispanic/Latino MSM.	na	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Quantitative
Theses and Dissertations	2016	Foley, Shaylen; Keene, Danya	"For the safety of our health": A Qualitative Analysis of Pre-Exposure Prophylaxis (PrEP) Acceptability among Female Sex Workers in Malaysia	-	-	Universidade de Yale	-	na	NA	https://www.proquest.com/dissertations-theses/safety-our-health-qualitative-analysis-pre/docview/1793408467/se-2?accountid=8113	Female sex workers (FSW) in Malaysia are at substantially increased risk of acquiring HIV compared to the general female population. Daily oral pre-exposure prophylaxis (PrEP) offers a novel way to prevent HIV transmission in this population. This research aims to inform culturally relevant implementation of PrEP through a qualitative exploration of the factors that determine FSW willingness to use PrEP. In-depth, semi-structured interviews (n=30) were conducted with FSW in English, Malay, or Tamil. Transcribed and translated interviews were analyzed using a grounded theory approach. FSW expressed positive interest in PrEP but preferred it as a supplement to condoms, not a replacement. Perceived challenges to PrEP use included cost, adherence, side effects, and disinterest. FSW experiences with HIV and condoms support these reactions. This research bolsters prior work on the inapplicability of behavioral disinhibition to FSW and supports PrEP implementation in combination with condom promotion. Article	2016	Fonner V.A.; Dalglish S.L.; Kennedy C.E.; Baggaley R.; O'Reilly K.R.; Koechlin F.M.; Rodolph M.; Hodges-Mameletzis I.; Grant R.M.	Effectiveness and safety of oral HIV preexposure prophylaxis for all populations	AIDS	-	-	-	2699370	10.1097/QAD.0000000000001145	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84965013459&doi=10.1097%2fQAD.0000000000001145&partnerID=40&md5=917af1163d4ea9493f8ddee86c0ac5a0	Objective: Preexposure prophylaxis (PrEP) offers a promising new approach to HIV prevention. This systematic review and meta-analysis evaluated the evidence for use of oral PrEP containing tenofovir disoproxil fumarate as an additional HIV prevention strategy in populations at substantial risk for HIV based on HIV acquisition, adverse events, drug resistance, sexual behavior, and reproductive health outcomes. Design: Rigorous systematic review and meta-analysis. Methods: A comprehensive search strategy reviewed three electronic databases and conference abstracts through April 2015. Pooled effect estimates were calculated using random-effects meta-analysis. Results: Eighteen studies were included, comprising data from 39 articles and six conference abstracts. Across populations and PrEP regimens, PrEP significantly reduced the risk of HIV acquisition compared with placebo. Trials with PrEP use more than 70% demonstrated the highest PrEP effectiveness (risk ratio=0.30, 95% confidence interval: 0.21-0.45, P<0.001) compared with placebo. Trials with low PrEP use did not show a significantly protective effect. Adverse events were similar between PrEP and placebo groups. More cases of drug-resistant HIV infection were found among PrEP users who initiated PrEP while acutely HIV-infected, but incidence of acquiring drug-resistant HIV during PrEP use was low. Studies consistently found no association between PrEP use and changes in sexual risk behavior. PrEP was not associated with increased pregnancy-related adverse events or hormonal contraception effectiveness. Conclusion: PrEP is protective against HIV infection across populations, presents few significant safety risks, and there is no evidence of behavioral risk compensation. The effective and cost-effective use of PrEP will require development of best practices for fostering uptake and adherence among people at substantial HIV risk. Tenofovir Disoproxil Fumarate Fails to Prevent HIV Acquisition or the Establishment of a Viral Reservoir: Two Case Reports	Infectious Diseases and Therapy	-	-	-	21938229	10.1007/s40121-015-0102-x	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84977159791&doi=10.1007%2fs40121-015-0102-x&partnerID=40&md5=08bcbd9a43b937c74197529585a695c1m	The use of antiretrovirals as pre-exposure prophylaxis (PrEP) is highly efficacious in HIV prevention. The World Health Organization recently recommended Truvada® (Gilead Sciences, Inc.) or tenofovir disoproxil fumarate (TDF) for high-risk individuals, with limited data for single-agent TDF PrEP in men who have sex with men (MSM). We report two cases of TDF PrEP failure in MSM who had received long-term TDF for hepatitis B infection and had therapeutic levels of drug immediately after HIV acquisition. Rapid antiretroviral intensification at diagnosis of acute HIV infection failed to limit immune dysfunction or prevent the establishment of a viral reservoir. © 2015, The Author(s). Article	2016	Fox, Julie; Tiraboschi, Juan M; Herrera, Carolina; Else, Laura; Egan, Deirdre; Dickinson, Laura; Jackson, Akil; Olejniczak, Natalia; Back, David; Khoo, Saye; Shattock, Robin; Boffito, Marta	Pharmacokinetic/Pharmacodynamic Investigation of Single-Dose Oral Maraviroc in the Context of HIV-1 Pre-exposure Prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001108	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-27727157	To investigate the pharmacokinetics/pharmacodynamics of single-dose maraviroc 300 mg in HIV-1 exposure compartments. Maraviroc concentrations in blood, secretions (vaginal, urethral, oral, and rectal), and tissue (vaginal and rectal) were measured, and ex vivo challenge was performed in 54 healthy volunteers to study protection from HIV infection. Maraviroc Cmax occurred within 4 hours in most compartments. Concentrations from 4 to 72 hours were above intracellular (IC) IC90 in all compartments, range 15-8095 ng/mL. Mean AUC0-72 compartment-to-plasma ratios were highest in the rectum (45-819) and urethra (144) compared with the female genital tract (1.6-4.8) and saliva (0.2). No sex differences in AUC0-72 or Cmax were observed. No ex vivo protection from HIV-1BaL occurred in rectal or vaginal tissue. Despite high and sustained concentrations, single-dose maraviroc was not protective against ex vivo challenge of vaginal/rectal tissue. Article	2016	Frankis J.; Young I.; Flowers P.; McDaid L.	Who will use pre-exposure prophylaxis (PrEP) and why?: Understanding PrEP awareness and acceptability amongst men who have sex with men in the UK - A mixed methods study	PLOS One	-	-	-	19326203	10.1371/journal.pone.0151385	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84971659855&doi=10.1371%2fjournal.pone.0151385&partnerID=40&md5=f471e2e750fc6e7d3fc39b9aba1f9789	Background Recent clinical trials suggest that pre-exposure prophylaxis (PrEP) may reduce HIV transmission by up to 86% for men who have sex with men (MSM), whilst relatively high levels of PrEP acceptability have been reported to date. This study examines PrEP awareness amongst sub-groups of MSM communities and acceptability amongst MSM in a low prevalence region (Scotland, UK), using a mixed methods design. Methods Quantitative surveys of n = 690 MSM recruited online via social and sociosexual media were analysed using descriptive statistics and multivariate logistic regression. In addition, n = 10 in-depth qualitative interviews with MSM were analysed thematically. Results Under one third (29.7%) of MSM had heard of Pr EP, with awareness related to living in large cities, degree level education, commercial gay scene use and reporting an HIV test in the last year. Just under half of participants (47.8%) were likely to use PrEP if it were available but there was no relationship between PrEP acceptability and previous PrEP awareness. Younger men (18-25 years) and those who report higher risk UAI were significantly more likely to say they would use PrEP. Qualitative data described specific PrEP scenarios, illustrating how risk, patterns of sexual practice and social relationships could affect motivation for and nature of PrEP use. Conclusion These findings suggest substantial interest PrEP amongst MSM reporting HIV risk behaviours in Scotland. Given the Proud results, there is a strong case to investigate PrEP implementation within the UK. However, it appears that disparities in awareness have already emerged along traditional indicators of inequality. Our research identifies the need for comprehensive support when PrEP is introduced, including a key online component, to ensure equity of awareness across diverse MSM communities (e.g. by geography, education, gay scene use and HIV proximity), as well as to respond to the diverse informational and sexual health needs of all MSM communities. © 2016 Frankis et al. Article	2016	Frankis, Jamie S; Young, Ingrid; Lorimer, Karen; Davis, Mark; Flowers, Paul	Towards preparedness for PrEP: PrEP awareness and acceptability among MSM at high risk of HIV transmission who use sociosexual media in four Celtic nations: Scotland, Wales, Northern Ireland and The Republic of Ireland: an online survey.	Sexually Transmitted Diseases	-	-	-	1472-3263	10.1136/sextrans-2015-052101	https://dx.doi.org/10.1136/sextrans-2015-052101	OBJECTIVE: To assess the awareness and acceptability of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) and use sociosexual media at high risk of HIV infection in four Celtic nations. DESIGN: Cross-sectional study. METHODS: Online self-complete survey of 386 HIV-negative/status unknown MSM who reported condomless anal intercourse (CAI) with ≥2 men in the last year, recruited from gay sociosexual media. RESULTS: One-third (34.5%, 132/386) of the participants were aware of PrEP but over half (58.5%, 226/386) reported that they would be willing to use PrEP if it were available to them. Only men who regularly tested for HIV every 6months (adjusted OR 2.89, 95% CI 1.54 to 5.42) were more likely to be aware of PrEP. PrEP acceptability was only associated with reporting ≥5 CAI partners (OR 2.04, 95% CI 1.2 to 3.46) in the last year. CONCLUSIONS: Low levels of PrEP awareness were reported across these Celtic nations. Only one-third of high-risk MSM had heard of PrEP but over one-half would be willing to take a daily pill to prevent HIV infection. Sociodemographic factors, commercial gay scene proximity and social network use were unrelated to considering PrEP use. However, those reporting most CAI partners were more likely to consider PrEP use. Article	2016	Freeman, Robert C.	Toward Development of Enhanced Preventive Interventions for HIV Sexual Risk among Alcohol-Using Populations: Confronting the 'Mere Pause from Thinking'.	AIDS and Behavior	-	-	-	1573-3254 1090-7165	10.1007/s10461-015-1179-7	https://pubmed.ncbi.nlm.nih.gov/26362168/	The papers in this issue detail state-of-the science knowledge regarding the role of alcohol use in HIV/AIDS risk, as well as offer suggestions for ways forward for behavioral HIV prevention for at-risk alcohol-using populations. In light of recent evidence suggesting that the anticipated uptake of the newer biomedical HIV prevention approaches, prominently including pre-exposure prophylaxis, has been stalled owing to a host of barriers, it has become ever more clear that behavioral prevention avenues must continue to receive due consideration as a viable HIV/AIDS prevention approach. The papers collected here make a valuable contribution to "combination prevention" efforts to curb HIV spread. Article	2016	Gandhi M.; Glidden D.V.; Mayer K.; Schechter M.; Buchbinder S.; Grinsztejn B.; Hosek S.; Casapia M.; Guanira J.; Bekker L.-G.; Louie A.; Horng H.; Benet L.Z.; Liu A.; Grant R.M.	Association of age, baseline kidney function, and medication exposure with declines in creatinine clearance on pre-exposure prophylaxis: an observational cohort study	The Lancet HIV	-	-	-	23523018	10.1016/S2352-3018(16)30153-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84994182520&doi=10.1016%2fS2352-3018%2816%2930153-9&partnerID=40&md5=dd3b044e962e57158447e50a4d0b7c4e	Background As pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate and emtricitabine for the prevention of HIV infection is rolled out internationally, strategies to maintain effectiveness and to minimise adverse effects merit consideration. In this study, we aimed to assess reductions in renal function and predictors of renal toxicity in a large open-label study of PrEP. Methods As part of the iPrEx open-label extension (OLE) study, men who have sex with men or transgender women aged 18–70 years who were HIV negative and had participated in three previous PrEP trials from Brazil, Ecuador, Peru, South Africa, Thailand, and the USA were enrolled into an open-label PrEP study. There were no restrictions on current renal function for enrolment into iPrEx OLE, in which participants were given combination tablets of tenofovir disoproxil fumarate (300 mg) and emtricitabine (200 mg) and advised to take one tablet per day. At follow-up sessions every 12 weeks, participants' creatinine clearance on PrEP was estimated and in a subset of participants, hair samples were collected to measure tenofovir and emtricitabine concentrations (a measure of adherence and exposure) via liquid-chromatography–tandem-mass-spectrometry. Reductions in creatinine clearance from baseline were calculated and predictors of decline were identified by use of multivariate models. iPrEx is registered with ClinicalTrials.com, number NCT00458393. Findings Baseline characteristics were similar between all participants in iPrEx-OLE (1224 participants with 7475 person-visits) and those participating in the hair substudy (220 participants with 1114 person-visits). During a median of 72 weeks, the mean decline in creatinine clearance was −2·9% (95% CI −2·4 to −3·4; p trend <0·0001), but declines were greater for those who started PrEP at older ages: participants aged 40–50 years at baseline had declines of −4·2% (95% CI −2·8 to −5·5) and participants older than 50 years at baseline had declines of −4·9% (−3·1 to −6·8). In multivariate models, age and baseline creatinine clearance less than 90 mL/min predicted declines in renal function. We identified a monotonic association between percentage decrease in creatinine clearance and the number of doses of tenofovir disoproxil fumarate and emtricitabine taken per week, as estimated by hair concentrations of tenofovir and emtricitabine (p trend =0·008). Interpretation Our data suggest that the frequency of safety monitoring for PrEP might need to be different between age groups and that pharmacological measures can monitor for toxic effects as well as adherence. Article	2016	Garcia, Jonathan; Parker, Richard G.; Parker, Caroline; Wilson, Patrick A.; Philbin, Morgan; Hirsch, Jennifer S.	The limitations of 'Black MSM' as a category: Why gender, sexuality, and desire still matter for social and biomedical HIV prevention methods.	Global Public Health	-	-	-	1744-1706 1744-1692	10.1080/17441692.2015.1134616	https://pubmed.ncbi.nlm.nih.gov/26831639/	The USA faces disproportionate and increasing HIV incidence rates among Black men who have sex with men (BMSM). New biomedical technologies such as pre-exposure prophylaxis (PrEP) have been developed to address their HIV risk. Very little consideration, however, has been given to the diversity obscured by 'BMSM' as a category, to how this diversity relates to men's sexual partnering strategies, or to the relevance of these issues for new HIV prevention methods. We conducted a community-based ethnography from June 2013 to May 2014 documenting factors that affect the acceptance of and adherence to PrEP among BMSM. We conducted in-depth interviews with 31 BMSM and 17 community stakeholders, and participant observation. To demonstrate the diversity of social identities, we present a taxonomy of indigenous categories organised along the axes of sexual identity, sexual positioning, and gender performance. We analyse how HIV prevention strategies, such as PrEP, may be more effective if programmes consider how gender, sexuality, and sexual desire shape sexual partnering strategies. This article underlines the importance of attending to the diversity of sexual and social subjectivities among BMSM, of bringing the study of sexuality back into HIV prevention, and of integrating biomedical prevention approaches into community-based programmes. Article	2016	Giesler, Kyle E.; Liotta, Dennis C.	Next-Generation Reduction Sensitive Lipid Conjugates of Tenofovir: Antiviral Activity and Mechanism of Release.	Journal of Medicinal Chemistry	-	-	-	1520-4804 0022-2623	10.1021/acs.jmedchem.6b01292	https://pubs.acs.org/doi/10.1021/acs.jmedchem.6b01292	The pharmacokinetic properties of tenofovir (TFV) and other charged nucleoside analogues are dramatically improved upon conjugation to a lipid prodrug. We previously prepared reduction-sensitive lipid conjugates of TFV that demonstrate superior antiviral activity compared to other lipid conjugates including the clinically approved formulation, tenofovir disoproxil fumarate (TDF). In continuation of that work, we have synthesized next-generation conjugates with reduced cytotoxicity that retain potent antiviral activity against HIV-1 and HBV with a therapeutic index >100000 for our most potent conjugate. We also show that disulfide reduction is not responsible for prodrug cleavage unless 3-exo-tet intramolecular cyclization can occur, suggesting that enzymatic hydrolysis is predominantly responsible for activity of our prodrugs in vitro. Article	2016	Giguere R.; Frasca T.; Dolezal C.; Febo I.; Cranston R.D.; Mayer K.; McGowan I.; Carballo-Diéguez A.	Acceptability of Three Novel HIV Prevention Methods Among Young Male and Transgender Female Sex Workers in Puerto Rico	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1387-9	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84962683228&doi=10.1007%2fs10461-016-1387-9&partnerID=40&md5=7b3bd9b6fbd333cd6e050f7fdd2b2524	Sex workers need HIV-prevention methods they can control and incorporate easily in their work. We studied the acceptability of three methods: HIV self-test use with clients, oral pre-exposure prophylaxis (PrEP), and rectal microbicide gel. Four male and eight transgender female (TGF) sex workers in Puerto Rico completed a baseline survey with a quantitative measure of likelihood of use. From them, one male and four TGF also completed a 12-week study of rectal microbicide placebo gel use prior to receptive anal intercourse with male clients and evaluated via qualitative in-depth interviews and follow-up quantitative assessments how each method could be incorporated into their work. Most were interested in a rectal microbicide gel and able to use it covertly with clients. Challenges to using the HIV self-test with clients included the potential for both breach of confidentiality and confronting violent situations. Participants also expressed interest in oral PrEP, but raised concerns about side effects. © 2016, Springer Science+Business Media New York. Article	2016	Glaubius R.L.; Hood G.; Penrose K.J.; Parikh U.M.; Mellors J.W.; Bendavid E.; Abbas U.L.	Cost-effectiveness of injectable preexposure prophylaxis for HIV prevention in South Africa	Clinical Infectious Diseases	-	-	-	10584838	10.1093/cid/ciw321	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84982181867&doi=10.1093%2fcid%2fciw321&partnerID=40&md5=d6121fb45f3f3e867a1bab8efbf25446	Background. Long-acting injectable antiretrovirals such as rilpivirine (RPV) could promote adherence to preexposure prophylaxis (PrEP) for human immunodeficiency virus (HIV) prevention. However, the cost-effectiveness of injectable PrEP is unclear. Methods. We constructed a dynamic model of the heterosexual HIV epidemic in KwaZulu-Natal, South Africa, and analyzed scenarios of RPV PrEP scale-up for combination HIV prevention in comparison with a reference scenario without PrEP. We estimated new HIV infections, life-years and costs, and incremental cost-effectiveness ratios (ICERs), over 10-year and lifetime horizons, assuming a societal perspective. Results. Compared with no PrEP, unprioritized scale-up of RVP PrEP covering 2.5%-15% of adults prevented up to 9% of new infections over 10 years. HIV prevention doubled (17%) when the same coverage was prioritized to 20- to 29-year-old women, costing $10 880-$19 213 per infection prevented. Prioritization of PrEP to 80% of individuals at highest behavioral risk achieved comparable prevention (4%-8%) at <1% overall coverage, costing $298-$1242 per infection prevented. Over lifetime, PrEP scale-up among 20- to 29-year-old women was very cost-effective (<$1600 per life-year gained), dominating unprioritized PrEP, while risk prioritization was cost-saving. PrEP's 10-year impact decreased by almost 50% with increases in ICERs (up to 4.2-fold) in conservative base-case analysis. Sensitivity analysis identified PrEP's costs, efficacy, and reliability of delivery as the principal drivers of uncertainty in PrEP's cost-effectiveness, and PrEP remained cost-effective under the assumption of universal access to second-line antiretroviral therapy. Conclusions. Compared with no PrEP, prioritized scale-up of RPV PrEP in KwaZulu-Natal could be very cost-effective or cost-saving, but suboptimal PrEP would Erode benefits and increase costs. © 2016 The Author 2016. Article	2016	Glaubius R.L.; Parikh U.M.; Hood G.; Penrose K.J.; Bendavid E.; Mellors J.W.; Abbas U.L.	Deciphering the effects of injectable pre-exposure prophylaxis for combination human immunodeficiency virus prevention	Open Forum Infectious Diseases	-	-	-	23288957	10.1093/ofid/ofw125	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85015866494&doi=10.1093%2fofid%2fofw125&partnerID=40&md5=7c1c3a85585665beebf75c76875d036d	Background. A long-acting injectable formulation of rilpivirine (RPV), under investigation as antiretroviral pre-exposure prophylaxis (PrEP), may facilitate PrEP adherence. In contrast, cross-resistance between RPV and nonnucleoside reverse-transcriptase inhibitors comprising first-line antiretroviral therapy (ART) could promote human immunodeficiency virus (HIV) drug resistance and reduce PrEP's effectiveness. Methods. We use novel mathematical modeling of different RPV PrEP scale-up strategies in KwaZulu-Natal, South Africa, to investigate their effects on HIV prevention and drug resistance, compared with a reference scenario without PrEP. Results. Pre-exposure prophylaxis scale-up modestly increases the proportion of prevalent drug-resistant infections, from 33% to ≤37%. The change in the number of prevalent drug-resistant infections depends on the interplay between PrEP factors (coverage, efficacy, delivery reliability, and scale-up strategy) and the level of cross-resistance between PrEP and ART. An optimistic scenario of 70% effective RPV PrEP (90% efficacious and 80% reliable delivery), among women aged 20-29 years, prevents 17% of cumulative infections over 10 years while decreasing prevalent resistance; however, prevention decreases and resistance increases with more conservative assumptions. Uncertainty analysis assuming 40%-70% cross-resistance prevalence predicts an increase in prevalent resistance unless PrEP's effectiveness exceeds 90%. Conclusions. Prioritized scale-up of injectable PrEP among women in KwaZulu-Natal could reduce HIV infections, but suboptimal PrEP effectiveness could promote the spread of drug resistance. © The Author 2016. Symptoms, Side Effects and Adherence in the iPrEx Open-Label Extension	Clinical Infectious Diseases	-	-	-	10584838	10.1093/cid/ciw022	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84966470739&doi=10.1093%2fcid%2fciw022&partnerID=40&md5=65aefb7bf8ca96af342c04345432c9eb	Blinded clinical trials have reported a modest and transient "start-up syndrome" with initiation of tenofovir-based pre-exposure prophylaxis (PrEP). We evaluate this phenomenon and its effect on adherence in an open-label PrEP study. Methods. In the iPrEx open-label extension (OLE) study, an 18-month open-label, multi-site PrEP cohort taking daily oral coformulated tenofovir/emtricitabine, we examined the prevalence and duration of PrEP-associated symptoms and their effect on adherence, assessed by drug levels in dried blood spots tested monthly for the first 3 months. Results. Symptom reports peaked within the first month, with 39% reporting potentially PrEP-related symptoms compared to 22% at baseline. Symptoms largely resolved to pre-PrEP levels by 3 months. Symptoms varied substantially in frequency by study site (range in 1-month symptoms: 11% to 70%). Nongastrointestinal (GI) symptoms were not associated with adherence (odds ratio OR = 1.2, 95% confidence interval CI, .4-3.7); however, GI-associated symptoms in the first 4 weeks were inversely associated with adherence at 4 weeks (OR = 0.47, 95% CI, .23-.96). Reports of GI symptoms were associated with 7% (95% CI, 4%-11%) of suboptimal adherence in this cohort. Conclusions. PrEP-associated symptoms in the open-label setting occur in a minority of users and largely resolve within 3 months. GI symptoms are associated with amodest reduction in PrEP adherence, but good adherence is possible even in the presence of frequent symptom reports. © 2016 The Author. The original PrEP regimen used oral daily dosing regardless of the timing of possible HIV exposures. The rationale for daily dosing is that HIV exposures may be unanticipated or unpredictable and daily dosing ensures continuous therapeutic drug concentrations	NA	English	United Kingdom	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Goedel W.C.; Halkitis P.N.; Greene R.E.; Hickson D.A.; Duncan D.T.	HIV Risk Behaviors, Perceptions, and Testing and Preexposure Prophylaxis (PrEP) Awareness/Use in Grindr-Using Men Who Have Sex With Men in Atlanta, Georgia	Journal of the Association of Nurses in AIDS Care	-	-	-	10553290	10.1016/j.jana.2015.11.005	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84959461420&doi=10.1016%2fj.jana.2015.11.005&partnerID=40&md5=f6d922ed45ca25dd6749e583ce0ad773	Geosocial-networking smartphone applications such as Grindr can help men who have sex with men (MSM) meet sexual partners. Given the high incidence of HIV in the Deep South, the purpose of our study was to assess HIV risk and preexposure prophylaxis (PrEP) awareness and use in a sample of HIV-uninfected, Grindr-using MSM residing in Atlanta, Georgia (n = 84). Most (n = 71; 84.6%) reported being somewhat or very concerned about becoming HIV infected. Most (n = 74; 88.1%) had been tested for HIV in their lifetimes. About three fourths (n = 65; 77.4%) were aware of PrEP, but only 11.9% currently used the medication. HIV continues to disproportionately impact MSM and represents a significant source of concern. As the number of new infections continues to rise, it is important to decrease risks associated with acquisition and transmission of HIV by increasing rates of HIV testing and the use of biobehavioral interventions such as PrEP. © 2016 Association of Nurses in AIDS Care. Article	2016	Goedel, William C; Halkitis, Perry N; Greene, Richard E; Duncan, Dustin T	Correlates of Awareness of and Willingness to Use Pre-exposure Prophylaxis (PrEP) in Gay, Bisexual, and Other Men Who Have Sex with Men Who Use Geosocial-Networking Smartphone Applications in New York City.	AIDS and Behavior	-	-	-	1573-3254	10.1007/s10461-016-1353-6	https://dx.doi.org/10.1007/s10461-016-1353-6	Geosocial-networking smartphone applications are commonly used by gay, bisexual, and other men who have sex with men (MSM) to meet sexual partners. The purpose of the current study was to evaluate awareness of and willingness to use pre-exposure prophylaxis (PrEP) among MSM who use geosocial-networking smartphone applications residing in New York City. Recruitment utilizing broadcast advertisements on a popular smartphone application for MSM yielded a sample of 152 HIV-uninfected MSM. Multivariable models were used to assess demographic and behavioral correlates of awareness of and willingness to use PrEP. Most participants (85.5 %) had heard about PrEP but few (9.2 %) reported current use. Unwillingness to use PrEP was associated with concerns about side effects (PR = 0.303; 95 % CI 0.130, 0.708; p = 0.006). Given that more than half (57.6 %) of participants were willing to use PrEP, future research is needed to elucidate both individual and structural barriers to PrEP use among MSM. Article	2016	Goldenberg, David, MD	Psychological Issues and PrEP in Private Practice	Journal of Gay & Lesbian Mental Health	-	-	-	19359705	doi.org/10.1080/19359705.2015.1105520	https://www.tandfonline.com/doi/full/10.1080/19359705.2015.1105520	When pre-exposure prophylaxis (PrEP) was newly marketed towards and available to urban men who have sex with men, a cultural phenomenon with deeply personal psychological implications began. The widespread availability of PrEP resurrected long-dormant conflicts in patients, therapists, and primary care providers about sexual acts between men; about sexual agency and autonomy; and re-traumatization from similar conflicts believed to have been worked through during earlier decades of the HIV/AIDS epidemic. Patients often are not aware of the depth of psychological implications. If a therapist is unaware of the momentous cultural event, he or she may over-interpret, missing or distorting important assessments of risk, danger and safety. A therapist's over-identification with the event may lead to under appreciation and exploration of the depths and multi-determination of intra-psychic meaning and symbolism including the patient's conscious and unconscious use of the cultural phenomenon to express myriad intra-psychic and inter-personal conflicts. In this paper I describe five HIV-negative patients' reactions to PrEP as it was becoming widely marketed and debated in New York City. Treatment And Prevention for female Sex workers in South Africa: protocol for the TAPS Demonstration Project	BMJ Open	-	-	-	20446055	10.1136/BMJOPEN-2016-011595	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85036538045&doi=10.1136%2fBMJOPEN-2016-011595&partnerID=40&md5=c41d99cdd06a28c9d435657831b37929	Introduction: Updated guidelines from the WHO recommend antiretroviral treatment for adults with HIV at any CD4 count and daily oral pre-exposure prophylaxis (PrEP) for people at substantial risk of HIV infection. However, implementation challenges may hinder the ability of programmes to translate these recommendations into successful practice. This demonstration project is the first to integrate PrEP and immediate treatment (ITx) for female sex workers (FSWs) in South Africa to answer operational research questions. Methods and analysis: This is a prospective cohort study where the main outcome is retention at 12 months. The study population is recruited into two arms across two urban sites: (1) PrEP for HIV-negative FSWs (n=400) and (2) ITx for HIV-positive FSWs with CD4 greater than national guidelines (n=300). We investigate process and other health indicators, uptake and use of PrEP and ITx through qualitative research, and evaluate cost-effectiveness analysis combined with estimates of impact through epidemiological modelling. Ethics and dissemination: The Treatment And Prevention for female Sex workers in South Africa (TAPS) Project was designed as an implementation study before emtricitabine/tenofovir disoproxil fumarate was licenced as an indication for PrEP in South Africa. Therefore, clinical trial requirements for ethical and South African Medicines Control Council approvals were followed. Results will be disseminated to participants, local health officials and other stakeholders, as well as in peer-reviewed journals and at conferences. © 2016 BMJ Publishing Group. All rights reserved. Article	2016	Grant, Jenna M	From subjects to relations: Bioethics and the articulation of postcolonial politics in the Cambodia Pre-Exposure Prophylaxis trial.	Social Studies of Science	-	-	-	0306-3127	10.1177/0306312716632617	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-27263238	Controversies about global clinical trials, particularly HIV trials, tend to be framed in terms of ethics. In this article, I explore debates about ethics in the Cambodia Pre-Exposure Prophylaxis trial, which was designed to test the safety and efficacy of tenofovir as a prevention for HIV infection. Bringing together studies of public participation in science with studies of bioethics, I show how activists around the Cambodian Pre-Exposure Prophylaxis trial circulated and provoked debates about standards of research ethics, as opposed to research methodology. This postcolonial bioethics was configured through the circulation of and debate about ethics guidelines, and historically and culturally specific relations of vulnerability and responsibility between foreigners and Cambodians and between Cambodian leaders and Cambodian subjects. I argue that this shift in the object of ethical concern, from the experimental human subject to the relation between subjects and researchers, illustrates how a postcolonial field of articulation reformulates classical bioethics. Theses and Dissertations	2016	Grant, Robert M	What people want from sex and preexposure prophylaxis	-	-	University of California	-	1746-630X	https://doi.org/10.1097/coh.0000000000000216	https://escholarship.org/uc/item/3xs962hm	Purpose of reviewAs demand for preexposure prophylaxis (PrEP) increases, we are learning more about what people want from sex and PrEP.Recent findingsPrEP demand has reached a tipping point in the USA and is increasing rapidly. Although the primary benefit of PrEP use is biological, to reduce risk of HIV infection, PrEP users often express an alternative set of social and emotional benefits that are provided by PrEP. These collateral benefits of PrEP have salience, affect, and are experienced in the present, which are compelling drivers of human behavior. PrEP use has been associated with feeling safe during sex, usually in contrast to ruminations related to fear of HIV or intimate partner violence or control. PrEP can create empowerment, or agency, defined as the capacity and autonomy to act on one's own behalf, because it provides control over one's vulnerability to HIV and relief to women and men who may otherwise worry about whether their partners will use a condom, take antiretroviral therapy, or disclose their HIV status accurately. Planning for sexual and social goals in calm moments is also empowering. These highly desired collateral benefits of PrEP could be undermined, or eliminated, if PrEP is implemented in ways that are coercive or that foment fear of sexual risk compensation, drug resistance, toxicity, or moral judgment.SummaryCurrent PrEP implementation provides direct and indirect benefits that are highly desired. Article	2016	Grant, Robert M; Sevelius, Jae M; Guanira, Juan V; Aguilar, Jana Villayzan; Chariyalertsak, Suwat; Deutsch, Madeline B	Transgender Women in Clinical Trials of Pre-Exposure Prophylaxis.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001090	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4969062	Lessons were learned with trans women who participated (as volunteers and investigators) in trials of HIV pre-exposure prophylaxis (PrEP). Trans women are not men. Compared with men who have sex with men, trans women trial participants were more likely to be involved with transactional sex, had more sexual partners, and were less likely to have PrEP medications detected in blood. Trans women define themselves differently in different cultures. One best practice is to ask at least 2 gender questions: sex assigned at birth and current gender. More information is needed to fully situate PrEP efficacy for trans women, including analysis of drug-drug interactions between PrEP medications and feminizing hormones and PrEP drug penetration into neovaginal tissues. Including trans women in studies is helpful only if their participation is specifically reported, as could occur in a table of baseline characteristics of the enrolled cohort. Gender-affirming care is important to foster appropriate uptake and use of PrEP. Such care includes use of preferred pronouns and names, safety to use the bathroom of choice, and access to gender-affirming hormone therapy and surgery. The consistent finding that PrEP works when taken across diverse populations having diverse practices related to gender, sexual intercourse, and hormone use provides a basis for offering PrEP to people at substantial risk of acquiring HIV although some subgroups may not have been fully represented in trials. Nonetheless, specific PrEP implementation science for trans women (and men) is essential to develop best practices for PrEP delivery and use.	transgender, HIV, HIV prevention, iPrEX, PrEP	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Gredig D.; Uggowitzer F.; Hassler B.; Weber P.; Nideröst S.	Acceptability and willingness to use HIV pre-exposure prophylaxis among HIV-negative men who have sex with men in Switzerland	AIDS Care	-	-	-	9540121	10.1080/09540121.2016.1146212	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961216025&doi=10.1080%2f09540121.2016.1146212&partnerID=40&md5=0f9c54bb7ceda47b4f3ba698125285a6	Pre-exposure prophylaxis (PrEP) is discussed as an additional HIV prevention method targeting men who have sex with men (MSM). So far, PrEP has not been approved in Switzerland and only little is known about the acceptability of PrEP among MSM living in Switzerland. Given the slow uptake of PrEP among MSM in the USA, the objectives of the study were to investigate the acceptability for PrEP and to identify factors influencing the acceptability for this prevention method and the willingness to adopt it. During a 4-month period we conducted five focus group discussions with 23 consecutively sampled HIV-negative MSM aged 22-60 years living in Switzerland. We analyzed the data according to qualitative content analysis. The acceptability of PrEP varied considerably among the participants. Some would use PrEP immediately after its introduction in Switzerland because it provides an alternative to condoms which they are unable or unwilling to use. Others were more ambivalent towards PrEP but still considered it (1) an additional or alternative protection to regular condom use, (2) an option to engage in sexual activities with less worries and anxieties or (3) a protection during receptive anal intercourse independently of the sexual partner's protective behaviour. Some participants would not consider using PrEP at all: they do not see any benefit in PrEP as they have adopted safer sex practices and did not mention any problems with condom use. Others are still undecided and could imagine using an improved form of PrEP. The results provide a valuable basis for a model explaining the acceptability of PrEP among MSM and suggest including the personal HIV protection strategy in the considerations adopted. © 2016 The Author(s). Article	2016	Grov, Christian; Rendina, H. Jonathon; Jimenez, Ruben; Parsons, Jeffrey T.	Using Online Settings to Identify Gay and Bisexual Men Willing to Take or With Experience Taking PrEP: Implications for Researchers and Providers	AIDS Education and Prevention	-	-	-	8999546	10.1521/aeap.2016.28.5.378	https://www.proquest.com/scholarly-journals/using-online-settings-identify-gay-bisexual-men/docview/1826251690/se-2?accountid=8113	Given the ongoing HIV epidemic, it is essential to identify gay and bisexual men who are interested in starting PrEP as well as active PrEP users. We report on online survey data gathered over a 17-month period in 2014-2015 from gay and bisexual men identified through six sources of recruitment (n = 2903): Facebook, a hookup website, two geosocial-sexual networking apps (herein "App 1: Pop-up ads" and "App 2: Banner ads"), and two types of listservs (one focused on general gay nightlife, and one focused on gay sex parties). Willingness to take PrEP were as follows: sex party listservs (71.3%), both apps (69.8%), Facebook (67.6%), hookup website (65.2%), and nightlife listservs (50.5%). Experience having taken PrEP was as follows: sex party listservs (23.4%), App 2: Banner ads (22.5%), nightlife listservs (17.1) Facebook (14.2%), App 1: Pop-up ads (12.4%), and hookup website (2.1%). In multivariable modeling, willingness to go on PrEP was independently associated with being younger, single, a person of color, and having been tested for HIV in the past 12 months. Source of recruitment was largely unassociated with willingness to start PrEP. Number of recent male partners, number of recent condomless anal sex (CAS) events, and when data were collected (i.e., time in months) were not significantly associated with willingness to start PrEP. In multivariable models, experience having taken PrEP was positively associated with sexual identity as gay, number of recent male sex partners, number of recent CAS acts, being tested for HIV in the past 12 months, and time (in months). Experience taking PrEP varied greatly by recruitment source, suggesting both researchers and providers might be well served to utilize digital mediums to effectively identify these individuals; however, should do so with caution as not all digital options may prove fruitful. Article	2016	Grov, Christian; Rendina, H. Jonathon; Parsons, Jeffrey T.	How Different are Men Who Do Not Know Their HIV Status from Those Who Do? Results from an U.S. Online Study of Gay and Bisexual Men.	AIDS and Behavior	-	-	-	1573-3254 1090-7165	10.1007/s10461-015-1284-7	https://pubmed.ncbi.nlm.nih.gov/26767536/	We compared self-described HIV-positive (31.6 %, n = 445), HIV-negative (56.8 %, n = 801), and HIV-unknown (11.6 %, n = 164) gay and bisexual men on sociodemographic and behavioral characteristics. Participants from across the U.S. were enrolled via a popular sexual networking website to complete an online survey. In total, 44.8 % of HIV-negative and HIV-unknown men said they had not been tested for HIV in the CDC-recommended last 6 months. HIV-unknown men significantly differed from HIV-negative and HIV-positive men in sexual behavior and HIV status disclosure patterns. HIV-unknown men were more willing than HIV-negative men to take PrEP; however, HIV-unknown men were significantly less likely than others to have health insurance or a primary care provider. Given the observed differences, researchers should consider analyzing men who are HIV-unknown distinctly from HIV-negative and HIV-positive men. Article	2016	Grov, Christian; Rendina, H. Jonathon; Whitfield, Thomas H. F.; Ventuneac, Ana; Parsons, Jeffrey T.	Changes in Familiarity with and Willingness to Take Preexposure Prophylaxis in a Longitudinal Study of Highly Sexually Active Gay and Bisexual Men.	LGBT Health	-	-	-	2325-8306 2325-8292	10.1089/lgbt.2015.0123	https://pubmed.ncbi.nlm.nih.gov/27183232/	PURPOSE: For gay and bisexual men (GBM), research suggests that familiarity with preexposure prophylaxis (PrEP) has been increasing since being approved by the United States Food and Drug Administration in 2012. However, it is less clear how willingness to start using PrEP has changed over time. Likewise, some have expressed concerns regarding the potential for risk compensation (i.e., reduced condom use) were one to start PrEP; however, again, it is unclear how risk compensation may have changed over time. METHODS: We conducted baseline and 12-month assessments with 158 highly sexually active HIV-negative GBM in New York City who were assessed between 2011 and 2014. We examined change over time both between participants (based on when they entered the study), as well as within each participant (over the 12 months of his involvement). RESULTS: Familiarity with PrEP increased over time (both between and within participants); however, willingness to take PrEP did not change (neither between nor within participants). Few men believed PrEP would cause their condomless anal sex (CAS) to increase and this did not change over time. However, a majority believed PrEP would increase temptation for CAS, and this did not change over time within participants. Sexual compulsivity symptomology was associated with higher willingness to take PrEP and perceiving that PrEP would increase one's temptations for CAS. Furthermore, recent CAS was associated with greater willingness to take PrEP, a perception that PrEP would increase one's likelihood to engage in CAS, and a perception that being on PrEP would increase one's temptation for CAS. CONCLUSIONS: Participants became more familiar with PrEP over time; however, willingness to start PrEP did not change, and this may serve as an opportunity for providers to discuss PrEP with their patients. Men who engaged in CAS were interested in PrEP and preexisting patterns of sexual behavior may be the primary determinant of CAS while on PrEP. Article	2016	Günthard, Huldrych F; Saag, Michael S; Benson, Constance A; del Rio, Carlos; Eron, Joseph J; Gallant, Joel E; Hoy, Jennifer F; Mugavero, Michael J; Sax, Paul E; Thompson, Melanie A; Gandhi, Rajesh T; Landovitz, Raphael J; Smith, Davey M; Jacobsen, Donna M	Antiretroviral Drugs for Treatment and Prevention of HIV Infection in Adults: 2016 Recommendations of the International Antiviral Society–USA Panel	JAMA - Journal of the American Medical Association	-	-	-	0098-7484	https://doi.org/10.1001/jama.2016.8900	https://jamanetwork.com/journals/jama/fullarticle/2533073	ImportanceNew data and therapeutic options warrant updated recommendations for the use of antiretroviral drugs (ARVs) to treat or to prevent HIV infection in adults.ObjectiveTo provide updated recommendations for the use of antiretroviral therapy in adults (aged ≥18 years) with established HIV infection, including when to start treatment, initial regimens, and changing regimens, along with recommendations for using ARVs for preventing HIV among those at risk, including preexposure and postexposure prophylaxis.Evidence reviewA panel of experts in HIV research and patient care convened by the International Antiviral Society-USA reviewed data published in peer-reviewed journals, presented by regulatory agencies, or presented as conference abstracts at peer-reviewed scientific conferences since the 2014 report, for new data or evidence that would change previous recommendations or their ratings. Comprehensive literature searches were conducted in the PubMed and EMBASE databases through April 2016. Recommendations were by consensus, and each recommendation was rated by strength and quality of the evidence.FindingsNewer data support the widely accepted recommendation that antiretroviral therapy should be started in all individuals with HIV infection with detectable viremia regardless of CD4 cell count. Recommended optimal initial regimens for most patients are 2 nucleoside reverse transcriptase inhibitors (NRTIs) plus an integrase strand transfer inhibitor (InSTI). Other effective regimens include nonnucleoside reverse transcriptase inhibitors or boosted protease inhibitors with 2 NRTIs. Recommendations for special populations and in the settings of opportunistic infections and concomitant conditions are provided. Reasons for switching therapy include convenience, tolerability, simplification, anticipation of potential new drug interactions, pregnancy or plans for pregnancy, elimination of food restrictions, virologic failure, or drug toxicities. Laboratory assessments are recommended before treatment, and monitoring during treatment is recommended to assess response, adverse effects, and adherence. Approaches are recommended to improve linkage to and retention in care are provided. Daily tenofovir disoproxil fumarate/emtricitabine is recommended for use as preexposure prophylaxis to prevent HIV infection in persons at high risk. When indicated, postexposure prophylaxis should be started as soon as possible after exposure.Conclusions and relevanceAntiretroviral agents remain the cornerstone of HIV treatment and prevention. All HIV-infected individuals with detectable plasma virus should receive treatment with recommended initial regimens consisting of an InSTI plus 2 NRTIs. Preexposure prophylaxis should be considered as part of an HIV prevention strategy for at-risk individuals. When used effectively, currently available ARVs can sustain HIV suppression and can prevent new HIV infection. With these treatment regimens, survival rates among HIV-infected adults who are retained in care can approach those of uninfected…	Biomedical and Clinical Sciences; Public Health; Clinical Sciences; Immunology; Health Sciences; Medical Microbiology; Prevention; HIV/AIDS; Infectious Diseases; Evaluation of treatments and therapeutic interventions; 6.1 Pharmaceuticals; Infection; Good Health and Well Being; AIDS-Related Opportunistic Infections; Adolescent; Adult; Aged; Anti-Retroviral Agents; CD4 Lymphocyte Count; Drug Therapy; Combination; Female; HIV Infections; HIV-1; Humans; Male; Middle Aged; Post-Exposure Prophylaxis; Pre-Exposure Prophylaxis; Pregnancy; Prognosis; Treatment Failure; Viral Load; Viremia; Young Adult; Medical and Health Sciences; General & Internal Medicine; Biomedical and clinical sciences; Health	English	United States	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Switzerland	Western and Central Europe and North America	Review
Article	2016	Gust, Deborah A; Soud, Fatma; Hardnett, Felicia P; Malotte, Charles K; Rose, Charles; Kebaabetswe, Poloko; Makgekgenene, Lebogang; Henderson, Faith; Paxton, Lynn; Segolodi, Tebogo; Kilmarx, Peter H	Evaluation of Sexual Risk Behavior Among Study Participants in the TDF2 PrEP Study Among Heterosexual Adults in Botswana.	Journal of Acquired Immune Deficiency Syndromes	-	-	-	1944-7884	10.1097/QAI.0000000000001143	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6066668	OBJECTIVE: Among participants of a clinical trial to test the efficacy of tenofovir/emtricitabine in protecting heterosexual men and women living in Botswana from HIV infection, the aim was to determine (1) if sexual risk behavior, specifically condomless sex acts and number of sex partners, changed over time, (2) factors associated with condomless sex acts and number of sex partners, and (3) the effect of participant treatment arm perception on risk behavior to address the possibility of risk compensation. METHODS: A longitudinal modeling of rates of risk behaviors was used to determine if the rate of condomless sex acts (#acts/person) and rate of sex partners (#partners/person) changed over time and which factors were associated with behavior change. RESULTS: One thousand two hundred participants were analyzed over 1 year. There was a 25% decrease in the rate of sex partners among participants sexually active in the last 30 days. The rate of reported condomless sex acts was greater for males rate ratio (RR) = 1.34; confidence interval (CI): 1.07 to 1.67 and participants whose sexual debut in years was ≤15 years of age (RR = 1.65; CI: 1.14 to 2.38) and 16-17 (RR = 1.68; CI: 1.22 to 2.31) compared with those ≥20 years. Rate of reported sex partners was greater for males (RR = 3.67; CI: 2.86 to 4.71) and participants whose age at sexual debut in years was ≤15 (RR = 2.92; CI: 2.01 to 4.22) and 16-17 (RR = 2.34; CI: 1.69 to 3.24) compared with those ≥20. There was no effect of participant treatment arm perception on risk behavior. CONCLUSIONS: Our study of preexposure prophylaxis to prevent HIV infection found no evidence of risk compensation which may have been due to participants' motivations to reduce their risk behaviors and risk-reduction counseling.	clinical trial, tenofovir/emtricitabine, risk compensation, sexual risk behavior	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Clinical
Article	2016	Haberer J.E.	Current concepts for PrEP adherence in the PrEP revolution: From clinical trials to routine practice	Current Opinion in HIV and AIDS	-	-	-	1746630X	10.1097/COH.0000000000000220	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84950259515&doi=10.1097%2fCOH.0000000000000220&partnerID=40&md5=9de740d174228a6fba32667cea1546ea	Purpose of review The review describes the current understanding of adherence to oral preexposure prophylaxis (PrEP), methods for adherence measurement, approaches to supporting PrEP adherence, and guidance for defining PrEP adherence goals within the larger context of HIV prevention. Recent findings PrEP adherence has generally been higher in recent trials, open-label extensions, and demonstration projects compared with the initial clinical trials; potential explanations include known PrEP efficacy and different motivations to take PrEP. Recent studies have explored adherence monitoring through electronic pill containers, short message service (SMS), and drug concentrations in hair and dried blood spots. The few PrEP adherence interventions developed to date include combinations of enhanced counseling, feedback of objective adherence measurement, and SMS. Conceptualization of PrEP adherence is evolving. The goal is not 100% adherence indefinitely, as it was in clinical trials. PrEP adherence should be defined with respect to HIV exposure, which varies over time by sexual behavior and use of other prevention strategies. Summary PrEP adherence beyond clinical trials has generally been high enough to achieve reliable HIV prevention. Future efforts to measure and support PrEP adherence should focus on the context of risk for HIV acquisition, accounting for dynamic behaviors and choices among HIV prevention options. Article	2016	Hakre S.; Blaylock J.M.; Dawson P.; Beckett C.; Garges E.C.; Michael N.L.; Danaher P.J.; Scott P.T.; Okulicz J.F.	Knowledge, attitudes, and beliefs about HIV pre-exposure prophylaxis among US Air Force Health Care Providers	Medicine (United States)	-	-	-	257974	10.1097/MD.0000000000004511	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84983462469&doi=10.1097%2fMD.0000000000004511&partnerID=40&md5=5146fe043ef4d5813594c9e515c90377	Providers are central to effective implementation of HIV pre-exposure prophylaxis (PrEP). Primary care providers (PCP) and infectious disease physicians (ID) in the US Air Force (USAF) participated in a cross-sectional survey regarding knowledge, attitudes, and beliefs toward HIV PrEP. Characteristics associated with PrEP knowledge were assessed in univariate and multivariate analyses. Among 403 (40% of 1015 providers) participants, 9% (PCP 383, ID 20) ever prescribed PrEP. In univariate analysis, years in practice, number of HIV-infected patients treated in the past 12 months, past prescription of antiretrovirals for HIV prevention, frequency of prescribing PrEP in the past 12 months, and ever being questioned by a patient about PrEP were associated with PrEP knowledge (P < 0.05). In multivariate analysis, providers who had ever prescribed antiretrovirals to prevent HIV (AOR: 2.37, 95% CI: 1.27-4.42) had greater odds of high PrEP knowledge. Despite concerns about medication side effects (overall 67%: PCP 68%, ID 85%) and prescribing PrEP without clear evidence (overall 60%: PCP 65%, ID 62%), 64% (PCP 65%, ID 85%) of participants indicated PrEP should be offered in the Military Health System and 68% (PCP 70%, ID 100%) disagreed with the statement that their patient population was not at risk for HIV infection. Successful PrEP implementation in the USAF will require continued education and training of primary care providers to improve knowledge and mitigate concerns about PrEP. Article	2016	Hall E.W.; Heneine W.; Sanchez T.; Sineath R.C.; Sullivan P.	Preexposure prophylaxis modality preferences among men who have sex with men and use social media in the United States	Journal of Medical Internet Research	-	-	-	14388871	10.2196/jmir.5713	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84973500181&doi=10.2196%2fjmir.5713&partnerID=40&md5=dce5bfce1b9a8a30eaaca563f4f4644f	Background: Preexposure prophylaxis (PrEP) is available as a daily pill for preventing infection with the human immunodeficiency virus (HIV). Innovative methods of administering PrEP systemically or topically are being discussed and developed. Objective: The objective of our study was to assess attitudes toward different experimental modalities of PrEP administration. Methods: From April to July 2015, we recruited 1106 HIV-negative men who have sex with men through online social media advertisements and surveyed them about their likelihood of using different PrEP modalities. Participants responded to 5-point Likert-scale items indicating how likely they were to use each of the following PrEP modalities: a daily oral pill, on-demand pills, periodic injection, penile gel (either before or after intercourse), rectal gel (before/after), and rectal suppository (before/after). We used Wilcoxon signed rank tests to determine whether the stated likelihood of using any modality differed from daily oral PrEP. Related items were combined to assess differences in likelihood of use based on tissue or time of administration. Participants also ranked their interest in using each modality, and we used the modified Borda count method to determine consensual rankings. Results: Most participants indicated they would be somewhat likely or very likely to use PrEP as an on-demand pill (685/1105, 61.99%), daily oral pill (528/1036, 50.97%), injection (575/1091, 52.70%), or penile gel (438/755, 58.01% before intercourse; 408/751, 54.33% after). The stated likelihoods of using on-demand pills (median score 4) and of using a penile gel before intercourse (median 4) were both higher than that of using a daily oral pill (median 4, P<.001 and P=.001, respectively). Compared with a daily oral pill, participants reported a significantly lower likelihood of using any of the 4 rectal modalities (Wilcoxon signed rank test, all P<.001). On 10-point Likert scales created by combining application methods, the reported likelihood of using a penile gel (median 7) was higher than that of using a rectal gel (median 6, P<.001), which was higher than the likelihood of using a rectal suppository (median 6, P<.001). The modified Borda count ranked on-demand pills as the most preferred modality. There was no difference in likelihood of use of PrEP (gel or suppository) before or after intercourse. Conclusions: Participants typically prefer systemic PrEP and are less likely to use a modality that is administered rectally. Although most of these modalities are seen as favorable or neutral, attitudes may change as information about efficacy and application becomes available. Further data on modality preference across risk groups will better inform PrEP development. ©Eric William Hall, Walid Heneine, Travis Sanchez, Robert Craig Sineath, Patrick Sullivan. Article	2016	Hanscom B.; Janes H.E.; Guarino P.D.; Huang Y.; Brown E.R.; Chen Y.Q.; Hammer S.M.; Gilbert P.B.; Donnell D.J.	Preventing HIV-1 infection in women using oral preexposure prophylaxis: A meta-analysis of current evidence	Journal of Acquired Immune Deficiency Syndromes	-	-	-	15254135	10.1097/QAI.0000000000001160	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84983022112&doi=10.1097%2fQAI.0000000000001160&partnerID=40&md5=915eb1ac5a8b2aa60e90348e1a9e0a4a	The World Health Organization has issued an early release revision to its antiretroviral guidelines in which PrEP (pre-exposure prophylaxis in the form of daily oral, fixed dose combination tenofovir disoproxil fumarate/emtricitabine) is recommended as a prevention option to all people at substantial risk of acquiring HIV. However, lack of effectiveness in 2 major women-only PrEP trials, VOICE and FEM-PrEP, continues to be a cause for concern about achieving effectiveness for women in Southern Africa. We conducted a series of meta-analyses of oral effectiveness of tenofovir disoproxil fumarate/emtricitabine in women including all 5 randomized placebo-controlled trials that included women. An adherence-based meta-analysis model showed that with high levels of adherence (75%), oral PrEP is estimated to be effective (relative risk 0.39, 95% confidence interval: 0.25 to 0.60). Provided that these results apply to women in Southern Africa, future prevention trial designs in that region should account for potentially reduced HIV incidence when PrEP is available. © 2016 Wolters Kluwer Health, Inc. Article	2016	Heffron R.; Pintye J.; Matthews L.T.; Weber S.; Mugo N.	PrEP as Peri-conception HIV Prevention for Women and Men	Current HIV/AIDS Reports	-	-	-	15483568	10.1007/s11904-016-0312-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84961212215&doi=10.1007%2fs11904-016-0312-1&partnerID=40&md5=c55b6cc86ffd86ef39dd7e6001d16b5a	Daily oral tenofovir (TDF)-based pre-exposure prophylaxis (PrEP) is an effective HIV prevention strategy and recommended for men and women with substantial risk of HIV acquisition. The peri-conception period, the stage prior to pregnancy when condom use is necessarily reduced, has elevated HIV risk that can be mitigated by PrEP use. Data from a randomized trial suggest that peri-conception PrEP use by HIV-seronegative women does not increase the risk of pregnancy loss, birth defects or congenital anomalies, preterm birth, or infant growth faltering. Women considering PrEP use throughout pregnancy must weigh the known increased risk of HIV acquisition with unknown risks of drug effects on infant growth. PrEP has been used safely by HIV-seronegative men with HIV-seropositive female partners who have become pregnant. As an effective user-controlled HIV prevention strategy, PrEP offers autonomy and empowerment for HIV prevention and can be recommended alongside antiretroviral therapy, fertility screening, vaginal self-insemination, intercourse timed to peak fertility, medically assisted reproduction, and other safer conception strategies to provide multiple options. The integration of PrEP into safer conception programs is warranted and will safely reduce HIV transmission to women, men, and children during the peri-conception period. © 2016, Springer Science+Business Media New York. Dose Frequency Ranging Pharmacokinetic Study of Tenofovir-Emtricitabine after Directly Observed Dosing in Healthy Volunteers to Establish Adherence Benchmarks (HPTN 066)	AIDS Research and Human Retroviruses	-	-	-	8892229	10.1089/aid.2015.0182	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84954149594&doi=10.1089%2faid.2015.0182&partnerID=40&md5=dba4a0d06a1357ba3ca57aa25103be76	Oral preexposure prophylaxis (PrEP) trials report disparate efficacy attributed to variable adherence. HPTN 066 was conducted to establish objective, quantitative benchmarks for discrete, regular levels of adherence using directly observed dosing of tenofovir (TFV) disoproxil fumarate (TDF)/emtricitabine (FTC). Healthy, HIV-uninfected men and women were randomized to one of four oral regimens of fixed-dose TDF 300 mg/FTC 200 mg tablet for 5 weeks with all doses observed: one tablet weekly (one/week), one tablet twice weekly (two/week), two tablets twice weekly (four/week), or one tablet daily (seven/week). Trough serum TFV and FTC, peripheral blood mononuclear cell (PBMC), and CD4+ TFV-diphosphate (TFV-DP) and FTC-triphosphate (FTC-TP) concentrations were determined throughout dosing and 2 weeks after the last dose. Rectosigmoidal, semen, and cervicovaginal samples were collected for drug assessment at end of dosing and 2 weeks later in a subset of participants. The 49 enrolled participants tolerated the regimens well. All regimens achieved steady-state concentrations by the second dose for serum TFV/FTC and by 7 days for PBMC TFV-DP/FTC-TP. Steady-state median TFV-DP predose concentrations demonstrated dose proportionality: one/week 1.6 fmol/106 PBMCs, two/week 9.1, four/week 18.8, seven/week, 36.3. Further, TFV-DP was consistently quantifiable 2 weeks after the last dose for the ≥4/week regimens. Adherence benchmarks were identified using receiver operating characteristic curves, which had areas under the curve ≥0.93 for all analytes in serum and PBMCs. Intersubject and intrasubject coefficients of variation (%CV) ranged from 33% to 63% and 14% to 34%, respectively, for all analytes in serum and PBMCs. Steady-state PBMC TFV-DP was established earlier and at lower concentrations than predicted and was the only analyte demonstrating predose concentration dose proportionality. Steady-state daily dosing serum TFV and PBMC TFV-DP was consistent with highly effective PrEP clinical trials. HPTN 066 provides adherence benchmarks for oral TFV/FTC regimens to assist interpreting study outcomes. © Copyright 2016, Mary Ann Liebert, Inc. 2016. Article	2016	Hendrix, Craig	When is a PrEP candidate ready for phase 3?	The Lancet HIV	-	-	-	2352-3018	10.1016/S2352-3018(16)30162-X	https://www.thelancet.com/journals/lanhiv/article/PIIS2352-3018(16)30162-X/abstract	Long-acting products for HIV pre-exposure prophylaxis (PrEP) are in development to reduce the daily burden of oral drugs. Long-acting alternatives include monthly intravaginal rings proven for prevention (dapivirine), bimonthly implantable drugs proven for treatment (cabotegravir and rilpivirine), and possibly yearly implantable devices still in preclinical development. In The Lancet HIV, Ian McGowan and colleagues contribute substantially to progress with long-acting rilpivirine,1 highlighting the benefits, limitations, and puzzles of long-acting PrEP development. How should one apply their new data to inform the efficient advancement of long-acting rilpivirine PrEP development? Article	2016	Henrard S.; Wyndham-Thomas C.; Van Vooren J.-P.; Goffard J.-C.	HIV infection : Reaching a zero risk of transmission; Transmission du VIH : Est-ce une fatalité ?	Revue Médicale de Bruxelles	-	-	-	353639	NA	https://pubmed.ncbi.nlm.nih.gov/28525231/	Despite a global reduction in the prevalence of HIV-infection, the HIV-epidemic is far from over. The prevention of HIV-transmission in all its forms (sexual, mother-to-child etc) must therefore remain a pillar in the fight against AIDS, and both potent and accessible prevention strategies are required. In addition to the classical and wellknown methods such as the condom, ant iretroviral therapy represents a potent prevention tool and the residual risk of transmission of correctly treated HIV-positive persons is virtually nihil. Antiretroviral therapy may and should be used in the prevention of HIV-transmission as Treatment as Prevention (TasP), Pre-Exposure Prophylaxis (PrEP), and Post- Exposure Prophylaxis (PEP). However, because of their exorbitant costs, the accessibility of these prevention strategies is limited, particularly for the most vulnerable populations. Article	2016	Herrera, Carolina; Armanasco, Naomi; García-Pérez, Javier; Ziprin, Paul; Olejniczak, Natalia; Alcamí, José; Nuttall, Jeremy; Shattock, Robin J	Maraviroc and reverse transcriptase inhibitors combinations as potential preexposure prophylaxis candidates.	AIDS	-	-	-	1473-5571	10.1097/QAD.0000000000001043	https://dx.doi.org/10.1097/QAD.0000000000001043	OBJECTIVE: Receptive anal intercourse in both men and women is associated with the highest probability for sexual acquisition of HIV infection. As part of a program to develop an effective prevention strategy, we performed an ex-vivo preclinical evaluation to determine the efficacy of multiple double combinations of maraviroc (MVC) and reverse transcriptase inhibitors (RTIs). DESIGN: The entry inhibitor, MVC, a nucleotide RTI, tenofovir and two non-nucleoside RTIs, UC781 and TMC120 (dapivirine, DPV), were used in double, combinations against a panel of CCR5-using clade B and clade C HIV-1 isolates and against MVC-escape variants. A gel-formulated version of MVC-DPV combination was also tested. METHODS: Indicator cells, cocultures of immature dendritic cells with CD4T cells, and colorectal tissue explants were used to assess antiviral activity of drug combinations. RESULTS: All dual MVC-RTI combinations tested inhibited MVC-sensitive and resistant isolates in cellular and colorectal explants models. All the combinations were positive with no reduction in the activity of MVC. In tissue explants, the combinations against all viral isolates tested produced an increase in the activity of MVC. An initial gel-formulation of MVC-DPV combination showed greater and prolonged antiviral activity of MVC in mucosal tissue explants. CONCLUSION: This study demonstrates that combinations based on antiretroviral drugs inhibiting HIV transmission at viral entry and reverse transcription have potential as prevention strategies against colorectal transmission of HIV-1 including MVC-resistant isolates. Preclinical evaluation with colorectal tissue explants indicates that a gel-formulation of MVC-DPV is an effective candidate colorectal microbicide. Article	2016	Herron P.D.	Ethical Implications of Social Stigma Associated with the Promotion and Use of Pre-Exposure Prophylaxis for HIV Prevention	LGBT Health	-	-	-	23258292	10.1089/lgbt.2014.0114	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84969245674&doi=10.1089%2flgbt.2014.0114&partnerID=40&md5=1f234a4e0dc961049b7db5a06f5dcec0	Identifying sources of and eliminating social stigma associated with the promotion and use of pre-exposure prophylaxis (PrEP) for the prevention of sexually acquired HIV infection among men who have sex with men (MSM) is both a moral imperative and necessary requirement to ensure that public health objectives of HIV prevention can be met. This article will examine and address ethical concerns and criticisms regarding the use of PrEP, barriers to its promotion, and use among MSM and examine the types of social stigma associated with PrEP. An ethical justification for both healthcare and LGBT communities to address and overcome social stigma regarding the use of PrEP among MSM is offered. © Copyright 2016, Mary Ann Liebert, Inc. 2016.	ethics; HIV/AIDS; men who have sex with men (MSM); pre-exposure prophylaxis (PrEP); social stigma	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Review
Article	2016	Hill, Andrew M.; Pozniak, Anton L.	How can we achieve universal access to low-cost treatment for HIV?	Journal of Virus Eradication	-	-	-	2055-6640 2055-6659	10.1016/S2055-6640(20)30871-2	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5075345/	Mass production of low-cost antiretrovirals (ARVs) has already allowed over 17 million individuals to access treatment for HIV infection, mainly in low-income countries. It is possible to manufacture combination ARVs for $110 per person-year, using tenofovir (TDF), lamivudine (3TC) and efavirenz (EFV). New combinations of ARVs costing as little as $60 per person-year will be available in the near future. Pre-exposure prophylaxis using TDF in combination with either 3TC or emtricitabine (FTC) could also be provided for less than $90 per person-year. Voluntary licensing allows people in the poorest countries to access new ARVs at prices close to manufacturing costs. Patents on several key ARVs will expire by 2018 and should allow worldwide access to high-quality, low-cost triple combination therapy, such as TDF/3TC/EFV. Several protease inhibitors will also become available as generics by 2018. However, ongoing patent restrictions will lead to sustained high prices for the most recently developed ARVs in most middle- and high-income countries. These include the nucleotide tenofovir alafenamide, the integrase strand inhibitor dolutegravir and several single combination tablet regimens. We suggest that as patents for ARVs expire, health authorities first need to rapidly import and introduce generic versions of drugs such as abacavir, 3TC, EFV and TDF. Once these low prices have been established for these generics, cost-effectiveness of patented ARVs needs to be re-evaluated. It may no longer be justified to pay high prices for these drugs. A strategy of low-cost generic ARVs for most people, with higher-cost patented alternatives used as switch options, could allow for an increased number of people to receive ARVs in the context of fixed health budgets.	antiretrovirals; protease inhibitors; nucleoside analogues; health economics; integrase strand inhibitors; non-nucleosides	English	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	United Kingdom	Western and Central Europe and North America	Review
Theses and Dissertations	2016	HOAGLAND, BRENDA REGINA DE SIQUEIRA	Conhecimento, interesse, decisão sobre o uso e adesão precoce a profilaxia pré-exposição (PrEP) entre homens que fazem sexo com homens (HSH) e mulheres transexuais (TRANS) participantes no estudo PrEP Brasil'	-	-	Fundação Oswaldo Cruz	-	NA	NA	https://www.arca.fiocruz.br/handle/icict/37310	A profilaxia pré-exposição (PrEP) utilizando a combinação de dois antirretrovirais, o disoproxil fumarato de tenofovir (TDF) e emtricitabina (FTC), por via oral tem se mostrado eficaz na prevenção do HIV em homens que fazem sexo com homens (HSH) com alto risco de aquisição da infecção. O Brasil apresenta a maior população da América Latina vivendo com HIV/AIDS e uma epidemia concentrada em HSH com uma prevalência de 14,2% quando comparado a população geral, que é de 0,6%. A população jovem de HSH são quase 40% dos casos de AIDS, com um aumento de 41,3% (entre 15-19 anos) e 25,1% (entre 20-24 anos) entre 2004 e 2013. Apesar da população de mulheres transexuais (Trans) representarem uma parcela menor que os HSH, elas apresentam índices extremamente elevados de risco e diagnóstico de infecção pelo HIV. Deste modo a epidemia de HIV persiste sem decréscimo entre HSH e Trans, com uma elevada proporção desses indivíduos desconhecendo sua condição sorológica. Neste contexto, foi desenhado o PrEP Brasil (NTC01989611), um estudo multicêntrico, aberto, de demonstração de PrEP para acessar a intenção de uso, viabilidade e segurança de oferecer PrEP no Sistema Único de Saúde (SUS) para a população de HSH e Trans de alto risco para o HIV. Objetivo: Descrever o conhecimento, o interesse e a decisão sobre o uso e a adesão precoce à PrEP entre HSH e Trans, através dos níveis de TDF/FTC medidas em amostras de sangue seco (DBS) coletadas na visita de semana 4 e seus fatores associados no estudo demostrativo PrEP Brasil. Primeiro Artigo: Descrever o conhecimento e interesse da PrEP entre HSH e TRANS participantes do PrEP Brasil. Conhecimento e interesse para usar PrEP assim como outros métodos de prevenção foram dados na forma de percentuais. Modelos de regressão logística foram usados para explorar e quantificar os fatores associados ao conhecimento e aceitabilidade de PrEP. Variáveis com p < 0.1 na análise bivariada foram incluídos nos modelos ajustados iniciais. O modelo ajustado final incluiu variáveis que resistiram significantes (no limite de 5% da significância) assim como as variáveis que foram consideradas de confusão (qualquer uma que modificasse o odds ratio estimado em mais que 10%). A prevalência do HIV foi calculada excluídos os casos faltantes (n=52 não realizou teste rápido do HIV). Segundo Artigo: Descrever a decisão de uso e a adesão precoce a PrEP entre HSH e mulheres transexuais através da medição dos níveis séricos de Tenofovir e Emtricitabina em amostras de sangue seco coletadas em papel de filtro (DBS) na semana 4 do estudo PrEP Brasil, assim como seus fatores associados. Também foram descritas as características demográficas e de risco da população incluída no estudo. Variáveis descrevendo as características dos indivíduos potencialmente elegíveis (incluídos e não incluídos), assim como por centro de estudo que o participante foi incluído foi apresentado em números absolutos e proporções. As distribuições foram comparadas usando análises de qui-quadrado e Kruskal-Wallis. A decisão de usar PrEP foi definida como o número de participantes incluídos dividido pelo número de participantes potencialmente elegíveis na pré-triagem menos aqueles vii clinicamente inelegíveis (nas vistas de triagem e inclusão). Os preditores dos níveis de TDF/FTC foram acessados utilizando modelos de regressão logística ordinal. Apenas variáveis estatisticamente significantes a 5% no modelo não ajustado foram mantidas no modelo ajustado. Os resultados foram reportados como odds ratio, que podem ser interpretados como o efeito no odds sendo a categoria dos níveis de drogas mais altos versus os mais baixos. A associação de sintomas gastrointestinais e os níveis de drogas,medidos na visita de semana 4, foram também analisados usando modelos de regressão logística ordinal. Adicionalmente, para explorar possíveis efeitos do uso de hormônios nos níveis de TFV-DP em Trans, foram feitas duas abordagens de modelagens, o de foi usado: 1) modelo de regressão logística usando ≥4 doses/semana como resultado e uso/não-uso de hormônios como a variável dicotômica explanatória, 2) modelo de regressão logística linear com concentrações de TVF-DP como a variável contínua de resultado e uso/não-uso de hormônios como a variável dicotômica explanatória. As análises foram feitas usando o PROC GENMOD disponível no Software SAS e a suposição de odds proporcional foi verificada através do Teste de Pontuação. Conclusões: O estudo mostrou que a aceitabilidade e o interesse pela PrEP foi elevada entre HSH e mulheres transexuais e associada a comportamentos sexuais de alto risco para infecção pelo HIV, indicando que estes indivíduos estão interessados em novas estratégias de prevenção. Os resultados sugerem que a PrEP pode ser implementada com sucesso no Sistema Único de Saúde brasileiro para esta população específica. A elevada proporção de indivíduos com alcançaram níveis séricos protetores de TDF/FTC é encorajador e a alta adesão a PrEP sugere que esta pode ser uma estratégia eficaz na redução da infecção pelo HIV entre HSH e Trans em nosso meio.	1.PrEP;2. Article	2016	Hoffman L.F.; Francis N.K.; Catallozzi M.; Francis J.K.R.; Stanberry L.R.; Rosenthal S.L.	Inclusion of Adolescents in Clinical Trials for Sexually Transmitted Infections: A Review of Existing Registered Studies	Journal of Adolescent Health	-	-	-	1054139X	10.1016/j.jadohealth.2016.01.007	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84960397356&doi=10.1016%2fj.jadohealth.2016.01.007&partnerID=40&md5=ab1533eaa0dcb3c5b77a6b9c33bc07a9	Purpose: Despite their heightened risk of sexually transmitted infections, minor adolescents (<18 years old) are often excluded from clinical trials. The results of trials of adults should not be assumed to generalize to minors. Methods: Two public clinical trial registries were first searched using microbicide or PrEP with STD, STI, HIV, or HSV and with gel, ring, or film, and then searched using prevention/sexually transmitted diseases with gel. Studies were classified based on the information provided in the registry. Results: The searches yielded 111 unique studies. Only 9.0% (n = 10) included minors. They were under-represented in Phase 0-II studies and over-represented in studies of individuals infected with human immunodeficiency virus. Conclusions: Minor adolescents should be included during all stages of development and before they have acquired an infection. Future studies should examine the challenges of including minor adolescents in trials and how to overcome these barriers. © 2016 Society for Adolescent Health and Medicine. All rights reserved. Article	2016	Hoffman S.; Guidry J.A.; Collier K.L.; Mantell J.E.; Boccher-Lattimore D.; Kaighobadi F.; Sandfort T.G.M.	A Clinical Home for Preexposure Prophylaxis: Diverse Health Care Providers' Perspectives on the "purview Paradox"	Journal of the International Association of Physicians in AIDS Care	-	-	-	23259574	10.1177/2325957415600798	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84953224374&doi=10.1177%2f2325957415600798&partnerID=40&md5=1b20e40d2c7904f9f568bee5e5e8903f	Background: One barrier to wider preexposure prophylaxis (PrEP) availability is uncertainty about the most appropriate providers and practice settings for offering PrEP. Methods: The authors conducted in-depth interviews with 30 clinicians - primary care and HIV specialists - in the New York City (NYC) region to explore issues related to PrEP rollout, including who should provide it and in what settings. Results: A diverse group favored offering PrEP in non-HIV specialty settings in order to reach high-risk HIV-negative individuals. Yet, for each clinical skill or ancillary service deemed important for providing PrEP - knowledge of the medications, ability to assess and counsel around sexual risk behavior, and ability to provide support for retention and medication adherence - participants were divided in whether they thought primary care providers/practices could achieve it. Five participants strongly favored providing PrEP in HIV care practices. Conclusion: Although there may be multiple "homes" for PrEP, implementation research is needed to identify the most effective delivery approaches. © The Author(s) 2014.	biomedical HIV prevention; health care provider; implementation; preexposure prophylaxis (PrEP)	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	Qualitative
Theses and Dissertations	2016	Hoffmann, Christopher	Enhancing PrEP uptake among MSM: Findings from interviews with researchers and practitioners	-	-	University of Pittsburgh	-	NA	NA	http://d-scholarship.pitt.edu/27530/1/HoffmannC_MPHThesis_April2016.pdf	BACKGROUND: HIV pre-exposure prophylaxis (PrEP) is a prescription antiretroviral medication that an HIV-negative person who is at high risk for HIV infection takes once per day to prevent infection. The most recent National HIV/AIDS Strategy identifies increasing PrEP uptake among men who have sex with men (MSM) as a pillar of ending the AIDS epidemic. Extant literature suggests that barriers to PrEP uptake among MSM are related to access, stigma, and knowledge/attitudes. METHODS: From February-March 2016, semi-structured interviews were conducted with researchers and practitioners in the HIV prevention field who work with MSM in Pittsburgh, Pennsylvania (n=11). An interview guide was used that asked about PrEP barriers and ways to mitigate these barriers. Interview recordings were transcribed and analyzed for key themes using ATLAS.ti software. RESULTS: The original list of 39 codes was condensed into five key themes. The five key themes are that PrEP is empowering; PrEP barriers are multidimensional and overlapping; episodic PrEP is viewed favorably; PrEP needs, access, and perceptions differ by race and age; and risk compensation is real, but it should not be used to prohibit PrEP uptake. A list of all PrEP barriers identified in the interviews is presented. PUBLIC HEALTH SIGNIFICANCE: For public health practice, participants in these interviews identified stigma as more significant of a barrier to PrEP uptake for MSM than its discussion in the existing literature would suggest. PrEP enhancement efforts should simultaneously target multiple barriers across constructs for maximum effectiveness, avoid shaming overtones, and be inclusive of black MSM. A table is presented that may serve as a map to intervention design. Research is needed to test the association of PrEP use and STI incidence in US-based samples, to fine-tune local PrEP uptake efforts in other regions, and to monitor unintended consequences of PrEP uptake in the near or distant future. Article	2016	Holt M.; Lea T.; Kippax S.; Kolstee J.; Ellard J.; Velecky M.; Murphy D.; De Wit J.	Awareness and knowledge of HIV pre-exposure prophylaxis among Australian gay and bisexual men: Results of a national, online survey	Sexual Health	-	-	-	14485028	10.1071/SH15243	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84982853997&doi=10.1071%2fSH15243&partnerID=40&md5=ffa2cc318be77f4cbe76954390e97bcc	Background Expanded access to HIV pre-exposure prophylaxis (PrEP) is being actively debated in Australia. Awareness and knowledge of this HIV-prevention method have not been assessed in detail in the primary affected population, gay and bisexual men. Methods: Awareness and knowledge of PrEP were assessed among Australian gay and bisexual men, who were asked to complete a national, anonymous, online survey in 2015. Associations with PrEP awareness were identified using multivariate logistic regression and associations with PrEP knowledge were identified using multivariate linear regression. Results: Among 1251 participants, 954 (77%) were aware of PrEP. The most common sources of information were gay community media, Australian websites and friends. Awareness of PrEP was independently associated with older age, living in a capital city, having a university degree, being tested for HIV, being HIV-positive, having condomless anal intercourse with regular male partners, and ever having taken post-exposure prophylaxis. Men in monogamous relationships were less likely to be aware of PrEP. Among men who were aware of PrEP, the mean PrEP knowledge score was 6.8 out of 13. Relatively few participants knew that taking PrEP involved regular clinical monitoring and that in Australia PrEP was only recommended for people at risk of HIV. Better knowledge was independently associated with living in a capital city, having a university degree, being in full-time employment, being HIV-positive, and ever having taken post-exposure prophylaxis or PrEP. Conclusions: To assist in appropriate PrEP uptake, we recommend educating gay and bisexual men about current Australian prescribing guidelines and how PrEP is accessed in Australia. © 2016 CSIRO. Article	2016	Hood J.E.; Buskin S.E.; Dombrowski J.C.; Kern D.A.; Barash E.A.; Katzi D.A.; Golden M.R.	Dramatic increase in preexposure prophylaxis use among MSM in Washington state	AIDS	-	-	-	2699370	10.1097/QAD.0000000000000937	https://pubmed.ncbi.nlm.nih.gov/26562845/	Objective: HIV preexposure prophylaxis (PrEP) is efficacious, but uptake has been slow. In Washington State, most insurance plans, including Medicaid, pay for PrEP, and the state supports a PrEP drug assistance program. We assessed trends in PrEP awareness and use among MSM in Washington. Design and setting: Serial cross-sectional survey conducted annually at the Seattle Pride Parade between 2009 and 2015. Methods: In a convenience sample of MSM who reside in Washington State and deny ever testing HIV positive (n=2168), we evaluated the association between calendar year and self-report of PrEP uptake and awareness using descriptive statistics and multivariable relative risk and logistic regression. Regression models included HIV risk and demographic covariates. Results: In 2015, 23% 95% confidence interval (CI): 16%, 31% of high-risk MSM reported currently taking PrEP. The percentage of high-risk MSM who reported ever taking PrEP increased from 5% in 2012 to 31% in 2015. PrEP use among lower-risk MSM was low and stable, between 1 and 3% in 2012-2015. In multivariable analyses, PrEP use was associated with later calendar years (2015 vs. 2012: adjusted relative risk=2.29, 95% CI: 1.16, 4.52) and elevated HIV risk (adjusted relative risk=2.92, 95% CI: 2.00, 4.25). The percentage of high and lower-risk MSM who had heard of PrEP increased from 13 to 86% and from 29 to 58%, respectively. Conclusion: PrEP awareness is high and the use has rapidly increased over the last year among MSM in Seattle, Washington, USA. These findings demonstrate that high levels of PrEP use can be achieved among MSM at high-risk for HIV infection. © 2016 Wolters Kluwer Health, Inc. All rights reserved. Article	2016	Hoots, Brooke E; Finlayson, Teresa; Nerlander, Lina; Paz-Bailey, Gabriela	Willingness to Take, Use of, and Indications for Pre-exposure Prophylaxis Among Men Who Have Sex With Men-20 US Cities, 2014.	Clinical Infectious Diseases	-	-	-	1537-6591	10.1093/cid/ciw367	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5009903	BACKGROUND: Pre-exposure prophylaxis (PrEP) is an effective prevention tool for people at substantial risk of acquiring human immunodeficiency virus (HIV). To monitor the current state of PrEP use among men who have sex with men (MSM), we report on willingness to use PrEP and PrEP utilization. To assess whether the MSM subpopulations at highest risk for infection have indications for PrEP according to the 2014 clinical guidelines, we estimated indications for PrEP for MSM by demographics. METHODS: We analyzed data from the 2014 cycle of the National HIV Behavioral Surveillance (NHBS) system among MSM who tested HIV negative in NHBS and were currently sexually active. Adjusted prevalence ratios and 95% confidence intervals were estimated from log-linked Poisson regression with generalized estimating equations to explore differences in willingness to take PrEP, PrEP use, and indications for PrEP. RESULTS: Whereas over half of MSM said they were willing to take PrEP, only about 4% reported using PrEP. There was no difference in willingness to take PrEP between black and white MSM. PrEP use was higher among white compared with black MSM and among those with greater education and income levels. Young, black MSM were less likely to have indications for PrEP compared with young MSM of other races/ethnicities. CONCLUSIONS: Young, black MSM, despite being at high risk of HIV acquisition, may not have indications for PrEP under the current guidelines. Clinicians may need to consider other factors besides risk behaviors such as HIV incidence and prevalence in subgroups of their communities when considering prescribing PrEP. Article	2016	Hosek, Sybil; Celum, Connie; Wilson, Craig M.; Kapogiannis, Bill; Delany-Moretlwe, Sinead; Bekker, Linda-Gail	Preventing HIV among adolescents with oral PrEP: observations and challenges in the United States and South Africa.	Journal of the International AIDS Society	-	-	-	1758-2652	10.7448/IAS.19.7.21107	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84995377346&doi=10.7448%2fIAS.19.7.21107&partnerID=40&md5=3a3f22f8c15635765e08ee33fa00e433	INTRODUCTION: Adolescents and young adults aged <25 are a key population in the HIV epidemic, with very high HIV incidence rates in many geographic settings and a large number who have limited access to prevention services. Thus, any biomedical HIV prevention approach should prepare licensure and implementation strategies for young populations. Oral pre-exposure prophylaxis (PrEP) is the first antiretroviral-based prevention intervention with proven efficacy across many settings and populations, and regulatory and policy approvals at global and national levels are occurring rapidly. We discuss available data from studies in the United States and South Africa on the use of oral PrEP for HIV prevention in adolescent minors, along with some of the implementation challenges. DISCUSSION: Ongoing studies in the United States and South Africa among youth under the age of 18 should provide the safety data needed by the end of 2016 to contribute to licensure of Truvada as daily PrEP in adolescents. The challenges of completing these studies as well as foreseeable broader challenges highlighted by this work are presented. Adherence to daily PrEP is a greater challenge for younger populations, and poor adherence was associated with decreased efficacy in all PrEP trials. Individual-level barriers include limited familiarity with antiretroviral-based prevention, stigma, product storage, and social support. Structural challenges include healthcare financing for PrEP, clinician acceptability and comfort with PrEP delivery, and the limited youth-friendly health services available. These challenges are discussed in the context of the work done to date in the United States and South Africa, but will likely be magnified in the setting of limited resources in many other countries that are heavily impacted by HIV. CONCLUSIONS: Adolescent populations are particularly vulnerable to HIV, and oral PrEP in these populations is likely to have an impact on population-level HIV incidence. The challenges of disseminating an HIV biomedical prevention tool requiring daily usage in adolescents are formidable, but addressing these issues and starting dialogues will lay the groundwork for the many other HIV prevention tools now being developed and tested. Theses and Dissertations	2016	Hu, Minlu	THE ROLE OF EPITHELIAL INTEGRITY AND METABOLIZING ENZYMES IN TOPICAL MICROBICIDE EFFICACY FOR THE PREVENTION OF HIV SEXUAL TRANSMISSION	-	-	University of Pittsburgh	-	NA	NA	http://d-scholarship.pitt.edu/28694/	In order to further reduce the number of HIV-1 infections, efforts must be made to prevent new acquisition of HIV in healthy population. Although the antiretroviral-based topical (microbicides) and oral pre-exposure prophylaxis (PrEP) products have been evaluated in a number of clinical trials, the results from these studies have been inconsistent. The aim of my dissertation study is to examine whether the modulators of tissue integrity and metabolizing enzymes could affect antiretroviral drug exposure and efficacy in cervicovaginal tissues. First of all, we demonstrated that the several commonly used excipients which increased paracellular permeability of cervicovaginal tissue did not significantly reduce tenofovir (TFV) activity in HIV-1 prevention in an ex vivo explant tissue model. In addition, TEER, morphology, permeability, and MTT-based tissue viability do not necessarily change in parallel with each other and the use of a single measurement cannot accurately reflect the effect of excipients on cervicovaginal tissue integrity. Also, we found that the mRNA of several Phase I and II metabolizing enzyme isoforms, such as CYP1A1, CYP1B1 and UGT1A1, are highly expressed in the human female genital tract. In phosphorylating enzymes study, we found that the majority of TFV-related phosphorylating enzymes showed significantly decreased mRNA level in T cells as compared to their levels in cervicovaginal tissues. Furthermore, our results indicated that medroxyprogesterone acetate and progesterone treatments changed the activity of phosphorylating enzymes toward different directions in cervicovaginal epithelial cell line (VK2) and a T cell line (PM1). Additionally, we found that medroxyprogesterone acetate, progestone, IL1β and IL8 treatment resulted in altered tenofovir diphosphate level in a vaginal epithelial cell line and a T cell line. Taken together, these studies provide valuable information on the excipients' effect on multiple aspects of cervicovaginal tissue integrity, as well as what biological factors may affect the effectiveness of TFV and its clinical potential. Such information will facilitate the efforts toward optimized vaginal PrEP products for HIV-1 prevention. Theses and Dissertations	2016	Huei-Jiuan Wu, 吳慧娟	HIV Pre-Exposure Prophylaxis for Men Who Have Sex with Men in Taiwan: A Mathematical Modeling Study / HIV暴露前預防投藥策略對台灣男男間性行為傳染愛滋疫情的防治效果:數理模式研究	-	-	National Digital Library of Theses and Dissertations in Taiwan	-	NA	NA	http://ndltd.ncl.edu.tw/handle/24757060478623395698	Background: Men who have sex with men (MSM) are disproportionally affected by the HIV epidemic. There are now around 2,000 new MSM-HIV cases annually in Taiwan, under current HIV testing rate and antiretroviral therapy (ART) coverage. More effective strategy is urgently required to control the HIV epidemic in this vulnerable population. Both PROUD (2015) and IPERGAY (2015) studies demonstrated an 86% efficacy of PrEP, twice better than the 44% efficacy reported by the earlier iPrEX (2010) study. Therefore, previous modeling studies, which were based on iPrEX data, might under-estimated the actual impact of scaling-up PrEP among MSM. We aimed to evaluate the impact and cost-effectiveness of scaling-up PrEP on the MSM-HIV epidemic in Taiwan. Methods: We used the newest HIV surveillance and follow-up data to calibrate our HIV dynamic transmission model for MSM in Taiwan. We simulated the impact of scaling-up PrEP, Test-and-Treat, or both, on the future trajectory of HIV epidemic in MSM. We evaluate whether scaling-up PrEP will eliminate the MSM-HIV epidemic (incidence lower than 1/1000 per year, World Health Organization) in Taiwan, and whether such intervention is cost-effective. Findings: Scaling-up PrEP to 50% coverage or more will eliminate HIV among MSM by 2025. Annual HIV testing followed by immediate ART after HIV diagnosis in 90% of new cases will eliminate HIV epidemic by 2022. PrEP and Test-and-Treat are synergistic: if we target 15- to 44-year-old high-risk group, then 25% PrEP coverage in this group is sufficient to eliminate HIV epidemic by 2030 under biannual HIV testing followed by immediate ART in 75% of new cases. Cost analysis shows that NT$11.2 medical costs can be saved for every NT$1 spent on PrEP. Sensitivity analyses showed that efficacy of PrEP drug is the key factor for its role in HIV elimination, while method of administration (event-driven) and prioritization (high-risk group) are the key factors for its cost-effectiveness. Interpretation: PrEP is a highly effective HIV prevention strategy and is cost-saving. Our results support the simultaneous expansion of both PrEP and HIV "Test-and-Treat" in Taiwan, with the aim to eliminate HIV epidemic among MSM in the next 10 years. Theses and Dissertations	2016	Hughes, Alison J.	On the road to zero in San Francisco: understanding population dynamics, HIV transmission and internalized HIV stigma in order to get to zero HIV transmission, zero HIV-related deaths and zero HIV stigma	-	-	University of California – Berkeley	-	NA	NA	http://www.escholarship.org/uc/item/8j5842dj	As of December 31, 2015, there were 15,995 diagnosed and reported persons living with human immunodeficiency virus (HIV) who were residents of San Francisco, California at time of diagnosis. Approximately one quarter of men who have sex with men (MSM) in San Francisco are HIV-positive. Despite a high HIV burden, a higher proportion of HIV-positive San Franciscans are virally suppressed (72% in 2014 in San Francisco) than nationally (55% nationally in 2013), and 81% of all cases in San Francisco had at least one HIV viral load or CD4 test in 2014 (versus 71% nationally in 2013). Recently, new strategies have emerged to prevent HIV transmission, including post-exposure prophylaxis, treatment as prevention and pre-exposure prophylaxis (PrEP). With these new tools, the end of the HIV epidemic is within reach. New HIV diagnoses in San Francisco are now half of what they were a decade ago, down from 528 new HIV diagnoses in 2006 to 255 in 2015. The Getting to Zero (GTZ) consortium, formed in San Francisco after World AIDS Day in 2013, which is comprised of representatives from the San Francisco Department of Public Health, the University of California San Francisco, public and private medical providers, community based organizations, other San Francisco government agencies and people living with HIV (PLWH), aims to get to zero new HIV transmissions, zero HIV deaths and zero HIV stigma in San Francisco. My dissertation is aligned with the mission of the GTZ consortium.My dissertation seeks to address how the population dynamics of MSM (through migration and HIV serostatus) could affect the prevalence and incidence of HIV in San Francisco and may help explain why there is ongoing HIV transmission in the era of PrEP and treatment as prevention. The ability to migrate has increased for PLWH as survival markedly improved following introduction of combination antiretroviral therapy in 1996. Although there is a high frequency of migration among the general U.S. population and among PLWH in San Francisco, migration patterns of MSM in San Francisco have, to my knowledge, never been described. Output from the novel migration model outlined in Chapter 2 can be used to understand the dynamics of the MSM population in San Francisco and macro-level forces that could affect the prevalence and incidence of HIV in the population. Estimating the number of MSM by HIV status also allows researchers to have a denominator of this hidden population for use in estimating prevalence, incidence, service needs and funding allocations. Further, estimating the number of HIV-negative in-migrants relative to the overall MSM population is important because research has shown that recent MSM migrants to metropolitan areas are at increased risk of HIV acquisition because of higher risk behaviors. My results suggest that the overall MSM population and all the MSM subpopulations studied decreased in size from 2006 to 2014. Further, there were differences in migration patterns by race and by HIV serostatus.Next, given the goal of eliminating all transmission…	Epidemiology; HIV; internalized stigma; migration; pre-exposure prophylaxis; viral suppression	English	United States	Western and Central Europe and North America	United States	Western and Central Europe and North America	-	-	Quantitative
Article	2016	Hugo J.M.; Stall R.D.; Rebe K.; Egan J.E.; De Swardt G.; Struthers H.; McIntyre J.A.	Anti-retroviral Therapy Based HIV Prevention Among a Sample of Men Who Have Sex with Men in Cape Town, South Africa: Use of Post-exposure Prophylaxis and Knowledge on Pre-exposure Prophylaxis	AIDS and Behavior	-	-	-	10907165	10.1007/s10461-016-1536-1	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84986292266&doi=10.1007%2fs10461-016-1536-1&partnerID=40&md5=4ee68ef9c012e8950d997bfdb7b0afde	Men who have Sex with Men (MSM) have been affected disproportionately by the global HIV pandemic. Rates of consistent condom-use are low and there is a need for further biomedical prevention interventions to prevent new HIV infections. Post exposure prophylaxis (PEP) can reduce the risk of HIV, but uptake among MSM is low. Pre-exposure prophylaxis (PrEP), an innovative anti-retroviral-based HIV prevention tool might be an appropriate intervention for MSM who have recently accessed PEP that involves HIV negative individuals taking daily tenofovir+emtricitabine for HIV prevention. 44 MSM, attending a primary health-care level MSM-focused sexual health clinic in Cape Town, South Africa, who had initiated PEP were enrolled in this study. Participants were followed up after 2, 4 and 12 weeks. Self-administered electronic surveys were completed at the initial, 4 and 12 week visit. Barriers and facilitators to accessing PEP and remaining adherent were examined, as was knowledge about PrEP. Thirty-two participants (80 %) were <40 years of age (range 20–65 years). 35 % of the participants reported their reason for requiring PEP as condomless receptive anal intercourse. A further 20 % required PEP following condomless penetrative anal intercourse; 27.5 % required PEP due to a broken condom during receptive anal sex and 2 participants due to insertive anal sex. Three participants did not complete 28 days of PEP or were lost to follow up. Over half (58.5 %) of the participants reported being completely adherent to their regime; under a third (31.7 %) reported missing one PEP dose; and 9.8 % reported missing more than one dose. 36/40 (90 %) had heard of PrEP and 30/40 (75 %) indicated that they would use PrEP if it were accessible to them. That we enrolled 44 MSM who accessed PEP from a Department of Health affiliated clinic over 12 months, speaks to the low uptake by MSM of PEP services in South Africa. Adherence was high and demonstrates that adherence support is feasible from a state health clinic. Reported risk behaviors in some high-risk participants did not change over time, demonstrating the need for additional longer-term HIV preventions such as PrEP. PEP users could conceivably be transitioned from PEP to PrEP. © 2016, Springer Science+Business Media New York. Article	2016	Irungu E.M.; Heffron R.; Mugo N.; Ngure K.; Katabira E.; Bulya N.; Bukusi E.; Odoyo J.; Asiimwe S.; Tindimwebwa E.; Celum C.; Baeten J.M.; Donnell D.; Barnabas R.; Haberer J.; Haugen H.; Hendrix C.; Kidoguchi L.; Marzinke M.; Morrison S.; Morton J.; Ware N.; Wyatt M.	Use of a risk scoring tool to identify higher-risk HIV-1 serodiscordant couples for an antiretroviral-based HIV-1 prevention intervention	BMC Infectious Diseases	-	-	-	14712334	10.1186/s12879-016-1899-y	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85001060894&doi=10.1186%2fs12879-016-1899-y&partnerID=40&md5=6190a63a627e2288708ed0bc7aaf1b11	Background: Antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) reduce HIV-1 transmission within heterosexual HIV-1 serodiscordant couples. Prioritizing couples at highest HIV-1 transmission risk for ART and PrEP would maximize impact and minimize costs. Methods: The Partners Demonstration Project is an open-label, delivery study of integrated PrEP and ART for HIV-1 prevention among high risk HIV-1 serodiscordant couples in Kenya and Uganda. We evaluated the feasibility of using a validated risk score that weighs a combination of easily measurable factors (age, children, marital status, male circumcision status, condom use, plasma HIV-1 levels) to identify couples at highest risk for HIV-1 transmission for enrollment. Couples scoring ≥5 met the risk score eligibility criteria. Results: We screened 1694 HIV-1 serodiscordant couples and enrolled 1013. Of the screened couples, 1331 (78.6 %) scored ≥5 (with an expected incidence >3 % per year) and 76 % of these entered the study. The median age of the HIV-1 uninfected partner was 29 years IQR 26, 36 and 20 % were <25 years of age. The HIV-1 uninfected partner was male in 67 % of partnerships, 33 % of whom were uncircumcised, 57 % of couples had no children, and 65 % reported unprotected sex in the month prior to enrollment. Among HIV-1 infected partners, 41 % had plasma viral load >50,000 copies/ml. Conclusion: A risk scoring tool identified HIV-1 serodiscordant couples for a demonstration project of PrEP and ART with high HIV-1 risk. The tool may be feasible for research and public health settings to maximize efficiency and minimize HIV-1 prevention costs. © 2016 The Author(s). Article	2016	Irungu, E; Sharma, M; Heffron, R; Mugo, N; Ngure, K; Ying, R; Sianyo, C; Celum, C; Baeten, J; Barnabas, R	The Incremental Cost of Delivering PrEP as a Bridge to ART to HIV Serodiscordant Couples in Public HIV Care Clinics in Kenya	AIDS Research and Human Retroviruses	-	-	-	0889-2229	10.1155/2019/4170615	https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6521338/#:~:text=ART%20program%20costs%20in%20Kenya,partner%20in%20a%20serodiscordant%20partnership.	Background. In 2016, the Kenyan Ministry of Health (MOH) released guidelines that recommend preexposure prophylaxis (PrEP) for persons with substantial ongoing HIV risk, including those in HIV serodiscordant partnerships. Estimates of the costs of delivering PrEP within Kenyan public health facilities are needed for planning for PrEP scale up. Methods. We estimated the incremental annual costs of providing PrEP to HIV uninfected partners as a time-limited "bridge" until the infected partner is virally suppressed on ART within HIV serodiscordant couples as part of routine clinic care in Thika, Kenya. Costs were collected from the Partners Demonstration Project, a prospective evaluation of integrated delivery of preexposure prophylaxis (PrEP) and antiretroviral therapy (ART) to high-risk HIV serodiscordant couples. We conducted time and motion studies to distinguish between activities related to research, routine clinical care, and PrEP delivery. Costs (2015 US dollars) were collected from the MOH perspective and divided into staff, transportation, equipment, supplies, buildings and overhead, and start-up. Results. PrEP related activities conducted during the screening, enrollment, and follow-up visits took an average of 13 minutes, 51 minutes, and 12 minutes, respectively. Assuming a staff structure of 3 counselors, 1 nurse, and 2 clinicians, we estimate that 3,178 couples can be screened, 1,444 couples offered PrEP and ART, and 6,138 couples followed up annually in an average HIV care clinic. Using costs incurred by the MOH for personnel, drug, and laboratory tests, we estimate that the incremental cost of offering PrEP to HIV uninfected partners within existing ART programs is $86.79 per couple per year. Personnel and PrEP medication made up the largest portion of the costs. We estimate that the total cost to Ministry of Health of delivering integrated PrEP and ART program in public health facilities is $250.19 per HIV serodiscordant couple per year. Conclusions. Time-limited provision of PrEP to the HIV uninfected partner within HIV serodiscordant couples can be an affordable delivery model implemented in HIV care programs in Kenya and similar settings. These costs can be used for budgetary planning and cost effectiveness analyses. Article	2016	Izulla, Preston; McKinnon, Lyle R.; Munyao, Julius; Ireri, Naomi; Nagelkerke, Nico; Gakii, Gloria; Gelmon, Lawrence; Nangami, Mabel; Kaul, Rupert; Kimani, Joshua	Repeat Use of Post-exposure Prophylaxis for HIV Among Nairobi-Based Female Sex Workers Following Sexual Exposure.	AIDS and Behavior	-	-	-	1573-3254 1090-7165	10.1007/s10461-015-1091-1	https://link.springer.com/article/10.1007/s10461-015-1091-1	As ART-based prevention becomes available, effectively targeting these interventions to key populations such as female sex workers (FSW) will be critical. In this study we analyze patterns of repeated post-exposure prophylaxis (PEP) access in the context of a large FSW program in Nairobi. During close to 6000 person-years of follow-up, 20 % of participants (n = 1119) requested PEP at least once and 3.7 % requested PEP more than once. Repeat PEP users were younger, had a higher casual partner volume, and were more likely to use condoms with casual and regular partners, have a regular partner, and test for HIV prior to enrolment. Barriers to PEP included stigma, side effects, and lack of knowledge, suggesting repeated promotion may be required for higher rates of uptake. A small subset of FSW, potentially those with heightened risk perception, showed a higher frequency of PEP use; these individuals may be most amenable to rollout of pre-exposure prophylaxis. Article	2016	Jacobsen, Margo M.; Walensky, Rochelle P.	Modeling and Cost-Effectiveness in HIV Prevention.	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-016-0303-2	https://link.springer.com/article/10.1007/s11904-016-0303-2	With HIV funding plateauing and the number of people living with HIV increasing due to the rollout of life-saving antiretroviral therapy, policy makers are faced with increasingly tighter budgets to manage the ongoing HIV epidemic. Cost-effectiveness and modeling analyses can help determine which HIV interventions may be of best value. Incidence remains remarkably high in certain populations and countries, making prevention key to controlling the spread of HIV. This paper briefly reviews concepts in modeling and cost-effectiveness methodology and then examines results of recently published cost-effectiveness analyses on the following HIV prevention strategies: condoms and circumcision, behavior- or community-based interventions, prevention of mother-to-child transmission, HIV testing, pre-exposure prophylaxis, and treatment as prevention. We find that the majority of published studies demonstrate cost-effectiveness; however, not all interventions are affordable. We urge continued research on combination strategies and methodologies that take into account willingness to pay and budgetary impact. Article	2016	Jayakumaran J.S.; Aaron E.; Gracely E.J.; Schriver E.; Szep Z.	Knowledge, attitudes, and acceptability of pre-exposure prophylaxis among individuals living with HIV in an urban HIV clinic	PLOS One	-	-	-	19326203	10.1371/journal.pone.0145670	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84959431578&doi=10.1371%2fjournal.pone.0145670&partnerID=40&md5=2edb4b74f9f9264aec7d31e8e2ca583a	Introduction: Pre-exposure prophylaxis (PrEP) is an effective tool to reduce HIV transmission. The primary objective of this study was to assess awareness of PrEP by individuals living with HIV (HIV+) and acceptance of its use for their HIV negative (HIV-) partners. Methods: A cross sectional survey was conducted among individuals living with HIV who received care at an urban HIV clinic between January 2013 and June 2013. The survey examined knowledge, attitudes, and acceptability of PrEP, and perception of transmission risk of HIV. Chi-Square test and Fisher's Exact test were used to compare proportions. Results: Among 206 subjects living with HIV, 15.3% (32) had heard of PrEP. Men who have sex with men (MSM) were more likely to be aware of PrEP than all others (p = 0.003). Once educated about PrEP those who believed PrEP would reduce their partner's risk for HIV were more likely to recommend PrEP to their partner (p<0.001). 92% of all respondents said they would be "extremely likely/likely" to discuss PrEP use with their provider. Of 159 subjects whosemain partner was HIV-, MSM (p = 0.007), male participants (p = 0.044), and those who were consistently taking meds (p = 0.049) were more likely to be aware of PrEP. Those who perceived they were at risk of transmitting HIV (p<0.001) and those who were consistently taking meds (0.049) were more likely to agree that PrEP could reduce the risk of HIV to their partners. Conclusion: This study illustrates a low awareness of PrEP but once educated the willingness of a cohort of individuals living with HIV to recommend PrEP to their partners. Our findings demonstrate the importance of providers informing their patients living with HIV about PrEP, as these persons are an underutilized link to support the uptake of PrEP by their HIV-partners. Article	2016	Jenness S.M.; Goodreau S.M.; Rosenberg E.; Beylerian E.N.; Hoover K.W.; Smith D.K.; Sullivan P.	Impact of the centers for disease control's HIV preexposure prophylaxis guidelines for men who have sex with men in the United States	Journal of Infectious Diseases	-	-	-	221899	10.1093/infdis/jiw223	https://www.scopus.com/inward/record.uri?eid=2-s2.0-85009832962&doi=10.1093%2finfdis%2fjiw223&partnerID=40&md5=2de3fa50c0438df1712009fece4fedd8	Background. Preexposure prophylaxis (PrEP) is effective for preventing human immunodeficiency virus (HIV) infection among men who have sex with men (MSM) within trial settings. Population impact will depend on clinical indications for PrEP initiation, coverage levels, and drug adherence. No modeling studies have estimated the impact of clinical practice guidelines for PrEP issued by the Centers for Disease Control and Prevention (CDC). Methods. Mathematical models of HIV transmission among MSM were used to estimate the percentage of infections averted (PIA) and the number needed to treat (NNT) under behavioral indications of the CDC's PrEP guidelines. We modeled the contribution of these indications while varying treatment coverage and adherence. Results. At 40% coverage of indicated MSM over the next decade, application of CDC guidelines would avert 1162 infections per 100 000 person-years, 33.0% of expected infections. The predicted NNT for the guidelines would be 25. Increasing coverage and adherence jointly raise the PIA, but reductions to the NNT were associated with better adherence only. Conclusions. Implementation of CDC PrEP guidelines would result in strong and sustained reductions in HIV incidence among MSM in the United States. The guidelines strike a good balance between epidemiological impact (PIA) and efficiency (NNT) at plausible scale-up levels. Adherence counseling could maximize public health investment in PrEP by decreasing the NNT. © The Author 2016. Book	2016	Johnson, Leah M.; Swarner, Stephanie L.; van der Straten, Ariane; Rothrock, Ginger D.	Methods for Assessing the Adherence to Medical Devices	-	Methods for Assessing the Adherence to Medical Devices	-	NA	-	NA	https://books.google.com.br/books/about/Methods_for_Assessing_the_Adherence_to_M.html?id=fEAI0AEACAAJ&redir_esc=y	Assessing patient adherence to medication is necessary to distinguish between nonadherence and inferior drug efficacy, which is crucial to avoid poor clinical outcomes. Adherence measurements pose various challenges, because many methods rely on subjective assessments or slow and costly measurements, which are infeasible in resource-poor settings. Recent developments of new medical devices for delivery of medications requires additional considerations in adherence. In this report, we propose that medical devices may serve a dual-functional purpose: to deliver the drug(s) and monitor adherence. We provide an illustrative case study that involves assessing the adherence of vaginal rings for delivery of antiretroviral drugs for pre-exposure prophylaxis (PrEP) of HIV. Article	2016	Juusola J.L.; Brandeau M.L.	HIV Treatment and Prevention: A Simple Model to Determine Optimal Investment	Medical Decision Making	-	-	-	0272989X	10.1177/0272989X15598528	https://www.scopus.com/inward/record.uri?eid=2-s2.0-84960098318&doi=10.1177%2f0272989X15598528&partnerID=40&md5=a129278d3720ec1c0015f16d36893988	Objective. To create a simple model to help public health decision makers determine how to best invest limited resources in HIV treatment scale-up and prevention. Method. A linear model was developed for determining the optimal mix of investment in HIV treatment and prevention, given a fixed budget. The model incorporates estimates of secondary health benefits accruing from HIV treatment and prevention and allows for diseconomies of scale in program costs and subadditive benefits from concurrent program implementation. Data sources were published literature. The target population was individuals infected with HIV or at risk of acquiring it. Illustrative examples of interventions include preexposure prophylaxis (PrEP), community-based education (CBE), and antiretroviral therapy (ART) for men who have sex with men (MSM) in the US. Outcome measures were incremental cost, quality-adjusted life-years gained, and HIV infections averted. Results. Base case analysis indicated that it is optimal to invest in ART before PrEP and to invest in CBE before scaling up ART. Diseconomies of scale reduced the optimal investment level. Subadditivity of benefits did not affect the optimal allocation for relatively low implementation levels. The sensitivity analysis indicated that investment in ART before PrEP was optimal in all scenarios tested. Investment in ART before CBE became optimal when CBE reduced risky behavior by 4% or less. Limitations of the study are that dynamic effects are approximated with a static model. Conclusions. Our model provides a simple yet accurate means of determining optimal investment in HIV prevention and treatment. For MSM in the US, HIV control funds should be prioritized on inexpensive, effective programs like CBE, then on ART scale-up, with only minimal investment in PrEP. © The Author(s) 2015. Article	2016	Kagaayi, Joseph; Serwadda, David	The History of the HIV/AIDS Epidemic in Africa.	Current HIV/AIDS Reports	-	-	-	1548-3576 1548-3568	10.1007/s11904-016-0318-8	https://pubmed.ncbi.nlm.nih.gov/27188298/	HIV testing of African immigrants in Belgium showed that HIV existed among Africans by 1983. However, the epidemic was recognized much later in most parts of sub-Saharan Africa (SSA) due to stigma and perceived fear of possible negative consequences to the countries' economies. This delay had devastating mortality, morbidity, and social consequences. In countries where earlier recognition occurred, political leadership was vital in mounting a response. The response involved establishment of AIDS control programs and research on the HIV epidemiology and candidate preventive interventions. Over time, the number of effective interventions has grown; the game changer being triple antiretroviral therapy (ART). ART has led to a rapid decline in HIV-related morbidity and mortality in addition to prevention of onward HIV transmission. Other effective interventions include safe male circumcision, pre-exposure prophylaxis, and post-exposure prophylaxis. However, since none of these is sufficient by itself, delivering a combination package of these interventions is important for ending the HIV epidemic as a public health threat. Article	2016	Kamble, T K; Gadewar, Pradyumna M; Kansal, Subodh	Preexposure Prophylaxis for HIV: An Emerging Preventive Strategy to End Ongoing Pandemic.	Journal of the Association of Physicians of India	-	-	-	0004-5772	NA	https://pesquisa.bvsalud.org/portal/resource/pt/mdl-27734641	HIV/AIDS continues to have an extraordinary public health impact. Although the HIV/AIDS epidemic on the whole is plateauing, it is spreading rapidly among certain populations. We enumerate here some HIV preventive modalities that have been demonstrated to be effective in various target populations if properly implemented and adhered to. Some other new strategies are also showing promise in clinical trials. Article	2016	Karuga, Robinson Njoroge; Njenga, Serah Nduta; Mulwa, Rueben; Kilonzo, Nduku; Bahati, Prince; O'reilley, Kevin; Gelmon, Lawrence; Mbaabu, Stephen; Wachihi, Charles; Githuka, George; Kiragu, Michael	"How I Wish This Thing Was Initiated 100 Years Ago!" Willingness to Take Daily Oral Pre-Exposure Prophylaxis among Men Who Have Sex with Men in Kenya	PLOS One	-	-	-	1932-6203	10.1371/journal.pone.0151716	https://pubmed.ncbi.nlm.nih.gov/27073896/	Background The MSM population in Kenya contributes to 15% of HIV incidence. This calls for innovative HIV prevention interventions. Pre-exposure prophylaxis (PrEP) has been efficacious in preventing HIV among MSM in trials. There is limited data on the willingness to take daily oral PrEP in sub-Sahara Africa. PrEP has not been approved for routine use in most countries globally. This study aimed to document the willingness to take PrEP and barriers to uptake and adherence to PrEP in Kenya. The findings will inform the design of a PrEP delivery program as part of the routine HIV combination prevention. Methods Eighty MSM were recruited in 2 Counties in December 2013. Quantitative data on sexual behaviour and willingness to take PrEP were collected using semi-structured interviews and analysed using SPSS. Qualitative data on knowledge of PrEP, motivators and barriers to uptake and adherence to PrEP were collected using in-depth interviews and FGDs and analysed using Nvivo. Analysis of data in willingness to take PrEP was conducted on the HIV negative participants (n = 55). Results 83% of MSM were willing to take daily oral HIV PrEP. Willingness to take PrEP was higher among the bi-sexual and younger men. Motivators for taking PrEP were the need to stay HIV negative and to protect their partners. History of poor medication adherence, fear of side effects and HIV stigma were identified as potential barriers to adherence. Participants were willing to buy PrEP at a subsidized price. Conclusions There is willingness to take PrEP among MSM in Kenya and there is need to invest in targeted education and messaging on PrEP to enhance adherence, proper use and reduce stigma in the general population and among policy makers. Article	2016	Katz, David A.; Dombrowski, Julia C.; Bell, Teal R.; Kerani, Roxanne P.; Golden, Matthew R.	HIV Incidence Among Men Who Have Sex With Men After Diagnosis With Sexually Transmitted Infections.	Sexually Transmitted Diseases	-	-	-	1537-4521 0148-5717	10.1097/OLQ.0000000000000423	https://pubmed.ncbi.nlm.nih.gov/26967302/	BACKGROUND: Men who have sex with men (MSM) are at high risk for acquiring HIV infection after diagnosis with other sexually transmitted infections (STIs). Identifying the STIs associated with the greatest risk of subsequent HIV infection could help target prevention interventions, particularly preexposure prophylaxis (PrEP). METHODS: Using matched HIV and STI surveillance data from Washington State from January 1, 2007, to June 30, 2013, we calculated the incidence of new HIV diagnoses after different STI diagnoses among MSM. Men entered observation at the time of their first STI diagnosis during the study period and exited at HIV diagnosis or June 30, 2013. Cox proportional hazards regression was used to conduct a global comparison of rates. RESULTS: From January 1, 2007, to June 30, 2013, 6577 HIV-negative MSM were diagnosed as having 10,080 bacterial STIs at 8371 unique time points and followed for 17,419 person-years. Two hundred eighty (4.3%) men were subsequently diagnosed as having HIV infection for an overall incidence of 1.6 per 100 person-years (95% confidence interval, 1.4-1.8). The estimated incidence of HIV diagnosis among all MSM in the state was 0.4 per 100 person-years. Men who have sex with men were at the greatest risk for HIV diagnosis after being diagnosed as having rectal gonorrhea (HIV incidence, 4.1 per 100 person-years), followed by early syphilis (2.8), urethral gonorrhea (1.6), rectal chlamydial infection (1.6), pharyngeal gonorrhea (1.1), late syphilis (1.0), and urethral chlamydial infection (0.6; P < 0.0001 overall). CONCLUSIONS: Men who have sex with men diagnosed as having rectal gonorrhea and early syphilis were at the greatest risk for being diagnosed as having HIV infection after STI diagnosis. These men should be prioritized for more intensive prevention interventions, including PrEP.
